2. This new query execution plan will be included to the search space and algorithm will find the best optimum query execution plan from new search space [5].

B. Query optimization using Machine Learning (Neural Network)

Components of Query optimizer involves the large numbers of hand – tuning. To overpower this

shortcoming machine learning can be applied to data management. Neo is the proposed system based on neural network. Neo means neural optimizer. It is an innovative algorithm based on learning that depends on deep neural networks to develop query execution plan.

Neo bootstraps its query optimization model from currently available optimizers and keeps on learning from incoming queries, building upon from its successes and learning from its failures. This model certainly adapts the fundamental data pattern and is persistent to estimation errors. Based on an experiment, when neo system is bootstrapped from a simple optimizer like postgreSQL, it makes use of traditional query optimizer as a source of proficient demonstration. Neo uses this to bootstrap its basic strategy. This technique is called as "learning from demonstration" considerably accelerates the learning process by minimizing training period from days to only few hours. Neo model is comprised of following elements: [6]

- Expertize collection
- Model building
- Featurizer
- Plan search
- Value model

Expertize collection: This is the first phase of the neo model. This phase primarily creates the experience from the traditional query optimization. This phase is only used to develop query execution plan (QEP) for every query sample workload. These query execution plan following their waiting times are added to Neo's experience. This experience is used as the base during the training phase [6].

Model Building: This is the second phase. In this phase Neo produces an initial value model from the experience gathered by the above expertize phase.

This value model is based on deep neural network which has an architecture planned to estimate the final execution time of a given partial or complete execution plan for a given query. This model is trained using supervised learning technique. This phase includes modifying each query submitted by user into features that are beneficial for machine learning model [6].

Featurizer: This model modifies each query into features beneficial for machine learning model. These features contain both query – level information and plan – level information. Neo model works well with several featurization techniques. Neo's value model uses tree convolution to process tree structures query execution plan [6].

Plan search: Once the query – level information is computed, Neo makes use of value model to search over the space of query execution plans and determines the plan with the minimum estimated execution time. Neo model executes best – first search in search space, with the help of value model as heuristic. A complete plan created by Neo, which includes join ordering, join operators and access paths is sent to the underlying query execution engine [6].

IV. Future Work and Summary

This paper contains the detailed description about different approaches and methods for query optimization. The main objective of query optimization is to minimize the transmission cost. Query can be optimized in two stages by creating search space and selecting optimal plan from the search space. The paper is divided into two main sections. First section briefs about query optimization and second section specifies different methods for optimization in different environment. In relational or centralized database query can be optimized by eliminating resultant evaluation, iterative query processing, caching intermediate results, materialization and pipelining. These techniques are designed to target traditional database system with one – dimensional optimization objective. Cloud database systems are responsible for providing the users with a feasible query optimization solution to deliver the query results that satisfy the user constraints as well as minimize the multiple costs of query execution. Query optimization in cloud database can be done by optimizing pre-optimized query called as re-optimization. Re-optimization is combined with different existing methodologies producing the new technique

Abstract - **A blockchain is a growing list of records, called blocks, that are linked using cryptography. Blockchain contains a comprehensive approach in industries which requires to be protected from corruption, human error or human intervention. Land Registry is one of the use cases that involve plenty of intermediaries to place trust within the system. The present solutions in place are out of date. Land registration generally describes systems by which matters concerning ownership, possession or other rights in land will be recorded (usually with a bureau or department) to produce evidence of title, facilitate transactions and to prevent unlawful disposal. The knowledge recorded and therefore the protection provided will vary by jurisdiction .The current land registry system is rife with corruption and inefficiencies. With blockchain, we've an opportunity to mend many of those problems.**

I. INTRODUCTION

Land registration is a process by which matters concerning ownership, possession or other rights pertaining to the respective land may be recorded (usually with a office or department) to supply proof of ownership, facilitate transactions and to avoid discrepancy. Keeping track of who owns which pieces of land or property is difficult once you have hundreds or maybe thousands of years of land records and therefore the current systems in situ are outdated.

It's common to encounter discrepancies within the paperwork, including forged documents, counterfeit titles and, in some cases**,** a whole loss of all documentation. Such situations result in expensive court battles between conflicted parties. The transparent nature of blockchain can make it possible to trace how property changes hands. Blockchain's immutable, auditable and traceable features are enticing governments around the world to implement the decentralized technology within the land registry process. Using the blockchain technology it's possible to make a land registry and a history of transactions which will be easily verified at any given point. [1]

II. OBJECTIVE AND SCOPE

The objectives our project aims to achieve and its scope are:

1. Develop an accessible database to store land titles and transactions
2. To provide high capacity and throughput for millions of records
3. Data immutability that brings trust and auditability to the records
4. Quick retrieval of transaction histories

III. PROBLEM DEFINITION

Currently no solution exists to the issues faced within the existing land registry system. Thus, our system aims at building a true time record maintenance system that captures various attributes of land by using blockchain because the key technology. The system will let users to shop for and sell land securely while maintaining authenticity of the ownership. We've divided the project into 2 stages.

Stage I - will focus on shaping a base for the project. With intensive arranging, examination and structure, we'll guarantee that the important usage is smoother. Planning aims at deciding the agile methodology for arranging our land registry project. Analysis focuses on preparing an analysis of our own project. founded an itemized investigation on present enlistment and approval forms and conquering its impediments and execution

benchmarks. the planning phase focuses on designing of event system application.

Stage II will concentrate on building up the undertaking and guaranteeing that the planned highlights will function as we needed them to. This stage includes developing phase where,we will send a Blockchain in which the qualifications of purchasers and venders as hashes is put away likewise in this stage we will build up an interface for our users to list our their properties and get them approved. Testing includes doing the different test framework application. The last phase is deployment where beta testing for distinguishing any further mistakes, bugs and enhancements that can be performed.

IV. TOOLS & TECHNOLOGIES

Etherium: Ethereum is a distributed public blockchain network. Ethereum specializes in running the programming code of any decentralized software. In the Ethereum blockchain miners work to earn Ether, a kind of crypto token that fuels the community. Beyond a tradeable cryptocurrency, Ether is also used by application builders to pay for transaction expenses and offerings on the Ethereum network. There is a 2nd type of token this is used to pay miners fees for which includes transactions in their block, it is known as gasoline, and each clever contract execution requires a certain quantity of gasoline to be despatched at the side of it to trap miners to position it inside the blockchain. [5]

Metamask: MetaMask is a bridge that allows you to connect the distributed web with a normal web browser. It allows you to run Ethereum based Dapps right in your browser without implementing a full Ethereum node. It is a web browser extension that injects the Ethereum web3 API into every website's javascript context, so that Dapps can read from the blockchain.

MetaMask also lets the user create and manage their own identities, so when a Dapp wants to perform a transaction and write to the blockchain, the user gets a secure interface to review the transaction, before approving or rejecting it. Since it adds functionality to the conventional browser context, MetaMask requires the permission to read and write to any webpage.

Solidity: Solidity is an object-orientated language particularly evolved for contract writing. It is a high-stage language, which inherits traits from C++, Python, and JavaScript. The Solidity compiler compiles your source code into bytecode that runs on Ethereum Virtual Machine.Solidity is a statically-typed programming language designed for developing smart contracts that run at the EVM. With Solidity, builders are able to write programs that put into effect self-enforcing commercial enterprise logic embodied in clever contracts, leaving a non-repudiable and authoritative record of transactions. [5]

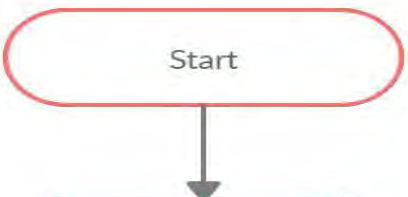
Ganache: Ganache could be a personal blockchain for Ethereum development you'll use to deploy contracts, develop your applications, and run tests. It's available as both a desktop application in addition as a command-line tool (formerly referred to as the TestRPC).

Ganache Accounts shows the accounts generated and their balances. Blocks shows each block as mined on the blockchain, together with gas used and transactions. Transactions lists all transactions run against the blockchain. Contracts lists the contracts contained in your workspace's Truffle projects. Events lists all events that are triggered since this workspace's creation. Ganache will try and decode events triggered by contracts in your Truffle project. Logs shows the logs for the server, which is beneficial for debugging. [6]

Web3: Web3 is a extensive movement and an inclusive set of protocols aiming to make the web and the net extra decentralized, verifiable, and relaxed. WEB3 is the imaginative and prescient of the serverless internet, the decentralized web. An net in which users are in control in their very own statistics, identity and future.

Remix IDE: Remix is a Solidity IDE that’s used to write, compile and debug Solidity code.
Solidity is a high-level, contract-oriented programming language for writing smart contracts. It was influenced by popular languages such as C++, Python and JavaScript.

V. METHODOLOGY



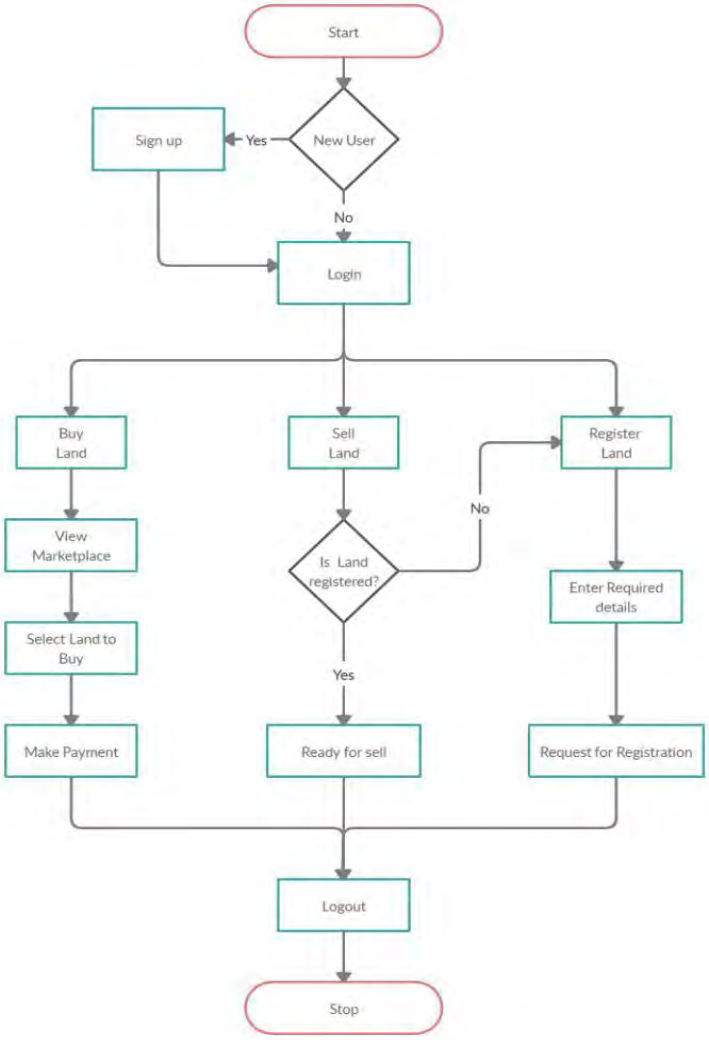


Fig 5.1: Flow chart: User [3]

Fig 5.2: Flow chart: Registrar [3]

User: For buying land

1. The user will register on the portal.
2. The user can view the marketplace and check the different properties listed.
3. As per his requirements the user can select the land to buy.
4. On selection of land, the payment can be made.
5. When user buys property, registration need not be requested as it will already be a part of blockchain from the seller's end.

User: For selling land

1. The user will register on the portal.
2. For registered property, the user can list it out for sale.
3. If the property is not registered, the user will have to fill in the required details and documents and request for registration,
4. Upon completion of registration process, the property can then be listed for sale.

Registrar

1. The registrar will login into the portal.
2. He can view the registration requests on the dashboard.
3. The registrar can accept and reject requests based on the details uploaded by the requester.
4. The accepted requests will be stored as a block in the blockchain.

VI. FUTURE SCOPE

Currently the proposed system can be used to authenticate and validate property ownership and allow the user to put up properties for sale.as the verified user ownership information gets stored as a block in blockchain, it becomes secure due to security aspects of blockchain. The information will be available to different departments as per their usage. The resultant system will serve as an easy, quick and cost efficient record maintenance and retrieval system. The current project can be extended by increasing the area coverage. The proposed system can be extended to different states. The project can be further integrated with maps for better geographical identification and understanding. The system can be used as a secure and trustworthy resource to store, maintain and retrieve property information of various users over a given region.

VII. SUMMARY

The project aims at delivering a trustworthy and reliable system that will make land registration process hassle-free while maintaining security. Large amounts of records can be stored easily. The transparent nature of blockchain can make it possible to trace how property changes hands. Also, the challenges of time delays, involvement of middlemen and frauds can be overcome.

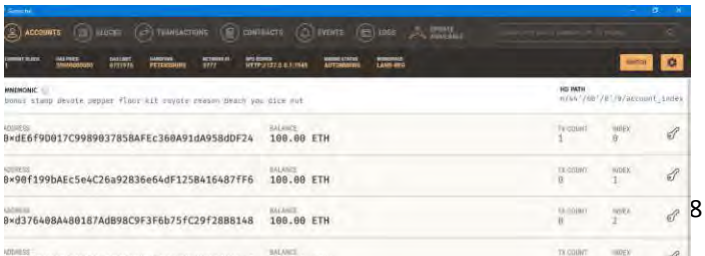
The capacities required for the venture are reasonably in the attainable range. A GUI is required, for the clients to make their records and rundown out their properties for selling or for enlisting another one. The enrollment office requires an interface for confirming the ownership. Verified data will be included to the blockchain. The GUI will be kept basic and moderate. This application will have numerous positive applications on society. It will improve the validity of the clients and give validness to proprietorship. The philosophy that we decided for our task is Agile. Light-footed enables us to be adaptable, oversee evolving necessities, deal with the regularly expanding extension just as get purchaser viewpoint

.

VIII. RESULTS

Fig 8.1: Land Registry Smart Contract

Fig 8.2: Land Registry Smart Contract [6]



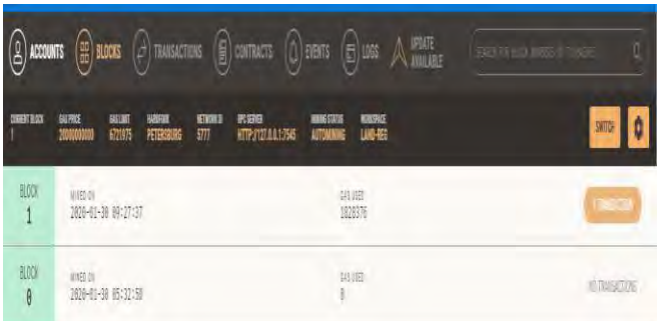


Fig 8.3: Mined Blocks

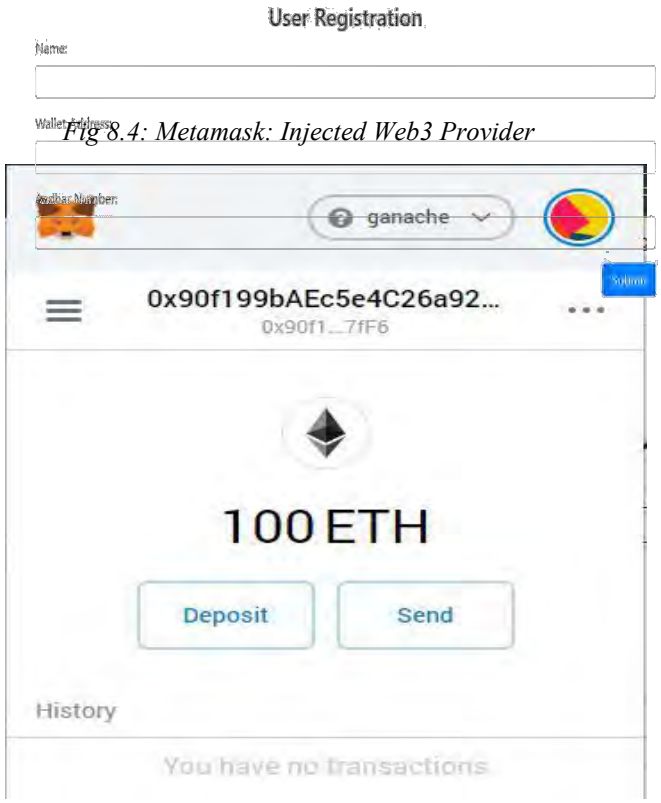

Fig 8.4: Metamask: Injected Web3 Provider

Fig 8.5: User Registration Page

IX. CONCLUSION

The Blockchain based Land registry system will facilitate integration and validation of land records over a given region. The system allows users to buy, sell and register new properties. It is easy to use and a secure way of buying and selling land. Blockchain provides the key feature of security which allows the registrar to validate the user's authenticity in a hassle freeway. As the verified user's record is entered in a block in blockchain its can surely be relied upon. The problem of discrepancies and false records is eliminated in our system. Thus, it can be guaranteed that the property listed by a user belongs to him only. This makes the system trustworthy.

Abstract

The increasing list of records that are widely known as blocks, which are linked using the cryptographic hash of the previous blocks, is referred to as blockchain. The Blockchain technology allows distributed public records that hold absolute data in a secure and encrypted way and ensure that transactions can never be changed. The Bitcoin and other crypto currencies are the most prevalent instances of blockchain practices.

Now-a-days there are many researches in the blockchain technology are used to find solutions for so as to find real-world problems.

After Bitcoin, many digital currencies incepted. For many years it was misunderstood that blockchain can be used only for maintaining the online currency transaction record. There was less awareness about the applications of blockchain

One of the most appropriate instance is in inheriting features of the Blockchain for online Voting or decentralized Voting. In this paper, we propose a voting solution that is made using the Ethereum protocol. It utilizes the properties of smart contracts to impose strict rules surrounding the ballots of an election. These ballots are both autonomously and collectively provable and maintain all of the desired properties of the blockchain (like immutability). This is achieved by maintaining the voter privacy and ballot integrity. The system described shows clear potential for Blockchain technology to become a dominant part of applications coveting to provide transparency and security in public states.

Keywords—Blockchain, Online Voting, Ethereal, Encryption, Blockchain voting features.

I. INTRODUCTION

In Modern technology Online, voting is thought as the most glitchy because of its major security issues. Online voting is only beginning to make headway in modern society. It might seem strange that the acceptance of this method of voting has been so slow, but if you take a closer look at the issues involved, the reason will become clear. Online or remote voting iscertainly convenient, but it also leads to vast chances for spoofing the results. A conceded voting protocol can lead to large-scale changes to the choices made by voters. This means that online voting imposes extremely severe necessities on the security of every aspect of voting. We believe that the blockchain technology is the omitted link in the architecture of a practicable online voting system. It's been challenging to develop an online voting system to satisfy the legal requirements of a democratic country. Blockchain technology has come up with interesting features, which can make the impossible looking process a easy victory. Blockchain offers an infinite range of applications among which online voting is the one. The diverse features of Blockchain technology can make a positive change Blockchain technology offers the diverse features which can make the change. With rise in the population increases to maintain democracy is difficult, trying to satisfy all strata of people. Using blockchain technology uncertain issues related to people's identity and about transparency in long distances and complex trades, like in election systems can be maintained. This problem can be solved by building a more transparent system through which people can vote. blockchain technology that can support us reduce our uncertainties about identity. In this paper, Our implementation is to be deployed on Ethereum's testnet to demonstrate usability, scalability and efficiency by making blockchain based voting system.

II. DEFINITION

The traditional paper ballot voting can be replaced by voting using Blockchain technology. The security issues can be easily dealt as I t is cryptographically secured, transparent, public ledger technology which can eliminates the trust breach between central authority and voters, and hence providing the portable and democratic voting solution with only a minor

requirement of an individual knowing to operate a mobile phone.

A blockchain is a "cryptographically secure transactional singleton machine with shared-state." "Cryptographically secure" means that the creation of digital currency is secured by complex mathematical algorithms that are obscenely hard to break. "Transactional singleton machine" means that there is a single canonical instance of the machine responsible for all the transactions being created in the system. In other words, there's a single global truth that everyone believes in. "With shared-state" means that the state stored on this machine is shared and open to everyone.[6].

The blockchain is built on a decentralized network, which retains the transactional records in the form of blocks in chronological order. The first block is identified as a genesis block. The other succeeding blocks are linked to the previous block. Hash value of the previous block is stored in every block thus linking all the blocks together. Hash is generated depending on the transaction records in the block. Changing the record in block changes the hash and thus makes the chain invalid. This makes the Blockchain immutable.

III. LITERATURE REVIEW

Author implemented the system in which a voter is given a token that allows them to cast vote for their chosen candidates [2]. Privacy is a seminal work that has research on end-to-end (E2E) Evoting which has become a flourishing field. Familiarly, the notion of being E2E verifiable refers to have two attributes: First, every voter can verify if their vote has been cast as desired, recorded as cast. Second, anyone can verify if all votes are tallied as recorded[5]. The proposed number of E2E verifiable schemes and some of these are used in practice[6]. A voting system, called DRE-i (DRE with integrity) [15], to achieve E2E verifiability without involving any tallying authorities (TAs)[1]. DRE-I has precipitation strategy that requires the pre-computed data to be securely stored and accessed during the voting phase. This introduces the possibility for an rival to break into the secure storage module and com- promise the privacy of all ballots. To overcome this disadvantage, they provided the voting system DRE-ip(DRE-i with enhanced privacy). DRE-ip achieves E2E verifiability without TAs and concurrently a significant stronger privacy guarantee than DRE-i [3]. The two assumptions in which the two probability distribution (g a , gb , gab): a, b are randomly and independently chosen from Z q and (g a , gb , gc): a, b, c are randomly and independently chosen from Z q are computationally indistinguishable in the security parameter n = log(q). Our Proposed System works over an elliptic curve in an ECDSA like group setting or a DSA like multiplicative cyclic group setting where the decisional Diffie-Hellman (DDH) assumption is implemented. [5]

Ethereum is an open-source, public, Blockchain based distributed computing platform and operating system featuring smart contract (scripting) functionality. Blockchain voting can be implemented in different phases[4]. Most common stages are as follows: Initialization, Registration, Ballot casting, verification, Tallying results, Revealing results.

Various systems use a different methods by combining a few phases together. The proposed system is using the following phases,

1) Voter registration is the phase in which voter provides personal information. The information is verified by authorized personnel and stored into the blockchain.

2) Creating private Blockchain for voter registration information is the step in which a new Blockchain combined with Merkle hash tree is created to store the voter's information Merkle hash tree is also known as a binary hash tree. Merkle hash tree is used to store a large set of data and to efficiently summarize and

verify the integrity of that large data set. Merkle tree has the following features: i) Ability to verify whether a transaction is included in a block ii) Light-clients. iii) Overall performance and scalability iv) Simplified Payment Verification or (SPV).

3) Voter Authentication is the step in which the physical verification of voter is done based on the record stored in private Blockchain.

4) Voting and tallying phase is the last step where actual voting is done and the results are tallied and displayed to the voter.

Features of Blockchain voting:

Eligibility: This property states that only eligible users can vote. Eligibility criteria can be different for different countries. One of the criteria is the age of the user who is casting the vote. In India person who is above 18 yrs old is allowed to cast the vote.

Privacy: Privacy is one of the most important aspects of democratic voting. Voters privacy should be maintained. No one should be able to know how a particular person voted or to whom the particular voter voted.

Coercion resistance: No one should be able to force the voter and should not have the ability to distinguish between whether the voter voted the same way he/she was instructed to vote.

Physical verification: Physical verification is necessary to know whether the actual voter voted or the bogus person voted on the identity of another voter.

Forgiveness: The voter should be able to alter the vote at any time before the election ends. This is related to the coercion resistance. Even if the coercer forced the voter, a voter should be able to change the vote afterward.

Verifiability: This property states that everyone involved in the voting process should be able to verify the results. This brings transparency in the election. Also, an individual voter should be able to verify whether his/her vote is counted or not.

Immutability: The voter's vote should be immutable. No one should be able to change the vote of any voter without proper concern of the voter. All the records should be immutable.

IV. IMPLEMENTATION OF BLOCKCHAIN VOTING

There are many platforms to implement Blockchain voting but the most used platform is Ethereum. It is open-source, public, Blockchain based distributed computing platform and operating system featuring smart contract (scripting) functionality. When using Ethereum, computational expenses are manifested as gas price. An initial gas value is set, which can be used to perform the operations. Blockchain voting can be implemented in various phases. Most common phases are as follows: Initialization, Registration, Ballot casting, verification, Tallying results, Revealing results.

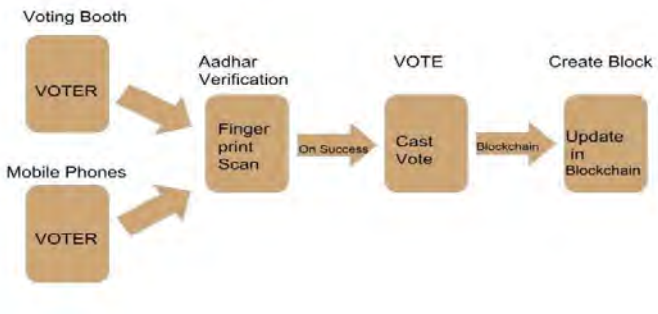

Fig.1 Architecture diagram of the system

We will concern about the features achieved by implementing Blockchain voting this way. Since our voting is based on Blockchain, many features get inherited from the Blockchain itself, such as End-to-end verifiability, transparency, immutability etc. This

feature of Blockchain solves some of the legal requirements of democratic voting.

But with this advancement there comes some possible threats such as maintaining anonymity becomes harder. Different research papers have proposed various implementations to solve these problems. Those implementations are as follows.

Shamir's secret sharing scheme is used by polys voting system. The idea is based on the concept that one will need k points to interpolate the polynomial of degree k-1. for e.g, 2 points are must for drawing a line segment or 3 points are must for drawing a curve. So one can share a secret among n person in such a way that it can only be recovered by k people(k<=n), we need to hide that secret in the formula of a polynomial of degree k-1. This implementation maintains the privacy of every user even if the data is visible to everyone. So the problem of transparency and privacy is solved at the same time.

Homomorphic encryption is another concept which can be used to provide anonymity. Homomorphic encryption is the encryption technology which can be implemented using the exponential ElGamal cryptosystem. The basic idea is to allow the authorities to tally the ballots without actually decrypting them thus providing the privacy and security to the system. Exponential ElGamal is a cryptosystem which is used for encryption of the voter data and provides the additive Homomorphic property to the system.

Another way of implementing homomorphic encryption is Pallier encryption. Homomorphic encryption is nothing but to perform computation on encrypted data such that computations are performed originally on decrypted data. Doing a fully modular form of multiplication in fully homomorphic encryption is computationally intensive and slow. So, partial homomorphic encryption scheme such as pallier encryption is used. This adds two ciphertexts and multiplies one ciphertext with another plain ciphertext.

V. COMPARISON OF RESULTS

One-time Ring Signature techniques can also be used to protect anonymity. Un-linkable signature is used at the receiver end. In this scheme, no observer can determine whether the transactions are sent to a particular receiver address or the two addresses are associated with each other. To keep the anonymity at sender side ring signature technique is used. Here the sender generates a unique ring structure with a fracture in it using the public key produced by other signers and completes the ring using the private key.

Error! Reference source not found. shows results of experimentation.

	Polys[5]	Bronco Vote[1]	Ranked Choice Voting[2]	Bit Congress[4]	Follow My Vote[4]
Eligibility	yes	yes	yes	no	yes
Anonymity	yes	yes	yes	yes	yes
Verifiability	yes	yes	yes	yes	yes
Integrity	yes	yes	yes	yes	yes
Physical Verification	-	no	no	-	-
Forgiveness	-	-	yes	yes	yes

Even though Blockchain provides many features, there are some limitations and issues of Blockchain. The first issue is of majority attack, which is nothing but, if someone has more than 51% of computational power then he/she can modify the transaction data. Another issue related

Blockchain is Fork Problem. When the system comes to a new agreement or new version, then the Blockchain network is divided into two types, new nodes, and old nodes, so after version change, old

nodes could not agree with the new nodes and thus a problem occurs.

VI. CONCLUSION

In this paper, we have presented the features of the online voting system and how different systems have addressed those features. Many systems have managed to address most of the features effectively. Some of the features are inherited from the blockchain and remaining are solved by some encryption techniques like Homomorphic encryption. Although most of the systems have effectively used the features of Blockchain, there are some features of online voting which are not addressed yet.

Performance evaluation of different stress factors for Type-2 Diabetes Mellitus using logistic regression model

Rohini Patil[1], Dr. Kamal Shah[2]
Terna Engineering College, Navi Mumbai[1]
Thakur college of Engineering and Technology Mumbai.[2]
rohinipatil@ternaengg.ac.in, kamal.shah@thakureducation.org

Abstract — **Rising prevalence of diabetes is a concern today. Not only in India but across the world. Although awareness has increased to some extent, many people with diabetes have limited knowledge about risk factors before the diagnosis of disease. For chronic disease prevention there is a necessity to find out such risk factors and manage them appropriately. Statistical techniques can be employed to understand the risk of diabetes in different age group of people. This research is planned to predict risk of type 2 diabetes in people with different age groups according to different levels of stress factor and to find risk of diabetic. The Proposed system works on six different stress factors.To develop an adaptive model the preprocessing step has been applied along with logistic regression. The results suggest that the logistic regression algorithm may be useful for predicting the risk of diabetes among non-diabetic people.**

Keywords—Diabetes Mellitus,risk,Stress

I. INTRODUCTION

Machine learning algorithms can build a model from data used for prediction, decision making or solving some task. Predictive analytics uses statistical, analytical queries or machine learning methods for predicting potential outcomes [1]. Past and current data can be used for predicting future activity, behaviour and trends. Healthcare is one of the areas where predictive analytics can be of significant value. Today, diabetes represents a significant health burden among families and in turn on the country. The incidence and prevalence of both are on rise worldwide and in India.

Type 2 diabetes mellitus is a chronic condition which occurs because of decreased synthesis of insulin by the pancreas or ineffective utilization of insulin. Diabetes mellitus is broadly divided into three main types; type 1 (insulin dependent) diabetes, type 2 diabetes and gestational diabetes.

In type 1 diabetes, because of the deficiency of insulin, body does not properly metabolize food which results in high blood glucose level. Because of inability of pancreas to produce insulin it has to be given from outside hence patients need lifelong injections of insulin. Type 2 diabetes occurs due to ineffective utilization of insulin [2]. Type 2 diabetes mellitus is common than insulin dependent. Type 2 diabetes can be prevented by healthy life- style.

Gestational diabetes occurs during pregnancy [3]. Women with gestational diabetes have high risk of developing type-2 diabetes. Gestational diabetes is diagnosed regular checking of blood glucose during pregnancy.

In pre-diabetes, blood glucose levels are elevated but not as high as diabetes mellitus [4]. Pre-diabetes is a risk factor for diabetes so precaution need to be taken at earlier stage.

The two well-known international associations i.e. World Health Organization (WHO) and International Diabetes Federation (IDF) produce report on epidemiology. According to the report of the World Health Organization (WHO) published in 2016, diabetes is the seventh leading cause of death [5].

According to the International Diabetes Federation (IDF), India **is** the second largest country with diabetes cases with an estimated 73 million adults between the age group of 20-79 years. Current burden of diabetes in India is 49% of world burden and this is expected to reach 151 million by 2045, posing a major health challenge for the country [6]. Diabetes is associated with several complications including those related to eye, nerves, arteries, kidney and heart [7].

This research is carried out to predict type 2 diabetes risk based on daily lifestyle activities such as different stress factors and other indicators used to predict the disease which creates a simple diagnostic application. This simple application may be useful for diagnostic purpose and the results may also be useful for improving health.

II. REVIEW OF LITERATURE

For predicting risk of diabetes among people with different age groups based on life style of a person data mining approach is used. Decision trees model is used for predictive analysis. The results suggested that the people whose age is above 45 years have more prevalence of diabetes and the risk factors included hypertension, lipid level, body mass index (BMI) and the history of myocardial infarction [4].

Another group of researchers used traditional and hybrid approach as a predictive model. They showed hybrid model to be more accurate than traditional model [8]. In another model diabetic patients were classified in three age groups i.e. 18 to35, 36 to55 and >55 years, using adaboost and decision tree model. The decision tree model they have used is J48 [9].

For accuracy improvement researcher developed a model with two level algorithm i.e. unsupervised k-means and logistic regression applied on 14 attributes for predicting the risk of type 2 diabetes mellitus [10].

The researcher applied Chi-squared test and used classification and regression tree (CART) model has

been shown to provide accuracy of 75% for the prediction of diabetic based on daily lifestyle. Blood Pressure was identified as a significant factor for the development of diabetes along with junk food, sleep, family history, rice intake and the physical activities performed [11].

For prediction of risk of diabetes investigators develops a web application by using classifiers and a real data set. They have been used Different models like Artificial Neural Network, Decision Tree, Naïve Bayes, Logistic Regression, and Random Forest algorithm for prediction analysis. Out of these, Random Forest algorithm was selected for the prediction of diabetes risk as it gives best performance. In this approach, input variables are randomly selected and used for creating the application [12].

Harris et al. shows how perceived stress is a strong risk factor for type 2 diabetes. They show Direct and indirect effect of stress on diabetes through risk factors, like BMI, hypertension, and physical activity. This study is only female centric [13].

Martinez et al. shows how stress affect diabetes. They found an increased risk for T2D in people exposed to stressful conditions, traumatic events, mental health problems, depression. [14].

Perveen S. et al. shows the relationship between diabetes mellitus and individual risk factors of Metabolic Syndrome, Logistic regression is used for validation of predictive power of risk along with data sampling techniques [15].

III. MODEL AND ALGORITHM

In this study, we collected the data through paper based and web-based questionnaires. Although different factors such as gender, history of diabetes, daily activities, amount of sugar, exercise, stress, food habit, BMI, family history, systolic blood pressure, blood glucose, diastolic blood pressure and smoking playing a key role in the development of risk of type 2 diabetes, we focused only on stress related factors such as, Workload, poor salary, deadlines, travel, repetitive work, unplanned work for prediction of type 2 diabetes.

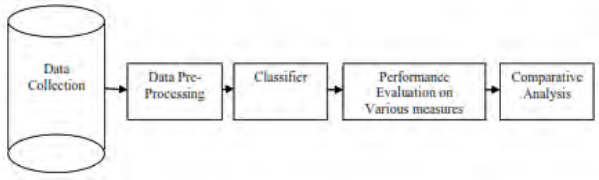

Figure 1. Proposed system model

Figure 1 above shows proposed system model used in our study. Data were collected from diabetic and non-diabetic people both. The collected information was entered in the excel sheet, cleaned for homogeneity means firstly. For building a prediction model data analysis was performed by applying preprocessing step and a suitable machine learning model which improves the accuracy.

A. Data preprocessing

In this cross-sectional study (single visit), data were collected from225 people including both diabetic and non-diabetic people. Out of 225 people, 207 responses were eligible for analysis. Other 18 responses were not considered for data analysis because of the incomplete entries or some missing information.

Some variables Body mass index (BMI) and height required a transformation. Height was collected in feet and then converted to (centimeters) whereas BMI was calculated by dividing weight (kg) by height (meters) squared. The questions were related to stress related factors such as workload, poor salary, deadlines, travel, repetitive work, unplanned work, for prediction of type 2 diabetes. Table 1.describes different attribute used in dataset.

Sample variables

TABLE 1: ATTRIBUTE DESCRIPTION

No.	Variables	Description	Possible value
1	Sex	Sex	1: Male 2: Female
2	Age	Age(years)	1 :18 to 34 years 2: 35 to 44 years 3: 45 to 54 years 4: 55 to 64 years 5: 65 above
3	Weight	Weight(kg)	Numeric
4	Height	Height(m)	Numeric
5	BMI	Body Mass Index (Kg/m^2)	1:underweight 2:eutrophic 3:overweight 4: obese
6	Stress	Stress	1: Very low 2: Low 3: Average 4: High 5: Very high

B. Logistic regression model

which can map input data item to a given category. A statistical approach for analyzing a dataset where one or more independent variables which determine an outcome using logit function. It is binary classification problem. The outcome is measured in the form of dichotomous variable means whether a person is diabetic or non-diabetic. Logistic regression algorithm is used for predicting and classifying medical problem, for automatic disease diagnosis.

Logistic regression algorithm, called as logit model. It uses linear equation with independent predictors. Consider n input variables where their values are indicated by x1, x2, ..., xn. Let z be a probability to indicate an event will occur and 1-z be a probability such that event will not occur. The logit model shown in the following equation,

$$Z = \frac{e^y}{1+e^y} \quad (1)$$

$$\log\left(\frac{z}{1-z}\right) = y \quad (2)$$

$$\log\left(\frac{z}{1-z}\right) = \text{logit}(z) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n \quad (3)$$

Where β0 is the intercept and β1, β2… βn are the regression
coefficient

IV. EXPERIMENTAL RESULT

Using python toolkit, we analysed and evaluated our model using following aspects .
K-fold cross validation

Cross -validation is a technique of reducing overfitting. In our study we have applied 10- fold cross validation. Model was
trained and tested 10 times. In this initial samples were partitioned into 10 sub-samples from that 9 subsamples were used for training and each subsample was retained as validation data.
Performance parameter
To assess the performances of models, Let TP as true positives (correctly predicted number of instances), FP as false positives (incorrectly predicted no of instances), TN as true negative (the no of instances are negative but predicted correctly), FN as false negatives (the no of instances are negative but predicted incorrectly). From the outcome of accuracy some substantial performance parameters such as precision Recall, F1-score are as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} X100 \quad (4)$$

$$\text{Precision} = \frac{TP}{TP+FP} x100 \quad (5)$$

$$\text{Recall} = \frac{TP}{TP+FN} X\,100 \quad (6)$$

$$\text{F1-Measure} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (7)$$

Table 2.shows Statistical measure of various stress related
factors.
Table 2.Accuracy parameter for different stress related factor

Factor	Parameters		
	Precision	*Recall*	*F1-score*
Workload	0.75	0.76	0.73
Poor Salary	0.70	0.73	0.70
Deadlines	0.75	0.76	0.73
Travel	0.77	0.78	0.76
Repetitive work	0.75	0.76	0.73
unplanned work	0.75	0.76	0.73

Figure 2.shows comparison of different stress factors such as workload, poor salary, deadlines, travel, repetitive work and unplanned work.

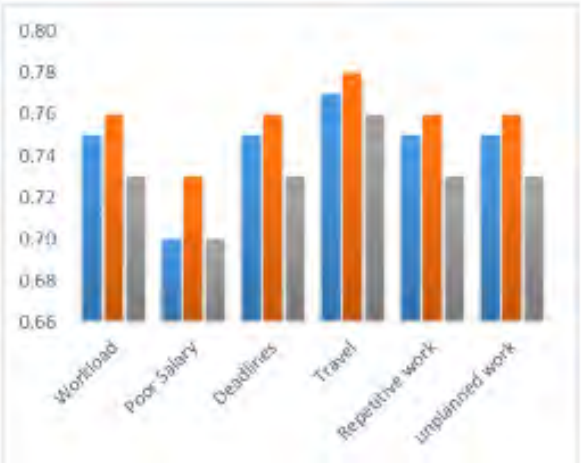

Figure 2.Statistical comparison on various measures

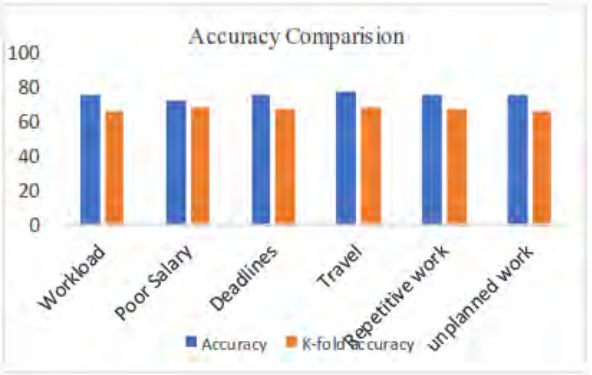

Figure 3. Accuracy comparison of stress parameter
For chronic diseases, stress must be reduced. Comparison of different stress parameters is shown in figure 3.

V. LIMITATIONS

Small number of responses, limited number of risk factors and use of single analytical method for prediction modeling are the limitations of our study. These findings need to be evaluated by using larger data sets of diabetes and non-diabetes people with multiple prediction modeling techniques. Considering the above listed limitations readers should carefully extrapolate findings of our study

VI. CONCLUSION AND FUTURE WORK

The parameter such as gender, age, body mass index (BMI) along with the Stress factors such as Workload, poor salary, deadlines, travel, repetitive work, unplanned

work. Stress is identified as a important risk factor for development of diabetes, in this work, use of logistic regression model provided accuracy of 76%, for prediction of diabetes. Further research can be done to evaluate effect of gender, age and other risk factors on the risk of diabetes

Abstract— **While Developing a healthcare application Managing Patient's personal data has always been a challenge since the app requires information such as symptoms, Date of birth and his/her current health state. In the IT Sector, the integrity and Confidentiality is the major concern for every organization. As the rise in the attacks on the data are at fire nowadays, The Uphill task was to make the app more secure and providing right authentication. Apart from the Privacy concern, drawing data from the database and Use it in a way to provide the right kind of prescription was a challenge but Artificial intelligence played significant role in achieving the desired result. Measuring Project's success is depend on various parameters like performance, efficiency and data interoperability. Since the application works on the android platform. The app has to check whether the device satisfies all the minimum requirements of memory size, processor speed, accessibility to various Application programmable interfaces (API). The central parameter of success is the accuracy at which the machine learning algorithm predicts the diseases for which it is trained. It is expected to be above 96% -98% to make a real difference, as medical diagnosis has very rigorous standards The secondary parameters are the response and loading time of each modules. A high value of module latency can make any user impatient. Besides these 2, the other parameter is the number of features that work without any bugs. This parameter should be ideally above 90% as well, or it can make users frustrated. Sharing Data between different platforms is also one parameter as the app is supposed to collect data from the user input and generate result based on the past history and results it acquired.**

I. INTRODUCTION

Mobile healthcare applications (Apps) gets more attention due to the ability to modernize healthcare delivery, for example, patients can check their daily activity and habits on Mobile Healthcare apps by using android, it gives them the advantage of solving their query of their symptoms and get an expert response from the Expert System in the form of identification of the disease and medication the cure their illness. Patients gets an access to the medical information and expert system independent of their current place and time and content can be dynamically adjusted to the current context and terminal type. This proposed system, is designed to partially ease the stress, financial burden, and workload on the doctor.

This application which runs on any Android version. This apps and service usability has to be user- friendly, and usefulness of the system due to great spectrum of potential future users and variety of their needs and expectations from system's functionalities. While the session is transferred, an additional mechanism session consistency must be done to protect storage and to avoid transfer of invalid session data. Due to the various network varieties that may be used, it's extremely attainable that communication is interrupted unexpectedly which a system should be ready to save current session information and change a user to continue antecedently started session while not data loss.

When the applying is resumed on a similar terminal over a unique network or on a replacement terminal, a replacement authentication method should defend security. as a result of this could happen oftentimes, it's necessary that the revived authentication is each easy and secure. professional systems are being progressively utilized in medical environments like hospitals, laboratories, and medical aid units, with a read to rising the standard of health care and reducing the chance of incorrect medical selections. Transformation of those systems into mobile solutions would extend their edges and facilitate their integration into medical environments. New generations of mobile devices supply user new modes of interaction with health worker systems.

Our approach involves the utilization of a mobile client-server model using net services so as to transfer the presently offered web-based system onto associate automaton platform. The server is devoted to supply associate interpretative report of the obtained check results, whereas the shopper acts as a convenient user front-end. Communication between the shopper and also the server relies on net services. The patients have their user accounts on the patient web and may access the service from distant places or their homes, cars or offices victimization differing types of networks (e.g. Wi-Fi, GPRS, 3G).

II. PROPOSED WORK

Pervasive healthcare system makes use of wearable medical sensor with wireless interconnections to monitor patient's condition and to provide healthcare services for

patient wellbeing. This dissertation is aimed at investigation and development of secure and pervasive architectural prototype for patient monitoring and remote medical care which reflects the unique and efficient wireless solution for monitoring patient in a secure way with a solution of various technological issues. Most important part of pervasive healthcare system is the Body Sensor Network (BSN) which is a suitable combination of wearable tiny devices attached to the patient's body to monitor patient's physiological data (or BSN data). Sensors continuously monitor and collect patient's data and send it to a remote server through a wired or wireless network. This server can be called Database Server (DBS).

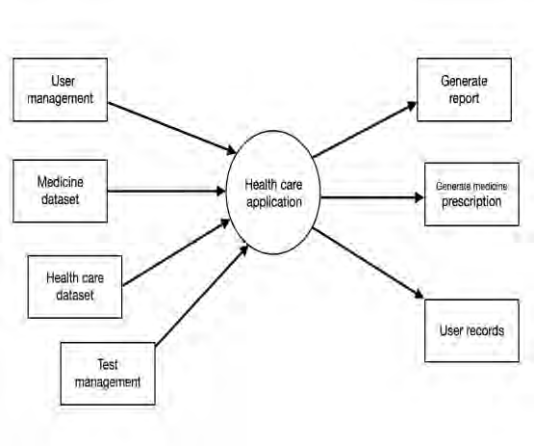

Figure 1

III. LITERATURE SURVEY

1. AI Using AI to improve hospital inpatient care, Daniel Neill, (2013) - Adopt best practices for preventive care and patient safety have huge and directly measurable impacts on both healthcare costs and patient outcomes.

   Solution: Clinical decision support systems (CDSS) were one of the rest successful applications of AI.

   Research Gaps: Practice management, Presence of DSS.

2. AI in healthcare and research, Natalie Banner, (May 2018) - A range of healthcare and research purposes, including detection of disease, management of chronic conditions, delivery of health services, and drug discovery.

   Solution: The app Ada Health Companion uses AI to operate a chat-bot, which combines information about symptoms from the user with other information to offer possible diagnoses.

   Research Gaps: Detection of disease, using chat bot in AI.

IV. FEASIBILITY STUDY

The project relies on open source software, such as python, R, NumPy and SciPy. The functionality provided by these software's is enough to construct a product capable of usage for healthcare applications.
For the machine's learning and training, we will use freely available datasets. These sets run into thousands of lines, and thus can provide enough learning capability to the software. Due to these 2 being freely available, the project is very low cost and thus feasible from an economic standpoint. The expected total cost is thus 0 rupees. As such, we do not need any outside funding. The project will be expected to make minimal sales, due to the presence of a variety of other similar tool and the slow adaption of software's by the medical community. The capabilities required for the project are fairly in the feasible range. Most of the planned feature hinge around processing datasets. A GUI is required, which will be done with the PyGUI framework. The GUI will be kept simple and minimalist. For the hospital searching and insurance selection, we will use readily available data. We also have a feature for users to set personal data, preferences. For the machine learning, we will use Neural networks to train our datasets, both of which are available on open source repositories.
On an operational level, the software will need to run intensive processing tasks while it's in its learning phase. Since the learning phase is a very short process, it is doable without the need for extra hardware. The software will be deployed as a Desktop application and will need users to download it. It will also need internet to operate.

V. RESULTS AND DISCUSSION

1. Expected Results

When the user puts in the symptoms, some algorithms like decision tree, naive bayes algorithm are applied on the data set of the user which is been entered by the user by selecting the pre-defined symptoms in the app and there will be some flow of questions and at the end a report is been generated using these algorithms and medicine is prescribed for the same. The application has proven to gain significant and drastic change in the healthcare industry by enabling common people to get their problems or diseases diagnosed at their place and their availability.

Deployment phase is still under construction, modules are to be implemented yet. The GUI by itself is not very difficult to deploy. We have multiple ways of offering interfaces, such as web interfaces and command line interfaces. It will expand to a desktop GUI in the

future as well. The web interface will be deployed using heroku or AWS, depending on the relative cost

of hosting. Once all the API's are ready the app will work as expected.

Detailed analysis of the project has been done and vast research in context of literature and previously published articles has been carried out. The outcome remains the emerging progress in the field of healthcare using the application. Providing the range of healthcare and research purposes, including detection of diseases, management of chronic condition, delivery of health services and drug recovery along with the best possible prescription available. Documentation of the entire project has been done and all the prerequisites been maintained.

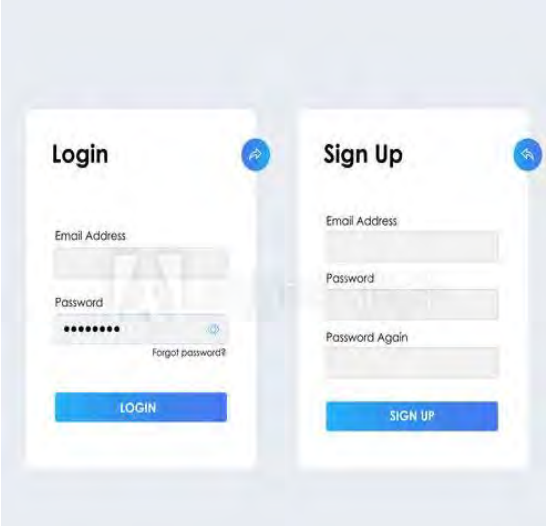

Figure 2

Discussions

Detailed analysis of the project has been done and vast research in context of literature and previously published research papers of IEEE has been carried out. The outcome remains the emerging progress in the field of healthcare application using Artificial Intelligence. Providing the range of healthcare and research purposes, including detection of diseases, management of chronic condition, prescribing medicines.

VI. CONCLUSION AND FUTURE SCOPE

AI technologies have the ability to help address significant health challenges and the strength to overcome every possible limitations and problems where the humans can generally inhale more efforts and time. The application has proven to gain significant and drastic change in the healthcare industry by enabling common people to get their problems or diseases diagnosed at their place and their availability. Henceforth this will result in saving lot of time for both, the patient & doctor and also saving a handy amount which the common people usually invests in getting their tests done on the basis of doctor's Doubts. Because of this innovation, the laboratory tests will become inexpensive and reduction in prices will be observed. This application will have a remarkable impact on healthcare industry.

As per the literature survey we have some deterministic goals for our android app which are as follows; getting the high accuracy rate, flow of algorithms, correct medicine prescription for the diseases, graphic user interface. The developments of the project in the future are aimed at careful consideration of the disease. This can make a prediction of the diseases by looking at a medical history of a number of patients. There after, the team intends to build a web framework to create a rich user interface.

SMART WARDROBE – IOT BASED APPLICATION

Jay Dalal, Anshul Dalmia, Jaimin Desai
Information Technology, Thakur College of Engineering and Technology, Kandivali.
Mumbai, India

Abstract – **Every individual faces a problem of what to wear, almost every day. The problem isn't that you don't have enough outfits to wear, but fact that you have no track of the clothes you keep wearing again and again and those you haven't touched for a long time. A smart wardrobe not only helps you track your clothes but also get suggestions on what to wear according to the events of your calendar. The system generates statistical reports of the frequency of usage of the clothes which helps you decide the ones you could sell or donate. You can also manage your clothes from anywhere with a mobile application.In this thesis project, our goal is to put together a set of technologies into a system that could be used to aid the user in the planning of their clothes. In order to achieve this goal, we need to be able to identify which clothes are worn very often and those which are seldom used. We need to categorize our clothes like Casual, Formal, Dinner Party, Business Party, Social Function and so on. The application will provide statistics to show the clothes that are being worn frequently and those that haven't been touched for a long time. Application can further suggest the user to sell the unwanted clothes or donate them to charity.Smart Wardrobe is a fairly new area of research and literature on the subject is not readily available or accessible, whatever that exists is mainly conference proceedings or reports on projects most of which have not been progressively developed or didn't get to be marketed commercially. The components include an Raspberry Pi 3 Model B, Arduino UNO, RFID system and Microsoft Azure Cloud assisted by a middleware application working together to give the user a new experience on how they interact with their wardrobe and at the same time enable the wardrobe to support the user in selecting their clothes to be wear in different occasion thereby saving their time they would have spent in the manual Selection and at the same time reducing on the stress associated with the activity.In the future, this project can be extended to provide suggestions to the user according to the weather forecast. Weather detecting sensors can be embedded into the system to detect the weather and suggest appropriate clothes. The app will also give more detailed analysis of the statistical data and machine learning will be used to provide better suggestions.**

I. INTRODUCTION

Today, individuals have access to an array of smart applications like smartphones, laptops, smart televisions, refrigerators, microwave ovens, etc. However, there aren't many smart devices for the bedroom department of the house. One prominent and important feature that exists in the bedroom is a wardrobe or closet. In fact, over 80% of the respondents we surveyed agreed to have access to a wardrobe. Smart wardrobe helps users manage their clothes inside their wardrobe. Besides having an attached screen to show the status of each cloth, it can also push all data into a cloud and further sync up data with a mobile application. User can get suggestions on what to wear today from their phone app based on the events in their calendar and the weather.In this thesis project, our goal is to put together a set of technologies into a system that could be used to aid the user in the planning of their clothes. In order to achieve this goal, we need to be able to identify which clothes are worn very often and those which are seldom used. We need to categorize our clothes like Casual, Formal, Dinner Party, Business Party, Social Function and so on. The application will provide statistics to show the clothes that are being worn frequently and those that haven't been touched for a long time. Application can further suggest the user to sell the unwanted clothes or donate them to charity.

II. MATERIAL AND METHODS

Materials:-

1) Hardware components:

i) Raspberry Pi 2 Model B

ii) Arduino UNO

iii) JT2850 RFID module

iv) JT606 RFID antenna

2) Software apps and online services:

i) Microsoft Windows 10 IoT Core

ii) Microsoft Azure

iii) Service Bus, Web Apps, SQL DB

iv) Arduino IDE

v) Microsoft Visual Studio 2015

vi) Android Studio

3) Hand tools and fabrication machines:

i) Microsoft PC running Windows10 with Visual studio 2015 installed

ii) Android Phone

iii) Raspberry Pi USB Wi-Fi dongle

Methodology:-

Phase I:

1) Planning: Applying agile methodology for Smart Wardrobe for better usage of resources and time with great performance.

2) Analysis: Prepare a detailed analysis on Smart Wardrobe system and overcoming its limitation in our system.

3) Design: Integration of data and designing of system.

4) Coding: Writing the code for RFID module and taking help of open source.

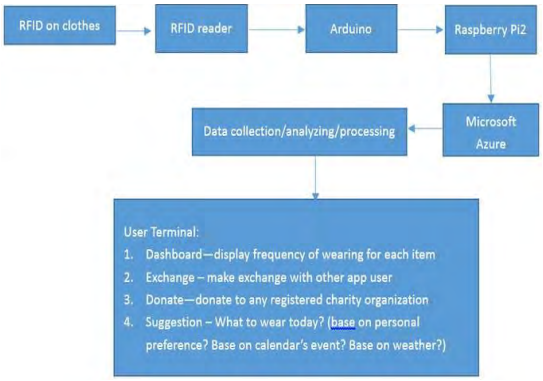
5) Implementation: For first time registration, user will need to let RFID reader read the tag and a push notification will be shown inside user's mobile phone application. User will need to key in further details about his cloths for example color, type, name, etc. Once record is created, system will automatically track the item taking out or putting in from wardrobe. After consolidating data, a report will be generated and give user better idea of which cloth is most preferred or which is most unwanted.

Phase II:

1) Testing: Doing the various tests on smart wardrobe system like unit testing, integration testing, and system testing etc. of test case data to check if the integrated system functions are as desired by the client.

2) Deployment: Conduct beta testing for identifying any further errors, bugs and improvements that can be performed. After the testing and approval, deploy the proposed system.

Workflow:-



The project will consist of 4 main components: user terminal (phone, pc, tablet), Raspberry Pi2, RFID reader, and Microsoft Azure. For first time registration, user will need to let RFID reader read the tag and a push notification will be shown inside user's mobile phone application. User will need to key in further details about this clothes for example colour, type, name, etc.

All clothes stored inside wardrobe has a RFID tag attached to it. Whenever the clothes are put in or taken out from wardrobe, they will be tracked by RFID reader and arduino board. The sensor data will then send over to Raspberry pi 2. After processing the data, Raspberry Pi2 will then send the data to Azure SQL database.

Once wardrobe data is sync up with universal app, the app will further show user which cloth is most frequently chose and which one has the least frequency.

III. RESULT

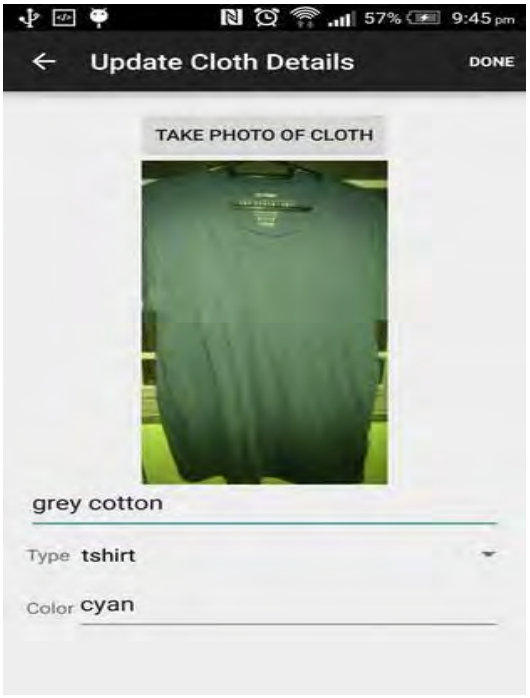
Expected Outcome:-

-Phase I:

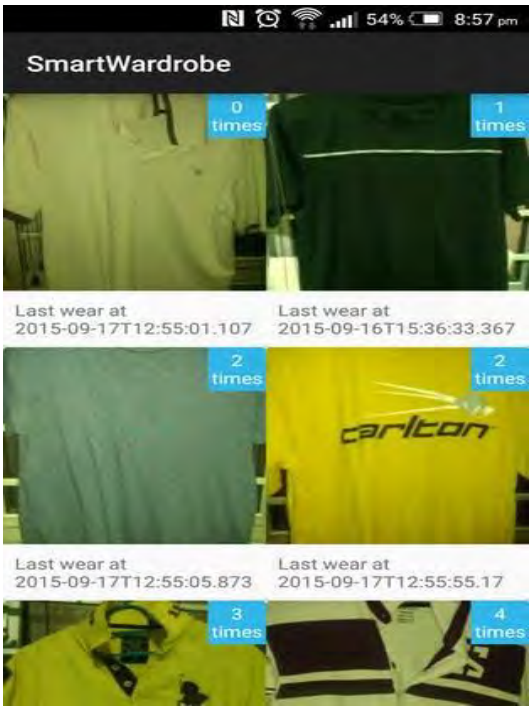
This system will be instrumental into keep tracking of wearing frequency of cloths in wardrobe. It will also suggest a garment on basis of least recent used phenomenon. This system will store usage data and log data on Azure Cloud, this will furnish user to access data from anywhere anytime.

-Phase II:

Any bugs later found will be dealt with and new features like suggestions through weather tracking will be implemented.



To add a new cloth to app



Cloth detailsFrequency of usage

IV. DISCUSSION

In the future, this project can be extended to provide suggestions to the user according to the weather forecast. Weather detecting sensors can be embedded into the system to detect the weather and suggest appropriate clothes. During rain, the system may remind the user to carry an umbrella and avoid wearing white, while on the other hand, during a sunny day, the app suggests the user to wear light colored clothes. The app will also give more detailed analysis of the statistical data and machine learning will be used to provide better suggestions. The hangers could be equipped with LED lights that illuminate at the search of a particular cloth making it easier for the user to locate it in the wardrobe. One of the most important thing aspects to consider in the future is to reduce the effective cost of the system so that everyone can affordit.

V. CONCLUSION

Thus by this we conclude that the proposed system for smart wardrobe can be used effectively by fashion bloggers, organization etc. Not only an organizer but a normal person can use the system as it is simple to understand. As is, the system may require quite some changes to realize a user experience that would be acceptable but at least we have provided a basis for future research. We have identified challenges and future enhancement.

Smart Bag Using IoT

Sneha Jaiswal, Akshara Lagwankar, Ms. Payal Borchate

Department of Information Technology, Thakur College of Engineering and Technology, Mumbai, India.

Abstract – **The proposed system uses the technique of Internet of Things in order to track the bags. In this, hardware would be created and installed which would be having the basic arduino board with a GPS module and an alarm being connected to it. A map has been created which would be synchronized in order to track the location of the bag.**

Furthermore, the map has the features that as soon as the bag gets lost or theft and it moves away from the owner and goes out of a particular range, the alarm would start ringing so that the owner gets notified where exactly the bag is. Also it would help the owner to track down the location of the bag which could be seen on the map as the markers would be dropped which gives us the location of the bag as it moves away from the owner.

Keywords: Raspberry Pi, Bluetooth, GPS, Android application

I. INTRODUCTION

When people travel, they travel with their luggage anywhere they go so it is what a part of their journey becomes. Baggage however when carried needs to be carried to places and with great care because it contains many important and necessary things. In today's world as we know the amount of theft and forgery has been considerably increased hence there is a need to keep our dear ones and our belongings safe. However, what would happen if this luggage gets lost or robbed in the middle of your journey it would be a menace because it would contain all your important things or sometimes documents. Hence, to provide a solution to this problem would include introducing the concept of smart bags thereby providing a better security. It is one of the alternative solutions where instead of looking after your baggage every now and then where the passengers follow the bag, the bag follows them.

I. PROPOSED SYSTEM

The proposed system uses the technique of Internet of Things in order to track the bags. In this, hardware would be created and installed which would be having the basic arduino board with a GPS module and an alarm being connected to it. A map has been created which would be synchronized in order to track the location of the bag. Furthermore, the map has the features that as soon as the bag gets lost or theft and it moves away from the owner and goes out of a particular range, the alarm would start ringing so that the owner gets notified where exactly the bag is. Also it would help the owner to track down the location of the bag which could be seen on the map as the markers would be dropped which gives us the location of the bag as it moves away from the owner.

II. METHODOLOGY USED

Agile methodology mainly focuses on the incremental and the iterative development of the different project phases. It controls and determines how the various stages are implemented and what kind of environment is involved. The project is first divided into different phases, and then the responsibility of developing these phases is given in the hands of the various developers. At every stage of the project development it is continuously monitored and taken care of. These developers developing the phases have particular amount of time period and tasks involved with them. To remain in sync with the other members of the team they have to complete their task within the stipulated amount of time.

The meetings however are conducted on a regular basis where all the members of the team have the right to put forth their ideas along with any requirement or concern. The product backlogs are

III. FEASIBILITY STUDY:

a. Executive Summary

Project is related to Smart Bags.

i. The project maintains two levels of users:-

1. Administrator Level-Owner
2. User Level-Data Entry Operator

ii.Main facilities available in this project are:-

1. Maintaining the daily time-table.
2. Providing temperature sensing.

discussed in these meetings where the requirements of the project to be completed along with the resources are mentioned. However, during the development of the project it is bound to have certain changes. These changes are discussed and team is required to document it along with their consent. Some changes involved may be bad for the future but certain changes turn to be good in the overall run of the project. The changes can be from the customer side or the developers' side. Agile is considered to be a methodology that is ready to accept and work on any change that occurs during any phase of the project which can be from any side of the project. It is flexible methodology that welcomes change during any stage of the project. After the development phase each task or each developed phase is tested in different environment. This helps the team members to determine what would be the next phase of the project. Every iteration of the project involves a testing phase. It requires close communication with the project master along with team members and the product owner for the development of the project

3. Providing GPS location tracking.
4. Reminding customers of the luggage.
5. Providing the weight capacity of the bag.
6. User can set a reminder for his/her different requirements.

b. DEFINE BUSINESS PROBLEM OR OPPORTUNITY

The Software is for the automation of Smart Bags. It maintains one level of user:-

i.User Level The Software includes:-

ii.Maintaining customer details.

iii.Providing and maintaining all kinds of storage facilities for a customer.

iv.Reminding and giving an alert to the user as per requirements.

c. REQUIREMENTS AND PURPOSE OF THE STUDY

i.Hardware Requirements

- Raspberry pi, Virtual Assistant
- Bag

ii.Software Requirements

iii.Android Studio

- *Purpose*
- Delightful Bags provide following facilities like:-
- Taking orders from the customer.
- Delivering ordered meal timely
- Bill computation
- Record maintenance.

d. DESCRIPTION OF THE OPTIONS ASSESSED

Based on research conducted over the Internet we identified the following alternatives for the MMS:

- Continue to use the current system.
- Utilize a packaged solution. The bag providers who require this software can purchase the product and host them in their own environment. Less amount of programming and re- programmingisrequiredfor customizing the system and implementing them.
- Develop a customized bag solution which meets all requirements satisfactorily and is also built with a scalable scope.

e. ASSUMPTIONS USED IN THE STUDY

Every user should be:

•Comfortable bag usage.

- He/she must have proper internet connection.
- He/she must also have basic knowledge of English too.

f. AUDIENCE IMPACTED

It can be used in anywhere as far the internet services are provided.

g. FINANCIAL OBLIGATION

The financial and the economic questions during the preliminary investigation are Verified to estimate the following:

i. The cost to conduct a full system investigation.
ii. The cost of hardware and software for the class of application being considered.
iii. The benefits in the form of reduced cost.
iv. The proposed system will initially give the minute information, as a result the performance is improved which in turn may be expected to provide increased profits.

II. HARDWARE DESCRIPTION

The various components required for the development of the project Smart Bag using IOT along with their estimated budget is as shown below:

- RASPBERRY PI 3 MODEL B INBULT BLUETOOTH AND Wi-Fi.: The main component for designing of the system for internet based system.
- Intel i3-2120 3.3GHz Processor: Computer system processor
- HITSAN 3x Heat Sink Kit +Transprent Acrylic Case+Cooling Fan For Raspberry Pi
- SunFounder USB 2.0 Mini Microphone for Raspberry Pi 3, 2 Module B & RPi 1: microphone for interaction between the system and the users
- Model B+/B Laptop Desktop PCs Skype: optional for advance use
- GSM MODEM MODULE BOARD WITH SMA ANTENNA - CALL SMS GPRS facility
- USB GPS receiver module BMP180
- Digital Pressure Sensor Raspberry Pi
- BS-708 UBX-G7020 USB GPS receiver module with antenna replace BU-353S4: For location tracking facility
- BU353S4 - suitable for laptop and automobile
- BMP180 Digital Pressure Sensor Arduino Raspberry Pi Compatible Sensor for Senior
- Design Capstone Design Project

DESIGN AND IMPLEMENTATION

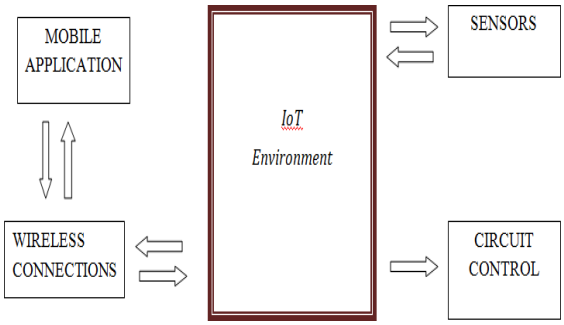

Fig 5.2.2

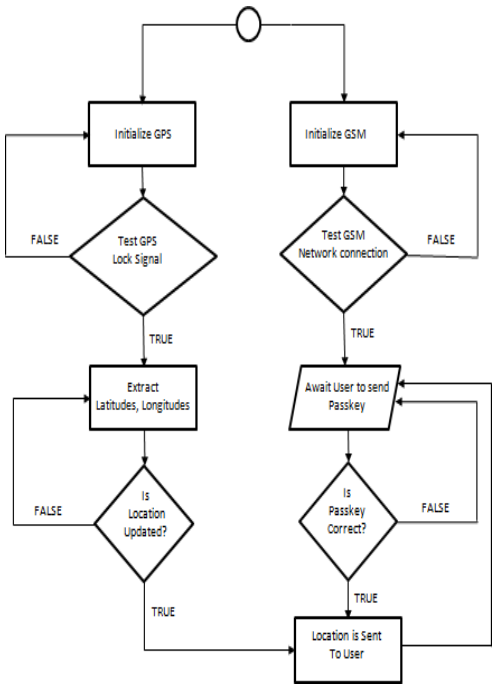

Fig 5.2.1

6.Future Scope

In future, we are planning to include some interesting features like automatic object avoidance, stair case climbing and some extra woman safety features. These extra features make the bag more powerful and user friendly.

IV. CONCLUSION:

The progress in science & technology is a non-stop process. New things and new technology are being invented. As the technology grows day by day, we can imagine about the future in which thing we may occupy every place. The proposed system based on microcontroller is found to be more compact, user friendly and less complex, which can readily be used in order to perform several tedious and repetitive tasks. Though it is designed keeping in mind about the need for school kids, it can extended for other purposes such as commercial & research applications. Due to the GPS tracking working logic: probability of high technology (Android) used this system is well software controlled. The feature makes this system is the base for future systems. In future we can use this idea of smart bag to packing system in factories, shops, super markets etc.

This project idea shows the implementation of tracking the bags which are either lost or stolen using IoT. Certain procedures and techniques have been made and proposed in order to achieve the same. Experimentation has been done and maps have been created in order to track the location of the bags which are misplaced and lost.

Experiment results further concludes that the bags can be easily tracked based upon the hardware installed in them and then by tracking that hardware and tracking the route, directions and location of the bag with the help of a map.

Real-Time Multiple Object Detection on Low Constrained Devices using Lightweight Deep Neural Network

Dr.Vinayak Ashok Bharadi, Namdeo Baban
Research Scholar, IT department FAMT, Mumbai University Ratnagiri, India
vinayak.bharadi@famt.ac.in, namdeobadhe1982@gmail.com

Abstract— **During the past few decades, deep neural networks have attracted considerable attention due to their wide applications in filtering, combinatorial optimization, style transfer, pattern recognition, computer Vision and some other areas. object detection is one of the challenging task in computer vision field. There are many popular deep neural networks based object detection methods. The popular ones are Region-based Convolution Neural Networks (RCNN), Single Shot Multi object Detector (SSD) and You Only Look Once (YOLO).All these models require huge computation and large power consumptions which is a big challenge for real-time multiple object detection deployments on resource constrained devices, e.g., mobile phones or embedded gadgets. The combined version of SSDlite and Mobile Nets gives better result for object detection and tracking on resource constrained devices .In this paper, the SSDlite-mobilenet_COCO models are trained on GPU GTX 1660 GeForce GTX 1660 Ti using MS- COCO dataset and tested on using RabberiPi 3 B+. The performance in terms of Frame per second (FPS) of the models on GPU as well as CPU was tested.**

Keywords—Object Detection, Single Shot multi object Detection, MobileNet

I. INTRODUCTION

Object detection (OD) [1] is the most challenging part of any of image processing applications. Given an input image, OD algorithm outputs multiple objects with a class label and its location(usually in the form of bounding box coordinates).It usually helpful to find real-world object instances like car, bike, TV, flowers, and humans in still images or Videos. It can achieve this by learning the special features each object possesses. Most Common applications of object detection are pedestrian detection in road safety system, self-driving cars, emotion detection from

facial expression, Human activity recognition, object tracking in surveillance System, people counting in crowd areas, relief and rescue operations medical imaging, understanding aerial images etc. The images can have object instances from same classes, different classes or no instances at all.

There are many issues present like the variation in size, dark lighting, occlusion, rotation, low- resolution, appearance, complex background other factors all will seriously affect the object detection

performance. The traditional object detection method such as background subtraction, temporal differencing, optical flow, Kal man filtering, support vector machine, and contour matching [2] are normally used to find the features from images manually. But all are not able to detect object accurately.

During the past few decades, deep neural networks have attracted considerable attention due to their wide applications in filtering, combinatorial optimization, style transfer, pattern recognition, computer Vision and some other areas. Deep neural networks have been proven to be effective in various areas. Deep neural networks have achieved state-of- the-art performance in these fields compared with traditional methods based on manually designed visual features.

Convolutional Neural Network (CNN), a successful Artificial Neural Network-based deep learning algorithm, is used in recognition of visual patterns directly from pixel images with variability [3]. CNNs are like traditional neural network, but with deeper layers. CNNs model temporal and spatial associations of features commonly applied to image classification and face recognition. It uses a set of layered functions (i.e., convolution layers) on every possible sections of an inputs array of values in computing the output.In 2012 ImageNet Large Scale Visual Recognition Challenge (ILSVRC) [4], Hinton and his student Krizhevsky [5] had applied CNN to image classification and achieved top5 error

15.3% vs 26.2% of the conventional method.

II. RELATED WORK

Object Detection using Region-based Convolutional Neural Networks(R-CNN) was proposed by Ross Girshick[3]. R-CNN is a special type of CNN that is able to locate and detect objects in images: the output is generally a set of bounding boxes that closely match each of the detected objects, as well as a class output for each detected object. The image below shows what a typical R-CNN outputs:

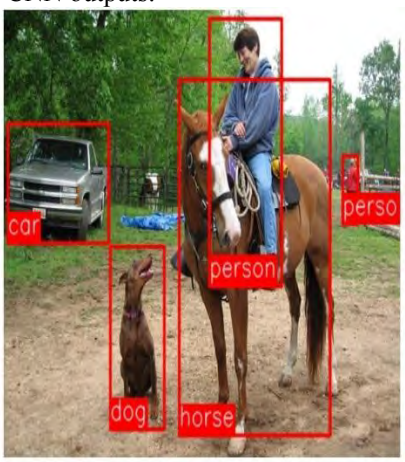

Fig 1 Multiple Object Detection

Region based CNN Models find a bunch of boxes in the image and checks if any of these boxes contain any object. RCNN uses selective search to extract these boxes from an image (these boxes are called regions).There are number of challenges that have to be addressed in order to give a more reliable detection system. R-CNN has problem with respect to heavy and long dataset. Object detection happens in two steps region of interest identification and then actual classification and the performance decreases for unlabeled dataset. R-CNNs does not look at the complete image. Instead, parts of the image which have high probabilities of containing the object.

Regression-based YOLO (You Only Look Once) model was proposed by Joseph Redmon, Santosh Divvala[4].YOLO has a single convolutional network predicts the bounding boxes and the class probabilities for these boxes directly from full images in one evaluation. The problem with YOLO Model is that it only predicts 1 type of class in one grid hence, the performance degrades with small objects within the image, for example detecting a flock of birds.

Single Shot Multi Box Detector (SSD) was proposed by Wei Liu, Dragomir Anguelov[5]. SSD is a multi-scale sliding window detector which slides a local window across the image and identifies at each location whether the window contains any object of interests or not. SSD Model is a modification of the VGG16 architecture. It is

based on a feed-forward convolutional network that produces a fixed-size collection of bounding boxes and scores for the presence of object class instances in those boxes, followed by a non-maximum suppression step to produce the final detections. SSD Model take one single shot to detect multiple objects within the image, while R-CNNS need two shots, one for generating region proposals, one for detecting the object of each proposal. Thus, SSD is much faster compared with two-shot R-CNN Models.

But there are also some limitations of SSD Models like it not only confuses objects with similar categories (e.g. animals) but also produces worse performance on smaller objects, as they may not appear across all feature maps.

Objet detection using Region based CNN, YOLO and SSD models require huge computation and large power consumptions which is a big challenge for real-time multiple object detection deployments on resource constrained devices, e.g., mobile phones or embedded gadgets. A resource constrained scenario means a computing task must be accomplished with limited resource supply, such as computing time, storage space, battery power, etc. Running deep learning models is computationally expensive. SSDlite is a light weight model is primarily used to locate object and Mobilenet classify the object.

SSDlite requires only 2.1 M parameters as compared to Base SSD model (14.8M)[6] SSD_Mobilenet_v2 is a combination of MobileNetV2 and SSDLite can produce the multiple

object detection. MobileNetV2 + SSDLite is 20× more efficient and 10× smaller while still outperforms YOLOv2 on COCO dataset [6]II. PROPOSED WORK

In the proposed system, SSDlite_Mobilenet_v2_COCO model is trained on GPU GTX 1650 Ti server USING MS COCO datasets. It includes all 164K images from COCOs

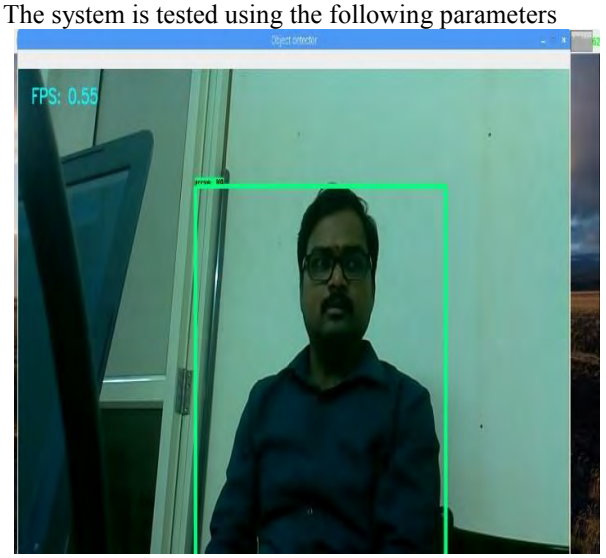
2017 (training 118K, validation 5K, test-dev 20K, test-challenge 20K). It covers 172 classes: 80 thing

classes, 91 stuff classes and 1 class 'unlabeled'.

The trained model is retrained and deployed on RasberiPi 3 Model B has features a quad-core 64-bit ARM Cortex A53 clocked at 1.2 GHz. Input image is taken by a camera is attached to RasberiPi 3 Kit.A model is retrained and results are checked with GPU results.

III. RESULTS & DISCUSSION

The system is tested using the following parameters

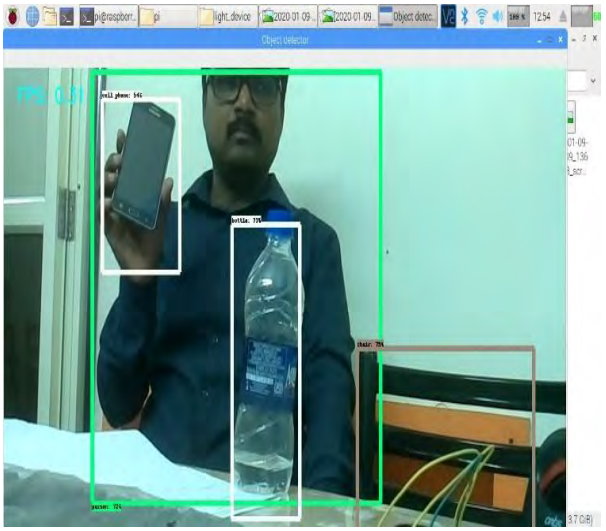


Frame per second (FPS)

Mean average Precision (mAP) The results are pending

Single Object Detection Result

.



IV. CONCLUSION AND FUTURE WORK

The SSDlite_Mobilenet_v2_COCO model is trained on MS COCO datasets. It is deployed on Raspberry Pi 3 Model B. It detects single as well multiple objects in image. The performance of the model on GPU is faster as compared to low constrained devices in terms of FPS. In future, Due to low processing speed and storage space if we run the model for long time, the model restarts again. In future, we will focus on how to improve the FPS by reducing the number of layers and normalization techniques.

Android Employee Tracker

Pranjali Kasture, Aishwarya Nambiar, Shubham Mundhra
IT, Thakur College of Engineering and Technology
Mumbai, India

Abstract—**In the past few years the development and growth of Android based applications have had a great impact on people's lives. The objective of an Android Employee Tracker is to track the location of an employee and track the productivity of an employee. This system or application will automate the tracking and monitoring process of an employee and increase the productivity and efficiency of all the employees. This in turn will increase the overall efficiency and productivity of an organization. The system is a coalition of a web-based application and an android application wherein the employees will use the android application and the management uses the web-based application. This system is intended to monitor field employees where the tracking of an application is necessary in order to monitor the productivity. When the employee opens the android application, the application will take the employee to the login page. The login page will contain the classic login fields such as login id and password. The employee will click a picture with the photo clicking option and submit along with user id and password. This will take the employee to the page where the location in terms of latitude and longitude coordinates are displayed and the field for describing the purpose of the employee's visit.**
The management will receive a notification or an update through the web-based application where they can check the location details of all the places visited by the employee as well as the log details with the time and the picture as proof.
Using this system, the employees will be monitored and hence
improves the productivity of the employees. This type of application and system could dramatically improve the productivity and efficiency of an organization.

Keywords—location, GPS, photograph, log details, maps.

I. INTRODUCTION

Based on the previous experiences such as inconsistency in data, loss of data, problems in tracking employees, problems in scheduling future activities for the Employees, we are implementing a new generation Android Employee Tracking System. The aim of the Android Employee Tracker application is to automate the employee tracking and monitoring process and improve the productivity and efficiency of the employees and management. This is an essential step in improving the organizational growth of a company and helps improve its overall productivity.

II. PROBLEM DEFINITION

The rapid growth of android based applications are creating a great impact on our lives. The aim of the Android Employee Tracker application is to automate the employee monitoring process. This approach also helps in improving the organizational growth of a company and also increases the overall productivity of the organization. This system helps the administrator and Human Resources department to keep track of the employees who go for field work. Since GPS location of the employee is tracked, so employee will not attempt to add proxy attendance. The system should be robust and be able to make productivity report. The system should be able to take input from the employee's application for tracking purpose. The system should be able to maintain the records of all employees.

Phase wise planning of the system

Planning: Applying agile methodology for tracking employees for better usage of resources and time with great performance.

Analysis: Prepare a detailed analysis on present tracking
systems and overcoming its limitations in our system. **Design:** Integration of data and designing of android and web application.

Coding: Writing the whole system app code and taking help
of open source.

Implementation: Giving user to test alpha testing and gathering centric analysis of performance, feedback, and try to improve the quality of result/output.

Testing: Doing the various test on the system app like unit testing, smoke testing, stress testing, integration testing, regression testing, system testing, etc. of test case data to check if the integrated system functions are desired by the organization.

Deployment: Conduct beta testing for identifying any further errors, bugs and improvements that can be performed. After testing and approval, deploy the proposed system.

III. BACKGROUND

Android Employee Tracker is an advanced monitoring technique which uses android application and web application for automating

the entire monitoring process in an organization or company [1]. This system increases accuracy in managing employees, manager and company's data. This application is important in the global environment to find out the strategic trend of resource utilization in the organization [2]. This system is a combination of a web application and android application where the employee (user) will be usin the android application and the administrator as well as the Human Resources department will use the web application [3]. This system is meant for employees who work in the field and need their location to be tracked. The main reason behind this application is Managing and keeping track of employees is cumbersome and problematic [4]. The Android Employee Tracker assists in the management, monitoring, searching, tracking, updating of employee's record.
where admin will view image and GPS location in web application.
After Login, GPS location of the employee will be tracked automatically by the system and send to the admin after every 5 minutes.
When employee logs out of the system again the image will be
captured as well as GPS location will be send to the admin.

IV. METHDOLOGY USED

Agile methodology mainly focuses on the incremental and the iterative development of the different project phases. It controls and determines how the various stages are implemented and what kind of environment is involved. The project is first divided into different phases, and then the responsibility of developing these phases is given in the hands of the various developers. At every stage of the project development it is continuously monitored and taken care of These developers developing the phases have particular amount of time period and tasks involved with them. The agile methodology used in the development in Android Employee Tracker is based on regular communication with the client. The agile methodology takes into account flexible planning, customer involvement, constant evaluation and risk management. The website development depends on the requirements of the client and the quality of communication with them. The project is developed using Android Development Toolkit(ADT) along with Visual studio 2010 and SQL.

Feasibility Study:

1. Executive Summary

Project is related to Android Employee Tracker
It is a combination of following two applications:
Web application
Android Application

Main facilities available in this project are: -
Maintaining records of employees.
Efficiently tracking employee's location.
Providing field locations to the employees.
Maintaining backup data of all employees.
Updating Employees about the upcoming projects.

2. Define business problem or opportunity

Combination of web as well as android application: User (employee) used android and admin (HR) uses the web application.
When the user will login to the system his image will be captured and his GPS location will be send to the admin

Every user should be:
Comfortable of working with computer
He must have knowledge in developing Android

Application
He must also have basic knowledge of web and development skills

3. Purpose of the study

Purpose

The system produced will be very easy to use
It provides facilities like:

It will be easy to maintain.
The system will be very cost friendly
The system will have interactive user interface

In case any part stops working, all the parts are readily available in the market and are very cheap
The system is based on basic modules which are easy to replace/swap if needed. This shall make it easy to
maintain and to work on.

4. Audience impacted

It is designed for industry with field employees that impact the overall productivity and revenue of the company.

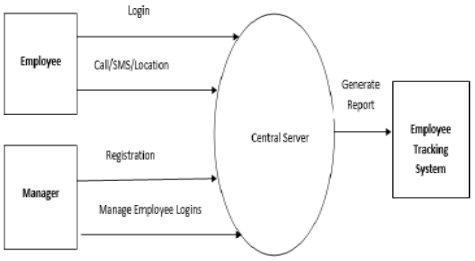
Technical feasibility

As already many employee tracking applications are available but
when it comes to security this is more secure than any other application.

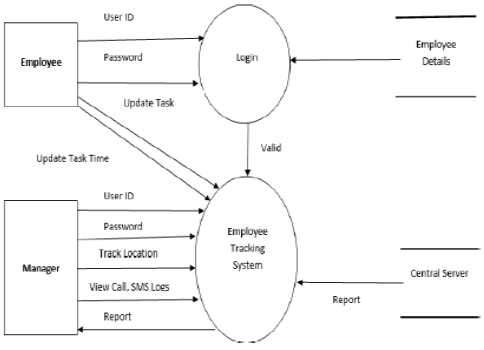
Economic feasibility
As this application is organization specific it will only cost for the
database server to keep backup and host the system on the server.

Socio-cultural feasibility
As Android Employee Tracker is all about managing employees there will be complete transparency between the organization and the employees.V. DESIGN AND IMPLEMENTATION

Dataflow Diagram



F Level 1



Level 2

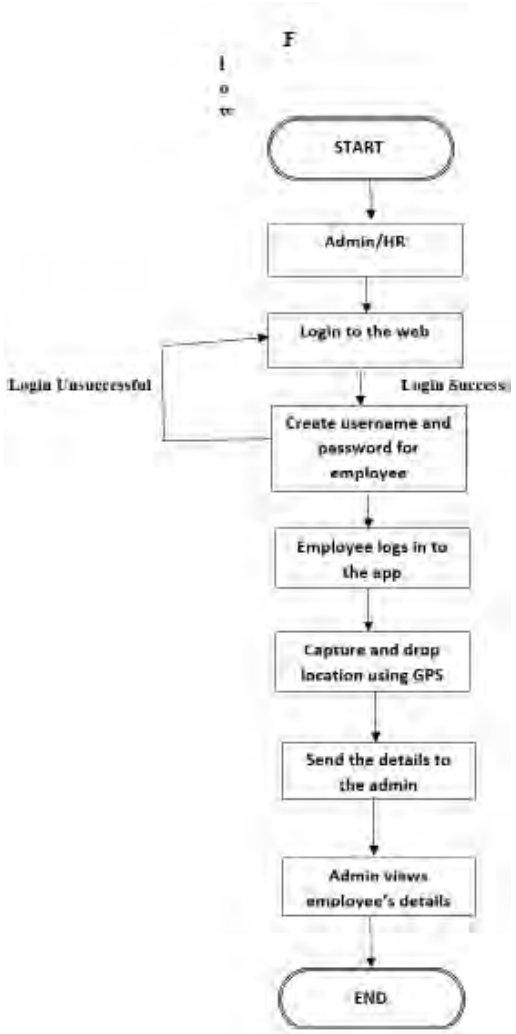


Fig 1: Flow diagram of a system

VI. RESULT

We successfully achieved to eliminate the disadvantages of other messaging systems such as advertisements, distraction
because of friends or other spam messages, fake rumors.
We managed to eliminate the subscription system and instead
of paying in repetitive manner client can own this with one time pay and can get customized according to its needs which is not provided in others.
The latitude and longitude detected by the system has about
90% accuracy wherein the exact location along with neighboring landmarks is visible on the map.

Screenshots:
Web Application:

Fig 2: Login page of web application

Fig 3: Manage Employees

Fig 4: View Location on Maps

Fig 7: View Photograph as proof

Fig 5: Salary Generation

Android Application:

Fig 6: Login Page of Android Application

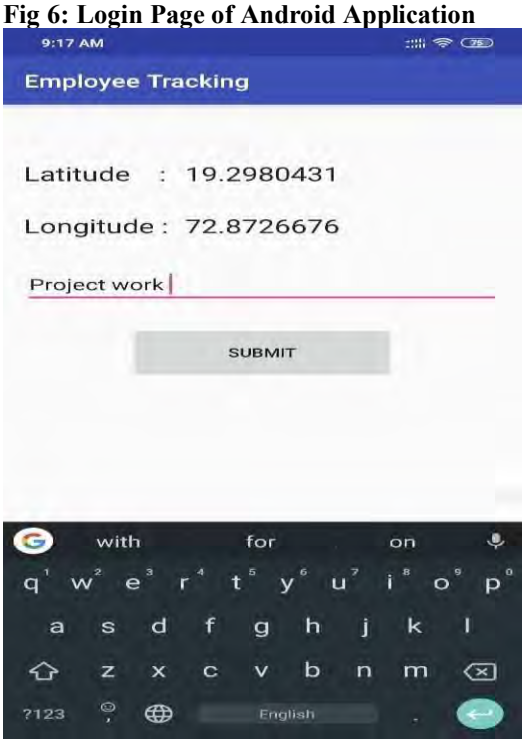

Fig 7: Employee submits location and reason for visit

VII. CONCLUSION:

It can be concluded that with the designed system (Android Employee Tracker), custom tracking can be effectively used by any organization.

Android Employee Tracker application leads to understand tracking using GPS.

Using the web application, the administrator is able to track the employee's location as well as view the subsequent photo uploaded. This web application will also be able to

add, delete or edit an employee's details as well as generate

an employee's salary according to the number of days the

employee was logged into the system.

The system apart from tracking locations can be used to measure the number of working hours and that resulting in the accurate calculation of payroll. A centralized system where all the employees are using one system for in house or out house project, achieving the highest level of efficiency.

This improves the efficiency and productivity of the work done and improves the organization's overall value.

VIII. FUTURE SCOPE:

The system apart from tracking locations can be used to measure the number of working hours and that resulting in the accurate calculation of payroll. A centralized system where all the employees are using one system for in house or out house project, achieving the highest level of efficiency.

Autonomous chatbot building for enhanced user interaction

Vishal Vishwakarma, Vidit Vora, Shubham Singh, Rahul Neve
(Information Technology, Thakur College of Engineering & Technology, India)

Abstract – **Chatbots are being widely used these days to improve the customer engagements and user interaction when the user visits the websites. The applications of chatbots range from HR services, customer support to helping people with bank transactions. The main problem arises when a website owner needs to create his own chatbot based on the website's content. The task of creating a chatbot is very tedious and requires the user to define the intents and entities [4] by himself. Though there are API available in the market, the website owner needs some knowledge about how chatbots work and then he will be able to deploy it. This process requires a lot of time and also data collection from the website is a cumbersome task. The task of gathering data for the chatbot and then feeding it to the API can be automated. We can use a scraper that will gather URLs and text from the given domain name by the user and then feed that data to an NLP engine which will learn on the given data and a basic chatbot which the user can converse with and also deploy will be available in no time. We need to scrap and summarize text and then provide that to the NLP engine. We have explored different NLP algorithms that can be used by the engine on the provided text. This helps us in getting a clear understanding of how NLP algorithms will work and which ones to be used. Majority of the NLP algorithms use POS i.e. Parts of Sentence tagging which is used to key the sentences. A crawler is used to get links from the provided domain name. The crawler is able to gather around 40-50 links based on the domain name.**

The NLP engine is trained on English language beforehand and Analysis of context [1] view needs to be done for the purpose of showing the user what the bot has interpreted from the provided query. This results in reduced number of typed messages and the user is also able to get answer for his query as quickly as possible as the user is able to edit in the dialog flow what the bot thinks and then accordingly proceed with the conversation.

Keywords: Chatbot, automated, bot builder, crawling, entities, intent

I. INTRODUCTION

We aim to create an autonomous chatbot based on the given URL which is provided by the user. The system should be able to get relevant information from the URL/free text that is provided and also form business logic accordingly and that should act as a data for the chatbot. The crawling of web-pages for a given website should be done quickly and then a virtual agent should be ready to answer questions for that given bot. The manual work which is required to build conversational chatbot needs to eliminated to a great extent. The time should be reduced as the user should be able to deploy chatbots on the fly. The cost of this process should be bare minimum as small businesses should be able to deploy affordable chatbots on their websites. Further, to increase customer engagement an attractive dialog flow UI needs to be developed which will have context[1] view i.e. it will show what the bot inferes from a given query of a user and the user should be able to change the value if wrongly interpreted thus helping the user to get his information quickly.

II. MATERIALS & METHODS

Software specifications:- User requirements:
Browser: last stable version of Chrome/Firefox
Developing environment: Operating System: Ubuntu 18.04
Language: Python 3.5, Node js, HTML/CSS for designing the landing page
Frameworks: PyTorch/Tensorflow
Softwares: git (version control), sublime text, pycharm

Hardware specifications (developing environment):-
CPU: 3.2GHz
RAM: >= 8GB
Hard Drive: >=100GB
Network: Wifi/Broadband connectivity

Customer Interaction Details

Website URL: The customer needs to enter his website URL of which he intends to create a chatbot. The URL is compulsorily needed as the system requires the URL to successfully crawl and scrape the website provided for information.

Email-id: The user requires to enter his own email id and then verify it, we need this as malicious user may enter the website name and make the server busy thus causing lag for other users.

Facebook page access token: If the user wishes to deploy the chatbot over his facebook page, we need to

have the access token generated by Facebook for it

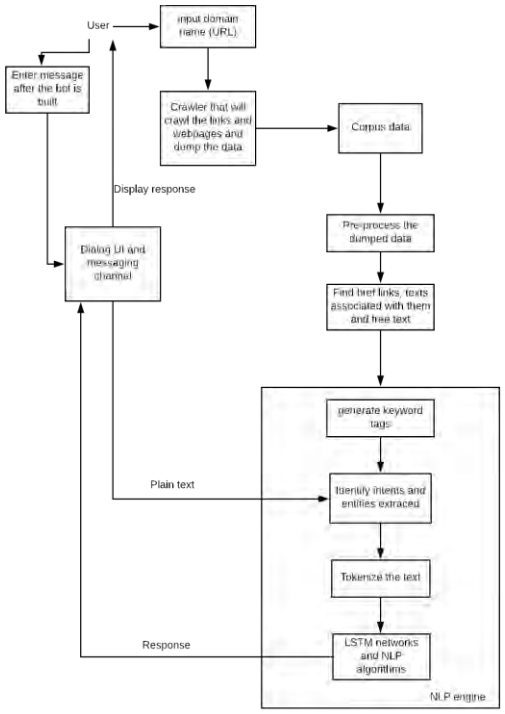

Fig 2.1 : Block diagram explaining the working of the system

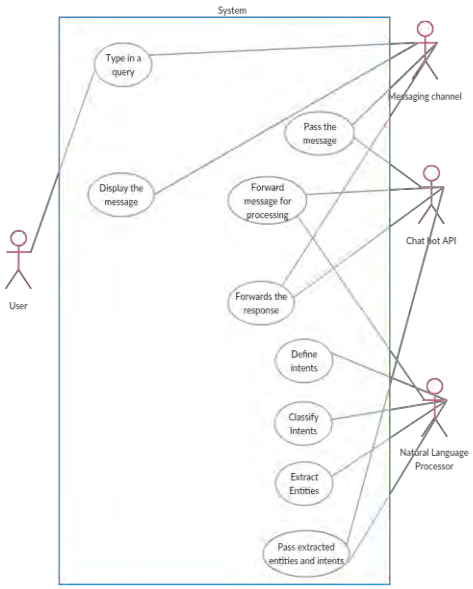

Fig d 2.2: Use case diagram when the system will be eployed.

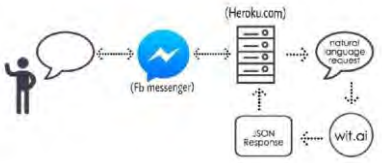
of of concept to show existing way of creating bots: A sample bot was deployed on facebook essenger after obtaining the links crawled on the llege website. The process of feeding the URL to the was manual. The purpose of doing this was to check ow difficult it is to deploy a chatbot on the facebook en doing it manually.



wh

2.3 Flow diagram for the implemented PoC

his process was manual and very cumbersome. The nly automated thing in this process was the crawling of e website. In further phases we plan to make the entire rocess automated as proposed earlier.

III. RESULT

We were able to create a crawler that retrieved links provided the URL of the webpage using existing libraries. The task of surveying various design techniques for conversational agents was also undertaken and the algorithms were analyzed and finalized for our use case. LSTM[6] networks were explored using the Tensorflow API and training the bot first for the English database.

Fig 3.1: Output of the crawler

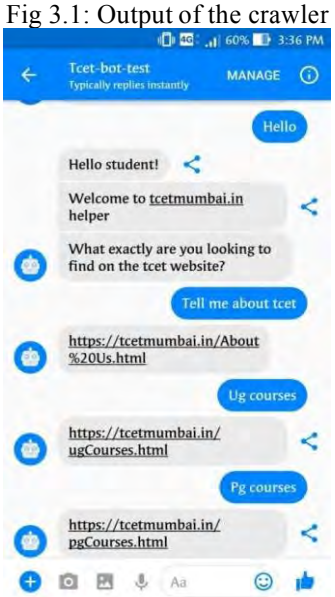

Fig 3.2: Deployed test bot on facebook messenger that replies with crawled URLs

IV. DISCUSSION

The project needs to be diversified by increasing the limit on the number of webpages that is supposed to be crawled. The user should get an option to deploy the bot on a cloud of his choice and a platform that he desires rather than forcing the user to deploy the bot using our cloud server of their choice. The further stages involve working on the GUI of the chatbot and working towards context[1] view, which will hopefully prove to be beneficial to the users that will visit the website owner's website and use the chatbot that was created by our system.

Spelling check in the user query when he enters a message in the chatbot can be done to improve the precision values when the response is generated. The user can have an option to use a dedicated crawler for his own website that will track the changes that are taking place on his website and then update the training data for the bot as well. In further stages, user can just link his FAQ and help pages in the input url and the system will be focused on that only. Thus making a dedicated helper chatbot for the website.

In the current scope there is no scope for user to access how the bot trains itself and the website owner is also not able to create his own personalized conversations that were not able to capture by the crawler used. This will help in filling the gaps that an autonomous bot faces, the learning is not always correct, but the user can intervene to make it correct and then make the committed value as part of the correct values. This will help when the bot encounters the same question again by the user, this time the bot will answer the query correctly. This makes the system a truly learning system.

V. CONCLUSION

Using scrum[8] methodology, we have successfully created a proof of concept wherein the user was able to crawl[7] the links of the provided website and then manually fed to the API. The task of feeding the gathered URLs is not yet automated. A basic command line bot trained to answer basic English questions was also created. We have also explored various NLP algorithms that will be used in the further stages to create the NLP engine. Using Long Short Term Memory networks for chatbots is one of the quickest way to train the bot and it also provides very accurate results. Context[1] view seems to be a very promising feature as during the study it was found that majority of the available chatbots in the market fail to interpret what the user is trying to say but using context[1] view, we will bridge this gap by showing after each message what the bot is interpreting from the user's message and thus enabling the user to edit the view and then proceed with the conversation. This feature is not yet implemented in the mainstream chatbots and thus incorporating it in our project will make it a novelty and also help us to gain insight on how users adapt to these new context[1] view feature and thus helping us to create a comparative study for the same.

Drowsiness Face Detection

Vishal Mishra, Manav Mishra, Kanishk Mishra
Information Technology, Thakur College of Engineering and Technology, Kandivali Mumbai, India

Abstract: **Road Accidents is one of the serious problems seem emerging in the world today. About 1, 05,000 ever year die due to road accidents. It is mainly either due to poor infrastructure or poor driving habits. With the emergence of IT and It's multiple avenues that its offers has proved to be boon to humankind. Drivers Drowsiness is one of the major problems seem emerging and sincere efforts is expected to tackle the problem in order to safe-guard safety of the drive and people in general and also smooth transportation. Detecting real-time drowsiness is done with the help of efficient techniques with consideration of eye and mouth ad primary constraints. It mainly discusses the level of drowsiness and major implementation in consideration. The application is being in C#, python, with OpenCV which uses the webcam which is positioned straight to the face and eye of the driver so as to get the the details of the constraints through eye and mouth. This will enable the extraction of the facial images which will be used to compare with different templates feed through training of the data. It also uses HAAR classifier to extract EAR ratio. The project t is of three types based on physiological, behavioral and the one on vehicular based which is integrated with webcam which is used to alert him upon finding drowsiness while driving.**

I. INTRODUCTION

The project aims at building a face detection system to see the intensity of drowsiness in drivers though system which can be embedded into vehicle system for detection of drowsiness while driving. In the past the number of road accidents have increased by road-side vehicle drivers. The Primary reasons were found to be mainly because of inability to see and inattentiveness. With past studies and researches, it has been of major concern to develop a system which could help drivers while driving. A lot of papers have been published with real time model having drowsiness face detection embedded in them. Amongst them are BMW with Driving Assistant plus, Ford with Active city stop etc.

According to the research conducted this system of vehicle safety helps to reduce and prevent road-side accidents by alerting drivers from getting drowsiness. This project effectively involves studying the drivers' patterns viz. his physical and behavioral patterns which effectively get driver from becoming drowsy. Some of the existing system use steering pattern monitoring, vehicle position in lane monitoring, driver eye/face monitoring etc. The systems available Audi with rest recommendation system, BMW with active driving assistant with attention which analyses the driving pattern which employ graphic symbols. Bosch which takes steering sensor, front mounted lane assists camera vehicle speed turning signal stalk and may other systems available in the list. Ford using driver alert, Honda available with Driver attention monitor Hyundai with its latest Driver Alert system i30.

The model is expected to be implemented in OpenCV python and open-source but as an alternative and ease of language and availability of resource other languages are also used as an alternative. It rings an alarm when drivers found sleeping. This is determining with the help of Famous Jones Viola algorithm also known as (HAAR). Through this the images of eye on its location from face is extracted and with the ratio of blinking proportional to time in terms of delay. The overall aim of the project is to improve efficiency in building the system and reducing the number of road-accidents

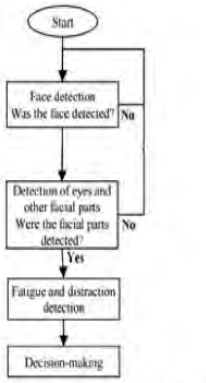
II. MATERIAL AND METHODS

This project application comprises the use of the following resources be it in hardware and software which is discussed as follows:

Hardware specifications:
Sensors
Bluetooth
Webcam

Software Specifications:
Microsoft Visual Studio
Any Text Editor (Visual Studio Code)
Procedure methodology

The output of the Viola Jones Algorithm is a trained Haar Classifier that is stored in a XML File which



Flowchart of the proposed system

can be loaded using the OpenCV function: cvLoad() and then cv Haar Detect Objects() is used to find objects similar to the ones it was trained on to train our own classifiers to detect other objects such as faces , eyes and mouth. This has been done with the OpenCV *haartraining* application, which creates a classifier from a training set of positive and negative samples. Steps are described discussed above as seen in diagram.

III. DISCUSSION

The camera successfully detects the movements of facial expression. The study and use of Jones Viola Algorithm and with help of Haar classifier in successfully extracting the facial images is the objective and its integration of the same with the help of the webcam matches the output

The intended project will take the facial images of the drivers face of measure various facial parameter, nodes on faces thereby working accurately serving its purpose to the fullest of detecting drowsiness. Python and OpenCV have been popular choices among the developers due to its vast library.

AI is currently on the boom. No doubt the future will belong to this domain. A lot of research has been done in the past and multiple advancement has been done in medical applications, fraud detection and self-automated car driving. This model will be an example of the superiority of AI and its branches in information technology.

The project takes the snaps of human faces measures on various inputs of eye-blinking rate, delay in eye blinking and other facial nodes for yawning and head distraction to gather images, match them with already available in database and alert the driver from mishap. The algorithm used are jones viola algorithm, Haar classifier.

The study is expected to apply the concepts and techniques of Artificial intelligence in building efficient sleep drowsy detection system. It's no doubt that the field of AI vast and the level of complexities it has in understanding neural networks deep learning, facial algorithm will offer an proper base for learning among the members.

Understanding of the various algorithm namely jones Viola algorithm popularly in building the system is of prime importance. In addition to that building and system for is compatibility over different devices and its integration in smart phones is of another concern which can be further incorporated or be an interesting base for future research.

IV. CONCLUSION

The algorithm presented in this paper forms the basis of many 'Real Time System' which gives highly accurate results in less time. This system was built keeping in mind every possible behavior of the driver and also the need for a quick computed result which is accurately achieved by the Viola Jones algorithm which is the backbone of Drowsy Detector Algorithm. In the current system when the multiple faces are detected the results are inaccurate. The optimum result would be, if multiple faces are detected then only the driver's face should get detected. This could be achieved using the Depth Calculations wherein the area of the rectangles of multiple faces are calculated and the largest area is selected since in most of the cases the driver's face would be ahead and all the extraneous faces would be behind the driver.

Heart Disease Prediction using Machine Learning and Artificial Intelligence

Darpan Mehra, Varun Mishra, Shridhar Kamble
Information Technology, Thakur College of Engineering and Technology/ Mumbai University, India

Abstract – **Heart related diseases or Cardiovascular Diseases are the main reason for a huge number of deaths in the world over the last few decades and has emerged as the most life-threatening disease, not only in India but in the whole world. So, there is a need of reliable, accurate and feasible system to diagnose such diseases in time for proper treatment. Machine Learning algorithms and techniques have been applied to various medical datasets to automate the analysis of large and complex data. Many researchers, in recent times, have been using several machine learning techniques to help the health care industry and the professionals in the diagnosis of heart related diseases.**

Data analytics is useful for prediction from more information and it helps medical centre to predict of various disease. Huge amount of patient related data is maintained on monthly basis. The stored data can be useful for source of predicting the occurrence of future disease. Some of the data mining and machine learning techniques are used to predict the heart disease, such as Artificial Neural Network (ANN), Random Forest, and Support Vector Machine (SVM).

Prediction and diagnosing of heart disease become a challenging factor faced by doctors and hospitals both in India and overseas. The main objective of this research project is predicting the heart disease of a patient using machine learning algorithms.

I. INTRODUCTION

Heart diseases have emerged as one of the most prominent cause of death all around the world. According to World Health Organisation, heart related diseases are responsible for the taking 17.7 million lives every year, 31% of all global deaths. In India too, heart related diseases have become the leading cause of mortality [1]. Heart diseases have killed 1.7 million Indians in 2016, according to the 2016 Global Burden of Disease Report, released on September 15, 2017. Thus, feasible and accurate prediction of heart related diseases is very important. Current approaches to predict cardiovascular risk fail to identify many people who would benefit from preventive treatment, while others receive unnecessary intervention. Today numerous doctor's facilities introduced some kind of quiet's data frameworks to manage their social insurance or patient information. These data frameworks commonly produce a lot of information which can be in distinctive organization like numbers, content, diagrams and pictures yet sadly, this database that contains rich data is once in a while utilized for clinical choice making. There is a lot of data put away in stores that can be utilized viably to guide a medical practitioners in decision making in human services.

II. II. MATERIAL AND METHODS

This project was carried out using data available on the website of University of California – Irvine to train our models.**Study Duration:** September 2018 to February 2019.

Number of Attributes: 75

Number of Significant Attributes: 13

1. #3 (age)
2. #4 (sex)
3. #9 (cp) (chest pain type)
4. #10 (trestbps) (resting blood pressure (in mm Hg on admission to the hospital)
5. #12 (chol) (serum cholesterol in mg/dl)

6. 6. #16 (fbs) (fasting blood sugar > 120 mg/dl) (1 = true; 0 = false)
7. #19 (restecg) (resting electrocardiographic results)
8. #32 (thalach) (maximum heart rate achieved)
9. #38 (exang) (exercise induced angina (1 = yes; 0 = no))

10. #40 (oldpeak) (depression induced by exercise relative to rest)
11. #41 (slope) (the slope of the peak exercise ST segment)
12. #44 (ca) (number of major vessels (0-3)

colored by fluoroscopy)

13. #51 (thal) (3 = normal; 6 = fixed defect;

7 = reversible defect)

14. #58 (num) (the predicted attribute)

We are using Tensorflow, Numpy, SciPy, and PyTorch; all of which are open source frameworks written in Python.

To avoid overfitting of the model, we would be following a step by step analysis of our deep learning model. The end result of the analysis is achieving accuracy of more than 90% for a cardiovascular disease and stroke prediction.

Algorithms used for analysis:

1) Random Forest Algorithm

Random forest is a concept falling under the general technique of random decision. This algorithm operates by creating a group of decision trees at training time

and outputting the class that represents the mode of classes or the mean prediction of the individual trees. Individual decision trees are generated using a random selection of attributes at each node to determine split. During classification, each tree casts a vote and the most popular class is returned. Using the Random forests, the variance can be reduced by averaging the deep decision trees trained with different parts of the training set. To form Random forests, tree predictors should be integrated in a way that each tree be dependent on the values of a random vector sampled independently and uniformly from all trees in the forest. We use this approach to predict flight delays in our database.

Random Forest is also a popularly supervised machine learning algorithm. This technique can be used for both regression and classification tasks but generally performs better in classification tasks. As the name suggests, Random Forest technique considers multiple decision trees before giving an output. So, it is basically an ensemble of decision trees. This technique is based on the belief that a greater number of trees would converge to the right decision. For classification, it uses a voting system and then decides the class whereas in regression it takes the mean of all the outputs of each of the decision trees. It works well with large datasets with high dimensionality

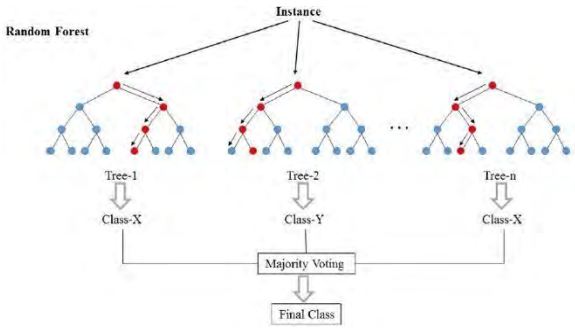

Figure 1: Random Forest Algorithm

2) Support Vector Machine (SVM)

Support vector machines exist in different forms, linear and non-linear. A support vector machine is a supervised classifier. What is usual in this context, two different datasets are involved with SVM, training and a test set. In the ideal situation the classes are linearly separable. In such situation a line can be found, which splits the two classes perfectly. However not only one line splits the dataset perfectly, but a whole bunch of lines do. From these lines the best is selected as the "separating line".

The best line is found by maximizing the distance to the nearest points of both classes in the training set. The maximization of this distance can be converted to an equivalent minimization problem, which is easier to solve. The data points on the maximal margin lines are called the support vectors. Most often datasets are not nicely distributed such that the classes can be separated by a line or higher order function. Real datasets contain random errors or noise which creates a less clean dataset. Although it is possible to create a model that perfectly separates the data, it is not desirable, because such models are over-fitting on the training data.

Overfitting is caused by incorporating the random errors or noise in the model. Therefore, the model is not generic, and makes significantly more errors on other datasets. Creating simpler models keeps the model from over-fitting. The complexity of the model has to be balanced between fitting on the training data and being generic. This can be achieved by allowing models which can make errors. A SVM can make some errors to avoid over-fitting. It tries to minimize the number of errors that will be made. Support vector machines classifiers are applied in many applications. They are very popular in recent research. This popularity is due to the good overall empirical performance. Comparing the naive Bayes and the SVM classifier, the SVM has been applied the most

3) Artificial Neural Network (ANN)

These are used to model/simulate the distribution, functions or mappings among variables as modules of a dynamic system associated with a learning rule or a learning algorithm. The modules here simulate neurons in nervous system and hence ANN collectively refers to the neuron simulators and their synapsis simulating interconnections between these modules in different layers [6]. The defining aspect of an ANN is the function implemented at each neuron and the learning algorithm for the dynamic weights assigned to the interconnections among neurons. What makes ANN stand apart is its ability to simulate human thought process coupled with continuous learning, growth and evolution. Also, it is capable of handling large number of parameters and large set of data with noise and yet achieves high accuracy.

Neural Network is built by stacking together multiple neurons in layers to produce a final output. First layer is the input layer and the last is the output layer. All the layers in between is called hidden layers. Each neuron has an activation function. Some of the popular Activation functions are Sigmoid, ReLU, Tanh etc. The parameters of the network are the weights and biases of each layer. The goal of the neural network is to learn the network parameters such that the predicted outcome is the same as the ground truth. Back-propagation along loss- function is used to learn the network parameters.

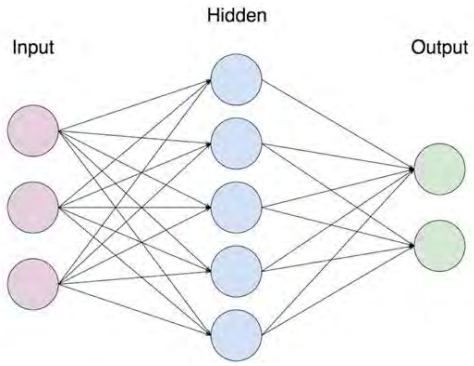

Figure 2: Artificial Neural Network

Sigmoidal Activation Function:

A sigmoid function is real-valued and differentiable, having a non-negative or non- positive first derivative, one local minimum, and one local maximum.
Sigmoid functions are often used in artificial neural networks to introduce nonlinearity in the model.
A neural network element computes a linear combination of its input signals, and applies a sigmoid function to the result. A reason for its popularity in neural networks is because the sigmoid function satisfies a property between the derivative and itself such that it is computationally easy to perform.
The activation function is given by:

1. Bipolar Binary Function:

$$f(x) = \frac{1}{1+e^{-\lambda x}}$$

2. Bipolar Continuous Function:

$$f(x) = \frac{2}{1+e^{-\lambda x}} - 1$$

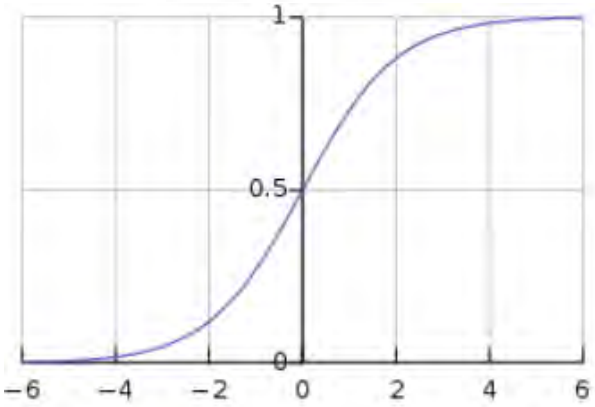

Figure 3: Sigmoidal Activation Function

ML, a branch of Artificial Intelligence, relates the problem of learning from data samples to the general concept of inference. Every learning process consists of two phases: (i) estimation of unknown dependencies in a system from a given dataset and (ii) use of estimated dependencies to predict new outputs of the system.
Figure 4: Proposed Methodology

Figure 4: Proposed Methodology

III. SOFTWARE AND LIBRARIES

Python:

To collect data a web scraper programmed in Python was used. Python's syntax allows programmers to express concepts in fewer lines of codes[13].
Python is intended to be a highly-readable language. It is designed to have an uncluttered visual layout, frequently using English keywords where other languages use punctuation. Furthermore, Python has a smaller number of syntactic exceptions and special cases than C or Pascal. Python uses whitespace indentation.
Why use Python for web scraping and not another thing? Python offers a module called 'urllib2', which has suitable functions to open websites and extract information easily.
Python is used to program the web scraper that is in charge of collecting the weather data for the model.

TensorFlow:

TensorFlow™ is an open source software library for high performance numerical computation. Its flexible architecture allows easy deployment of computation across a variety of platforms (CPUs, GPUs, TPUs), and from desktops to clusters of servers to mobile and edge devices. Originally developed by researchers and engineers from the Google Brain team within Google's AI organization, it comes with strong support for machine learning and deep learning and the flexible numerical computation core is used across many other scientific domains. [14]

IV. RESULT

After thorough analysis and synthesis of the training data as well as the test data, we were able to achieve an accuracy of more than 95% in all our three algorithms. On combining the results of these algorithm, a classification accuracy of 97.3%.

In other words, we are able to predict the cardiovascular diseases in 97 out of 100 patients. A report(graph) is shown below for all the algorithms:

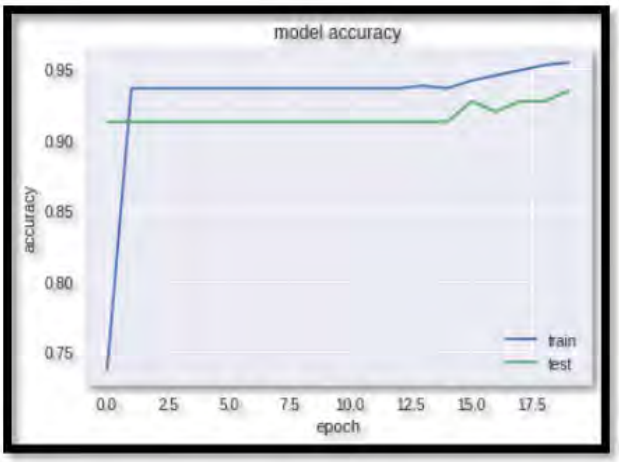

Figure 5: Random Forest Accuracy

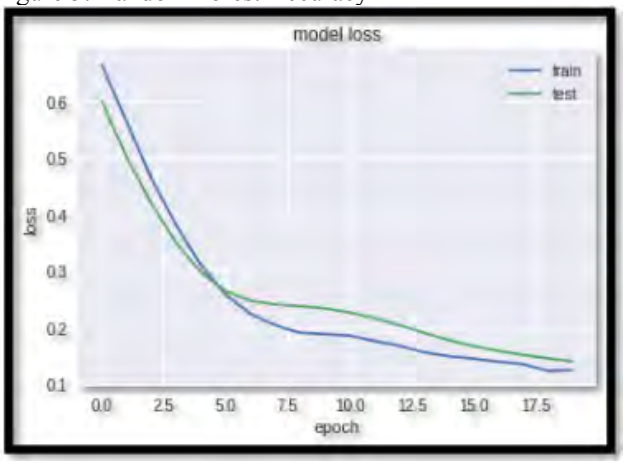

Figure 5: Random Forest Loss

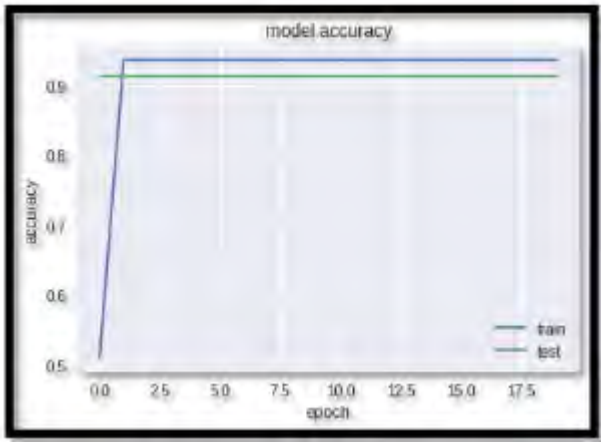

Figure 6: Support Vector Machine Accuracy

Figure 7: Support Vector Machine Accuracy

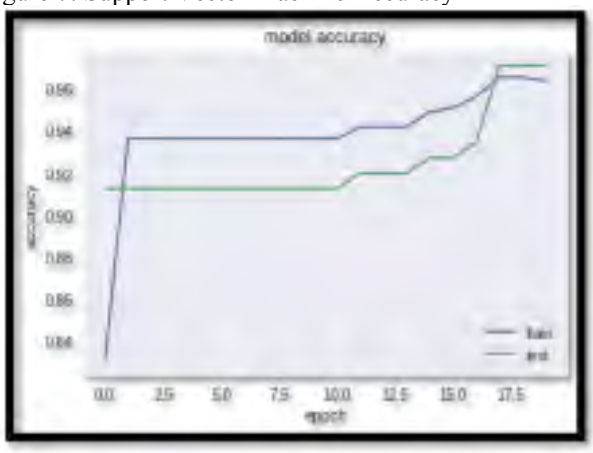

Figure 8: 3-Layer Neural Network Accuracy

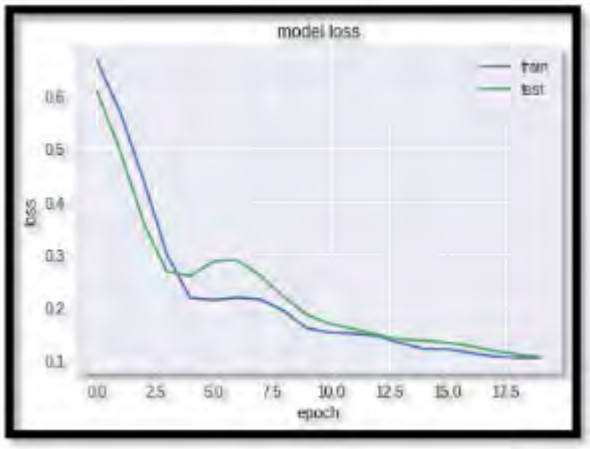

Figure 9: 3-Layer Neural Network Loss

V. CONCLUSION

This project provides the deep insight into machine learning techniques for classification of heart diseases. The role of classifier is crucial in healthcare industry so that the results can be used for predicting the treatment which can be provided to patients. The existing techniques are studied and compared for finding the efficient and accurate systems. Machine learning techniques significantly improves accuracy of cardiovascular risk prediction through whichpatients can be identified during an early stage of disease and can be benefitted by preventive treatment.

It can be concluded that there is a huge scope for machine learning algorithms in predicting cardiovascular diseases or heart related diseases. Each of the above-mentioned algorithms have performed extremely well in some cases but poorly in some other cases.

Public Address System

Krupal Vora, Neetala Parkar, Dhwani Desai, Dr. Rajesh S. Bansode
Information Technology, Thakur College of Engineering and Technology, India

Abstract – **The Public Address System is used to notify or address a group of people in a particular area over the speakers. The general use of the Public Address System is in the areas such as factories, fire departments, railways and many more. The current PA system contains a microphone which is connected to multiple speakers in the different locations. This current system is not very effective in the railways due to cacophony present in the environment of a railway station and the commuters are not properly notified. This project would help to minimize the problem by notifying the people through their personal devices. The existing systems that applied wireless public address system were unable to solve several technical challenges such as undiscoverable network, range limitation and jamming signals. The proposed system will be able to conquer the above limitations in an efficient manner. Public Address systems are being used at almost all the railway station in India. Although the world is becoming increasingly networked with each passing day, the PA system at stations remains an isolated one. The information is to be given to people for train availability and any emergency arising message on every passenger's phone in rail industries. A better approach is adopted to build a system which would help to overcome the problems of the current system. The new system would be able to send textual notifications to user's present on a particular railway terminal through application notifications process to user's personal device such as, the mobile phone.**

Keywords: MFCC Algorithm, Gaussian Mixture Model (GMM), notifications, text messages, public address system.

I. INTRODUCTION

A public address system (PA system) is an electronic distribution system using a microphone, amplifier and loudspeakers and sound amplification , used to allow a person to address a large public, for example for announcements at noisy and large air or rail terminals or at a sports stadium. The Railway network in Mumbai is 319kms long. There are five routes. They are two western railways, two Central railways and a harbour railway, which assists
6.6million to people travel through Mumbai. According to records, Mumbai Railway has the highest density of passengers in the world. To communicate information to a huge crowd on the railway a PA system is used. A new approach can be implemented by text based message system, using Mel-Frequency Cepstral Coefficients (MFCC) algorithm and Gaussian Mixture Model (GMM).

II. II. Material And Methods

1. Requirements

MATLAB
Android Studios
Android Device
Speech to text recognition software (MFCC Algorithm)

Server
Microphone

2. Methodology

2.1. MFCC

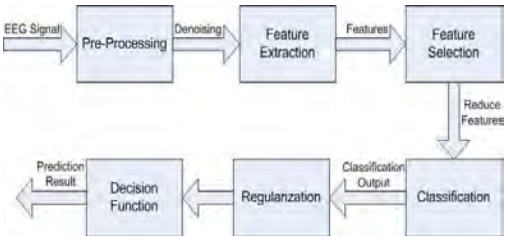

Fig 1: MFCC Algorithm Flow

The Mel-Frequency Cepstral Coefficients (MFCC) is one of the most prevalent and easy method to extract the spectral features from a human voice. The MFCC algorithm is widely popular among the speech recognition systems. The main features of the MFCC
include pre-processing or pre-emphasis, framing, feature extraction etc. The pre-emphasis method is needed because the components with high frequency have small amplitude as compared to the low frequency components. The pre-emphasis is the first step in the MFCC which helps to boosts these high frequencies for quality output. The input in the MFCC is a human voice i.e. analog signal, the analog signal is converted to digital signal to create samples. The framing method in the MFCC is used to create frames and acquire information from the samples. The feature extraction is a method to extract the features from the voice samples to create a cluster using the Gaussian Mixture Model (GMM).[1]

2.2. Gaussian Mixture Model (GMM)

The Gaussian Mixture Model (GMM) is a parametric probability density function which is represented as a weighted sum of Gaussian component densities. The GMM is a parametric model of probability distribution function of measuring features in a biometric system. The main feature of the GMM is used as a classifier to compare the different features extracted from the samples by the MFCC and create clusters of features with the Maximum Likelihood. The GMM is represented by Gaussian distribution and each Gaussian distribution is calculated by its mean, variance and weight of the Gaussian distribution.

The GMM uses the K-Mean algorithm for the creation of clusters.[1]

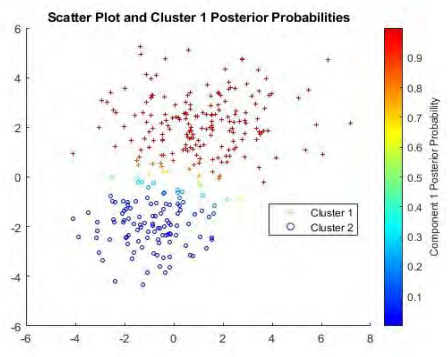

Fig 2: Scatter Plot and Cluster

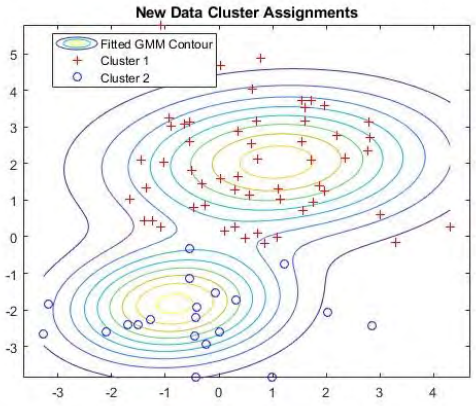

Fig 3: Cluster formation using GMM

2.3 System Flow

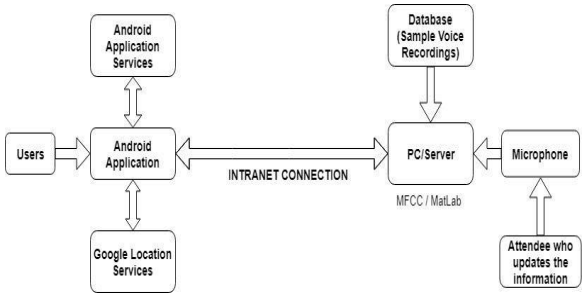

Fig 4: Block Diagram

- Referring to fig 4, the block diagram explains the working of text based public address system.
- In this approach we use text notification for addressing the passengers on the railway platform. According to our problem definition and objectives.
- The railway attendant will announce the update using a microphone which will pass through the MFCC Algorithm and Gaussian Mixture Model (GMM) for speech to text conversion.
- The registered passengers would receive the update via application notification, if the users are present in the mentioned range then and only then will they receive the messages which will be further tracked by the Google location API services installed in the android application.
- Android application helps in tracking the location of the passengers and thus a message will be sent on his/her personal device via text notifications.

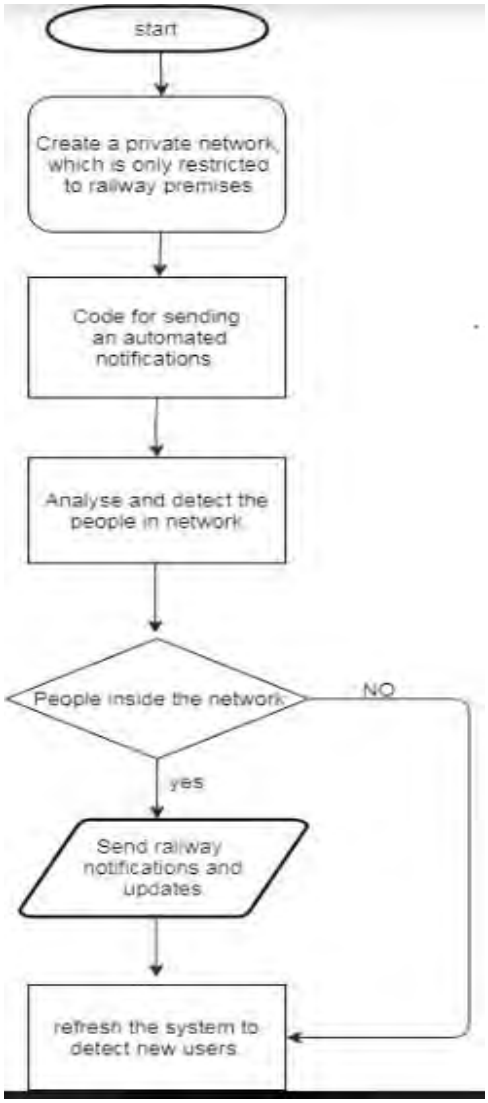

Fig 5: Flowchart

III. III. Result

A) Output

The new approach to public address system will provide the user/people travelling by the railway with satisfactory delivery of information. The system will convey the information to the personal devices of the

users through text messages. The main purpose of our system is to provide efficient means of communication medium to the users. People within the range of the Railway terminal will acquire the relevant information related to the terminal.

Fig 6: Announcement for Mumbai Central to Virar

In the above fig 6, the announcer provides a voice input regarding the information of the train. The announcer specifies that the train will be leaving from Mumbai Central to Virar from platform no.1 at 19:10 hours. The local is on time and is a fast train.

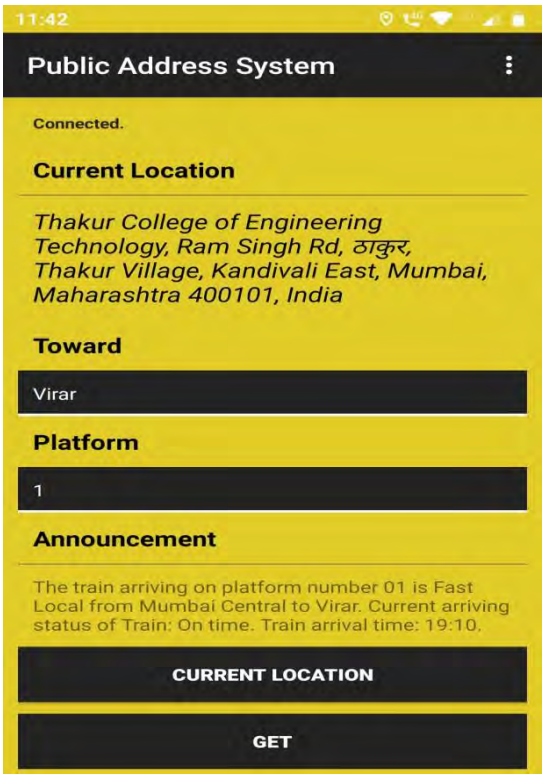

Fig 7: Notification from Mumbai Central to Virar.

The above fig 7, displays the notification for the above announcement for the train leaving from Mumbai Central to Virar from platform number 1. The above figure also displays the current location of the user.

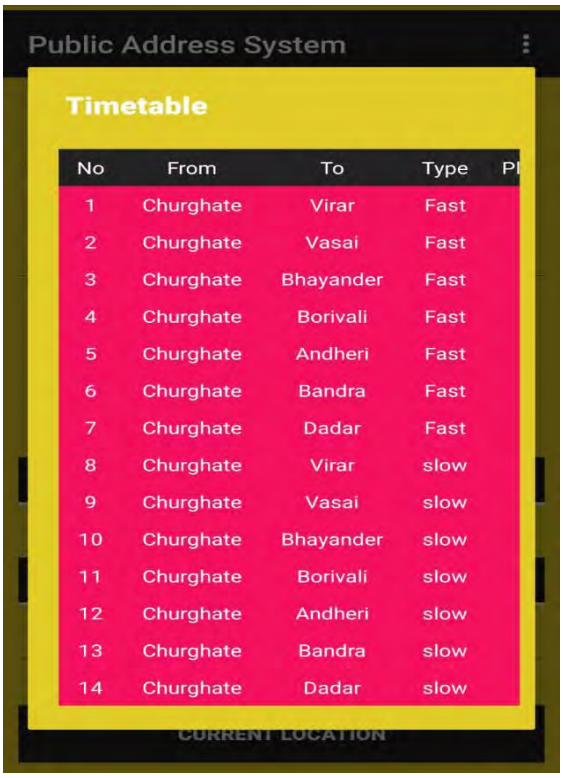

Fig 8: Train Schedule

In the above fig 8, the screenshot is rendering a schedule of the trains. The user can refer to the schedule and decide one particular train accordingly.

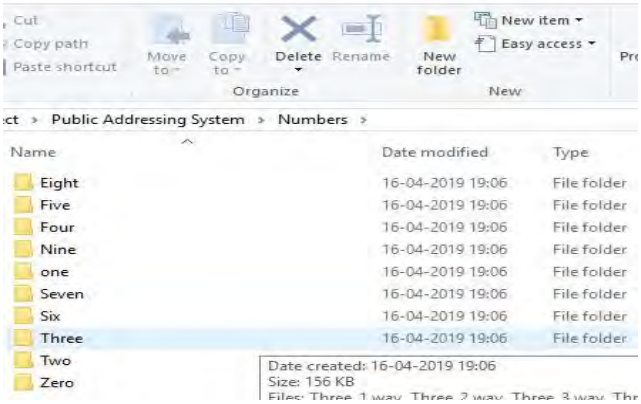

Fig 9: Database for Numbers

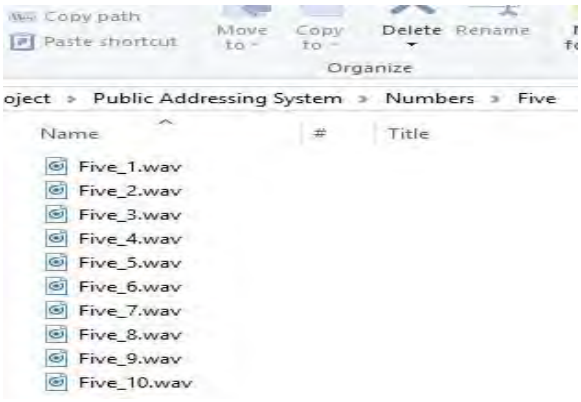

Fig 10: Voice Samples for Number Five

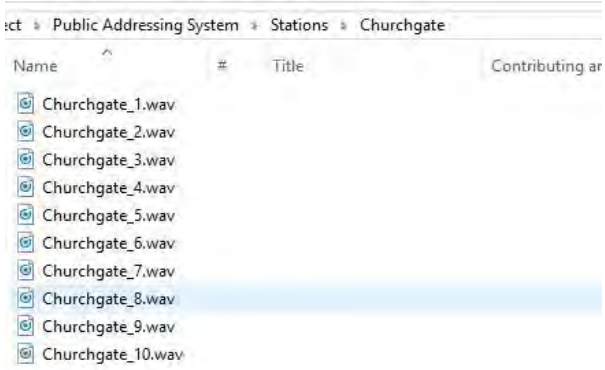

Fig 11: Voice Samples for Churchgate

Voice samples are recorded before the execution. The voice samples are trained by using MFCC Algorithm. The input voice is then compared with the configured voice samples. The algorithm then gives an output in a proper textual format.

Fig 12: Google Location

B) Outcomes

The proposed system will help enhance the current Public Address System for the Railways.

This system will create an efficient communication medium for the Railways to address scores of people.

C) Discussion of Results:

From the literature survey conducted and resulting research gaps acquisitions, the planned project tries to remove all the flaws and tries to provide an effective public address system to convey information to huge crowd. The main goal is to make a user friendly and efficient system for the Ministry of Railway.

IV. DISCUSSION

Public Address systems are being used at almost all the railway station in India. Although the world is becoming increasingly networked with each passing day, the PA system at stations remains an isolated one. The information is to be given to people for train availability and any emergency arising message on every passenger's phone in rail industries.

The need to build a system will help to overcome the problems of the current system. This new system would be able to send textual notifications to user's present on a particular railway terminal through SMS gateway process to user's personal device such as the, mobile phone.

The project aims to convert the speech of an announcer into text and send that text to Android smart phones using intranet. Now while using MFCC algorithm we can get a better voice quality and faster computation we also want to recognize what's said by the user. This is done by using trained samples stored in the databases for interpretation. The project can be mainly divided into two sections, one being the functioning of the MFCC algorithm and second being the development of android application. Understanding the android application development: To run Android apps our project already relies on an internet connection using a web based STT is a much better option. Application will consists of the admin server also the client supported API. The admin will update the information that is to be addressed to the crowd. The application will continuously check for any updates on the server relevant to the location. This will enable the application to send notifications to the relevant users.

Understanding the MFCC Algorithm and GMM: MFCC stands for Mel-frequency Cepstral coefficients. It is a voice recognition algorithm. Voice recognition works based on the premise that a person voice exhibits characteristics are unique to
different speaker. The signal can be greatly different due to many factors such as people voice change with time, health condition (e.g. the speaker has a cold), speaking rate and also acoustical noise and variation recording environment via microphone.

The main purpose of the MFCC is to extract the features from the samples and provide it to the Gaussian Mixture Model (GMM) to create clusters. This is done by a series of steps. The first step is the pre-emphasis method which helps to boost the high frequencies components of the speech signal which are lost during the speech

production. The input which is analog signal is converted into digital signal to create samples. The framing method is used to creates frames and acquire information from the samples. The main step of the MFCC is the feature extraction, in this the step the different from the samples are extracted and supplied to the GMM to create clusters.
The GMM is used as a classifier to compare the different features extracted from the samples by the MFCC and create clusters of features with the Maximum Likelihood. The GMM uses the K-Mean algorithm for the creation of clusters.

V. CONCLUSION

The Public Address Systems are used for communicating to scores of people at a same time. The commonly used systems are wired. The expansion of installing heavy wiring is complex and time consuming. This paper we help overcome the current issue and implement a wireless public address system.
On the basis of literature survey and analysis we conclude that new approach stated is more efficient, low cost yet high energy usage. This method is easier and less complex to implement. The new approach can catch a market in future.

Filtering political sentiment analysis using social media

Purvi sankhe1 Gaurav Jangir2 Suraj Kanojia3 Krunal Kothari4
Information Technology, Thakur College of Engineering & Technology, India

Abstract – **Using Analytics has been as essential study for the purpose of predicting and classifying data. Nowadays analytics is used in every field ranging from Businesses to sports. Similarly using analytics for analysing recent trends and happenings on social media has been popular. Social media has been a powerful platform for people from around the world to connect with each other and to share their views or sentiments. Therefore, gathering sentiments from social media and applying analytics in order to extract knowledge is an interesting domain. Political sentiment of people using social media is important as it helps us in gaining knowledge about political views of people. There are lots of political organizations around the world which are very active on social media and similarly many people are expressing their political sentiment in the form of tweets, posts, videos on social media. Therefore, analysing these data from the social media helps us in predicting, classifying, gaining insights of recent trends in politics. There are lots of approach to such systems which help in analysing the political sentiment such as Naive Bayes Approach which classifies data based on trained model and similarly classifying it on the basis on decisions applicable through Naive Bayes model. But this approach does not give guarantee for accuracy in classifying data. It is also based on conditional probability which makes it more complex. Another approach to analysing such social media data (tweets, posts, videos) is using lexicon-based approach which uses lexicology based on the patterns of words, emphasis of words used and semantic orientation of words or phrases used in social media posts. This approach has increased accuracy but still there are setbacks as it cannot recognise pure intent.**

The main objective of this System is to analyze tweets from twitter using Twitter API and analyzing social media data for political sentiment using neural network-based approach for predicting, classifying and getting insights of sentiment on the social media. This approach is used as it analyses past human behavior which was absent from lexicon-based approach.

I. INTRODUCTION

"Political Sentiment analysis using social media" is system developed for analyzing the political sentiment or view of the people on social media who use social media regularly to express their political feelings. Here the tweets from twitter is first gathered/extracted, both current tweets and historical using Twitter API. These tweets are gathered based on search criteria lie date, time, keyword, age. Once the data is searched and collected from Twitter API, an Excel file (.CSV file) is generated. Once the CSV file is generated, the algorithm- Lexicon approach is applied and analytics for the tweets is shown. The overall system has two main modules that are, Twitter API and a python (.py file) which consists of algorithms for analyzing, predicting and providing us with knowledge of political sentiments on the social media.

This software can be aimed for analytics and data scientist to gather the political sentiments using both lexicon-based system and neural network system. Then evaluate the effective reports/analysis or take appropriate decisions required. The system is an application of web analytics and can be effective for political or non-political purposes.

Problem definition:

In the proposed system, we will use a Twitter API through which we will gather both current and historical tweets and will gather the required data with the help of search criteria. Then system will contain a Python file which will convert the collected data from Twitter API into a CSV file. This CSV file will then be fed to another python file which will apply the lexicon algorithm and provide us with the political sentiment analytics. CSV file can be modified by applying labeled sentiment and can be used for training neural network. Features of the project includes

Real-time data extraction from pre-processing
Automatic CSV file creation using python file
Search criterion provided for further analysis
Lexicon based approach based on lexicology
Accuracy for prediction through neural network model
Classification provided by model

Background:

A lot of data analysis is being done these days in various sectors like retail industry, corporate sectors in order to increase the business value. These types of analytics maybe misused by political parties to generate curated post according to user sentiments and spread false information.

To prevent this type of misuse, political posts which are unethical or false can be prevented by our system to be spread and reach our audience.

But analyzing political sentiments through social media is kind of difficult as many political posts, tweets are influential in some or the other way, hence it becomes difficult to analyze the exact political sentiment.

II. MATERIALS & METHODS

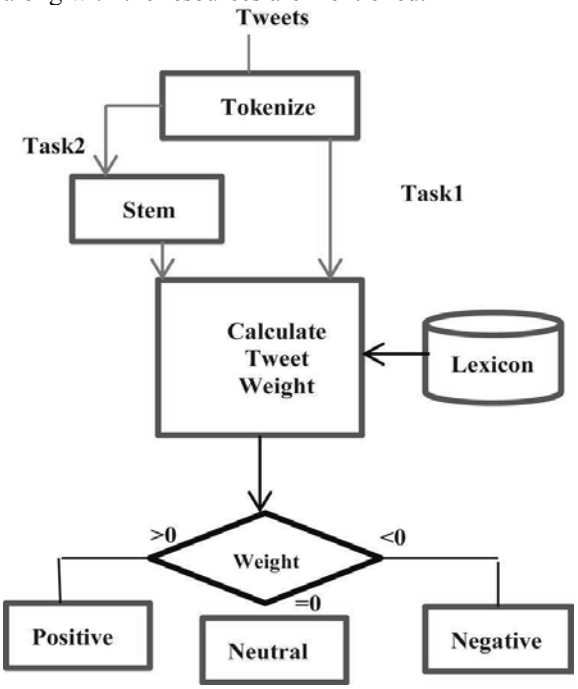
tools. Hence, this project is economically feasible. No heavy Hardware requirement or paid software is in use.

Technical feasibility**:**

This project was based on lexicography and uses Twitter API which is already available in the form of library. Neural Network based approach uses machine learning algorithm requires complex algorithms for accuracy but is feasible from technical point of view.

Agile

Agile methodology mainly focuses on the Operational feasibility**:**
This project requires initial infrastructure, IDEs incremental and the iterative development of the different project phases. It controls and determines how the various stages are implemented and what kind of environment is involved. The project is first divided into different phases, and then the responsibility of developing these phases is given in the hands of the various developers. At every stage of the project development it is continuously monitored and taken care of. These developers developing the phases have particular amount of time period and tasks involved with them. To remain in sync with the other members of the team they have to complete their task within the stipulated amount of time.
The meetings however are conducted on a regular basis where all the members of the team have the right to put forth their ideas along with any requirement or concern. The product backlogs are discussed in these meetings where the requirements of the project to be completed along with the resources are mentioned.



Feasibility Study
Economic feasibility**:**
This project uses all Open Source Software and and tools for initial phase. Though the setup requires integration phase activities but once the setup is done, it is easily operational and is feasible.

Social feasibility:
Generally, this project is based on social media itself, hence social feasibility is a must requirement. The people and political organizations must adopt this system and should find it easy to use our system. Our system is simple in the sense that it uses simple interface.

Stakeholders
The stakeholders include follows: -
Political Organizations.
Social media users
analysts and data scientists

Project Scope
Following would be included in the scope: -
Provide an easy access to social media posts.
Provide better analysis system.
Increase the proper utilization of data for better functionality.
Reduce the maintenance cost of operations.
Improve the accuracy of prediction.
Reduce total cost of the processes.

Requirements and Purpose of the study
Equipment- Hardware:
CPU: Single Core 2.4 GHZ
RAM: 512 MB
Operating System: Windows 10
Hard Drive: 1 GB
Network: Wi-Fi/BroadbandSoftware:
Twitter API library
1.Python IDE
2.CMD Console
3.Python 2 and above

Assumptions and Risk
Assumptions:
- Management will ensure that project team members are available as needed to complete
- project tasks and objectives.
- The employees are willing to change business operations to take advantage of the functionality offered by the new improved technology.
- The core committee will participate in the timely execution of the Project Plan (i.e., timely approval cycles and meeting when required).
- Failure to identify changes to draft deliverables within the time specified in the project timeline will result in project delays.
- Project team members will adhere to the Communications Plan.

Constraints:
Due to the nature of law enforcement,
Resource availability is inconsistent

Risks:

Accurate identification of the systemrequirements, interpretation and design depend on the patience and commitment of the people and staff in focus.

IV. V. CONCLUSION

The Political Sentiment analysis using social media is developed using Python IDE, data mining concepts and machine learning concepts. It fully meets the objectives of the system for which it has been developed. The system will reach a steady state where all bugs would have been eliminated as per the planning and Deployment date. The system will be operated at a high level of efficiency and all the political organization and social media users who are active and engaged in politics and users associated with the system understands it. From the tests performed on the new system\design it will improve on the overall performance on the accuracy of social media posts sentiment analysis, thus the system solves the problem that it was intended to solve. Furthermore, computerization of polling system is not just a matter of technological innovation and development; it is a process which involves individual, organization and society in general.

V. DISCUSSION

The project findings show that a dataset of twitter's tweets can be generated using API and this dataset can be used further to analyze and generate model to classify tweets for further filtering of post and safeguard our public interest and intention from political manipulation.

Through this we hope to achieve faster and efficient solution for political sentiment analysis which will reduce the time and complexity of algorithm. The expected result of this project will be to meet political organization's expectation and fulfill all the specified requirements. This project will serve both the political

parties & social media users which will help them analyze the views and sentiments and provide with appropriate decisions to unfold in the future in case of politics.

The project has a vast scope in future. Project can be updated in near future as and when requirement for the same arises, as it is very flexible in terms of expansion. The following are the future scope for the project:Training the system against large datasets can help in increasing accuracy and scale it to 90%.Election poll result prediction generation

Safety Companion

Harsh Agarwal, Priyank Dave, Tanish Jain, Purvi Sankhe
Thakur College of Engineering and Technology, Mumbai, India
hagarwal754@gmail.com, priyankdave26@gmail.com, jaintanish173@gmail.com, purvi.sankhe@thakureducation.org

Abstract—**Safety companion deals with the development of an information communication technology that can help in protecting vehicles from accidents with the help of the internet of things and a mobile application which works together to protect the driver and other passengers in the vehicles. Along with this, a platform to avail different automobile services as well. The death of the victim can be prevented by removing the causes (pre-accidental) and post accidental by immediately informing the rescue team which will provide the assistance. Thus this system designed here is a system that will bring about the communication to the rescue team to deal with the necessary situation. The system takes various parameters like direction of acceleration, speed, obstacle distances etc. These parameters are used to predict and avoid the accidental situation. The system will send the GPS location of the user with the help of GSM module based on the decision making of the microcontroller (Arduino) and update the rescue team and guardian. Current system doesn't help to avoid pre-accidental causes. The system solves the problem in two parts the one with the mobile application and the other in IoT. Further, the system can be used to track the theft of the vehicle and can also provide an interface for the easy processing and claim of vehicle insurance.**

Keywords— Arduino, GSM, GPS, mobile application, Pothole Detection etc.

I. Introduction

Today, traffic safety is one of the main priorities of the government. Considering the importance of the topic, identifying the factors of road accidents has become the main aim to reduce the damage caused by the road accidents. Road safety means development and management of the roads, provision of safer vehicles, and a comprehensive response to accidents. The costs of fatalities and injury due to traffic accidents have a great impact on the society. In recent years, researchers have paid a great attention towards determination of the factors that significantly affect the traffic managements and roadways accidents. Thus a system for communication of such mishap is needed to be designed. Hence we are designing a system for communication.

II. Background

Road safety becomes major public health concern when the statistics show how more than 3000 people around the world succumb to death daily due to road traffic injury. The huge economic losses are an economic burden for developing countries. The road data are necessary not only for statistical analysis in setting priority targets but also for in depth study not only for statistical analysis in setting the priority targets but also for the in-depth study in identifying the contributory factors to have a better understanding of the chain of events

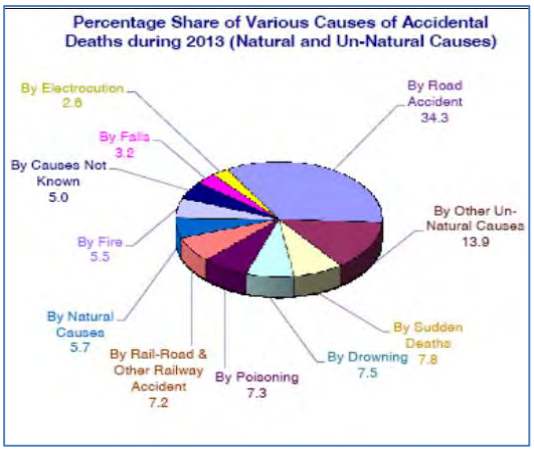

Fig. I: Statistics of major deaths (2003-2013)

The above figure shows the percentage share of various causes of accidental deaths which include Electrocution, falls, and fire, by Rail-Road, Poisoning, Sudden Death, Natural Causes and Un-Natural Causes. The most noticeable one was 'By Road Accidents' i.e. 34.3%.

According to the NCRB (National Crime Records Bureau) report, during the decade 2003-2013, the natural deaths were around 10% whereas the unnatural deaths were the major part. In Unnatural deaths the major cause behind the deaths was the road accident. The road accidents were the major cause of death (of about 42-45%). Maharashtra has reported the maximum deaths due to road accidents (15.7% of the overall accidental deaths).

Road accidents has increased due to surge in the motorization both due to increase in population and increased vehicular penetration.

Further internal mining in the data was done and major reasons of the road accidents were found. They include: over-speeding, drunken driving, distraction to the driver, red light jumping, potholes, bad weather, etc. and certain post accidental reasons for death were lack of communication in time to the ambulance and police department about the crash.

III. Literature Survey

Ancy John, Nishant P.R. et al. [2], proposed a system which is composed of two separate design units: transmitter unit and receiver unit. Security system includes alcohol sensor, eye sensor and smoke sensor. Accident detection system comprises of GPS and GSM in cell phones. As collision occurs, piezoelectric sensor will detect the signal and sends it to ATmega328P

microcontroller. Then, the GPS available in the smart phone will start communicate with the satellite and get the latitude and longitude values and name of place of accident will be send to the previously set phone numbers of relatives, ambulance services etc Accidents due to over speed, drowsy and drunken conditions of the driver are prevented. In heavy traffic zone, speed is controlled automatically without the interference of the driver. Thus we can reduce alcohol and drowsy related road accidents.

Sadad Mahamud, Maliha Monsur, Saniat Rahman Zishan. et al.[3] , explained about a system based on microcontroller Arduino. Here Arduino is our main controlling unit. After receiving the data from the sensors and GPS module it first fetches the data than decode the data and finally execute its operation. Arduino which is the main microcontroller unit is connected with 10 DOF IMU Sensor (accelerometer sensor) etc With an accelerometer you can either get a really "noisy" info output that is responsive or you can get a "clean" output that's sluggish.

Amit.V.Kachavimath1 Nagaraj.C et al.[1], presented that an Accident Alert System using android would be more convenient, relatively secure and utilize fewer resources .In case of the proposed system all the facilities provided are same as in the case of existing system but the proposed system provides all the functionalities in a single device with less cost. This system is developed and implemented to track the vehicle and detect the accident very quickly and easily so that to proceed with the further action items. The Android platform provides several sensors that let you monitor the motion of a device. Two of these sensors accelerometer and gyroscope are always hardware-based and three of these sensors gravity, linear acceleration and rotation vector sensors can be either hardware-based or software-based. Based on the drawbacks of the existing system, we need to design the optimal solution for accident detection using single hardware and software configured device. This helps in identifying and tracking of accident in most effective and less time consuming approach.

Poojitha Shetty, Sachin P C, Supreeth V Kashyap, Venkatesh Madi et al.[5], used Apriori Algorithm for finding Association rule among the items of transitions in each individual dataset based on support and confidence. Further they used Naïve Bayes algorithm for classification. Apriori algorithm require large amount of data storage as it generates candidates table first which consists of analyzing the dataset for each data item(Time complexity=n^n where n is number of items or values in the dataset) hence it takes a lot of time to generate patterns for a dataset of 2MB.

Ms. Gagandeep Kaur, Er. Harpreet kaur et al.[4], used Regression and Co-relation models used for analysis of the accident data and implemented it using R's IDE Integrated Development Environment (R studio) which is graphical and statistical computing tool on road accidental dataset for analyzation. R is free software, GNU package used for analyzing the datasets to vaticinate the hidden patterns and trends. Regression and Co-relation models used for analysis of the accident data. Neural networks are the better way to predict and analyze things in a better way and in a more accurate way with the help of various parameters.

Priyanka A. Nandurge, Nagraj V. Dharwadhkar et al [6], used data partitioning to overcome heterogeneity of data. The proposed method uses k-means clustering method as the main task of segmentation of road accident data. Further, association rule mining is applied to discover the situations related with the occurrence of the whole data set and the occurrence of clusters recognized by the k-means clustering algorithm. The combined result of k-means clustering and association rule produces major information. Segmentation is used to reduce data heterogeneity using a number of measures such as expert knowledge, but there is no guarantee that this will result in the best segmentation of the group including road accidents. Cluster analysis can helps to segment road accidents data. The main difficulty of clustering algorithm is to estimate the number of clusters. In k-means clustering, value of k must be given by the user which is one of the limitations of this algorithm. If the value of k is incorrect then it may lead to incorrect clustering results.

IV. PROBLEM DEFINITION

The usage of vehicle is rapidly increasing and at the same rate the occurrence of accidents has also been increased. Accident due to some factors such as potholes can be prevented and incase of accident in time rescue of the victim can be done. The objective of this project is to build a system that detects potholes and helps driver to avoid them and in case of accident the necessary information of the accident is send to the rescue team and the guardian of the victim, so that necessary actions can be taken in time. Also to provide an application that can help the driver to avail the necessary services such as mechanics, fuel, safety etc. in case of emergency.

Phase 1: It deals with the deep study of the existing systems, by analyzing the previously available research papers and technologies.

Phase 2: The result of the literature survey and analysis based on various algorithms using previously available data on road accidents in various regions.

Phase3: The parameters that are the major reason for the accidents are detected and analyzed used to produce the design of the system. Planning the hardware and software to be used

Phase 4: implementation of the design using technologies planned in the above phases

Phase5: Testing and implementation of the software using the tools and of hardware using remote controlled car.

Phase 6: deployment of the prototype in the cars and to the automobile companies.

V. METHODOLOGY

The project involves use of hardware hence waterfall model is the best suited model to be followed for the development of the system.

Waterfall Model- Classical waterfall model divides the life cycle into a set of phases. This model considers that one phase can be started after completion of the previous phase. That is the output of one phase will be the input to the next phase. Thus the development process can be considered as a sequential flow in the waterfall. Here the phases do not overlap with each other.

- Requirement Gathering and analysis − All possible requirements of the system to be developed are captured in this phase and documented in a requirement specification document.
- System Design − the requirement specifications from first phase are studied in this phase and the system design is prepared. This system design helps in specifying hardware and system requirements and helps in defining the overall system architecture.
- Implementation − with inputs from the system design, the system is first developed in small programs called units, which are integrated in the next phase. Each unit is developed and tested for its functionality, which is referred to as Unit Testing.
- Integration and Testing − All the units developed in the implementation phase are integrated into a system after testing of each unit. Post integration the entire system is tested for any faults and failures.
- Deployment of system − Once the functional and non- functional testing is done; the product is deployed in the customer environment or released into the market.
- Maintenance − There are some issues which come up in the client environment. To fix those issues, patches are released. Also to enhance the product some better versions are released. Maintenance is done to deliver these changes in the customer environment.

Waterfall model is best suited for the projects where there are less number of requirements and for the hardware project designing.

The basic design of the overall project involves majorly three actors driver, service provider and the Guardian. The User will use the application to gain the services such as fuel, mechanic, etc. The service provider team will take care of the services by allocating the nearest mechanics and fuel provider on the spot where the user needs it. Further wherever in case of accident the Guardian of the driver or the user will be get the alert through SMS along with the location of the victim. Based on the location of the victim the nearest rescue team will allocated at the spot of the accident. The rescues team will take care of all the operation of the taking care of the victims. Below is the UML diagram which explains the complete process and interactions.

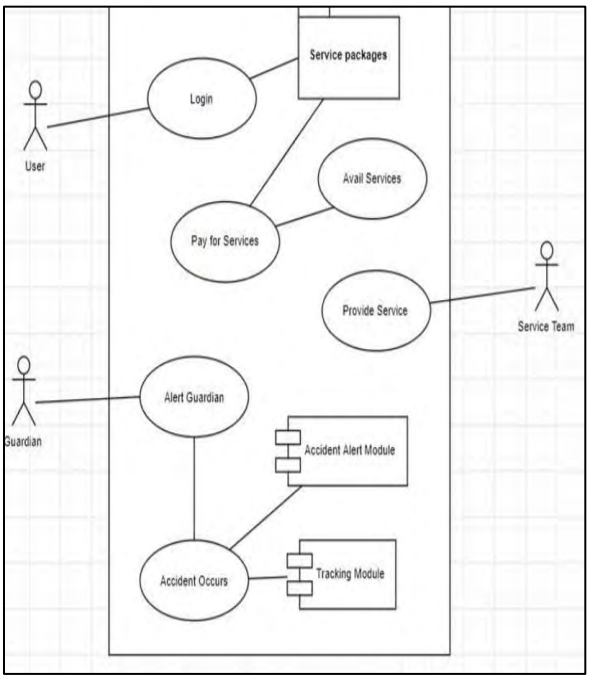

Fig. II: UML Use Case diagram

This UML Use Case diagram provides a use case considering the user/client, its guardian and the service team of the product itself. It deals with features such as login, payment for services, tracking and alerting modules and then alerting the guardian.

The construction of this system is done with the help of Arduino IDE that helps to upload the instructions in the hardware and Android application. Arduino Mega is used to control and adjust the external parameters based on the input parameters. GPS (Global Positioning System) is a small electronic circuit that allows to connect Arduino board to get position and altitude, speed, date and time on UTC.

The block diagram below represents the hardware components such as the ultrasonic sensors, accelerometer, GPS module, Wifi module and the GSM module which altogether work cordially in order to help the client.

The accelerometer senses the tilting of the vehicle. It

detects the abnormal tilt and ultrasonic sensor to detect the obstacles at the back. Thus in case of an abnormal tilt which is consider as a mishap has happened with the passengers and alert to the rescue team and the guardian of the passenger will be generated and necessary services or help will be provided

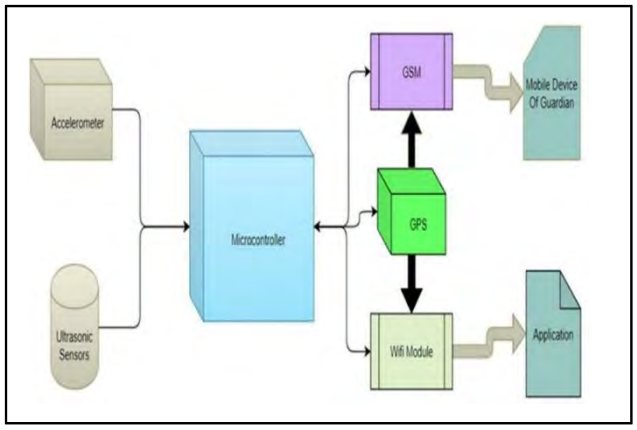

Fig. III: Block diagram of hardware module

The location will be shared to the rescue team and also to the guardian of the victim. GSM chip is used to establish a communication between mobile device or computing machine and a GSM or GPRS system. Accelerometer is a electromechanical device that will measure acceleration forces which may be static or dynamic. Ultrasonic sensor is used to measure distance to a vehicle by using sound waves. It measures distance by sending out a sound wave at a specific frequency and listening for that sound wave to bounce back.

Pothole detection can be done using ultasonic senor, the ultrasonic sensor will be positioned in alignment with the tyres of the car.

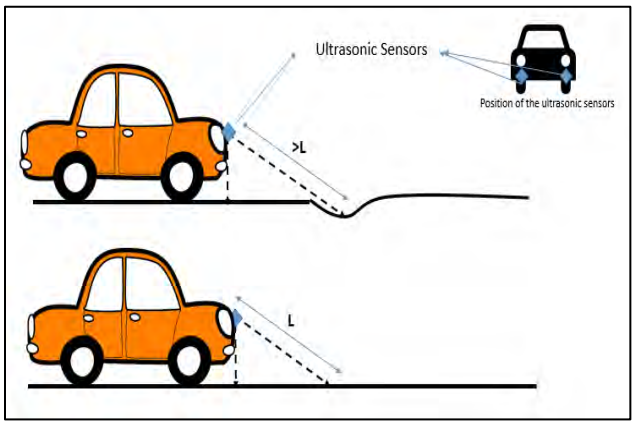

Fig. IV: Pothole detection

The principle on which the potholes are detected here is whenever there is a normal road, the distance calculated by the utlrasonic sensor remains constant whereas whenever there will be a pothole on the right or left tyre the alert of the same before the potholes appear to the driver.

VI. IMPLEMENTATION

The project implementation deals with the development of the application and the hardware implementation. The UI design of the project and the hardware implementation images are shown below in the figures. The UI consists of different tabs that allows user to interact and get the desired services as per his/her needs.

Fig. V: Homescreen

The Homescreen provides the client with the User Interface through which the client can get in touch with the system with just simple touches.

Fig. VI: Service Screen

This screen provides the user with various services which it can avail during an emergency, once it has logged in to the website.

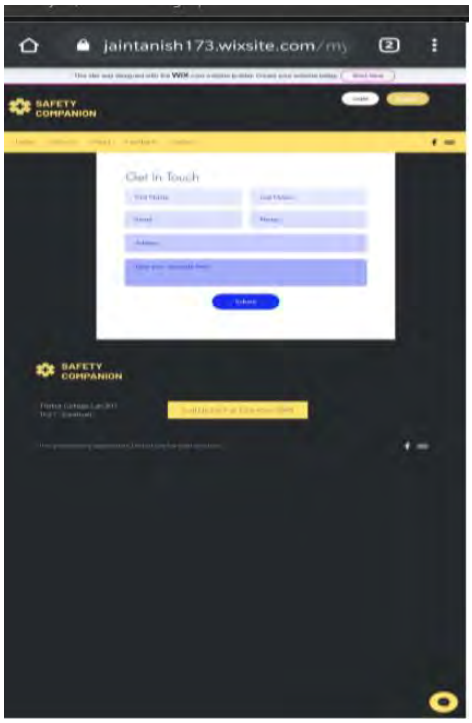

Fig. VII: Registration Form

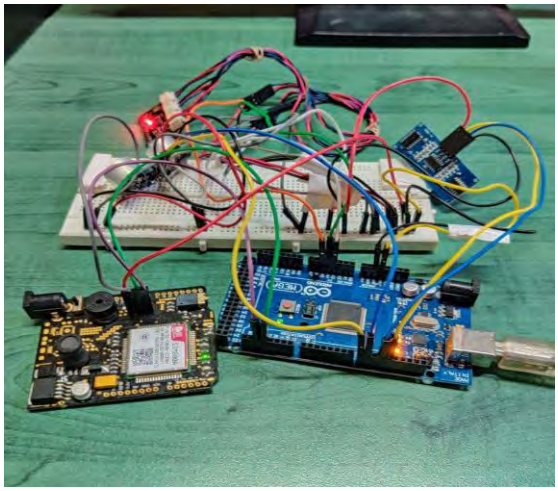
This form gathers the details of the client/user to which the system can later communicate whenever required along with the personal details.



Fig, VIII: The Hardware of the System

The internal connections of the hardware kit are demonstrated in the above figure which include Ardiuno MEGA, GSM module, Accelerometer etc.

VII. CONCLUSION

Hence we are able to implement 50 percent of the hardware and the software system. Iot system that provides the alerts about the accidents that helps to overcome accidental impact of the people. Thus IoT system has been used to sense the occurrence of the accident depending on the movement of the accelerometer. In case, if the accidents occurs, then the coordinates of the location will sent to the rescue team and to the guardian of the person so that they can reach in time. In addition to this there is a platform provided that user can use to avail different automobile services like mechanical, emergency fuel requirement, cab services, women safety services etc.

VIII. FUTURE SCOPE

In the future, we will further enhance the system so that it will also be able to perform "Potholes detection" which will also help to avoid damage to the vehicle and accidents that can occur because of the potholes. Automation in the car about the acceleration and breaks can brought about to avoid the accidental situations. Moreover, we can add more services in application which will enhance the user experience. Over the next 2 months, the team intends to build a model which will be mounted on the vehicle. The developments of the project in the future will be aimed at careful consideration of further user safety and comfort both on the device as well as the vehicle. Also, we can add a system of a module that will help the user for an easy claim of the vehicular insurance.

Trend Analysis on Twitter

Sundaresh Naryanan, Abhishek Singh, Kaustubh Shinde, Mr. Rahul Neve
(Information Technology, Thakur College of Engineering and Technology, India)

Abstract – **In social media forums, it is important for public's perception that an organization is well notify and able to provide services that truly meet their needs and interests. Social media activity by citizens is growing exponentially and there is some evidence that certain government agencies are embracing these engagements, and communication tools, albeit at a far slower pace than other societal sectors. The on-going provocation is that the government generally lacks behind when it comes to adaption of technology tools. Social media tools and social media analytics are no anomaly. While this paper focuses on government organizations, it's fair to say all federal organization are playing catch up with commonly employed social media communication platforms. The government is even further behind in the area of social media analytics, the cluster of data from online communication tools and the interpretation of this data to form actionable and relevant information. Solutions to the provocation of this knowledge discovery from the magnitude of social media data must be automated and sophisticated enough to detect sentiment, trends, influencers, and real time issues as they arise. The basis of any social media analytics solution will be the power of its search and discovery knowledge engine.**

Keywords: LDA algorithm, Clustering, Trend Analysis, Social Media Analytics

I. INTRODUCTION

Despite the talks in the market place regarding what social media is, or how it should, impact government operations, the use of information technology to change the way government works and engages with citizens is not new. President Bill Clinton, with the assistance of Vice President Al Gore, initiated what was then called The National Performance Review, which has evolved over time into The National Partnership for generating Government. That endeavour focused on generating greater operational efficiencies, as well as identifying how government could grasp the technology to work more effectively. The overall goal was to cut government costs. This undermines efforts to increase efficiency, effectiveness, and responsiveness. The proliferation of social media throughout American society has put the spotlight on a long standing troubling perception of government – that it is often slow to react and hesitant to move to new solutions and technologies that the general public has already adopted, vetted, and use in a ubiquitous manner. This slow adoptation is often a result of common issues, investigation of potential risks and security concerns, and/or compatibility analysis. Many argue this scrutiny and delay is overbearing and slows the services government agencies provide to the public; others argue it is simply a result of years of entrenched bureaucracy and regulations that lead to slow adaptation to a changing world and dynamic operating environment There are, of course, those who argue that this late-adopter role is one that is necessary to mitigate the risks to the mission of any given agency. In any case, it is clear that while a major part of society has made social media a permanent and complete aspect of their communication strategy, the government, with only a few exceptions, has not yet fully adopted by social media and analytics, and integrated them into how the government conducts its business. What is even unclear is just how government can grasp the myriad of social media tools and channels in order to provide superior service to a better informed and more engaged citizenry.

II. MATERIAL ANDMETHODS

Requirements

Web browser
Windows Operating System
Windows XP, Windows 7,8
MySQL Server

Methodology Used

For developing a project or software it is important to know the flow or which type of software development lifecycle model the system is going to use. Out of various SDLC models there is a need to choose the model which will be perfect for the project and therefore Iterative model has been selected.

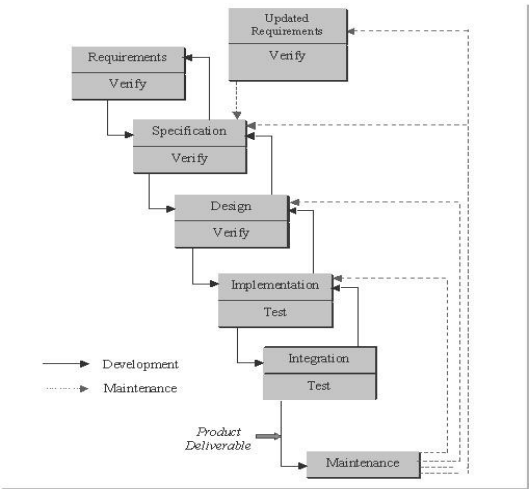
As the name suggest Iterative model is basically an iterative process where the input is processed through various phases and if it doesn't satisfy it is repeated until it becomes satisfactory.

The model consists of five phases namely:PHASE I:

1. Planning: Applying agile methodology for event system event planning for better usage of resources and time with great performance.
2. Analysis: Prepare a detailed analysis on present event system and overcome its limitation in our upcoming system.
3. Design: Integration of data and designing of system event app.
4. Coding: Writing the whole system app code and taking help of an open source.

PHASE II:

1. Testing: Doing various tests on system like unit testing, smoke testing, stress testing, integration testing, regression testing, system testing etc. to check whether the integrated system works as the client desires.
2. Deployment: Conduct beta testing for identifying bugs and errors left out and improvements that can be made. After the testing and approval, deploy the proposed system.

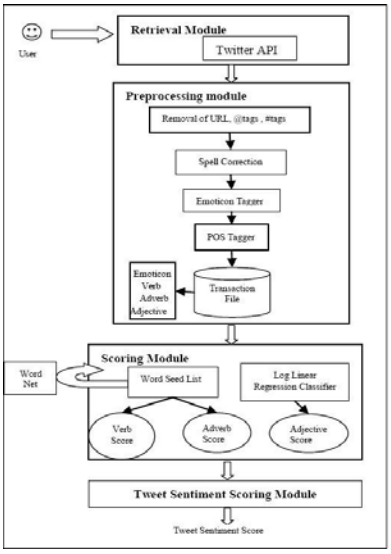


Feasibility Study

Prior developing the product or software it is necessary to know all the factors important for developing a good product. It is important to know the resource requirements, strengths and weakness of the project, etc. All these factors ultimately revolve around two major criteria cost and value, in order to know how much feasible, it is to create a project and how much profit will it return.

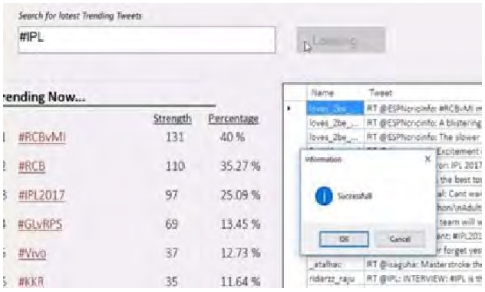
The feasibility of a particular software product can be determined from the following factors:-

1. Technical Feasibility.
2. Operational Feasibility.
3. Economic Feasibility.
4. Legal Feasibility.



III. RESULT

Users can look for social events happening around them through our web application. They can get acknowledged of recent trending events just by entering the keywords. Tweets from all around the world can be accessed with the click of a button **a) Output**



b) Outcomes

The client should be able to connect to the server properly without any problems. The connection establishment between the mobile device and the server should take minimal time. The mobile device should be able receive data from the server uninterruptedly. Information provided by the application should be correct and as per the user's need.

c) Discussion of the results

Connection can be established easily provided that the server is on. The connection with the server takes time as it uses Internet connection. Receiving data from the server takes time. Information coming from the database is correct.

IV. DISCUSSION

Before the introduction of our web application users had to have an access of Television or Newspapers to get aware about the trending events happening around us. To overcome this problem, we introduced a web application that could present you with trending tweets from around the

world with the click of a button. It becomes convenient for users to acknowledge themselves about the events around them through a non-complex application.
Latent Dirichlet Allocation Algorithm has been used to cluster the tweets into different categories.
The application responds quickly while making a decent decision. The application uses LDA algorithm which is efficient for clustering. Irrespective of users location he can access trending tweets around the world. Positive and negative tweets are being clustered to perform
sentimental analysis. Providing security to authorized user using Two
Factor authentication was a one of the major problem.

V. CONCLUSION

In this project we develop a real-time non parametric model to know about the recent trends. It successfully detects the recent trends and it also shows the trends according to the location of a user.

Innovative Approach for Project Allocation & Monitoring

Divyesh Gohil, YogeshKumar Mutha, Rahul Gupta, Neha Kapadia
IT-Department, Thakur College of Engineering, Kandivali Mumbai , India.
Divyeshgohil97@gmail.com, Yogmutha007@gmail.com,
guptarahulgi97@gmail.com,neha.kapadia@thakureducation.org

Abstract – **Innovative approach for Project Allocation and Monitoring is a web-application that allows the students, guide and admin to track the status of project of students. This project aims at providing for allocation of projects to groups based on their academic performance (like average CGPA of the group). In our project, there are four main modules. In the first module, the system allows the Student, Faculty and the Project coordinators to register themselves successfully in the system. In the second module, the student will login into their particular account and they will do their group formation process and they will set their preferences according to their domain. (The student who will form the group will be by default chosen as the group leader by the system.). In the third module, the allocation script will work, that will be done the by the Admin and the Project will be automatically allocated to a particular group, based on the preferences given by them during the group formation. So the last module goes with the monitoring part, in this the faculty can assign the work to an individual group, and the Group members of that particular group will update the status of the work at the end of the day and everything will be done through the system itself.**
Besides the research, the project also involved the design and development of a system that would help to monitor several projects across several regions. To this end, a web based project monitoring solution is desirable. The web solution has been used to specify and implement the framework to represent all the processes in project monitoring. The use of web technology has been motivated by an increased demand for information sharing, transparency and efficiency in project implementation.

I. INTRODUCTION

Innovative Approach for Project Allocation & Monitoring can be used by organizations or the colleges to make the entire process of allocating the project title online. This project has four roles in this system mainly, Administrator, a Project Guide, Project Coordinator and students. An administrator is the one, who has complete command over the system, he can log into the system and can see each everything which he desires to see (Student details, faculty details, information about a particular group, etc.).
The faculty members will register themselves as the guide and they will give minimum number of the project titles along with their description and their domain expertise. The student will register themselves as an individual and later on the group formation process and preferences selection will be done and individual group will get their own group leader and id by the system.
Now, the allocation script will work, that will be done the by the Admin and the Project will be automatically allocated to a particular group, based on the preferences given by them during the group formation. And the last module goes with the monitoring part, in this the faculty can assign the work to an individual group, and the Group members of that particular group will update the status of the work at the end of the day and everything will be done through the system itself.

II. MATERIAL AND METHODS

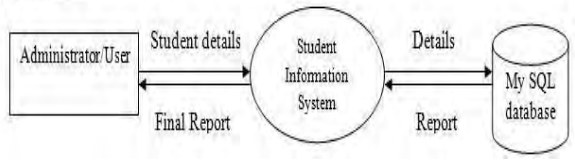
This project application comprises the use of the following resources be it in hardware and software which is discussed as follows:

Software Specifications:

Wamp server
Php dashboard
JavaScript/Html/Css
Code editor (like Sublime, Notepad++)
Browser

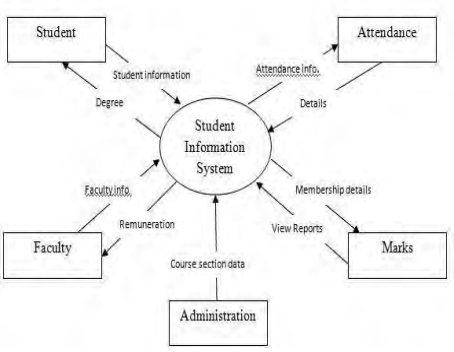
DFD Level 0 is also called a Context Diagram. It's a basic overview of the whole system or process being analyzed or modeled. It's designed to be an at-a-glance view, showing the system as a single high-level process, with its relationship to external entities. It should be easily understood by a wide audience, including stakeholders, business analysts, data analysts and developers.

Level 0 DFD :



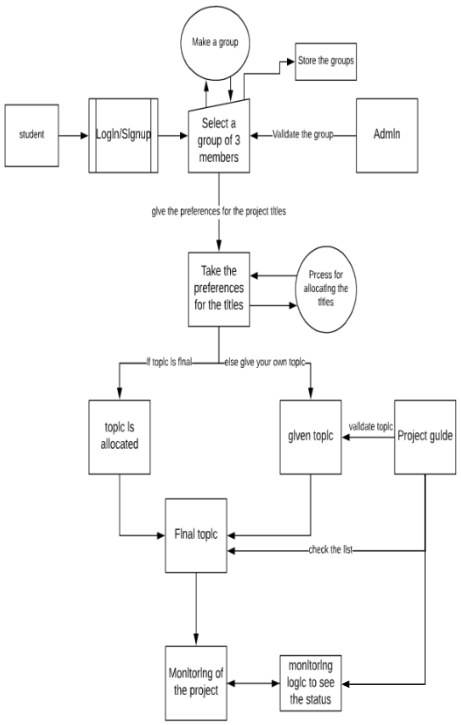
DFD level 0

Level 1 DFD:



DFD level 1

DFD Level 1 provides a more detailed breakout of pieces of the Context Level Diagram. You will highlight the main functions carried out by the system, as you break down the high-level process of the Context Diagram into its subprocesses.



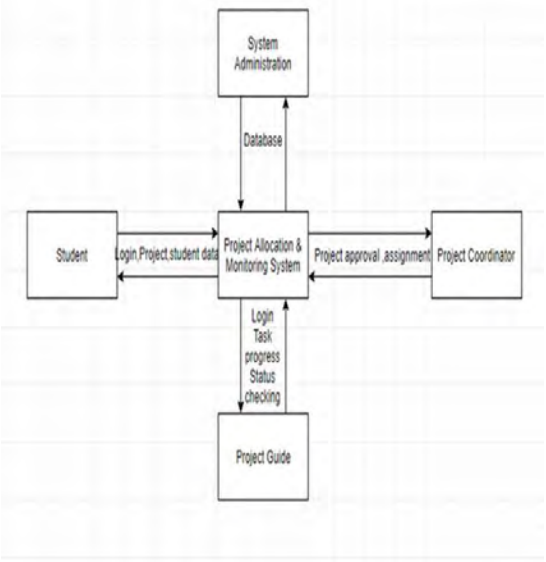
DFD level 2

DFD Level 2 provides a more detailed breakout of pieces of the Context Level Diagram. Now, the studnetWill Register himself over here by filling the basic details of about him. The faculty will register themselves by filling the details about them and giving project ideas along with three topics with their criteria and the description.

The aDmin will be able to look after each and everything and he will run the Allocate script and the Project will than

assigned to a group.

Block Digram :



Block Diagram

This Block Diagram gives a detailed information about the requirements of the Project in terms of the hardware and the software. Various Levels of Data Flow Diagram (DFD) shows the detailed description about the flow of the project. Level 0 describes the Entities involved in the Project, Level

1 Shows the interaction of the Entities with various Other Entities, whereas level 3 shows a detailed flow of the Project, where the student logs in, gives hi preferences for the Project, The faculty registers with the system gives their idea, Admin runs the Allocation script and the project is allocated to the Student. The faculty can assign work to individual group and the students will update from their side which will be tracked by the Faculty.

Procedure Methodology:

Front end for Student and Teacher side will be scripted where student can add his/her project topics & and can see his/her updates regarding the project. Teacher side scripting will be done where he/she monitor the student project development and growth. Admin side scripting will be done where adding of project topics as per message received by the student. Server side scripting will be done where all the data will be stored.

III. RESULT & DISCUSSION

Till now there where many colleges and universities which manually allocate projects assigned to the students. This process is basically carried out for the final year students. It means that the college allocates student group id, project details and a mentor who monitors student's progress. The entire job manually become tedious and time consuming. This project aims at making this job well-based so its saves time and efforts both on students' side as well as on faculty's side. It reduces time of the guide who allocate project to each and every student.

Next thing that motivates us from the project is, there won't be a situation where biasing is done because it will allocate project automatically on the given criteria. The student he or she should fulfill the criteria required to receive the project of their choice. Another motivation is to increase efficiency of current system so that it becomes easy for students as well as faculty to manage and use it.

According to this information project and mentor will be assigned to them. After allocation, students are responsible for fulfilling the milestones set by their mentors. Faculty members, after login, can view the groups under them and can track their progress by checking if deadlines are met proper attendance is met and schedule reports are submitted. A viewer need not log in. He simply can view the gallery aspect of project.

Snap shots of the results are**:**

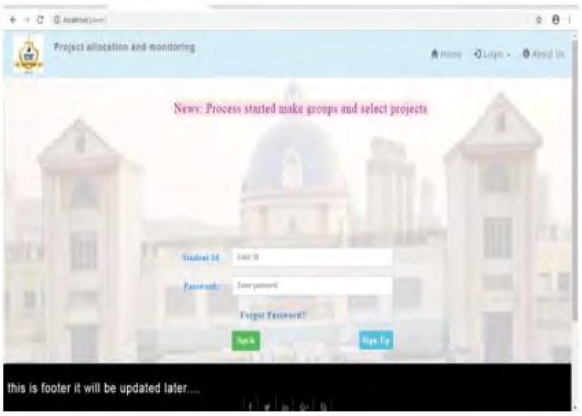


Fig 1 (Login Page For the Students)

Fig 2 (Student Registration)

Fig 3 (Group Formation Process)

Fig 4 (Group Formation and Project Preferences done)

Fig 5 (Faculty Registration)

Fig 6 (Faculty Login)

Fig 7 (Faculty Adding Project Titles)

Fig 8 (Admin Home Page)

Fig 9 (After the Allocation script run by Admin)

Fig 11 (Status tracked by the Guide)

IV. FUTURE SCOPE:

This system is able to manage the database and storing it for a list of student who have registered it.

Easy & safe way for student and faculty registration.

ncrease the proper utilization of time and resources.

Guide can effectively trace the progress of the group and can guide them accordingly.

Reduces the problem of lack of transparency between guide and students.

Student will get the project according to their preferences and the criteria while selecting the Project. projects to groups based on their academic performance (CGPA). The main part of this is the Allocation and monitoring hence the parameters of measurement for the allocation is academic performance like aggregate CGPA of the whole group (cumulative grade point aggregate) will be taken under consideration.

Innovative approach for Project Allocation and Monitoring is a web application that allows the input data to take place securely over the Internet. Finally, the system will able to efficiently monitor and maintain the progress as well as the performance of students on their project. The project guide can easily look upon the task done by the students. Maintain their daily updates and attendance with the faculty. Guide can track more than one group's progress. This entire job manually becomes tedious and time consuming. This project aims at making this job web-based so that it saves time and efforts both on student's side as well as on faculty's side and mapping of attendance can be done.

In our project, there are four main modules. In the first module, the system allows the Student, Faculty and the Project coordinators to register themselves successfully in the system. In the second module, the student will login into their particular account and they will do their group formation process and they will set their preferences according to their domain. (the student who will form the group will be by default chosen as the group leader by the system.).

In the third module, the allocation script will work, that will be done the by the Admin and the Project will be automatically allocated to a particular group, based on the preferences given by them during the group formation. So the last module goes with he monitoring part, in this the faculty can assign the work to an individual group, and the Group members of that particular group will update the status of the work at the end of the day and everything will be done through the system itself.

Features of the project:-

Automatic allocation of project based on academic performance Timely based monitoring of project and attendance To provide last five year project download option for reference To allocate project based on language learned

IV. CONCLUSION

Innovative approach for Project Allocation and Monitoring is a web-application that allows the students, faculty, Project coordinator and admin to track the status of project of students. This project aims at providing for allocation of

Diabetes Prediction Model

Dr.Sangeeta, Vhatkar, Nilesh Gupta, Rishabh Jain
Thakur College of Engineering and Technology, Mumbai,India
vhatkarsangeeta@gmail.com, itnileshgupta@gmail.com, jainrish97@gmail.com

Abstract – **Machine learning is a fairly new technology, with new developments coming up faster than most people can learn them. It is a cutting-edge technology in every sense of the word. In such a case, it is pertinent that we handle it with care. It could very well throw up results at an accuracy rate that is infeasible for medical applications. The capabilities required for the project are fairly in the feasible range. Most of the planned feature hinge around processing datasets. Due to the above, a challenge also visible here is the problem of dealing with huge amounts data and processing it thoroughly to get proper results.**
The central parameter of success is the accuracy at which the machine learning algorithm predicts the diseases for which it is trained. It is expected to be above 96% - 98% to make a real difference, as medical diagnosis has very rigorous standards. The secondary parameters are the response and loading time of each modules. A high value of module latency can make any user impatient. Besides these 2, the other parameter is the number of features that work without any bugs. This parameter should be ideally above 90% as well, or it can make users frustrated.

I. INTRODUCTION

While machines and robots may not completely replace doctors and nurses in the hospital, machine/deep learning and artificial intelligence are constantly transforming the healthcare industry. This technology not only has a huge potential, but also offers a whole fleet of applications, which can be implemented in the healthcare sector. The way in which healthcare operates has seen a dramatic change over the last couple of decades, and this change is expected to continue in the years to come.
Evolving from pattern recognition and computational learning theory of artificial intelligence, ML helps in building automated models that explore and analyze the available data sets to identify hidden patterns and make useful predictions, using recognition algorithms [3]. Today, ML is increasingly being implemented in the field of healthcare, especially in image registration, medical image processing, image-guided therapy, computer-aided diagnosis, image database retrieval, image annotation, etc. In this article, we have listed some of the key healthcare applications of ML and the ways in which ML has benefited this industry.
Artificial intelligence presents challenges due the complexity involved in getting the balance between too much and not enough. We may design systems which can process an extremely wide variety of inputs, but we cannot actively
ensure that the AI will respond to it in the way we want it to. It may present us an output which was intended to be for another input, or it may not be able to process it due to the load caused by the heavy processing on the interpreter. Thus, the challenge is not just of input handling or building features, but of efficiency as well.

II. PROPOSED WORK

Analysis of the current market scenario and technological capabilities is essential to the building of a project. Here we analysed various prevalent research papers pertaining to our project as a part of the literature survey. The project aims at creating an intelligent but lightweight healthcare assistant. This application will be able to help healthcare and other hospital staff work efficiently. This also aims at having a basic machine learning capability for disease prediction [3].
Our literature survey was focused on the capabilities
of the choices we made for the core part of the project, namely artificial neural networks and the use of wearable technology for data collection [4]. The initial phases focused on the planning and design of the project. We analysed extant products, customer interests and so on. For analysis, we looked at the current iterations of popular and cutting-edge algorithms used in machine learning, such as artificial neural networks and convolutional neural networks [4]. The analysis was openly available in numerous research papers. The design involved comparing the project with some similar projects.

The working is as follows:

III. LIT ERAT URE SURVEY

Prediction of Diabetes Diagnosis Using Classification Based Data Mining Techniques

In this paper [1], 1) Data mining algorithm renders the last dataset to find useful knowledge. 2) K means is a type of clustering which classifies the data without previous knowledge

Prediction of Onset Diabetes Using Machine learning.

In this paper [2], 1) Machine learning will help us predict early diabetes. 2) Multilayer perceptron is a type of neural network which help us to develop machine learning model.
Detection and Prediction of Diabetes Mellitus Using Back- Propagation Neural Network
In this paper [3] 1) a standard neural network (NN) consists of many simple, connected processors called neurons. 2) Re- cyclic neural networks are the deepest of all neural networks
A novel approach to predict diabetes by Cascading Clustering and Classification.
In this paper [4], 1) Clustering technique can be used to classify diabetes patients according to risk of having diabetes.
2)bagging and random forest can be used to design the model for machine learning

IV. FEASIBILITY STUDY

A .Economic feasibility:

The project relies on open source software, such as python, Scikit-learn, Matplotlib, IPython, Pandas, NumPy and SciPy. The functionality provided by these software's is enough to construct a product capable of usage for healthcare applications.

For the machine's learning and training, we will use dataset from kaggle provided by PIMA. These sets run into thousands of lines, and thus can provide enough learning capability to the software. Due to these 2 being freely available, the project is very low cost and thus feasible from an economic standpoint.

The expected total cost is around 4000 rupees. As such, we do not need any outside funding.

B. Technical

The capabilities required for the project are fairly in the feasible range. The backbone of the project is to create learning model.GUI will be built on using Django framework.
The learning model will be created by using neural networks. Other python packages can also be used for additional features.

C. Operational

Initially, the diabetes dataset is given into the data pre- processing module. The pre-processing module removes the irrelevant features from the diabetes dataset and gives the pre- processed dataset with relevant features to the machine learning algorithm. Then, the machine learning algorithm develops a learning model from the pre-processed dataset.
This learning model is known as knowledge model. The diabetes is predicted for a person's medical report or data using the learning model. Legal
Since the project deals with a sensitive topic (healthcare) with potential for major harm,

Much has been said about the ethical advantages of free software in general, and it is particularly true in a profession in which the sharing of instantly available, accurate information can make the difference between life and death. As medical software begins to offer decision support, risk management, performance rating, and analytic features, physicians should learn to be more careful with its usage.

D.Ethical

While the software is meant to help users with their health, there still is potential for improper usage leading to damage. The software should not be used as a substitute for doctors or professionally provided healthcare. Users must only use it to supplement the same. Much has been said about the ethical advantages of "free" software in general, and it is particularly true in a profession in which the sharing of instantly available, accurate information can make the difference between life and death.

As medical software begins to offer decision support, risk management, performance rating, and analytic features, physicians should not accept black boxes and secret formulas that constrain sharing and intimately affect patient care and reimbursement.

V. V. RESULTS AND DISCUSSION

Table: 5.1 Actual Results

Accuracy: 0.7359				
Confusion Matrix				
[52 28]				
[33 118]				
Classification Report				
Condition	Precision	recall	f1- score	Support
1	0.61	0.65	0.63	80
0	0.81	0.78	0.79	151
Avg./Total	0.74	0.74	0.74	231

VI. CONCLUSION AND FUT URE SCOPE

Currently the project focuses on gathering a structured authentic data. As medical data and

analysis is a sensitive field, the project intends to find an assimilation of the results of various algorithms and compare the accuracy.

Over the next 2 months, the team intends to build a model that best suits the input data. The model and the algorithms used are structured and developed using python as the main programming language and will use libraries like SciKit, NumPY, flask and Rasa for NLP.

The developments of the project in the future are aimed at careful consideration of the disease. This can make a prediction of the diseases by looking at a medical history of a number of patients.

Thereafter, the team intends to build a web framework to create a rich user interface. The comparison between existing results and actual results show a gap in accuracy that has to be closed. However, we were able to achieve more versatility, which was probably the reason that the algorithm was less accurate in the first place.In order todevelop this system, the dataset is collected from the University of California, Irvine(UCI) repository. Different machine learning algorithm namely probabilistic-based naïve Bayes (NB), function-based multilayer perceptron (MLP), decision tree-based random forests (RF) are used to build the machine learning model to carry out the diagnosis of diabetes. Furthermore, the machine learning model is tested with different testing methods such as 10-fold cross validation (FCV), use percentage split with 66% (PS), and use training dataset (UTD) to evaluate the performance of the machine learning model in terms of accuracy.
Different options were taken into consideration to improve the accuracy. So finally by removing outliers, categorizing data, keeping tree depth to 4 we were able to achieve desired accuracy. During this process we figured out few attributes that played an important role . Out of eight attributes Glucose, BMI, Pregnancies, Age and Insulin were the important ones. As per our results and data the other factors like Diabetes Pedigree Function, Skin Thickness and Blood Pressure had negligible effect in determining diabetes

Group Messaging Solution

Mr. Abhijit Kushwaha, Mr. Gaurav Gupta, Ms. Nikisha Mistry, Dr. Zahir Aalam
Thakur College of Engineering and Technology, Mumbai, India

Abstract: **In every organization, in order to work collaboratively we need people who come up together and communicate so that they can express their ideas and share best thoughts and have a good team work. In organizations, employees working on same project may be residing in different places of the world to communicate, they need channels which can hold their confidential messages and also protect the messages from networking security threats.**

Currently, we have a number of messaging applications like Slack, Gmail, Whatsapp, etc. Prominently organizations use Gmail for emailing or their own mail sending services for communication. But for mail reception we have a condition that mail receptor should know who has sent him mail. But there can be condition in which someone might spoof, pretending to be someone. For organizations which to segregate authorities as senior and junior and communicate among each other, this kind of platform could be vulnerable. In current systems, hackers could even attach viruses and other malwares to emails. If you want to send messages, you have to manually add the desired recipients.

The project implements application which would provide a way for communicating amongst teams and senior members of the team without hesitating and by implementing this project, members will also be able to put forward their views and points easily in front of the whole group members and senior authorities. Also this project will make the communication effective which will in turn benefit the team and their work. Also threat agents won't be able to send malicious files as this will be only message based and hence more secured. Also it will have a news feed section where latest news about the company will occur which will keep everyone informed about the current scenario and everyone will be on the same page.

The project also aims to identify confidential message sent using this messenger so that the confidentiality remains intact and admin can manage and see which user is using the confidential words also by implementing this, spam and rumor detection can also be implemented.

I. INTRODUCTION

Communication is the first step in every project life cycle. Communication holds key of the entire project because by communication team's form, by communication project working teams do information and requirement gathering of the project. If this step is given the required time and is done sincerely, the project development team will exactly understand what the client wants and they can start planning for the project and complete it without facing client dissatisfaction. For some organizations, the messages are very confidential because they may be passing tender messages that should not leak.

The main aim of our project is to successfully enable organization plan conversations with people based on roles.

The reader of this paper will be able to understand what the objectives of the project are. He will be able to compare the current system and will be able to compare the project and existing applications, overview of the project, importance of the project, background of the project and perspective of the stakeholders and customers.

This project application helps to function efficiently by providing platform for an organization to communicate amongst each other by eliminating the distractions created by other platforms such as Gmail, Facebook, etc. like advertisements, other distractions such as friends email during work and also prevent from sending malicious files. This project also helps to identify any spam, rumor or confidential message by detecting it in its sending state.This project has a news feed section which will keep the employees informed about the latest trends of the organisation.

II. PROPOSED SYSTEM

The proposed system will have all the features we have now thought about such as spam and confidential message detection, no advertisements, affordable, news feed, read aloud messages. Hence this project is meant to construct an application which will ease in communicating amongst themselves and also avoid distractions caused due to advertisements and other spam emails with also a feature to detect confidential or spam or rumor messages in the organization amongst themselves. Also it will have a news feed section which will be operated by the organization itself.

III. METHODOLOGY

We have used Agile methodology for making of this project. In Agile, companies keep iterating the project and testing it during software development life cycle. So this would help us do a lot of tasks simultaneously and develop an application exactly the way the client wants and assure security.

IV. Theory

As mentioned earlier we now understand how important communication for an organization is. So here we have come up with an application that is developed using Node.js.

The application intends to send and receive messages seamlessly with absolutely no delay and chaos. The network security is extremely important for the project. The network will only accept encrypted messages to pass through the network. An unencrypted message can be easily read by any sniffer. This is a kind of passive security attack because receptor of the message or the sender will never come to know that the message that belonged to him has reached him after someone reading it. The application has to also ensure that the attachments do not include a malware. All this is taken into account while developing the application. After the completion of the application in the testing phase, we have tested the application against several possible

security attacks and the application withstood most of them.

The data is stored locally in the application by using MySQL/MongodB database. End-to-End security that let safely exchange private information with each other without worrying about data. In addition to the protection of storage it has lots of modern features such as encryption support. The tools and techniques used by threat actors keep changing and adapting to the conventional security techniques currently in use. Role based DB authorizes the sender receiver and sends the requested resources only if the user has rights to else gives error. Using this system admin will able to get more info like complete logged details of every user including the IP address of each system. Also this messenger will detect any confidential message before sending it and will won't allow to send the message, instead it will alert the admin by informing them about it. It also has a news feed section which will have the current trends managed by the organisation itself.
In this project application the data will be stored periodically in a single machine. No emails required to send the mail hence easing work. Managing is must easier with dynamic Graphical User Interface (GUI). Using AES 128 bit encryption and decryption. A group or team can interact together or individually. Admin manages and assigns the roles of users. It does not have subscription pay scheme and hence saving money and only includes one time fee.

Feasibility Study**:**
Executive Summary

Project is related to Group Messaging Solution. It is similar to whatsapp but GMS will be a desktop application where the user is created by the admin and a unique certificate is generated for each user to identify his/her identity. Users will be assigned into groups i.e. into their respective departments by the admin. Each message will be encrypted by AES 256 bits and will include users certificate at the sender side and decrypted at the receiver side. An OCR technology will be introduced in this which can scan the document and convert the image into text as it is, since in GMS only text is allowed because of safety from Trojans, keylogers, viruses, steganography etc.

- The project maintains two levels of users: -
  - Administrator Level
  - Departmental Level
- Main facilities available in this project are: -
  - Maintaining hierarchy between users.
  - Maintaining logs of chat in the server.
  - Providing secure communication between end users.
  - Providing certificate to each user to maintain their identity.
  - Maintaining backup of data as per user requirements (between mentioned dates).
  - Administrator can only assign the users and provide them their identity.
  - News feed
  - Confidential, spam and rumor Message detection and alerting to admin.
  - Text to speech conversion of message.

Define business problem or opportunity

The Software is for a secure communication in an organization.
It maintains two levels of users: -

- Administrator Level
- Departmental Level

The Software includes: -

- Maintaining logs of chats in database server.
- Providing secure and encrypted communication between end users.
- News feed
- Confidential Message detection

- Purpose

Group Messaging Solution provide following facilities like:-

- ➢ Transparency between admin and users
- ➢ Encrypted Communication
- ➢ Backup of chat
- ➢ News feed
- ➢ Confidential Message detection

Assumptions used in the study

Every user should be:
• Comfortable of working with computer.

Audience impacted

It is designed for industry, start up organisations.

Financial obligation

The financial and the economic questions during the preliminary investigation are verified to estimate the following:

- The cost to conduct a full system investigation.
- The cost of hardware and software for the class of application being considered.
- The benefits in the form of reduced cost.

Recommended action

- Time evaluation is the most important consideration in the development of project.
- The time schedule required for the developed of this project is very important since more development time effect machine time, cost and cause delay in the development of other systems.

Technical Feasibility

- As already many chatting applications are available but when it comes to security GMS is more secure than any other application.

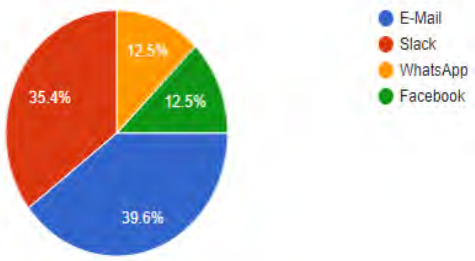
Economic Feasibility

- As GMS is organization specific it will only cost for the database server to keep backup.

Socio-Cultural Feasibility

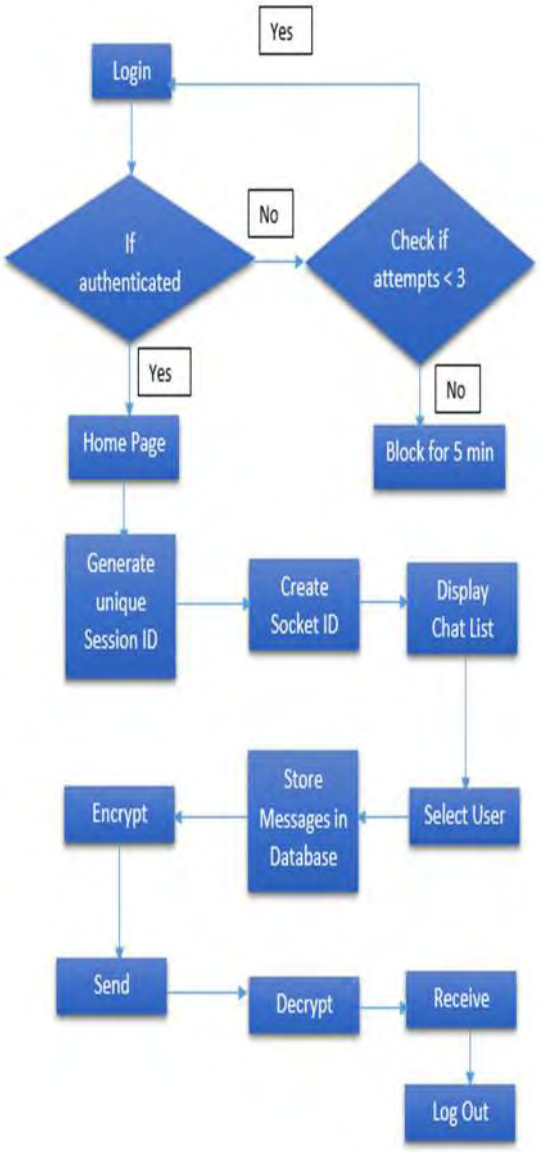
- As GMS is all about group communication there will be complete transparency between everyone.

Research/Technical/Project Work:
The different applications existing in the market today have a lot of features. They are all very easy to use. They are affordable facilities for usage by common man. All the features that the developers claim are indeed worth using. But they cannot be used by business organizations as they have to discuss several formal issues. The applications can have several security threats. We conducted research to study what features are needed by users and which platform they use regularly for communication. The users gave a number of ideas for development of better applications.
The survey can be depicted by the following pie chart:

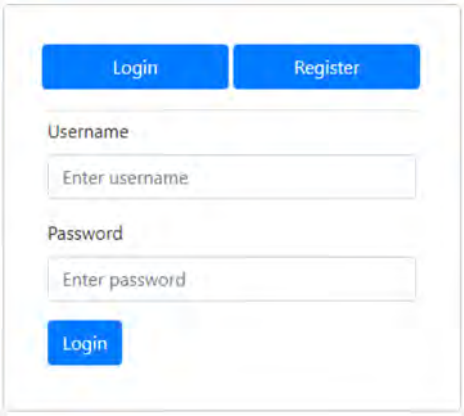


The project works as follows:

- First admin registers all the legit users and saves the credentials of each user in the database.
- When the user wants to enter the system, he has to get authenticated and authorized. For this, he enters credentials.
- These credentials are checked and matched with the ones in the database.
- If the credentials match, the user gets entry in the system else no.
- If the user enters wrong credentials, he is blocked for 5 minutes so that brute force attack can be avoided.
- After logging in a unique ID is generated known as socket ID and it is assigned to each user for concurrency control.
- User sends messages by selecting a user from the chat list and these messages in the database and all of them are sent in first in first out way.
- Before sending the message it will check if the message contains any confidential terms, if yes then the message won't be sent and instead admin will get notified. If no then the message will be sent.



Following are the screenshots of UI which is kept very simple and lightweight to increase the speed so that it can be even accessed by 2G network. Register option will only be available to the admin. And after user login he will have the access to chat list where he can select the group for communication or individual accordingly.



Following is the schema of the database used in this project which consists of user table which keeps the record of user such as username, password, socket-id, online time and other table defines the route of the message and the message. In future scope we can apply AI and deep learning to identify spam messages or confidential messages which are not supposed to be communicated.

1. user Table structure :

Field	Type	Null	Key	Extra
id	int(11)	NO	PRI	auto_increment
username	varchar(10)	NO		
password	varchar(20)	NO		
online	enum('N','Y')	NO		
socketid	varchar(20)	YES		

2. message Table structure :

Field	Type	Null	Key	Extra
id	int(11)	NO	PRI	auto_increment
from_user_id	varchar(45)	YES		
to_user_id	varchar(45)	YES		
message	text	YES		

The following snapshots represent the visuals of the database used in this project using WAMP Server and MySQL database.

	id	from_user_id	to_user_id	message
Edit Copy Delete	1	2	1	Hey
Edit Copy Delete	2	3	1	Hey
Edit Copy Delete	3	1	3	Hi Bro
Edit Copy Delete	4	2	1	It works !
Edit Copy Delete	5	1	2	Yeah it does :)

Check all With selected: Edit Copy Delete Export

After completion of this project we performed penetration testing on this so that we can secure it from the well-known OWASP top 10 vulnerabilities that are

1. Lack of Validation
2. Insecure Configuration Management
3. Broken Access Control
4. Broken Authentication and Session Management
5. Cross Site Scripting
6. Buffer Overflow
7. Injection Flaws
8. Improper Error Handling
9. Insecure Storage
10. Application Denial of Service

Also we have done necessary steps to prevent it such as blocking the user to access the platform if wrong credentials are entered multiple times also input value is escaped and filtered to prevent XSS and other attacks.

V. RESULT AND DISCUSSION

We successfully achieved to eliminate the disadvantages of other messaging systems such as advertisements, distraction because of friends or other spam messages, fake rumors.

We managed to eliminate the subscription system and instead of paying in repetitive manner client can own this with one time pay and can get customized according to its needs which is not provided in others.

VI. CONCLUSION

Thus by this we conclude that the proposed system (Group Messaging Solution) transparency will be there in a hierarchy. Also not only an industry but also other organizations where hierarch y is available. This system helps the group members to have a better communication amongst them and so that everyone can keep their idea and eliminate the research gap.

We first went for literature survey in which we understood several research gaps. There are several systems used for messaging but they have flaws. We conducted surveys to understand the advantages and disadvantages of those applications that the users face. Advantages and disadvantages were analyzed and feasibility study was made to understand what we can do to get better application.

So we tried and created application that is customizable as per what the user needs. The user can anytime think of changes and change the system. The User interface helps the user understand about the working of the system. Our work was based on agile methodology so we completed works in parts and then collaborated them. It removes annoying issues like advertisements. It also has news feed and message detection system which will help the employees stay on the same page and eliminate the spam and rumors and also admin can keep an eye on confidential message. The application can be used all time after paying once.

We successfully matched what was expected and we what is created.

Future Scope:

Through our project we have tried to fulfill all the technological gaps that we found out through the literature surveys and surveys that we conducted. But the project has future scope because it is an interactive project and can be advanced as per the needs and demands of the stakeholders. The following features can further be added to the project:

- Identify messages with priority.
- OCR technology to scan document and send it in text format.
- Adding dictionary.

VII. ACKNOWLEDGEMENT

We sincerely thank to our guide Dr. Zahir Aalam for his guidance and support for carrying out our project work. It is indeed a matter of pleasure and privilege to be able to present this project on **Group Messaging Solution**.

The completion of the project is a milestone in student's life and its execution is inevitably in hands of guide. We are highly indebted and appreciation of the project guide **Dr. Zahir Aalam** for his invaluable guidance and appreciation for giving form and substance to this report. It is due to his enduring efforts, patience and enthusiasm, which has given a sense of direction and purposefulness to this project and ultimately made it a success.

We would like to express our deep gratitude to the staff members for co-operation. Also we would like to thank our Dean R&D **Dr. Kamal Shah** and H.O.D **Dr. Rajesh Bansode** for his sincere support and guidance.

We would like to express deep regards and gratefulness to Principal **Dr. B. K. Mishra** for always encouraging students learn new technologies and implement them.

We would like to thank the non-teaching staff and friends who have helped us all the time in one way or the other.

Really it is impossible to repay the debt of all the people who have directly or indirectly helped us in completing the project.

E-KANBAN SYSTEM FOR SUPPLY CHAIN

Arisht Bhandari, Anand Jha, Tushar Jha
Thakur College of Engineering and Technology, Mumbai,India
arisht.bhandari.ab@gmail.com, jhaanand9716@gmail.com, jhatushar123@gmail.com

Abstract— **For years, many manufacturers had faced problems such as manual entry errors and lost cards. Therefore, they have implemented E-kanban system. It can be integrated into ERP (Enterprise Resource Planning) system, which enable real time- demand signal to supply chain and it will improve visibility. Data pulled from E-Kanban systems can be used to optimize inventory levels by better tracking supplier lead and replenishment times. Unlike traditional Kanban which uses traditional elements such as Kanban cards with barcodes and Electronic messages such as electronic data enterchange or email , Electronic Kanban is a signaling system which uses mix technology to trigger the movement of materials within a manufacturing facility. There are two most important types of Kanban system: production Kanban and transportation Kanban.**

I. INTRODUCTION

For years, many manufacturers had faced problems such as manual entry errors and lost cards. Therefore they have implemented E-kanban system. It can be integrated into ERP (Enterprise Resource Planning) system , which enable real time- demand signal to supply chain and it will improve visibility.
Data pulled from E-Kanban systems can be used to optimize inventory levels by better tracking supplier lead and replenishment times.

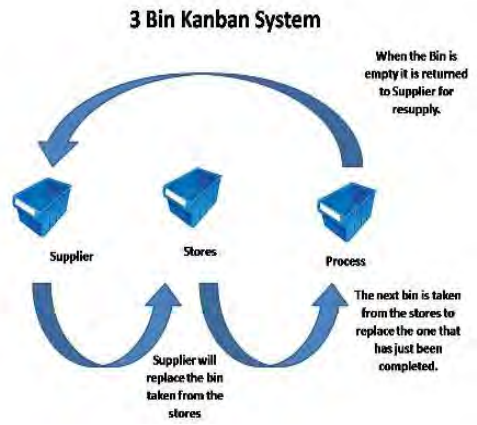
Kanban became an effective tool to support running a production system as a whole, and an excellent way to promote improvement. Problem areas are highlighted by measuring lead time and cycle time of the full process and process steps. One of the main benefits of kanban is to establish an upper limit to work in process inventory to avoid overcapacity. Other systems with similar effect are for example.[5] A systematic study of various configurations of kanban systems, of which CONWIP is an important special case, can be found in Tayur (1993), among other papers.

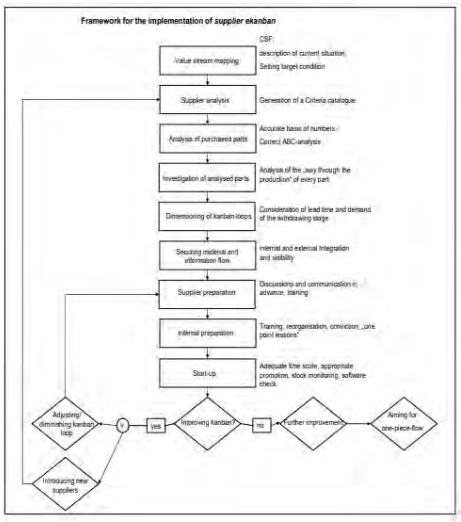
A goal of the kanban system is to limit the buildup of excess inventory at any point in production. Limits on the number of items waiting at supply points are established and then reduced as inefficiencies are identified and removed. Whenever a limit is exceeded, this points to an inefficiency that should be address

II. PROPOSED WORK

In this project we are going to create an application where the supplier falls short of his product, he sends the request through the application to the manufacturer. Then the system will register the requested product. Then manufacturer processes the requested product, and then sends a signal to the supplier regarding the completion of the product. It notifies the supplier to collect the product

The working is as follows:





III. LITERATURE SURVEY

In this paper [1], The kanban contains information that serves as a work order.It gives information concerning what to produce, when to produce, in what quantity, by what means and how to transport it.

In this paper[2] Current production literature alludes to the idea that, collectively, these advances have paved the way for application of Just-In-Time (JIT) production concepts, which were originally developed for mass production systems, in intermittent production systems.

This paper[3] This research work focuses on study of supply chain management of leading Indian and Multinational companies in lighting industry in India in order to understand how they are coping up with the forces of continuity and change.

IV. FEASIBILITY STUDY

- **Economic Feasibility (EFS):** The cost and benefits related with the implemented project compared and the project is economically feasible or not and it benefits outweigh costs. The system development cost will be significant. So the project is economically feasible.
- **Business Case**

  The Business Case provides an analysis of the business environment including-
  Expected customers: supplier, manufacturer.

I. Technical Feasibility:

Resources Required:
Software required: Android studio, angular js.
Hardware required: PC for development, smartphone for implementation.

V. Results and discussion

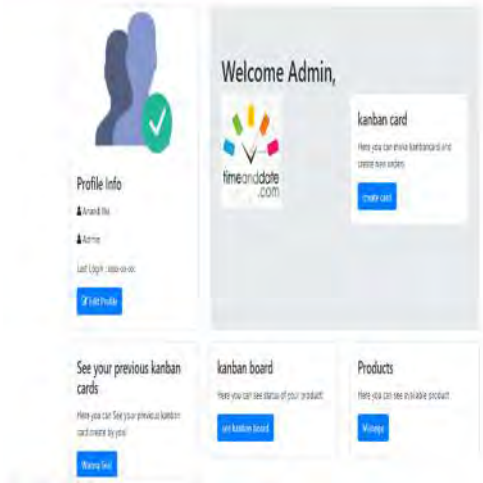

Fig 3 Manufacturer's GUI

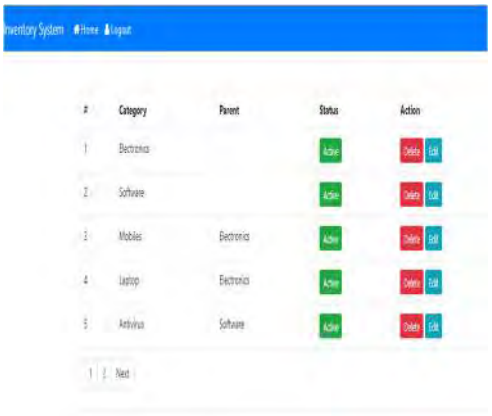

Fig 4. Product Categories

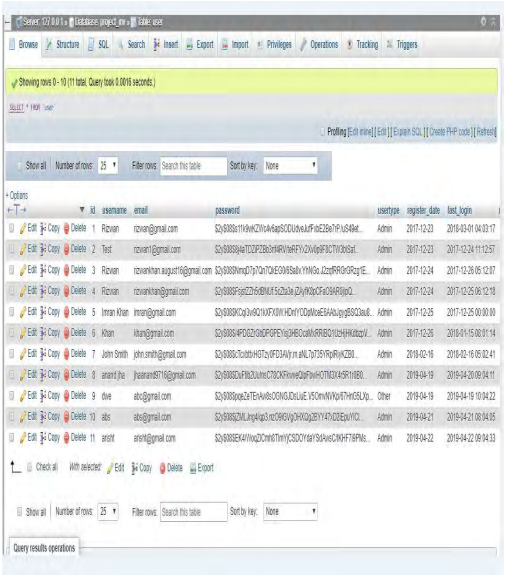

Fig 5. Admin Database

Fig 6 KANBAN Card Details

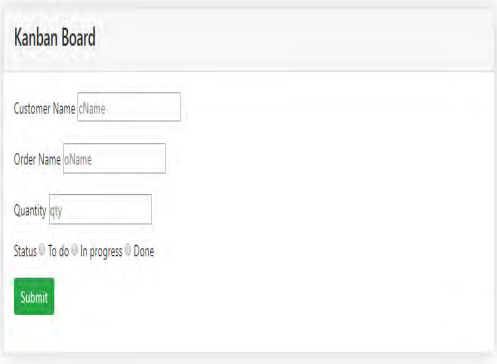

Fig 7. KANBAN Board

VI. CONCLUSION AND FUTURE SCOPE

Framework developed for the implementation of a supplier e-Kanban enhances operational tasks such as providing materials and guaranteeing a smooth run. The framework also allows strategic aims to be followed, and allows any underlying problems that may impact success to come to the surface, to be solved.

We had thus developed an internet-based application as a base for supplier e-Kanban. The application is password-secured and only for suppliers applying an e-Kanban system. By logging in to the system, every supplier can monitor the Kanbans, the different status of the Kanbans, and the current location of the container. Thus, the supplier has an overview of what will be needed shortly and can therefore prepare material in advance, before the actual signal arrives. This clarity gives the supplier more flexibility to ready the next Kanban.

With reference to reviewed work we were able to find and define the problem definition we were able to find and define problem definition. We were clear with the idea of problem definition, algorithms, tools (front end, back end) required to implement the same in phase I of the project.

We have thus achieved our goal and developed the desired system for the implementation of a supplier e-Kanban enhances operational tasks such as providing materials and guaranteeing a smooth run. The framework also allows strategic aims to be followed, and allows any underlying problems that may impact success to come to the surface, to be solved.

Student Attendance System using QR Scan Code

Tanvi Haldipur, Adarsh Kotian, Sumer Patel
Information Technology, Thakur college of Engineering and Technology,Kandivali
Mumbai, India

Abstract – **Most of the teachers/professor's waste about most of their time of the lecture taking the attendance for their students. Student attendance using QR scan is an application that is developed in order to ease out the life of teachers. This app will be able to take the attendance of the students with the help of QR codes. Nowadays most of the students have their own smartphone or at least a phone that could open web browsers, so availability of smartphones is not a major problem here.**

The day to day register work of the teachers is reduced. The teachers tend to spend most of their time taking the attendance using the old process of manually entering data into the registers. With the help of this application teachers will be able to enter the details of the student, the time the students QR code was scanned, the student ID all these data will be stored into the sheets.

This app will be a web app as well as it could be opened in any browser of your choice. The students will generate their QR codes by entering their data (the data will consist of the student's unique identification number, students full name and the time the students QR was scanned), which are generated dynamically so as to prevent any proxy. The teacher only will have a scanner application who will scan the dynamically generated QR codes and the data that is entered by the student is stored in the data sheet of the teacher for attendance purpose.

I. INTRODUCTION

Attendance Management System is software developed for daily student attendance in schools, colleges and institutes. It facilitates to access the attendance information of a particular student in a particular class on daily basis. The information is sorted by the application, which will be provided by the teacher for a particular class or classes. This system will also help in evaluating attendance eligibility criteria of a student for any remedial work need to give for monthly attendance generated by the report generated by the attendance application system. Problem definition:

This system will generate attendance of using QR Scan and generate reports to professor regarding monthly attendance and give a detailed report of all the defaulters in particular lecture in particular dates the students remained absent. This is hassle free system in which no use of pen and paper is required and saves time as mobiles are used by each and every body in today's world so once this application is installed it is convenient for professor as well as for student and even no proxy attendance will be marked.

Background:

Traditionally, the student attendance was taken in a manual way which was either using the formal or informal paper attendance sheet. The manually taken student attendance is uncomfortable in teaching and

II. METHODOLOGY USED

Learning situations to lecturers even to students. This project is developed to manage and reduce the current problems faced by the lecturers and students in a systematic and structured method. The system only can be functional after it is activated by the administrator or lecturer to identify and record students' attendance. This can prevent the student or other people to access it. There are some functions provided including adding and editing student attendance information, calculating the percentage of student attendance and printing the student attendance report adding leaves regarding medical if absentee. period and tasks involved with them. To remain in sync with the other members of the team they have to complete their task within the stipulated amount of time.

The meetings however are conducted on a regular basis where all the members of the team have the right to put forth their ideas along with any requirement or concern. The product backlogs are discussed in these meetings where the requirements of the project to be completed along with the resources are mentioned.

The project is first divided into different phases, and then the responsibility of developing these phases is given in the hands of the various developers. At every stage of the project development it is continuously monitored and taken care of. These developers developing the phases have particular amount of time. Agile

Agile methodology mainly focuses on the incremental and the iterative development of the different project phases. It controls and determines how the various

III. TECHNICAL WORK/RESEARCH

Feasibility Study

1. Executive Summary

Project is related to Student Attendance System using QR Scan.

The project maintains two levels of users: - Administrator Level-Owner

User Level-Data Entry Operator

Main facilities available in this project are: - Maintaining records of student's attendance. Maintaining monthly attendance details. Providing different professor the attendance.

Maintaining backup of data as per user requirements (between mentioned dates).

User or Administrator can search a student record by his/her name

2. Define business problem or opportunity

The Software is for the automation of Attendance Management.

It maintains two levels of users: - Administrator Level

User Level
The Software includes: - Maintaining student details.
Providing and maintaining all kinds related to attendance for professor ease.
Auditing and Report generation.

3. Requirements and purpose of the study
Hardware Requirements Processor RAM, Disk Space Pentium IV or higher Software Requirements Operating System.
Win-XP or higher.
MS Excel.
Web Development tools.
External APIs to generate QR codes dynamically. Purpose QR Scan provides facilities like: - Taking attendance easily.
Saves time
Saves pen paper usage
Record maintenance easily done

4. Description of the options assessed
Based on research conducted over the Internet we identified the following alternatives for the MMS:

Continue to use the current system. This will be referred as Alt 1.
Utilize a packaged solution. The colleges and schools who require this software can purchase the product and host them in their own environment. A lot of programming and re-programming is required for customizing the system and implementing them. Since this is a proprietary system the programming costs are at a premium. This will be referred to as Alt 2.
Develop a customized MMS solution which meets all requirements satisfactorily and is also built with a scalable scope. The programming costs will be on a regular cost. This will be referred to as Alt 3.

5. Assumptions used in the study
Every user should be:
• Comfortable of working with computer.
• He must have knowledge in developing Application for QR Codes.
• He must also have basic knowledge of web and development skills.

6. Audience impacted
It can be used in any attendance management from colleges, schools or workplace.

7. Financial obligation
The financial and the economic questions during the preliminary investigation are verified to estimate the following:
The cost to conduct a full system investigation.
The cost of hardware and software for the class of application being considered.
The benefits in the form of reduced cost.
The proposed system will give the minute information, as a result the performance is improved which in turn may be expected to provide increased profits.

8. Recommended action
Time evaluation is the most important consideration in the development of project.
The time schedule required for the developed of this project is very important since more development time effect machine time, cost and cause delay in the development of other systems.
A reliable Student Attendance System using QR Scan can be developed in the considerable amount of time

IV. DESIGN AND IMPLEMENTATION

4.1 DFD:
Level 0:

Fig: 4.1.1: DFD Level 0

Level 1

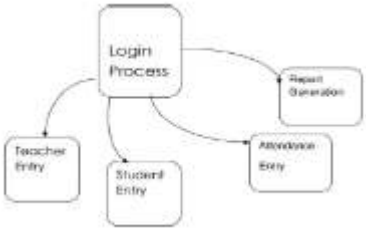

Fig: 4.1.2: DFD Level 1

Level 2:

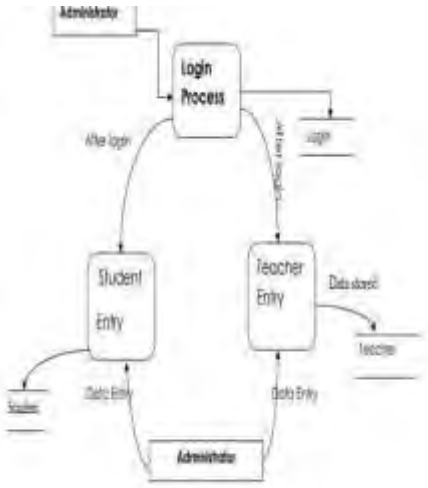

Fig: 4.1.3: DFD Level 2

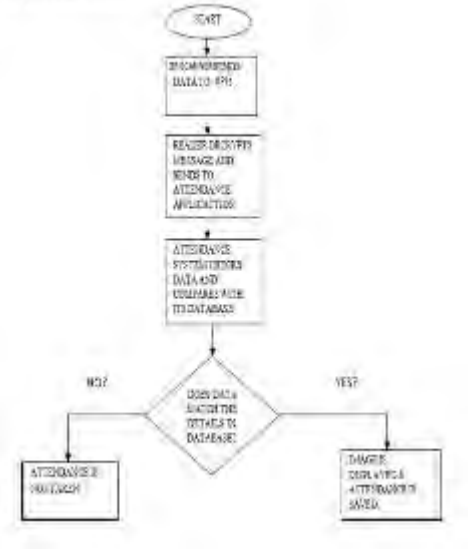
4.2 Flow chart:



V. RESULT AND DISCUSSION

After the complete analysis done through the previous sections of the paper. The results related are displayed below.

Actual output:

As far as Attendance is concerned a feedback system can be included. A section where students can download their assignments right from the website or WebApp also Push Notifications/SMS/Email of any changes that occur in the day to day schedule.

VI. CONCLUSION

With reference to reviewed work we were able to find and define the problem definition according to the methodology implemented.

We are clear with the idea of problem definition, algorithms, tools (front end, back end) required to implement the same.

We will follow phases shown above to implement proposed project for smooth development conduct.

We will try our level best to implement the proposed system to achieve the defined objectives.

VII. FUTURE SCOPE

As far as Attendance is concerned a feedback system can be included.

A section where students can download their assignments right from the website or WebApp also Push Notifications/SMS/Email of any changes that occur in the day to day schedule.

Style of list in references of some standards is as below;

Automated Healthcare Informatics On Service Management

Mansi Agarwal, Irshad Badarpura, Bhoomi Gandhi,Vikas Kaul
Information Technology, Thakur College of Engineering and Technology/ Mumbai University, India

Abstract – **Health care is the essential part of our lives, providing best medical facilities to people suffering from various ailments, which may be due to change in climatic conditions, increased work-load, emotional trauma stress etc. It is necessary for the Health care industry to keep track of its daily activities & History of its patients, doctors, nurses, ward boys and other staff personals that keep the Health care running smoothly & successfully. But keeping track of all the activities and their history on paper is very strenuous and error prone. It also is very inefficient and a time-consuming process. Observing the continuous increase in population and number of people visiting the Health care. Recording and maintaining all these records is highly unreliable, inefficient and error-prone. It is also not economically & technically feasible to maintain these records on paper. Thus, keeping the working of the manual system as the basis of our project.**
We are using a tableau tool for developing dashboards which help to eliminate the need of paper based visualization and help the Health care business users to effectively analyze and monitor the daily takes that are performed in the Health care. Basically, we use the data mining and business intelligence techniques and methods to provide the stakeholders with detailed inspection of the Health care workings. Also, we use a tool called Pentaho that provides business intelligence and OLAP services, reporting, Data mining and ETL Capabilities. Using this we extract only the data needed for analysis from the huge data sets.
In the future, this project can be extended to give more detailed analysis of the health care industry and solve problems such as maintaining manual record of data, studying the data manually and can help to save a lot to time. Also, it can be used to predict the outcomes and suggest measures that can be taken to prevent an error and significantly it will help to reduce labor costs.

I. INTRODUCTION

Healthcare are the essential part of our lives, providing best medical facilities to people suffering from various ailments, which may be due to change in climatic conditions, increased work-load, emotional trauma stress etc. It is necessary for
the Healthcares to keep track of its day-to-day activities & records of its patients, doctors, nurses, ward boys and other staff personals that keep the Healthcare running smoothly & successfully. But keeping track of all the activities and their records on paper is very cumbersome and error prone. It also is very inefficient and a time-consuming process Observing the continuous increase in population and number of people visiting the Healthcare. Recording and maintaining all these records is highly unreliable, inefficient and error-prone. It is also not economically & technically feasible to maintain these records on paper. Thus keeping the working of the manual system as the basis of our project. We are using a tableau tool for developing dashboards which help to eliminate the need of paper based visualization and help the Healthcare
business users to effectively analyze and monitor the daily takes that are performed in the Healthcare. Basically we use the data mining and business intelligence techniques and methods to provide the stakeholders with detailed inspection of the Healthcare workings.

II. II. Material And Methods

This prospective comparative study was carried out on patients of Department of general Medicine at Dr. Ram Manohar Lohia Combined Hospital, Vibhuti Khand, Gomti Nagar, Lucknow, Uttar Pradesh from November 2014 to November 2015. A total 300 adult subjects (both male and females) of aged ≥ 18, years were for in this study. (10) Study Design: Prospective open label observational study
Study Location: The study was done at IT Department, Bhakti Vedanta Hospital, Mira road,Thane,Maharashtra.
Study Duration: July 2018 to November 2018.
Sample size: 1 million patients.
To create the dashboards we extract the data from different data sources and data marts using a tool called Tableau and various Data warehousing techniques.
The different methodologies used are :

E-R Model:

It is a graphical illustration of entities and relationship to each other, usually used in computing in reference to the organization of data within databases or information system.

ETL process:

It is used to extract the data from different relational database sources then transform the data using calculations, concatenations, etc. and then load into the Data warehouse system.
The various technologies used are:

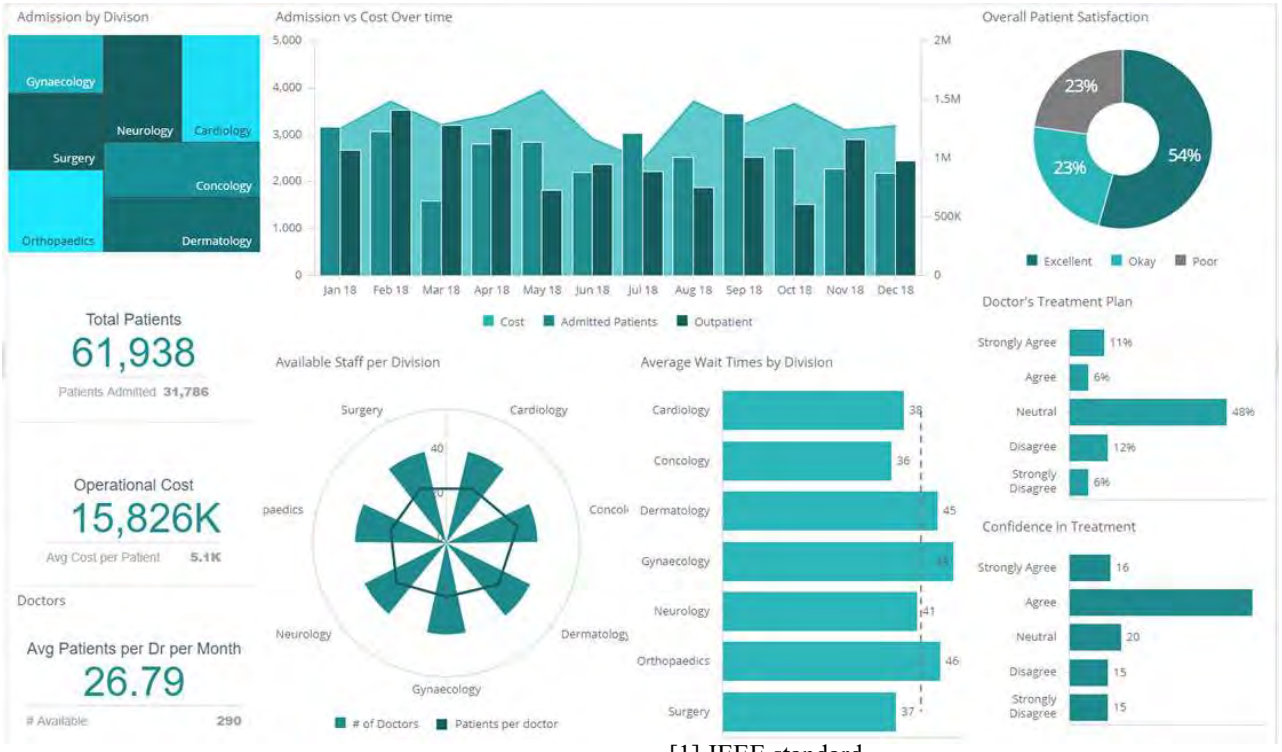
Tableau:

Tableau is a tool that helps to understand and analyze data. Users can generate and dispense an interactive and
shareable dashboard, which illustrate the trends, variations, and density of the data in the form of graphs and charts. Tableau can bind to files, relational and Big Data sources to acquire and process data. The software allows data blending and real-time combination, which makes it very eccentric. It is used by businesses, academic researchers, and many government organizations for visual data survey.

Pentoha:

Pentoha is a tool for creating relational and analytical report. It helps to create reports in HTML, Excel, PDF,
Text, CSV, and xml. Pentaho can take data from variety of data sources including SQL databases, OLAP data sources, and even the Pentaho Data Integration ETL tool.

III. III. Result



IV. IV. Conclusion

With reference to reviewed work we were able to find and define the problem definition we were able to find and define problem definition. We are clear with the idea of problem definition, algorithms, tools (front end, back end) required to implement the same. We will follow phases shown above to implement proposed project for smooth development conduct. We will try our level best to implement the proposed system to achieve the defined objectives.

Abstract— **Nowadays people use mobile phones and other mobile devices. Most of us have a small computing device that is always with us. People use it example for calling, as calendar and organizer. Mobile devices with GPS receiver are also used to find paths in navigation.**
The main idea of this thesis was to design a system that will run on most of phones and palms and will be helpful when visiting some new places and cities. This system should be able to find a route using user criteria.
The project belongs to the domain of Machine Learning and
Artificial Intelligence and the programming language used is python.
Many papers have been published, research have been conducted to analyze the methods to be used for developing a better intelligent tourist system and based on some of
those paper this project includes various points
Intelligent tourist system for better travel experience will enable the travelers to carry out their journey in an efficient manner. This project covers all the essential factors needed for traveling.
The additional functionality the project includes is videos from famous bloggers related to exploring new places. This functionality will help travelers to explore new places with ease. By using this feature the travelers can take some knowledge about the concerned places before visiting them.

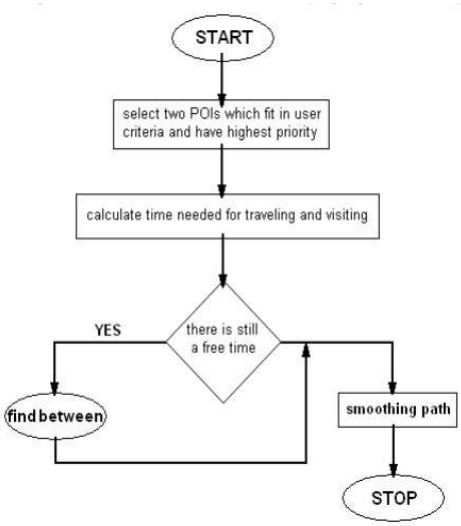
I. INTRODUCTION

The project aims at building an intelligent tourist system to
assist the travelers in exploring various tourist places. In the past number of applications have been developed for same. The Primary reason was to find an efficient manner of traveling. With past studies and researches it has been of major concern to develop a system which could help travelers while traveling. A lot of papers have been published with real time model having intelligent tourist system embedded in them.
accurate measurements but their cost is usually as high as several hundred dollars, making them uneconomical.
So this heart rate monitor with an optical sensor is a very useful instrument in knowing the pulse the patient..

II. PROPOSED WORK

The methodology that we chose for our project is Agile. While waterfall model is a tried and tested framework, it is not suitable for our project, due to the changeable nature and small team size. Agile allows us to be flexible, manage changing requirements, manage the ever-increasing scope as well as get consumer perspective.

The working is as follows:



III. LITERATURE SURVEY

[1]Literature Survey on Tourism Recommendation
Jitha P B, Reshma M
Recommender system, comparative description, mobile system, topic modeling
[2]Intelligent Tourist Information System
AyeshaShaikh,Sonal Rami,
Tirth Shah Recommendation technique, Shortest pathalgorithm, Intelligent tourist system, A* algorithm.IV. FEASIBILITY STUDY

- **Economic Feasibility (EFS):** The cost and benefits related with the implemented project compared and the project is economically feasible or not and it benefits outweigh costs. The system development cost will be significant. So the project is economically feasible.
- **Business Case**

The Business Case provides an analysis of the business environment including-
Expected customers:
The nature of the business:

IV. Technical Feasibility:

Resources Required: Programmers, Arduino.
Software required: Thing Speak, Arduino IDE
Hardware required: PC for development, hardware components for implementation.

V. Results and discussion

Thus after the implementation of prototype we finally come to a conclusion and discussion that the cost of our project or system has to be reduced and efficiency has to be improved as well. The main change to focus on is the size of the system. It has to be compact and easy to use in daily lives of users. So in next phase our primary goal is to focus on size and efficiency of the proposed system.

VI. CONCLUSION AND FUTURE SCOPE

Thus by this we conclude that the proposed system can be efficiently used by travelers and any normal person. This System provide all the traveling related information.

This will provide a way for efficient solutions for travelers economically in terms of money and time.This project also provides a knowledge of

Abstract. **Now a day's in Industries a hot topic as a trend has taken place termed as Data Processing Techniques Like Artificial Intelligence (AI), Deep Learning (DL) and Machine Learning (ML)[2]. Everyone maybe knowing bit glimpse or maybe they are expert in certain part/technique but one person calls it DL while at the same time the other one calls it ML. This techniques are being used in several sectors by huge com- panies like Google, Facebook, Microsoft etc[3]. As many of the keys and working are same in some perspective of Data Processing techniques but there is key difference between them where we can make differentiation how one Data processing technique is different from other Data processing technique [3]-[5]. In some sectors DL shows the output more exceptionally well were in some sectors ML takes credit of being more perfect. But with respect to computational methodology DL technique is more expensive. In this paper, we have investigated the key difference between Data Pro- cessing techniques and reviewed the comparative analysis of Data Processing tech- niques.**

Keywords. Artificial Intelligence; Machine Learning; Deep Learning; Data Pro- cessing Technique; Comparative Analysis.

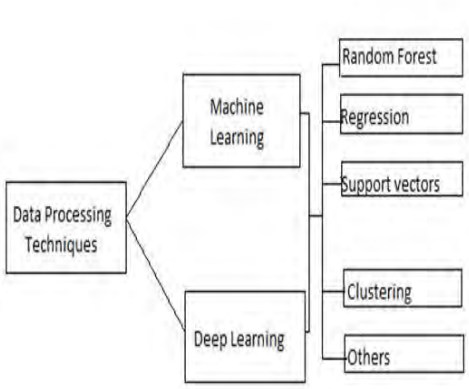
I. INTRODUCTION

Nowadays in many organizations, demand has been boosted due to importance of using predictive analysis or Data Processing techniques. But to know the compatibility of Technique with the System in which we are using it such that it gives the best possible or accurate result we should the key differences between the data processing tech- niques. Lets consider the most general or basic view that what the ML is all about , basically it refers to the computer which can make learning on its own without any manual code implemented on it but an good amount of data is feed to process and make self learning easy. Famous Alan Turing's seminal paper which was proposed in 1950 concludes that Learning Machine can fool a human and make them believe that it is real[1]. About Machine Learning and some part of Deep Learning such as Deep Neural Network (DNN) are playing an important role in making advancement where Machine Learning works on prediction and Deep Learning follows a wise flow of Hierarchy. There are two terms in machine learning i.e. supervised machine learning and unsuper- vised machine learning that is expected to be known by Data Scientists. Ensemble mod- eling uses a combination of approaches and semi-supervised machine learning comb both the techniques. The term supervised machine learning is one in which the user trains the program (Data set is known), such that it act's accordingly as the input is given to it whereas the term unsupervised machine learning generates the answer on unknown dataset. Supervised machine learning commonly uses techniques like Support Vector Machine (SVM), regression, random forests, decision trees, and support vector ma- chines. Unsupervised machine learning uses algorithms like clustering algorithm where Data scientists uses this type of techniques to find or discover new pattern in the given data set. See Fig.1. for basic classification of Data processing Techniques. Deep learn- ing is one of the form of Machine learning where it uses supervised or unsupervised algorithms, or both algorithms has been used. Deep learning is widely used in computer vision, natural language processing, neural networks (It is based on representation learning or feature learning). Google's 'Deep Mind' team has famous for making a con- volutional neural network which beat the ancient

Chinese game known as GO.

.1: Algorithms in Data Processing techniques.

Deep Learning has successfully implemented a strong field ranging from image processing, speech recognition with medical diagnosis to self or auto mate driving cars and as we discussed it is defeating human players in complex games such as Go, chess and etc. As it requires a huge set of data for processing proportionally the requirement of space also increases widely with the complexity of Deep Neural Networks (DNN). For training a DNN we require a high performance computing cluster (categorization of samples based on similarity in feature



II .RELATED THEORY

AntonioHernández-Blanco et al [1] mentioned in his article about Educational Data Mining. Where the terms like Learning Management System, Intelligent Tutoring System, Massive Open online courses. It is concerned with developments, research, and applying ML , data mining and statistical methods to detect pattern in large set of educational data which is used for analyzing the pattern present in the dataset.

Scott H. LeeID et al[2] proposed article on "A comparison of machine learning algorithms for the surveillance of autism spectrum disorder" – The data gathered from site and algorithm has been checked for 10 random train tests where 8 supervised learning algorithms has been applied . It has been noticed that the neural network and random forests almost same result with the accuracy of more than 87 %.

Nitish Srivastava et al[3] proposed Deep neural model concept has a large number of hidden non-linear layers which can solve a very complicated relations and can be implemented with less amount of training data . There are various types of penalties which can come to picture which leads to over fitting of Neural Networks. Dropout Neural Networks can also be trained using stochastic gradient as much similar to standard neural networks.

Yu Wang et al[4] mentioned that the DL based combination of CNNs where it is compatible of recoginising eight modulations with high identification accuracy where it requires a huge amount of data to follow a set of instructon by setting up an hierarchy. The approach can directly be implemented to CRs if more data signals are provided to it. Battista Biggioa,b,∗, Fabio Rolia,b et al[6] Said when a data is fed for the processing the more the experience increases or the learning increases of the machine the more better it will perform with the ability to stop the malware attacks or prevent security threats, most of the times the exact representation layer is not known by the attacker. To prevent the Poisoning attacks the term called data sanitization is used i.e. Detection of attack and simultanoeusly removal of it.

Hadeer Ahmed1(&), Issa Traore1, and Sherif Saad2 et al[7] has done classification techinque of ML and it has been used for Analysis of Fake news called Linear Support Vector Machine with Term Frequency-Inverted Document Frequency (TF-IDF) for feature Extraction. For classification we used ML with less amount of data where the question arises the system is making analysis and showing results with what accuracy, for that they purposed a accuracy results using SVM with different datasets. As the topic was new the good amount and perfect type of datasets were not avilable as they agree to run the model using publicly avilable dataset , Such as LIAR dataset.

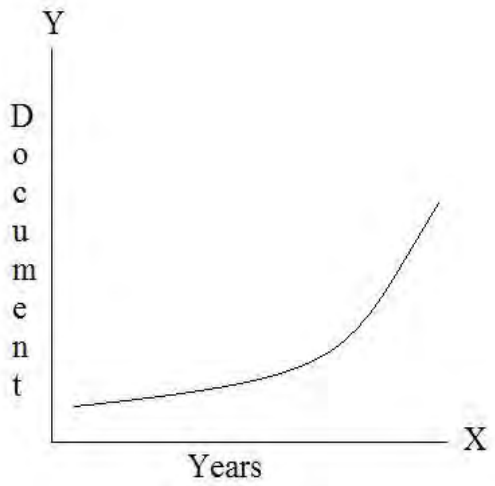
JO˜AO GAMA et al[8] elaborates the terms of Data Processing techniques exists from 90's but the avilability of data was not much therefore the use of such techniques were less but as the time passed , the amount of data keept increasing as the survey conducted according to [8] in 2012 the amount of data reached 2.8 zetabytes. Now a huge amount of data is avilable due to which the predictive and learning adaptivity with accuracy, is boosted. The amount of correct data present is directly proportional to the accuracy of the model. As per Statistics[9] the amount of data in 2020 will reach from 4.4 zetabytes to 44 zetabytes.

CHUANLONG YIN et al[10] mentioned that ML methodologies have been widely used for prevention of various types of attacks where the

technologies help Network Administrator to identify the threats and malware attacks and take preventive measures but it is not successful to solve the massive intrusion problem of data classification which arises in the real network scenario . Where Deep Learning has better potential to identify the representation layer and it achieve a special remarks in speech recognition , image recognition[11] and action recognition[12]-[13] .

Andreas Kamilaris et al[14] introduced Smart Farming with Deep learning, the Deep Learning technique has been used for tackling the challenges of farmming related problems in terms of productivity of the suitable crops with a lot many appropriate conditions. To get addressed and to tackle all the challenges, all the complexity like unpredictable and multivariate ecosystems they required the continuous monitoring support with all aspects which points towards the big data. Which required a imaging analysis with optical and x-ray imaging. With all this it is concluded that DL is the most promising aspect to use rather than that of ML techniques. See Fig.3. to analyse the subparts of techniques. DL extends ML by adding more extension to it.

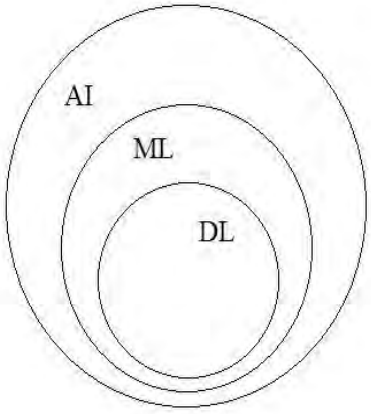
Kamran Kowsari et al[15] said that each year a lot of publications takes place due to which a lot of documentations are generated See Fig.2. , likely to be said that only scientific reasearchers each year produces massive number of documents. In 2014 around 2.4 million papers have been published which



itself is a large amount where every year it keeps on increasing

Fig.2. Graphical representation of incrementation in documentation over the years.

To handle such a large amount of data we need Deep Learning to come into picture where ML cannot handle such large amount of data. It will use



hierarchical document classification where hierarchical DL is used for text classification.

Fig.3. Domain Specifier (what is subpart of what).

II. METHODS

This section ensures that why the analysis is important on Data processing Techniques such that one should know that which technique will enhance the accuracy, compati- bility and endurance of models. With series of analysis we came to know that both the techniques (ML and DL) have their advantages and disadvantages based on the model what one individual want to implement. As such many papers mentioned number of models, which authors are trying to implement or have implemented but the compati- bility depends on the type and amount of data that one individual is going to gain cer- tainty with level of accuracy. In ML the machine is trying to learn with the past expe- rience i.e. it is trying to reduce the difference between the estimated value and the actual value which leads to decrease in the error and try to maximize the accuracy level to give more accurate predictions. For example if we want to predict the height on given data of weight or vice versa. See Fig.4. For reference.

Fig.4. Representation of Predictive analysis.

We can use more than one attribute for prediction for which we use Multi regression technique. The Deep Learning is the particular type of machine learning which uses mostly the same configuration of how our brain functions on neuron level if we want to analyze anything such as box then it follows hierarchical order to analyze the object, it first checks whether it has four sides or not , then it checks all sides are connected or no, further they are perpendicular to each other or no . This is how it analyze all the things on higher level like image processing, speech recognition and much more.

Fig .5. Formula for

IV . COMPARITIVE STUDY

The comparison on the basis of ML classifier such as Random Forest and Deep Learn- ing approaches with enhancement of Deep Neural Network using 2 , 4 and 7 layers. The software used for Random Forest is python library sci-kit[16] and for Deep Neural Network is python library keras[17]. Some layers have been chosen to perform and analysis the performance with increase in the number of layer. The formula for the accuracy See Fig.5.

$$\text{Accuracy} = \frac{TP + TN}{TM + TB}$$

TP -> True positives.
(The number of malware instances correctly classified)
TN -> True negatives.
(The number of benign instanes correctly classified)
TM -> Total number of malware instances.
TB -> True number of benign instances.

Fig.6 Flow chart of comparative analysis

Accuracy.

All DNN layers uses Exponential Linear units to activate the function. To analyze the flow of progress See Fig.6. Where the comparison in the form of flow chart of malware classification by both the techniques i.e. ML and DL. As presented the result for the same analysis the concept of ML classifier i.e. Random Forest has better results than that of 2, 4 and 7 layers of DNN [19]. Although if compared with all the 7 layers of DNN it gives the out-forming result with the accuracy of 99.21% .Refer Tabel.1. to analyze the accuracy of the classifier. If DNN - 4 layers used with AE-1L then it gives the highest accuracy where as if it is used with AE-3L then the accuracy decreases with approximation of 6%. As a result the best accuracy obtained by Random Forest and Deep Neural

Network is 99.78% and 99.21% respectively [18]-[19].

Classification Accuracy for Oasis Cross Sectional (1) and Longitudinal Data (2)

Classifier	Classification Accuracy (1)	Accuracy after Attribute Selection	Classification Accuracy (2)	Accuracy after Attribute Selection
J48	99.52%	99.52%	99.20%	98.66%
Naïve Bayes	99.28%	99.52%	96.78%	98.66%
Random Forest	92.55%	75.96%	90.08%	98.39%
Multilayer Perceptron	96.88%	99.52%	74.53%	97.32%

Table.1. Showing the accuracy of the classifier.

With the reference of table.1. it is clear that Random Forest is more compatible to show high accuracy then that of DNN, but in some cases like a paper proposed by Scott H. LeeID et al[2] on "The Comparison on ML algorithms for the surveillance of autism spectrum disorder" shows that Random Forest and Deep Learning approaches shows the same result .

Due to predictive technique, the Machine Learning has a trend grabs the interest to- wards neurodegenrative disorders. The major emerging global health issue termed as Dementia has been predicted at early stage. Due to which it has become easy to diag- nose Dementia. The predictive analysis with the help of four algorithms named as J48, Naive Bayes,Random Forest and Multilayer perceptron. The raw dataset partly col- lected from oasis-brains.org for processing. The work flow and the comparitive accu- racy factor analysis for each mentioned algorithm is as mentioned in Table.2. for refer- ence.

Classification Accuracy = (Correctly classified samples / Total number of samples) * (100)

ALGORITHM	ARTIFICIAL NEURAL NETWORK	SUPPORT VECTOR MACHINE	DECISION TREE
Big data based	Yes	Yes	Yes
Water quality factors	physical,bio,chemical	chemical	Biological , chemical
Structured data sets	Yes	Yes	Yes
Training data	60%	78%	70%
Testing data	20%	45%	30%
Real-time prediction	No	Yes	Yes
Simplicity	Yes	Yes	No
Accuracy	87%	Err 0.089	85%
Regression based	Yes	No	No
Supervised Learning	Yes	No	Yes
Sensors Used	No	Yes	No
Robustness	Yes	Yes	No
Flexibility	Yes	No	Yes
Data clustering	possible	possible	impossible

Table.2. Classification Accuracy for types of data.

The updated result for the comparison of ML algorithms based on the factors such as Big-data, water quality, structured datasets, training data, testing data, Real time pre- diction, simplicity, accuracy, Regression and many more. See Table.3. for analytics. To compare the algorithm's efficiency.

Table.3. Comparison of Algorithms Efficiency of ML Algorithm's of Machine Learning namely Artificial neural network, Decision tree, Sup- port vector machine.

V. CONCLUSION

If we want to select which network topology is best like bus , star , mesh or other we can't chose it because each has their pros and cons like wise if we want to chose be- tween AI , ML or say DL, we can't be sure for particular as mentioned they have their pros and cons. Further in future it is only going to keep increasing as the amount of data going to increase in future and the accuracy of the predictions and power of analysis will boost and a great artifact future is waiting for us as likely it is said that further more than oxygen , Artificial intelligence will become our need for survival. We will analyze and make more comparison when the accuracy will boost , with the help of models as per available technique

Mining Association Rules Based on Incremental Computing Of Big Data

Dr .Anil Vasoya, Akash Khandelia, Nishtha Mishra , Sonali Kamat
Department of Information Technology in Thakur College of Engineering and Technology, Mumbai, India

Abstract— **The discovery of association rule has been known to be useful in different sectors such as marketing, decision analysis, and business management. A vital application area of mining association rules is that the market basket analysis, which studies the buying behavior of shoppers by looking for sets of items that are frequently purchased together. With the growing use of record-based databases whose data is continually being added, the need for incremental mining has been called for in recent important applications. New transaction is appended in complex transaction database, and redundant transaction is discarded as time progresses. Extensive data collection is now a hallmark of information technology these days due to rapid increase of data within organizations. The difficult undertaking is the mining of Association administers in enormous databases. An Apriori calculation is usually used to discover from database the successive component sets. Be that as it may, on account of huge database it will be wasteful in light of the fact that it will require more I/O load. Later drawback of the Apriori algorithm is overcome by many algorithms / parallel algorithms (model). The paper analyzes the performance of the algorithm over different datasets and over n processors on a commodity cluster of machines. In the Apriori Algorithm all procedures need to synchronize after each pass. In the event that any procedure is doled out more burden than different procedures in the framework, the slowest procedure will direct the speed of the program. It is therefore important to ensure that load is equally balanced among all processes. Our algorithm decides the no. of running procedures and partitions, the load similarly in order to amplify the framework execution and its proficiency. Utilizing gradual figuring here suppliers a bit of leeway that the prepared information isn't handled again and just the new information entered is prepared each time which is less tedious. In this research paper we are going to use Distributed and Parallel association mining on big data while using Incremental mining with an aim to process a big chunk of data simultaneously in a short span of time.**

I. INTRODUCTION

To remove valuable and noteworthy data from huge information, the data innovation (IT) world is confronting enormous issues today. At present the information existing is in Tera or peta bytes and should increment to peta or zetta bytes in close by future in different organizations. Examples of such applications incorporate Web log records, financial exchange information; basic food item deals information, exchanges in electronic business, and every day climate/traffic records, to give some examples. Such information can be as organized, unstructured and semi-organized datasets.

Such information must be mined to get learned example from it and accordingly information mining methods and calculations are utilized.

Data Mining is a lot of technique that applies to huge and complex databases. This is to take out the haphazardness and find the concealed example. As this information mining techniques are quite often computationally escalated. We use information mining devices, procedures, and speculations for uncovering designs in information. There are excesses of main impetuses present. Also, this is the motivation behind why Data mining has become such a significant zone of study.

An Association rule assumes a significant job in late information mining procedures. The acquiring of one item alongside another related item speaks to an affiliation rule. Association rules are utilized to show the connections between information things. Association rules are as often as possible utilized for various purposes like showcasing, promoting and stock bazaar. Association precludes discover normal use of things.

This issue is propelled by applications known as market container investigation to discover connections between things obtained by clients. Databases may accumulate an unlimited quantity of knowledge to be mined. Mining association rules into such databases might involve significant processing power.

II. BACKGROUND

Association Rule Learning may be a general technique accustomed discovers associations amongst numerous variables. It's often utilized by grocery stores, retailers, and anyone with a bulky transactional database. Association rules are if/then statements that protection to get associations between apparently unrelated data in an exceedingly electronic information service or other information storehouse. An example of an association rule would be "If a customer buys a dozen breads, he is 80% likely to also purchase butter/jam." Association rules are shaped by analyzing data for frequent if/then patterns and using the criteria support and confidence to identify the most important associations. Support is an indication of how frequently the items emerge in the database.

In data processing, association rules are helpful for analyzing and predicting customer nature. They play a significant role in shopping basket data analysis, item clustering, catalog design. Programmers use association rules to construct programs of machine learning. Machine learning could be a form of computing that seeks to assemble programs with the potential to turn into more competent without being explicitly programmed.

III. RELATED WORK

In this section, we review some related work including frequent itemsets, incremental mining of frequent itemsets.

3.1 FREQUENT ITEM SETS

Let I = {i1, i2… in} be the set of all items. An itemset X is a nonempty subset of I. For brevity, an itemset can be denoted as X = {ij1, ij2…ijn} where 1<= j1, <j2,…<=n An itemset with k items is called a k-itemset. The duple (tid, X) is known as an exchange if tid is an exchange identifier and X is an item set. An exchange database TDB is a lot of exchanges, and |TDB| is the quantity of exchanges. An item set X is contained in exchange (tid, Y). Given an exchange database TDB, the recurrence of an item set X, indicated recurrence (X), is the quantity of exchanges in TDB that contain X. The help of an item set X, signified support (X), is given by

Support (X) = Frequency (X) / |TDB|

There are two kinds of item sets. The principal comprises of item sets that express just a solitary Boolean connection, either true or false, for example, {(butter, true), (chesses, true)}. For comfort, we can speak to this as {butter, cheese}, implying that butter and chesses were obtained together. Conversely, if an item set has a false connection {(butter, false), (chesses, false)}, it shows that these items were not acquired. In the subsequent kind, everything is a property estimation pair. Each characteristic may have different qualities, for example, {(age, youthful), (sex, male)}, and {(age, old), (sex, female)}. Here age and sexual orientation are two traits, (youthful, old) and (male, female) are their qualities.

3.2 INCREMENTAL MINING OF FREQUENT ITEM SET

The undertaking of steadily mining and refreshing successive item sets has come to speak to a significant field of research. After a database is refreshed, some current examples will probably never again be significant, and some new examples might be presented. In 1996, Cheung et al proposed the FUP calculation for productive upkeep of found affiliation rules when new information is added to an exchange database. FUP depends on Apriori and is utilized to find the new regular itemsets in a powerful database. The idea is to store the number of occurrences of the frequent itemsets found in a previous mining operation. By using these stored counts and scanning the newly added transactions, the overall count of the new candidate itemsets is eventually obtained. Leave dB alone a lot of new exchanges and TDB be the refreshed database (counting all exchanges from TDB and dB).An Itemset X is either visit or inconsistent in TDB or db. In this manner, there are four cases, as appeared in Table 1.In its first cycle, FUP filters db to acquire the quantity of events of every 1-itemset. Since the event includes of all successive itemsets in TDB are known ahead of time, the absolute number of events for a subjective X is effortlessly determined if X and db fall into case 2. In the terrible circumstance of case 3, TDB must be rescanned. Also, the following pass checks db to include the up-and-comer 2-itemsets in db. In the event that fundamental, TDB will be again rescanned on the off chance that 3. The procedure is rehashed until all continuous itemsets have been found. In the most pessimistic scenario, FUP doesn't lessen the quantity of outputs of the first database.

XinTDB/Xindb	Frequent Itemset	Infrequent itemset
Frequent Itemset	Case 1: frequent	Case 2: be easily calculated
Infrequent Itemset	Case 3 rescan the TBD	Case 4: infrequent

Table 1 Possible case for updating with FUP

In 1997, Cheung et al depicted the FUP2 calculation, which is a more broad gradual procedure than FUP. FUP2 is effective not just on the assignment of building up a database yet additionally on cutting information. Tomas et al proposed another strategy to quicken incremental mining, by keeping up a negative border. In 1999, Ayan et al proposed the Overhaul with Early Pruning (UWEP) strategy, which utilizes an energetic lookahead methodology to up grade existing visit itemsets by recognizing and expelling item sets that are occasional within the upgraded database. In 2001, Lee et al proposed the Sliding Window Sifting (SWF) approach. SWF allotments databases and applies a sifting edge to each segment to produce candidate item sets. In 2002, Veloso et al depicted the Crisscross calculation, which employments a list of tid's and computes maximally visit item sets within the upgraded database to maintain a strategic distance from producing various pointless candidates.

To overcome the destitute execution that results from rescanning the initial database, Chang et al proposed the NFUP calculation (''New FUP'') for effective incremental mining of association rules from huge exchange databases. NFUP could be an in

reverse strategy that as it were requires scanning the incremental database.

Rather than rescanning the initial database for a few recently created visit item sets within the incremental database,it checks the events of recently produced visit it emsets and essentially erases clearly occasional ones.

IV. QUICKLY UPDATE METHOD

The method of incremental mining is outlined in Fig. 1. Incremental mining is executed by utilizing the initial database, Incremental database and Unique Patterns/Rules as information source. The first database is continuously gigantic; in this manner, incremental mining conveys more dependable execution by extricating rules from the incremental database and combining them with the initial rules without filtering the initial database. In any case, a few calculations proposed within the past as it were decrease the number of times the database is checked instead of mining without checking the database.

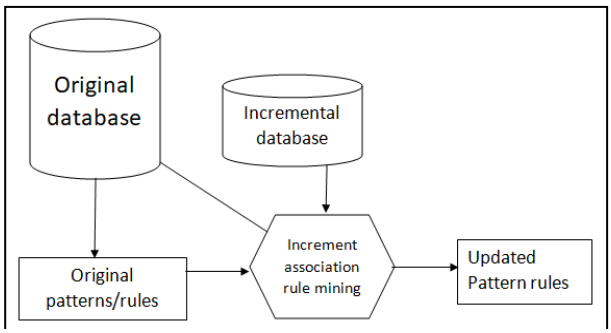

Fig 1: Process of incremental mining

Previously proposed calculations continuously have a back number, which may be an edge to choose visit itemsets. Be that as it may, agreeing to the long tail hypothesis total things that as it were show up rarely may create more benefit than all visit things together. The utilize of a bolster number set progresses productivity, but too creates issues, such as the issue incremental mining. With the coming of enormous information;the sum of modern exchange inf ormation has been expanding relentlessly, and rare things would be killed by to begin with developing a tree. Indeed in the event that these things were too ended up visit by the expansion of ensuing information, they would not be considered. In this way, the execution of incremental mining is required each time; i.e., all the information needs to be re-scanned, which lowers the performance.

This paper proposes the Rapidly Upgrade Strategy (QUM), which eradicates the conventional least bolster number to extend the adaptability of incremental affiliation run the show mining.

V. DATA SETS

The experimentation is carried out with the help of synthetic datasets that are generated through the use of a dataset generator that is publicly available. A data set is a gathering of data, frequently presented in tabular shape. Each column represents a particular variable. Each row corresponds to a specified associate of the data set in question. It gives values to every variable, such as transaction id and transaction of an object. Each value is known as a element. The data set might consist of data for one or more members, equivalent to the number of rows.

The Dataset is anonymzed and contains a sample of over 3 million grocery orders from more than 200,000 Instacart users distributed across 6 csv files. Now let's jump straight into the data and do some exploratory analysis. Let's first have a look at these files:

Orders: This file gives a list of all orders we have in the dataset. One row per order. The orders.csv doesn't tell us about which products were ordered. This is contained in the order_products.csv

order_id	user_id	eval_set	order_number	order_dow	order_hour_of_day	days_since_prior_order
2539329	1	prior	1	2	8	NA
2398795	1	prior	2	3	7	15
473747	1	prior	3	3	12	21
2254736	1	prior	4	4	7	29

Order_product_train: This file gives us information about which products (product_id) were ordered. It also contains information of the order (add_to_cart_order) in which the products were put into the cart and information of whether this product is a re-order (1) or not (0).

Order_id	Product_id	add_to_cart_order	reordered
1	49302	1	1
1	11109	2	1
1	10246	3	0
1	49683	4	0

Products: This file contains the names of the products with their corresponding product_id. Furthermore the aisle and department are included.

Product_id	Product_name	Aisle_id	Department_id
1	Chocolate sandwich cookies	61	19
2	All Seasons Salt	104	13
3	Robust Golden Unsweetened Oolong Tea	94	17
4	Smart Ones Classic Favorites Mini Rigatoni With Vodka cream Sauce	38	1

Order_products_prior: This file is structurally the same as the other_products_train.csv.

Order_id	Product_id	add_to_cart_order	reordered
2	33120	1	1
2	28985	2	1
2	9327	3	0
2	45918	4	1

Aisles: This file contains the different aisles.

Aisle_id	Aisle
1	prepared soup salad
2	Speciality cheese
3	energy granio bars
4	instant foods

Departments:

1	frozen
2	other
3	bakery
4	produce

VI. PROPOSED WORK

6.1 ASSOCIATION RULE MINING ALGORITHM

A rule of association implies definite interaction between a set of objects within a database. An association rule is an expression of the form A, B, where the elements are A and B. The observant logic of such a concept is that database transactions containing A are likely to contain B. Association rule is one of the data starting databases which can be used by a company decision maker to build and contribute to its overall earning. Agrawal et al. first established the rules on the mining of associations in databases in 1993. They considered the following example; 60 percent of the translations buying bread are also transactions buying milk.

The formal statement is as follows. Let I = {i1, i2… im} represent the set of literals, called items. The symbol T represents an arbitrary transaction, which is a set of items (Item set) such that T ⊆ I. Each transaction has a unique identifier, TID. Let D be a database of transactions. Assume X is an Item set; a transaction T contains X if and only if X ⊆T. An association rule applies in the form X→ Y, where X ⊆I, Y ⊆I and X ∩Y = (For example, (I = {ABCDE}, X = {AC}, Y = {BE}). An association rule X →Y, has two properties, support and confidence. When s% of transactions in D contains XU Y, the support of the rule X→ Y is s%. If some of the transactions in D contain X and, c% also contain Y, then the confidence in the rule X→ Y is c%. In general, the confidence is expressed in the form confidence(X → Y) = support (XUY)/support(X). Given the user-assigned minimum support (minSup) and minimum confidence (minConf) thresholds for the transaction database D, here the rules on the mining of associations are to consider all rules whose support and confidence surpass the two thresholds respectively.

6.2 INCREMENTAL ASSOCIATION RULE MINING

The mining of transactional database association rules is typically an offline process, as finding the association rules in large database is costly. New transactions are created with normal market-basket applications and old transactions may become obsolete as time progresses. As a result, incremental updating techniques should be developed to preserve the discovered association rules so that mining on the entire modified database is not redone. A database may allow frequent or occasional updates, and such updates may not only invalidate existing rules on associations but also activate new rules. Thus it is nontrivial to maintain such discovered rules in large databases. Considering an original database and newly inserted transactions, the following four cases may arise:

Case 1: An itemset is large in the original database and in the newly inserted transactions.

Case 2: An itemset is large in the original database, but is not large in the newly inserted transactions.

Case 3: An itemset is not large in the original database, but is large in the newly inserted transactions.

Case 4: An itemset is not large in the original database and in the newly inserted transactions.

Since itemsets in Case 1 are large in both the original database and the new transactions, they will still be large after the weighted average of the counts. Similarly, itemsets in Case 4 will still be small after the new transactions are inserted. Thus Cases 1 and 4 will not affect the final association rules. It could be a possibility that Case 2 may remove existing association rules, and Case 3 may add new association rules. A good rule-maintenance algorithm should thus accomplish the following:

1. Asses large set of objects in the original database and decide if are still significant in the revised database.
2. In the modified database, find out if any tiny itemsets in the original database can get huge.
3. Search for itemsets that only appear in newly inserted transactions, & determine if they are big in updated database.

6.3 DISCOVERING LARGE ITEMSETS

Algorithms for discovering large itemsets make multiple passes over the data. In the first pass, we count the support of individual items and determine which of them are large, i.e. have minimum support. In each subsequent pass, we start with a seed set of itemsets found to be large in the previous pass. We use this seed set for generating new potentially large itemsets, called candidate itemsets, and count the actual support for these candidate itemsets during the pass over the data. At the end of the pass, we determine which of the candidate itemsets are actually large, and they become the seed for the next pass. This process continues until no new large itemsets are found.

6.3.1 APRIORI ALGORITHM

Apriori is an algorithm for frequent item set mining and association rule learning over transactional databases. It proceed by identifying the recurring individual items in the database as well as extending them to bigger item sets as long as those item sets come out adequately often in the database. The frequent item sets examined by Apriori and can be used to create a conclusion association rules which depict interest to general trends in the database.

Figure 1 gives an overview of the Apriori Algorithm,

using the notation in Table 1. The first pass of the algorithm simply counts item occurrences to determine the large 1-item-sets. A subsequent pass, say pass k, consists of two phases. First, the large item-sets L_{k-1} found in the $(k-1)^{th}$ pass are used to generate the candidate item-sets C_k. Next, the dataset is scanned and the support of candidates in C_k is counted. For fast counting, we need to efficiently determine the candidates in C_k that are contained in a given transaction t.

K itemset	An item-set having k items
L_k	Set of frequent k itemsets (with minimum support)
C_k	Set of candidate k itemsets (potentially frequent)
P^i	Processor with id i
D^i	The database local to the processor P^i
C^i_k	Candidate set maintained with the Processor P^i

Table 2 Notations

```
1)  L1 = { Large 1-item-sets};
2)  k =2; // k represents the pass number
3)  while ( L_{k-1} <> 0 ) do
4)  begin
5)      C_k = new candidates of size k generated from L_{k-1};
6)      forall transactions t ϵ D do
7)          Increment the count of all candidates in C_k that a
    contained in t;
8)      L_k = All candidates in C_k with minimum support;
9)      k = k +1;
10) end
11) Answer = U_k L_k;
```

Fig 2: Apriori Algorithm

6.4 DISRIBUTED/ PARALLEL COMPUTING

Database will generate huge amount of data that need to be processed. Rules relating to mining association in such databases may involve significant processing power. A distributed network may be a potential solution to that problem. Moreover, lots of databases are distributed in nature which may assemble it more possible to use distributed algorithms. Moreover, lots of databases are distributed in nature which may assemble it more possible to use distributed algorithms. Calculation of the collection of large item sets in the database is the key structure of mining association rules. Distributed computation of large sets of objects faces many new problems. Obviously, one can measure large article sets locally, but a collection of locally large items may not be globally large. Since it is very costly to transmit the whole data set to other sites, one alternative is to put on air all the counts of all the item sets. Nonetheless, a database may take hold of very large combinations of item sets, and a huge amount of communication will be engaged for the moment.

VII. RESULT AND DISCUSSION

7.1 HORIZONTAL ALGORITHM

Let D be a transaction database. We view D as binary matrix of N rows and L columns, where each row is a transaction over some set of items, A = {a1... aL}, and each column represents one of the items in A.

The database D is partitioned horizontally between M players, denoted P1,...,PM. Player Pm holds the partial database Dm that contains Nm = |Dm| of the transactions in D, $1 \le m \le M$. The unified database is D = D1 ∪⋯∪ DM, and it includes N: = $\sum_{m=1}^{M} N_m$ transactions. An itemset X is a subset of A. Its global support, supp(X), is the number of transactions in D that contain it. Its local Support, $supp_m(X)$, is the number of transactions in Dm that Contained. Clearly, $supp(X) = \sum_{m=1}^{M} supp_m(X)$. Let s be a Real number between 0 and 1 that stands for a required support threshold. An itemset X is called s-frequent if $supp(X) \ge sN$. It is called locally s-frequent at Dm if $suppm(X) \ge sNm$.

For each $1 \le k \le L$, let F^k_s denote the set of all k-itemsets (namely, itemsets of size k) that are s-frequent, and $F^{k,ms}$ be the set of all k-itemsets that are locally s-frequent at Dm, $1 \le m \le M$. Our main computational goal is to find, for a given threshold support $0 < s \le 1$, the set of all s-frequent itemsets, Fs: = $U^L_{k=1} F^k s$. We may then continue to find all (s, c) association rules, i.e., all association rules of support at least sN and confidence at least c. (Recall that if X and Y are two disjoint subsets of A, the support of the corresponding association rule $X \Rightarrow Y$ is supp(X ∪ Y) and its confidence is supp(X ∪ Y)/supp(X).)

The Algorithm proceeds as follows:

(1) **Initialization:** It is assumed that the players have already jointly calculated $F^{k-1}{}_s$. The goal is to proceed and calculate $F^k{}_s$.

(2) **Candidate Sets Generation:** Each player Pm computes the set of all $(k-1)$-itemsets that are locally frequent in his site and also globally frequent; namely, Pm computes the set $F^{k-1,m}{}_s \cap F^{k-1}{}_s$. He then applies on that set the Apriori algorithm in order to generate the set $B^{k,m}{}_s$ of candidate k-itemsets.

(3) **Local Pruning:** For each $X \in B^{k,m}{}_s$, Pm computes suppm(X). He then retains only those itemsets that are locally s-frequent. We denote this collection of itemsets by $C^{k,m}{}_s$.

(4) **Unifying the candidate itemsets**: Each player broadcasts his $C^{k,m}{}_s$ and then all players compute $C^k{}_s$: = $U^M{}_{m=1} * C^{k,m}{}_s$.

(5) **Computing local supports**: All players compute the local supports of all itemsets in $C^k{}_s$.

(6) **Broadcast Mining Results**: Each player broadcasts the local supports that he computed. From that, everyone can compute the global support of every

itemset in C^k_s. Finally, is the subset of C^k_s that consists of all globally s-frequent k-itemsets.

In the first iteration, when k = 1, the set $C^{k,m}_s$ that the mth

Player computes (Steps 2-3) is just F^{k-1}_s, namely, the set of single items that are s-frequent in Dm. The complete FDM algorithm starts by finding all single items that are globally s-frequent. It then proceeds to find all 2-itemsets that are globally s-frequent, and so forth, until it finds the longest globally s-frequent itemsets. If the length of such itemsets is K, then in the (K +1)th iteration of the FDM it will find no (K + 1)-itemsets that are globally s-frequent, in which case it terminates.

A **running example**:

Let D be a database of N = 18 itemsets over a set of L = 5 items, A = {1, 2, 3, 4, 5}. It is partitioned between M = 3 players and the corresponding partial databases are:

D1 = {12, 12345, 124, 1245, 14, 145, 235, 24, 24}

D2 = {1234, 134, 23, 234, 2345}

D3 = {1234, 124, 134, 23}

For example, D1 includes N1 = 9 transactions, the third of which (in lexicographic order) consists of 3 items - 1, 2, and 4. Setting s = 1/3, an itemset is s-frequent in D if it is supported by at least 6 = sN of its transactions. In this case, F^1_s = {1, 2, 3, 4; F^2_s = {12, 14, 23, 24, 34; F^3_s = {124}; $F^4_s = F^5_s = \varnothing$,

And $Fs = F^1_s \cup F^2_s \cup F^3_s$. For example, the itemset 34 is indeed globally s-frequent since it is contained in 7 transactions of D. However, it is locally s-frequent only in D2 and D3.

In the first round of the FDM algorithm, the three players compute the sets $C^{k,m}_s$ of all 1-itemsets that are locally frequent at their partial databases:

$C^{1,1}_s$ = {1, 2, 4, 5}; $C^{1,2}_s$ = {1, 2, 3, 4}; $C^{1,3}_s$ = {1, 2, 3, 4}.

(Note that 15, 25, 45 are locally s-frequent at D1 but they are not included in $C^{2,1}_s$ since 5 was already found to be globally infrequent.) Hence, C^2_s = {12, 13, 14, 23, 24, 34}.

Then, after verifying global frequency, we are left with F^2_s = {12, 14, 23, 24, 34}

In the third round, the candidate itemsets are:

$C^{3,1}_s$ = {124}; $C^{3,2}_s$ = {234}; $C^{3,3}_s$ = {124}.

So, C^3_s = {124, 234} and, then, F^3_s = {124}. There are no more frequent itemsets.

7.2 VERTICAL ALGORITHM

First we use Partition algorithm(PAFI) to find clusters, th en we use Enhanced Apriori algorithm to find the commo nly used itemsets. Steps as followed:

(1) For a given set of transactions in the database D, it applies partition algorithm in order to find clusters based on the number of transactions. Here we are getting 2 clusters CL1 and CL2.

(2) Here CL2 has less number of transactions that is less than the threshold value so we are deleting the transactions in CL2 and we are concentrating on the transactions in CL1.

(3) Now apply the improved Apriori algorithm, by finding the count of an each item from D1.Since scanning is not done using the entire database transactions D it improves the efficiency. These set of items will be considered as candidates C1.These transactions will be considered as D1.

(4) D1 is scanned to generate C2 candidates and find the count of each candidate.

(5) Compare candidate support with minimum support. The candidates having less count than the minimum

(6) Support will be deleted. The above process is repeated for C3. This will be generated for Ck until Ck+1 becomes empty

VIII. CONCLUSION

In this paper, Association mining is proposed along with the improvements needed in the algorithm to make in efficient and better when it comes to large data sets. Here we see the usage of incremental mining by using Horizontal algorithm and Vertical algorithm on structured data. Where incremental mining helps us to avoid processing the already processed data again and saves the processed data at a location which is the used in future to find FIS while the new data is added, this gives us an advantage over other algorithms where the whole data is processed again example in Hadoop where MapReduce is used for this. This method is useful for small or medium datasets but not for big data analysis as it becomes time consuming. Here this research paper gives a brief idea of the results that can be achieved by using Partitioning and Distributed computing in Incremental mining using big chunks of data. The results and discussion shows us the steps carried out in both horizontal and vertical algorithms respectively.

Abstract—***Restaurants, nowadays, have become a prime business sector. In the last decade there has been a 21% growth in the new restaurants, setup around India itself. With the rising competition in market every food outlet craves a need to stand unique to attract customers. One of the key problems is the waiting system in restaurants during holiday seasons. The procedure can be advanced by the use of digital menus. The track records of the customers and their bills is also manually handled. This gives exposure to errors. This can be easily tackled by keeping a simple database. The strategy is to assign a tablet to each table with restaurant's application installed in it. The app not only enables the software to serve multiple needs of the customers, but also save their time.***

Keywords—order food, tablet, application, augmented reality

I. INTRODUCTION

A. Food is a very basic need of every animal on this earth and humans are no exception to it. Along with food, the magic of taste has been developed among humans, leading to the overwhelming business of restaurants across the world. Restaurants are a prime option taken into consideration while planning an outing. Hence, there is a lot of chaos and waiting during holiday season.

B. In the age of Modernization, technological advances have made lives faster, easier and better. Food ordering using AR is a similar attempt at enhancing the customer experience as well as digitalizing the food ordering protocol. The food ordering system is an internet based application utilized in mobile for table reservation in addition to food ordering. Every table is equipped with a tablet. Customers can either login or skip the login. They can order and check bill through the application. The restaurant staff (along with the receptionist and manager), will be connected on app. They will receive order and can accordingly prepare food, deliver it and accept payment. In the subsequent upgrades of the application, user experience will be enhanced.

II. BACKGROUND

When a customer arrives into the restaurant, a table is allotted. This table already has a tablet on it with an application running. The customer is provided with two choices, either to register or skip the registration, After the desired option is selected, then accordingly either a known session is created or a random session is created. After this a menu is appeared on the screen. The customer can browse through the menu and order accordingly. After the order is placed the current order statuses are displayed. Also, the data is being stored in the database on the backend simultaneously. According to the order, a bill is also generated. The application further asks whether the payment be done through cash or card. The app is based on the very idea of development of the business. The increase in the quality of a user experience through the application should be remarkable.

III. RELATED WORK

Kunal Raut, Priyanka Khare, Aishwarya Kamble, Sachin Deshpande's Augmented Reality in Restaurant helps us to understand different techniques to use AR in a restaurant. This method can fancy a restaurant and provide a real-time experience. Their research helps us know about the ongoing or finished projects into the similar stream. The paper suggested various features including "I am feeling lucky" which is based on environmental factors. Paper is mainly focused on to the AR part and it hence doesn't provide a customized app for a particular restaurant. It also doesn't include a system of proper food ordering and paying bills.[1]

Ashwini J, Ayisha Shetty, Chaithra, Lasya K Rao, Prof. Ramya D Shetty's Automated Food Ordering System identified the problems with the traditional food ordering method. They have highlighted that the most common blunder is waiters making mistakes with customer's orders. At times, a waiter can forget to add a specific item, make a change because a customer is allergic to certain substance, or forget to give the order to the kitchen. Impatient customers also call over the waiter/waitress frequently to find out the status of their order several times during their visit, wasting the waiter's service time. Customers have to wait for a waiter to take their order. They must rely on the waiter to remember their order and specific details. Their food may take longer to be prepared and served if the waiter has multiple tables. They may also get wrong bills since they cannot see their bill amount until their meal is complete. Waiters need to constantly check with the chefs to determine when food is ready. Conversely, chef needs to make sure waiters know that food is ready. Managers have to analyze hundreds of paper receipts to determine best-selling items, popular hours and customer satisfaction. They also require re-printing of menus when food is not available or a price needs to be changed. This can be costly and time-consuming to a restaurant.[13]

Adithya R, Abhishek Singh, Salma Pathan, Vaishnav Kanade's Online Food Ordering System proposes flexibility to the Customers/Users to order from either Restaurants or Mess. It will also provide Recommendations to the customers from the restaurants/mess owners uploaded on a daily basis. In the proposed system, there will be no limitation on the amount of order the customer wants. Also, same application can be used as a Startup Business for the

developers. It will provide real time customers feedback and ratings along with the comments to the restaurants/mess owner. It gives appropriate feedbacks to users, so if there is any error happened, then there will be a feedback dialog toward users. Online Food Ordering System is based on Internet of Things. It is a wireless food ordering system using android devices. Android devices have gained immense popularity and have revolutionized the use of mobile technology in the automation of routine task in wireless environment. Android is a Linux based operating system for mobile devices such as smartphones and tablets. Their objective is to design a system that is able to accommodate huge amount of orders at a time and automatically compute the bill. They have focused performance and acceptability in terms of security, user-friendliness, accuracy and reliability and to improve the communication between the client and customers is one of the objectives.[14]

IV. PROBLEM DEFINITION

The ambience in the restaurants can be improvised with use of digitalized menus. It also provides efficient working environment with minimal errors. The need for better facilities to the customer is the prime focus of the client. The proposed system, which includes Augmented Reality, is an upgrade, every restaurant deserves.

The purpose of this project is to develop a Food Ordering System which not only orders food but also helps in reserving table. So instead of waiting for the waiter to take orders one can look into the app and order food. Once the customer login it will redirect the customer to the application. The app will provide the Menu of the restaurant along with which the table no will also be displayed. Visualization of menu items using AR and provide the customers free entertainment facilities. It becomes difficult to manage restaurant during peak hours due to unavailability of waiters. Traffic Analysis needs to be done during long waiting and tables start filling simultaneously. Many people ordering at the same time can create some traffic on server. In such cases allotment of order preference needs to be done properly so the customer receive order in time. Along with this, service efficiency and effectiveness in the shortest possible time is expected by clients in the restaurant sector. As the system is online based, provision of internet through Wi-Fi should be done. Orders should be regularly and properly updated in the staff's portal/account. The procedure can be optimized with the help of internet and technology. It will help customers build a new experience of tracking order and provide entertainment while the order gets ready. There should be a way to recognize regular customers. Keeping a database can help in resolving this issue.

The Food ordering system serves many purposes, including reservation of a table of the respective restaurant. The main objective of the application is to optimize the food ordering and waiting system in a restaurant. Restaurants or food outlets at a mall to digitalize the waiting system and reduce labor can use this application. It can reserve a table, record user information, order food, display order status, inform the waiter assigned, entertain, generate bill and various other features. Another objective of this project is to provide better customer experience and make a good impression by a sophisticated system. Customer's personal information will be recorded, which can help the restaurants to analyze their business. There is a scope of lot of upgrades like games to play or books to read can be provided in the application for users until the order arrives.

V. OBJECTIVES

A. The app is based on the very idea of development of the business. The increase in the quality of user experience through the application should be remarkable. The customer has an easy control on what to order which also overcomes the communication barrier errors. The database maintain helps understand the likes and dislikes of the customers. A feedback form in the application can help in understanding their comforts and expectations. The digitization also helps in modernizing the ambience of the restaurant. The contact and emails of user can be used to notify them about the upcoming festive offers.

B. All the changes made in the applications are done for the comfort of customers. The customers play a vital role in this project. When a restaurant agrees to digitalize their menus, they put a heavy trust over its smooth working. The app will be carrying out updates based on customer responses which again favors the customer. This importance given to client will surely make one feel dazzled. While the order is being prepared, some game or recreational will be provided through app. The application will be interactive. There will be personal and better offers for regular customers.

VI. METHODOLOGY

The methodology that we chose for our project is Agile, while waterfall model is a tried and tested framework, it is not suitable for our project, due to the changeable nature and small team size. Agile allows us to be flexible, manage changing requirements, manage the ever-increasing scope as well as get consumer perspective. Agile has focus on customer satisfaction, which is a crucial aspect of any healthcare application. Patients need to be clued in to the process for the indispensable inputs they can provide.

Agile software development is a methodology for software projects under whose framework project requirements and solutions evolve through the collaborative effort of self-organizing and cross-functional teams and their customer and intended users. It advocates for flexible modelling and planning, flexible implementation, rapid delivery of code, and constant improvement, and it advocates speedy and flexible reactions to change.

The 12 agile principles are -

Our highest priority is to satisfy the customer through early and continuous delivery of valuable

software.

1. Welcome changing requirements, even late in development. Agile processes harness change for the customer's competitive advantage.
2. Deliver working software frequently, from a couple of weeks to a couple of months, with a preference to the shorter timescale.
3. Business people and developers must work together daily throughout the project.
4. Build projects around motivated individuals. Give them the environment and support they need and trust them to get the job done.
5. The most efficient and effective method of conveying information to and within a development team is face-to-face conversation.
6. Agile processes promote sustainable development. The sponsors, developers, and users should be able to maintain a constant pace indefinitely.
7. Continuous attention to technical excellence and good design enhances agility.
8. Simplicity - The art of maximizing the amount of work not done--is essential.
9. The best architectures, requirements, and designs emerge from self-organizing teams.
10. At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly

VII. SYSTEM DESIGN

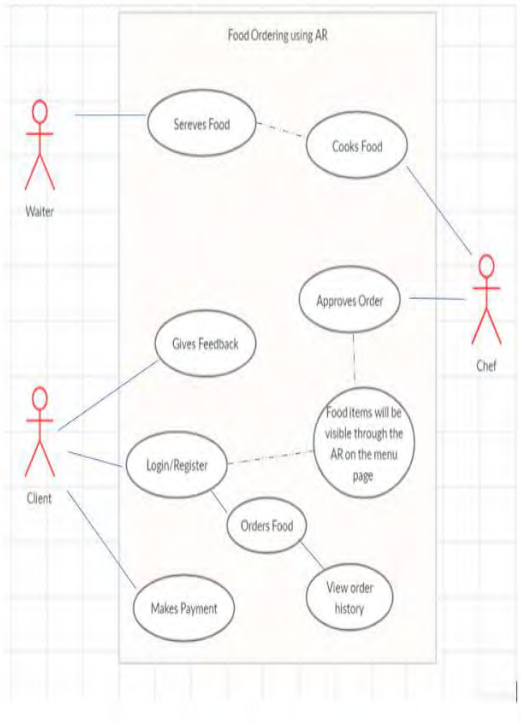

Fig.1 Use case Diagram

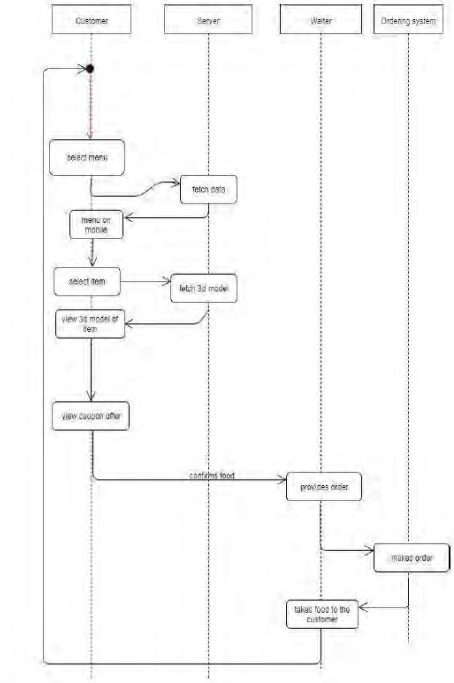

Fig.2 Sequence Diagram

VIII. RESULTS & DISCUSSIONS

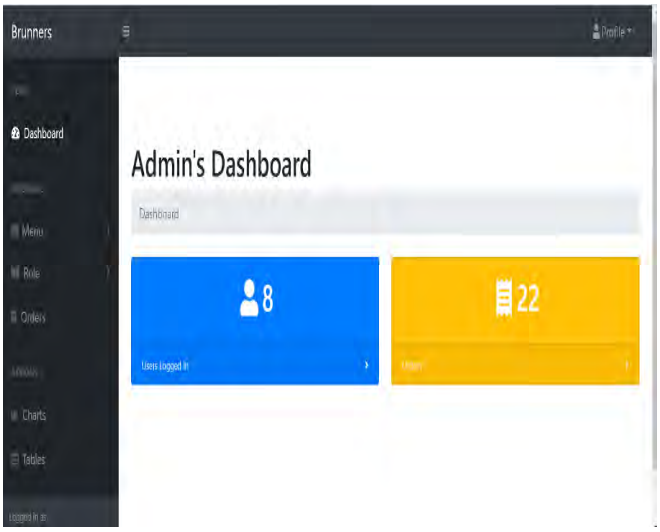

Fig.3 Admin Dashboard

The admin dashboard comprises of no. of customers logged in, total no. of orders received, no. of tables reserved.

It handles the following portal:

- Receptionist
- Customer
- Chef
- Waiter

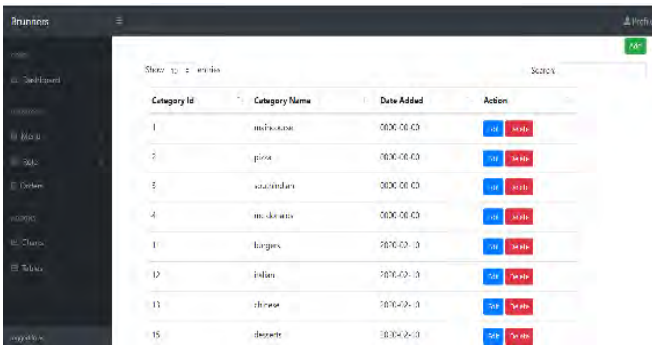

Fig.4 Category Page

The interface Menu comprises of Category and Product Page. In this section, Admin can Add, Update or Delete restaurant categories and products.

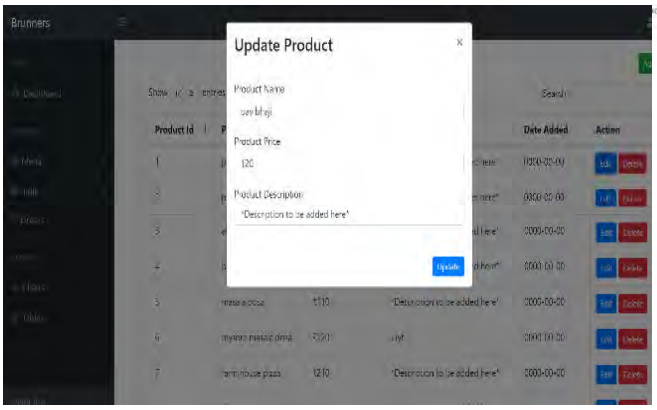

Fig.5 Update Product Page

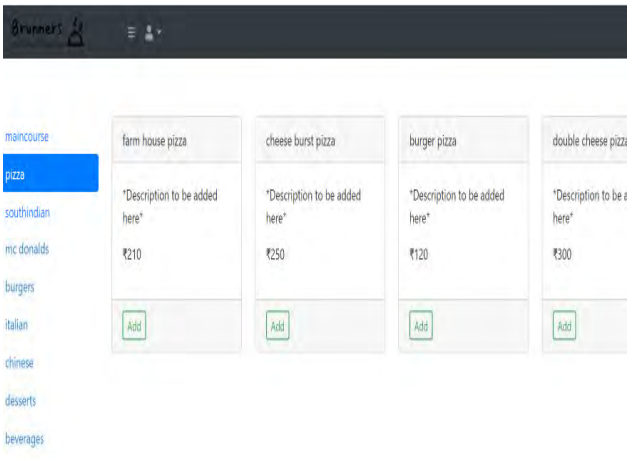

Fig.6 Menu Page

The Menu page gives information about the menu items which will be visible to the customers who have logged in through this website.

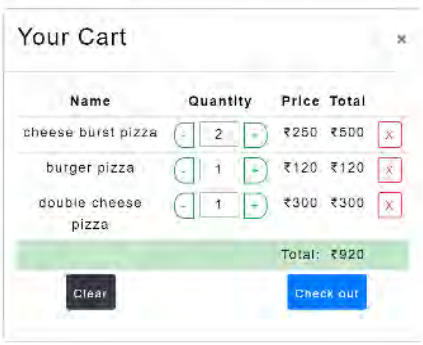

Fig.7 Cart Page

The cart page consists of the items which customers wishes to order. It has been designed with Ajax technology. The customer can view, delete or clear the product items.

Fig.8 Delete Cart Page

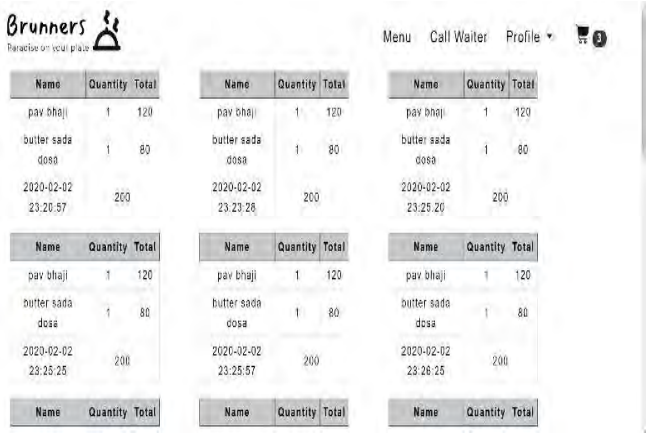

Fig.9 Previous Orders Page

This page gives details about the food items ordered by the customers in the past.

Fig.10 AR Snapshot

The above snapshot is of food item which is to be integrated with the website so when customer wishes to view the food item, it can be shown with the help of AR technology.

IX. CONCLUSION

By passage of time and popularity of the culture of using smartphones, the influence of this tool in all aspects was highlighted so that it has become an inseparable part of human life. The use of this capacity in the matters of business and directing users to the optimum and proper use of this tool is what customers and business owners are looking for. However, users tend to use technology in different situations more and more by increasing penetration of smartphones. A business can use this situation and benefit more that move before customers and prepare an appropriate condition in advance. Using application for ordering process causes to remove physical ordering and payment. In addition to more attraction, it provides more facilities to customers and business managers. This plan is not only to eliminate traditional ordering, but also to apply this smart ordering beside traditional method and attract customers and improve their sense of loyalty. Also, wasting time and energy of staffs will be reduced using this method and consequently customers are more satisfied.

- It is expected from the restaurant to provide Wi-Fi network to load the site. The developer will design such a system that would create two profiles, one for the manager/staff and one for the customer. The payment gateway should be well taken care of along with the security of the sensitive information.
- The project will be a new step towards digitalization in food business sector. Customers can track their order and estimate time by which they will receive order. A display has to be made available inside the kitchen for chefs to see the order.
- A ‘call’ button is also introduced in updated versions, which will notify waiter to visit a table. The motto of the project to optimize waiting system at restaurants is very well achieved. In future can also be helpful for food courts at some mall, where there exist multiple outlets.

E-Voting Using Blockchain

Ritika Arya, Neha Rathod, Kajal Rathod
Thakur College of Engineering and Technology Mumbai, India
aryaritika2101@gmail.com, nehakrathod48@gmail.com, kajalrathod086@gmail.com

Abstract- **Building an electronic democratic framework that fulfills the lawful necessities of officials has been a test for quite a while. Conveyed record advances is an energizing mechanical headway in the data innovation world. Blockchain advances offer a limitless scope of utilizations profiting by sharing economies. Security of advanced democratic is consistently the greatest concern when considering to execute a computerized democratic framework. With suchamazing choices in question, there can be no uncertainty about the framework's capacity to verify information and shield against potential assaults. One way the security issues can be possibly understood is through the innovation of blockchains. Blockchain innovation begins from the basic structural plan of the digital currency bitcoin. It is a type of dispersed database where records appear as exchanges, a square is an assortment of these exchanges. With the utilization of blockchains a safe and vigorous framework for advanced democratic can be formulated.The point of this report is to diagram our proposition to explaining the issues of computerized casting a ballot by utilizing blockchain innovation. The principle angle behind building up a blockchain based framework for casting a ballot is to give a simple to utilize methods for leading decisions for different sorts of gatherings and associations. Vote checking is likewise made simple by the application since it is simply an issue of questioning the database. A decent application that can anticipate framework disappointments on a broadly utilized stage can pick up acknowledgment among the potential clients.**

Keywords— Blockchain, Ethereum, Solidity, Hash Algorithm

I. INTRODUCTION

Casting a ballot, regardless of whether conventional expressive dance based or electronic democratic (e-casting a ballot), is the thing that cutting edge majority rules systems are based upon. In each majority rules system, the security of a political decision involves national security. The PC security field has for 10 years contemplated the potential outcomes of electronic democratic frameworks. With the objective of limiting the expense of having a national political race, while satisfying and expanding the security states of a political decision.

From the beginning of justly choosing up-and-comers, the democratic framework has been founded on pen and paper. Supplanting the conventional pen and paper conspire with another political decision framework is basic to restrict misrepresentation and having the democratic procedure recognizable and evident. Electronic casting a ballot machines have been seen as imperfect, by the security network, essentially dependent on physical security concerns. Enter blockchain innovation. A blockchain is a disseminated, permanent, indisputable, open record. These innovative highlights work through cutting edge cryptography, giving a security level equivalent as well as more prominent than any recently known database. The blockchain innovation is in this manner considered by many, including us, to be the perfect apparatus, to be utilized to make the new present day equitable democratic procedure.

In this manner, in the event that we actualize blockchain innovation into evoting framework (Blockchain-empowered e-casting a ballot (BEV)), every one of the votes can be recorded, overseen, tallied, checked, confirmed by the voters themselves and in any event, securing the voter character and protection.

Building an electronic democratic framework that fulfills the legitimate prerequisites of administrators has been a test for quite a while. Appropriated record advances is an energizing innovative progression in the data innovation world. Blockchain advancements offer an endless scope of utilizations profiting by sharing economies. This undertaking expects to assess the use of blockchain as administration to actualize dispersed electronic democratic frameworks. The undertaking elicitates the prerequisites of building electronic democratic frameworks and distinguishes the legitimate and innovative impediments of utilizing blockchain as an assistance for acknowledging such frameworks.

Security of computerized casting a ballot is consistently the greatest concern when considering to actualize an advanced democratic framework. With such grand choices in question, there can be no uncertainty about the framework's capacity to verify information and guard against potential assaults. One way the security issues can be conceivably unraveled is through the innovation of blockchain.

II. PROBLEM DEFINITION

To propose conceivably another e-casting a ballot convention that uses the blockchain as a straightforward polling station. The target of such a plan is given a decentralized design to run and bolster a democratic plan that is open, reasonable and freely obvious. Web-based

democratic - like a choice to paper polling forms or electronic democratic machines - has been recommended as an approach to support the number of dynamic voters, however perhaps even address political race security and respectability issues.

III. PROPOSED SYSTEM

Voter: A voter, distinguished by one's open key, Vipub, is viewed as a substance that is allowed to make a choice towards one of the up-and-comers. The voter, during the political race, will be called to settle on a decision, Ci that can run from a lot of predefined decisions, to fight messages

Central Authority (CA): All together for the e-casting a ballot convention to give confirmation that lone qualified voters can cast a ballot, it was considered essential for a Focal Power to be presentedFor a client to be made a decision about qualified, one must validate oneself to the Focal Position, CA, and get a token that demonstrates one's qualification to cast a ballot. Vote: A vote is a message of predefined structure which will be compared to a bitcoin exchange. Ethereum stage It takes the vote of the client and gives updation-in the democratic mean a specific up-and-comer.

The development incorporate stages like: During the instatement of a political race a beginning agreement must be put on the blockchain. This beginning agreement contains the entirety of the data that will be important to approve the squares as they are put, guaranteeing that none are put after time, that none are put without the proper marked token.Voting stage: It is where the voter claims for a vote. At the point when they make their accommodation, the voter must incorporate the segment portions of this marked token (division of the token into its segment parts is too expensive gas on the blockchain to be viewed as possible).

Checking stage: When the political decision has finished up, votes should be tallied. This stage enables every client to make just a single choice. Logging off: The enlisted client can log out from the framework.

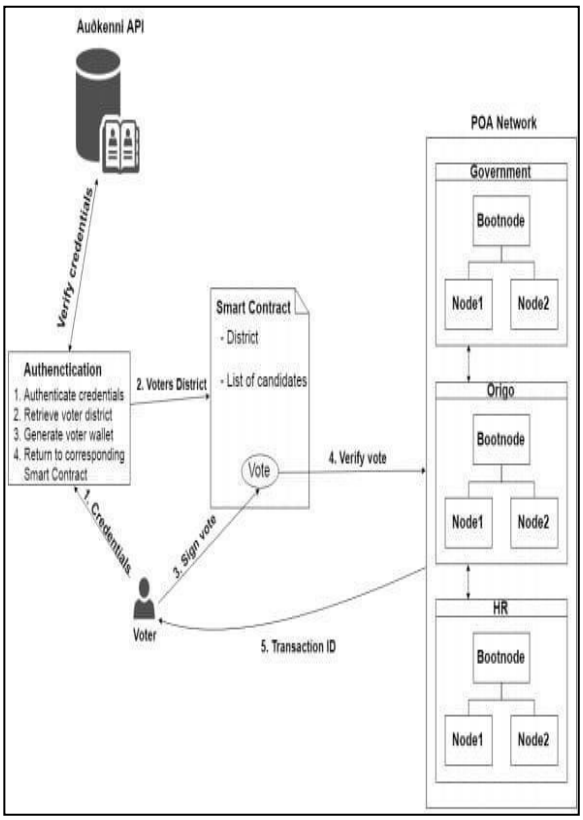

Fig 1: Voter Authenticates Himself And Casts Vote

IV. METHODOLOGY

Agile programming improvement alludes to a gathering of programming advancement systems dependent on iterative advancement, where necessities and arrangements develop through cooperation between self-sorting out cross-functional groups. Deft strategies or Coordinated forms for the most part advance a taught venture the executives procedure that supports visit assessment and adjustment, an authority reasoning that empowers cooperation, self-association and responsibility, a lot of building best rehearses proposed to take into account quick conveyance of top-notch programming, and a business approach that adjusts improvement to client needs and friends objectives. Nimble advancement alludes to any improvement procedure that is lined up with the ideas of the Lithe Declaration. The Statement was created by a gathering fourteen driving figures in the product business, and mirrors their experience of what approaches do and don't work for programming advancement.

Scrum is a subset of Agile. It is a lightweight procedure structure for light-footed improvement, and the most generally utilized one. A "process system" is a specific arrangement of practices that must be followed all together for a procedure to be predictable with the structure. (For instance, the Scrum procedure system requires the utilization of improvement cycles called Dashes, the XP structure requires pair programming, etc.)

A Scrum procedure is recognized from other coordinated forms by explicit ideas and practices, isolated into the three classes of Jobs, Ancient rarities, and Time Boxes. These and different terms utilized in Scrum are characterized beneath. Scrum is regularly used to oversee complex programming and item advancement, utilizing iterative and gradual practices. Scrum essentially expands profitability and diminishes time to benefits comparative with exemplary "cascade" forms. Scrum forms empower associations to alter easily to

quickly evolving prerequisites, and produce an item that meets advancing business objectives. A light-footed Scrum process benefits the association by pushing it to

- Increase the nature of the expectations.
- Cope better with change (and anticipate the changes)
- Provide better gauges while investing less energy making them.
- Be more responsible for the task calendar and state.

V. FLOWCHART

VI. RESULTS

Fig 4: Home Page For Casting Vote

In the above image, the home page is displayed where initially no vote is casted. The user will login and then cast a vote for any contestant i.e. Tom & Jerry.

Fig 5: First User's Vote Casted

After the user login, the vote has been casted to the contestant Tom. Henceforth, no vote can be casted to any of the other contestants.

Fig 6: Vote Casted By Another User

Another user logged in and casted a vote to the contestant Jerry. Once the vote is casted, no vote can be casted to any of the other contestants. If the user tries to vote again from the same account then an error message will be displayed.

VII. FUTURE SCOPE

Our election scheme allows individual voters to vote at a voting district of their choosing while guaranteeing that each individual voters vote is counted from the correct district, which could potentially increase voter turnout.

The future scope of the project includes the improvement in the security level of the complete system. In addition to that it would be necessary to meet some other confidential primitives to improve the security level of online voting system. The future improvement can also be done for voice verification, system crash and power failure so that the voters can vote with more assurance.

We will introduce aadhar card based voting in which a person can vote only by using his aadhar card number which is unique for everyone and by which one voter can vote only once.

VIII. CONCLUSION

Our implementation was tested on the Ethereum testnet network with different types and sizes of ballots. We used the smart contracts in Ethereum blockchain to keep a record of every user in our system as well as all the ballots and the information regarding them. We also utilized the smart contracts to achieve access control.

Adapting computerized casting ballot frameworks to make the open discretionary procedure less expensive, quicker and simpler, is a convincing one in current society. Making the discretionary procedure modest and speedy standardizes it according to the voters, expels a specific power hindrance between the voter and the chosen authority and puts a specific measure of weight on the chosen authority. It additionally opens the entryway for a more straightforward type of majority rules system, enabling voters to express their will on singular bills and suggestions.

Utilizing an Ethereum private blockchain, it is conceivable to send several exchanges for every second onto the blockchain, using each part of the shrewd agreement to facilitate the heap on the blockchain.

We have proposed an electronic democratic framework dependent on the Blockchain innovation. The framework is decentralized and doesn't depend on trust. Any enrolled voter will be able to cast a ballot utilizing any gadget associated with the Web. The Blockchain will be openly undeniable and conveyed in a way that nobody will have the option to degenerate it.

IX. ACKNOWLEDGMENT

We sincerely thank our guide Mr. Aaditya Desai for his guidance and constant support and also for the stick to our backs. We also thank the project coordinators for

arranging the necessary facilities to carry out the project work.
We thank the HOD, Dr. Rajesh Bansode, the Principal, Dr.B. K. Mishra, and the college management for their support.

***Abstract*— The process of identifying food item from an image is quite an interesting field with several applications. Since Food surveillance plays a significant role in health-related problems, it is becoming more necessary in our day-to-day life. In this paper, the main aim of the system is to classify the image of the food item using convolutional neural networks. We have implemented three specific algorithms – Resnet, SequentialNet and Google Inception V3. The accuracy of the Google Inception V3 is more efficient as compared to the other algorithms. The dataset used is – 'Food-101' to scan with the natural food item, thereby getting the most efficient trained algorithm for the system. Accordingly, recognition will be performed on each sectioned item utilizing deep learning models that are trained based on huge food datasets. Lastly as the future scope, volume and weight estimation can be performed on each recognized food item, followed by the nutrient assessment.**

***Index Terms* — Convolutional neural networks; Food 101 dataset; Food classification; Food Image recognition; ResNet; SequentialNet; Google Inception V3.**

I. INTRODUCTION

In the current age, people are cognizant about their nourishment and diet to keep away from either up and coming or existing diseases. Since people are subject to advance technologies, arrangement of an application to consequently monitor the people's food consumption, helps in numerous perspectives.[1] It builds the familiarity with individuals in their nourishment propensities and diet. In the course of the recent two decades, explore has been centered around naturally perceiving the nutritional information and their healthful data from pictures caught utilizing computer vision and deep learning[2]. Image recognition is among the most important fields of image processing and computer vision. Food image classification is a distinct branch of image recognition problem[1]. In recent times people are more conscious about their health. A majority share of the people is indulged in overeating and not being dynamic enough. Given how occupied and focused people are today, it's easy to neglect and monitor the food that they eat. This only expands the significance of legitimate arrangement of nutrients depending upon the proper natural food image classification using advanced algorithms.

With the speedy development of our society, additional attention has been paid to the standard of life, particularly the type of food that people tend to eat[3]. However, classifying food manually isn't applicable to the present fast-tempo society any longer. An automatic food organization with enlarged accuracy, improved speed and reduced cost is desperately required. In recent years, laptop vision systems are used

immensely in food recognition strategies.

Therefore, the aim is to develop such a system that will help to fulfil all these needs. The project mainly aims at recognizing the natural food image with an efficient resolution using various algorithms of high accuracy. A system which can classify food from image is necessary for a dietary assessment system. Classification of food images is extremely challenging since the dataset of food images is non-linear. This paper proposes a method that can classify food types with images. This project proposes the use of convolutional neural network to classify food images. The CNNs are an effective class of neural networks that is highly effective at the task of image classifying, object detection and other computer vision problems. We classified a food dataset named 'Food101' consisting different food categories. Later part of the image recognition system which will be useful for estimating the nutrients and calories which is of significance in order to have a daily track of the food intake. This is important as most of the teenagers eat a large amount of junk food which deteriorates their health due to which there may be high risk to their lives leading to Heart attack at a very small age. According to medical studies, overweight and obesity are generally the result of energy imbalance between the number of calories burned by the body for daily life activities and the amount of energy coming from consumed foods. The clinical treatment and prevention of overweight and obesity require the patients to measure, record, and control daily food intake. All of this can be avoided by recording everyday meals.

Hence food recognition is very important for classifying the food image and thereby help in the health control. Smartphone based food logging will done using this project where in the food item that a person eats is first captured using camera of the smartphone to showcase the classified image and recognize the food item. The research on food classification is focused around growing constant applications which catch pictures and train the AI models immediately. However, the efficient extraction of information from the images of food still remains a challenging issue. In this paper, an attempt has been made to classify the input images of food into different food categories with the help of

convolutional neural networks (CNNs)[5]. Since the CNNs can handle a large amount of data and can evaluate the features consequently, it has been used for the task of image classification of the food. The Food 101 dataset has been chosen as the working database for this methodology.

The task of the food detection system is first initiated with packaged food items. Recently, CNNs have been utilized to distinguish edges and shapes with extraordinary achievement. Here, motivated by this achievement the strategy is to take different food items by utilizing a CNN that distinguishes food outskirts[9].

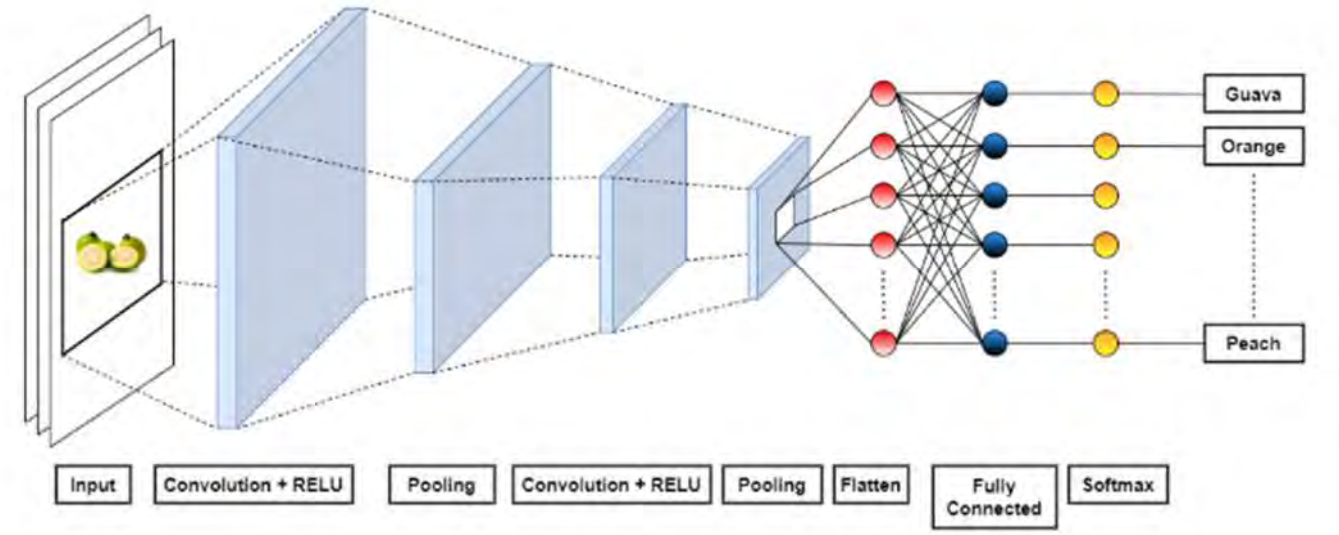

Figure 1: Convolutional Neural Network Layers for the proposed system

II. Related Work

To ease the weaknesses of these clinical strategies, researchers have been trying to come up with improved systems. A portion of these techniques requires the individual to take a photo of the food in order to recognize the food item using the natural image using the pre-trained network model to get the maximum accuracy[4]. Be that as it may, arranging food physically isn't pertinent to the present fast-tempo society anymore. An automatic food organization with expanded precision, improved speed and diminished cost is desperately required. In recent years, laptop vision systems are used immensely in food recognition strategies.

Therefore, we plan to grow such a system, that will satisfy every one of these necessities. The recognition is significant to This is significant as most of the young people eat a lot of low-quality food which deteriorates their wellbeing and leads them to diseases like Blood pressure, Obesity, Diabetes and so forth. Because of which there might be high risk to their lives prompting heart attack at a very young age. Medical studies uncovered that overweight and obesity are commonly the aftereffect of vitality lop-sidedness between the calorie originating from the consumed food and the quantity of calories consumed by the body for day by day life exercises. The clinical treatment and counteractive action of overweight and weight require the patients to gauge, record, and control day by day food consumption. The track of this can be maintained by recording each day meal.

Despite the fact that perceiving food among many classes is an exceptionally complex issue, figuring out how to identify their fringes is frequently simpler and less subject to the thought about classes. Along these images, the technique can get the remarkable execution of CNNs and always improve through extra preparing without depending on the food recognition result.

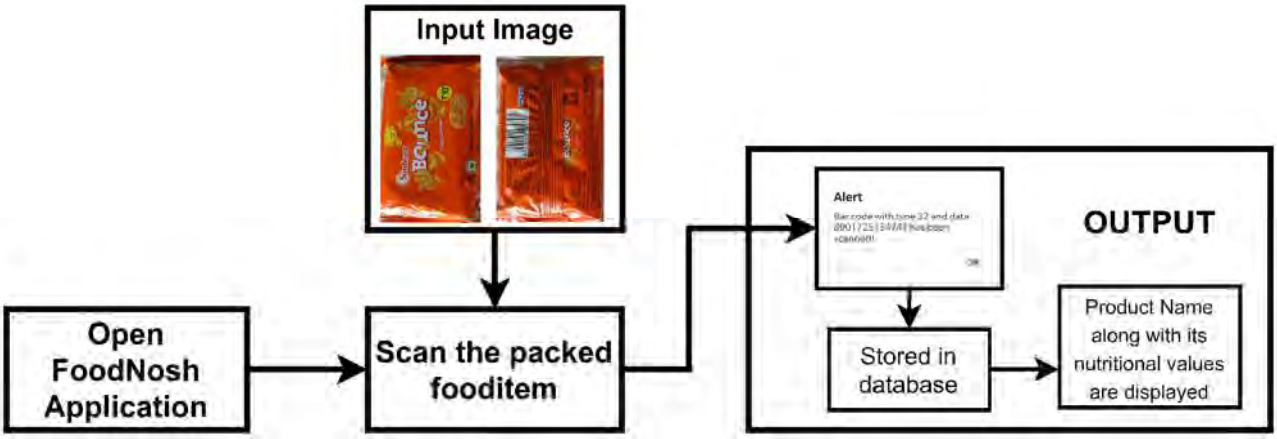
The present work intends to join a portion of the above strategies together, that makes a food classification system, that predicts the class of food the picture is in and recognizes the same. In the past few years, a variety of methods has been suggested for image classification and identification. CNN is used to automatically learn and extract features from the images which are then classified. However, the training process is very time-consuming, even using GPUs[9].

III. Literature Survey

Categorical Image Classification needs thousands of images to train the model for classification of food items [1]. Various types of food with different color and texture reflect the fact that the food image recognition is considered a challenging task. Also, same food items in different regions might have an all together a different look which makes it difficult to identify the food item. This crucial task is done using deep learning. However, deep learning has been widely used as an efficient image recognition method, and CNN is the contemporary approach for deep learning to be implemented [3].

CNN's really use next to no pre-processing. This implies that they might take in the filters that there must be a chance to be hand-made in other calculations.

CNN's basic tasks are feature recognition, picture classification, and recommendation frameworks. A recommendation system can be defined as a system that will recommend items to the users/customer within an environment/system depending on their past activities [10].



User needs to take the picture of the food using their mobile devices before and after the meal for the precise estimation of calories. The subsequent stage of the system is segmentation, each image will be broken down to separate different sections of the food image portion. Out of different tools accessible for segmentation, colour and texture segmentation tools are utilized for the successful estimation. Different food features including size, shape, shading and surface will be extracted and sent to classification step. Therefore, utilizing the above steps, segment of nourishment is recognized. At last, by evaluating the area of the food portion and utilizing some nutritional tables, the calorie estimation of the food will be extracted [5].

IV. Background

The algorithms used for the system are ResNet, SequentialNet and Google Inception V3. The main task is to recognizer the food item using the most efficient neural network model to recognize the food item and thereby estimate the nutrients. The main logic behind the recognition system is transfer learning and since according to the results Google Inception V3 is the most efficient algorithm with a greater accuracy, we use the transfer learning which uses a pre-trained neural network. Google Inception V3 model is divided into two parts a) Feature extraction with a convolutional neural network. b) classification part with fully-connected and softmax layers.

The image will be extracted and scanned using the pre-trained model to recognize the natural food image and give us the final result. Tensorflow is one of the libraries used for image classification in deep learning. Tensorflow is an open source software library which was developed by Google in the year 2015 for numerical computation. Tensorflow is specially designed to enable fast experimentation with deep neural networks[9].

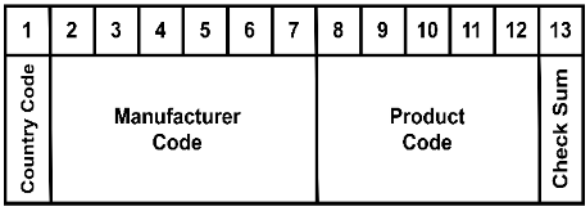


Figure 2: Barcode EAN 13 Format

Proposed System

Phase 1: For Packaged Food Items

In this particular phase we started with a proper solution for the packaged food items. Where we scan the barcode of the packaged food item and get the respective data for each product. In this system, we provide a recommendation system where it will help the user to decide whether to consume that food item or not and thereby give another option as well. The system works as mentioned below in the flowchart below. Where the product is scanned using our application "FoodNosh" after the successful login process the user will be able to scan the product and later the application will display the alert message with the details of the type of the food item and the corresponding barcode number. After the scan process the data will be stored in database in with all the details including all the nutritional values that will be extracted from the barcode. This will make it convenient to store that data of all the packaged food items in the database and thereby get a proper comparison with respect to which food item should be recommended instead of the one which is recently scanned by the user.

This will be a part of the recommendation system where the comparison will take place according to the medical data registered by the user and thereby, we can determine which food item shall be preferred.

This phase gives us a base to look after all the nutrients and compare them and thereby give a result to the user which satisfies them and their health at the same time. In this phase the nutrients and other values are

constantly maintained in order to track the total consumption of the user.

Phase 2: For Unpacked Food Items

The objective of our system is to design an automated application to classify food items running on a smart phone with working camera that makes it easy to record food item that are consumed during the day. Our objective isn't to essentially have high accuracy, because as explained such accuracy is not possible in real. Obviously, the more accurate the system is the better the final result, and this is the reason in this paper we have attempted to identify various food items precisely as possible. In any case, it is significant to understand that high accuracy is not possible while dealing with the images of the food item only.

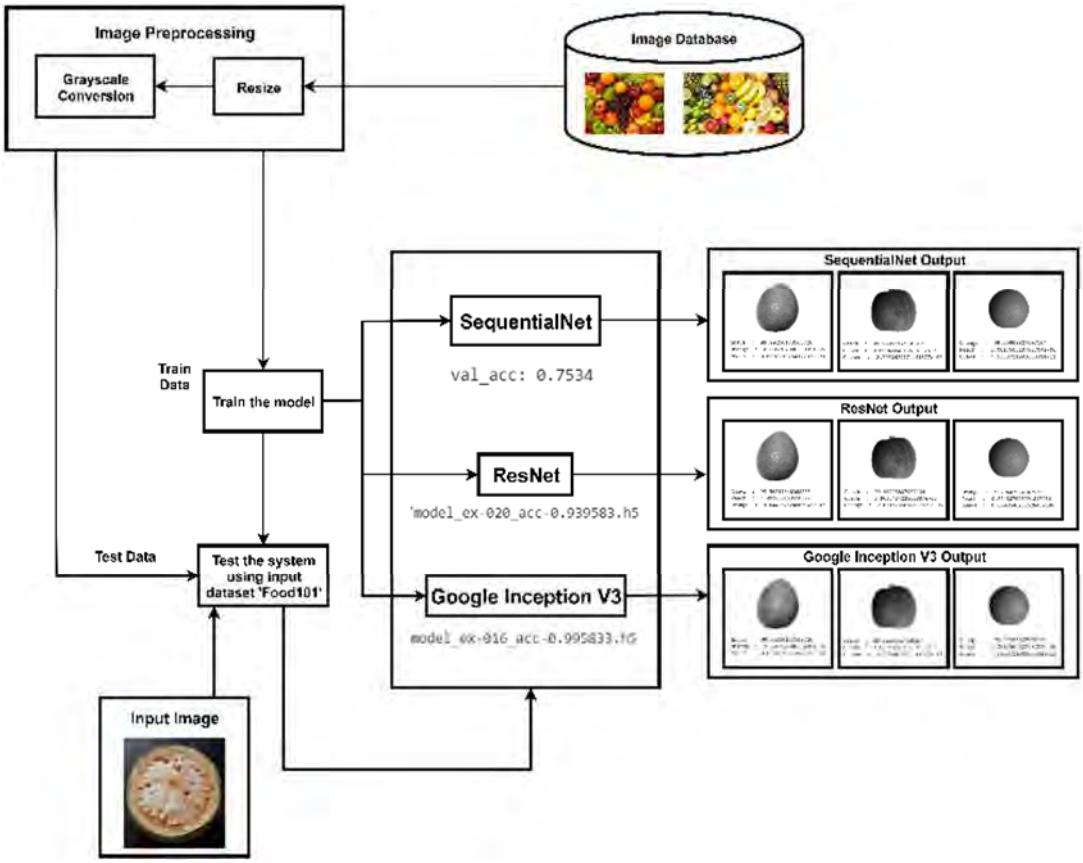
We propose a food image recognition system with various variant of CNN algorithms which can deal with different food items classification. Given an input as a food picture, first, the CNN can achieve all the recognition steps including highlight extraction, shift and distortion invariance and classification, and afterward, gives the output.[8].

Every classification system starts with the selection of the database which is in coherence with your systems requirements. For our system we chose to go with the Food-101 dataset which contains various RGB images of different kinds of food items. The images of the dataset are pre-processed before training the model for classification. For example, we perform conversion of the images to grayscale on the dataset. In addition, it's required to resize the image for their optimal use of size 70 x70. The original dataset we use is Food-101 which is an open 120-class food image dataset that is a food dataset that we establish containing only the images we want to train for and thereby increasing the accuracy and reducing the error rate and also to perform the testing on the trained model using the same dataset.

Here the main aim is to identify the most accurate algorithm to perform classification of the food items that are to be consumed. So, we have chosen to perform classification using 3 algorithms from the various options available. The choice of the first algorithm, is obvious SequentialNet because it is the most basic CNN algorithm. Since the main aim of the system is to provide the maximum accuracy, transfer learning algorithm is the most practical solution to go with. Therefore, we chose to go with ResNet and Google Inception v3 algorithm. We would apply training of the same dataset on 3 different algorithms and compare the accuracy of the same and also conclude the best amongst the 3 algorithms.

We use stochastic gradient decent to train our model with a batch size of 120 examples, initial learning rate of 0.01 and epoch of 200. A small learning rate is very important for the model to learn and it can reduce the model's training error. The classifier we use is SequentialNet because this probabilistic, linear classifier is effective in the model. We train the network with the trainset of 200 images, which takes about an hour.

Now, we are using the ImageAI library of python to implement the transfer learning algorithms of deep learning. Transfer learning algorithm is a model wherein knowledge used to solve a particular problem



is used to solve a different but related problem. ResNet and Google Inception v3 algorithms of transfer learning problem is used to classify the food item for the system[10].

Residual neural network (ResNet) is an artificial neural network (ANN) of pre trained neural network that builds on constructs obtained from pyramid cells of the cerebral cortex. It does this by skipping connections or by taking shortcuts to jump over some layers. ResNet does this using shortcut connections by directly connecting input of nth layer to some (n+x)th layer.

Google Inception v3 is an ANN of pre trained neural network used widely for image classification. The model itself is made up of symmetric and asymmetric building blocks including convolutions, average pooling, max pooling, concats, dropouts, and fully connected layers. Batchnorm is used extensively throughout the model and applied to activation units. Loss is computed using softmax.

Agile is the methodology adopted for the system, it is because of which we can adapt the change quickly to win the market, and this is a core competency. Therefore, we will use the agile methodology in order to get the result at a faster rate and thereby do not have to repeat the procedure if we come across some default errors which happens in Waterfall Model.

V. Analysis

The proper analysis for the system will help us to improve the ability to define the scope of the project and manage the project within that scope. It will also help us to learn how to identify and sequence the tasks, estimate duration of tasks, control variances, manage costs, and utilize resources. This will also help in understanding the qualitative and quantitative techniques for identifying, analysing, and mitigating risk, as well as the best ways and times to apply these techniques to the project environment[6] .

Despite the quality detection and inspection of the food item is not strictly related to the application domain of dietary food monitoring, we have decided to include information on this application domains so that the user can have a better overview of what has been done in the context of food image.

The system will give intensive instruction in project management fundamentals across the entire project life cycle. It will also provide demonstrated techniques and viable devices for planning, executing, and controlling an assortment of projects. It will also offer detailed and sophisticated instruction in the critical areas of scheduling key events, controlling costs, and managing risks.

The confusion matrix will show the accurately versus inaccurately named classes. From results, it is discovered that the CNNs are progressively suitable for image classification.

The system is meant to do a proper research of few deep learning algorithms and thereby getting the most efficient algorithm and comparatively a better accuracy. The algorithms provide features, for example, shifting and Max-pooling which give better classification rate for image classification than convolutional neural systems[7]. Convolving the image permits feature extraction, regardless of o its direction and position in the image. By completing this project, we will be able to configure a Food Detection and Nutrients Identification system to work (in a limited manner) to support project management.

We would need to fully understand the commercial situation and how to make use of SDLC, inspection and other crucial processes.

VI. Result And Discussion

The below picture shows the comparison about the accuracy and the effectiveness of the Algorithms – ResNet,
SequentialNet and Google Inception V3.

The trial method to implement the various algorithms was successful to understand which algorithm provides the best efficiency. Other algorithms like, MobileNet, Vgg19 which seem to be more efficient and will satisfy the accuracy required for the project.

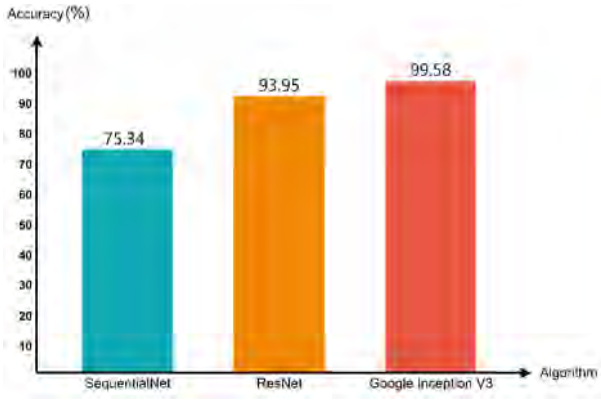


Figure 3: Comparison of the algorithms based on accuracy

The remaining work after the procedure of classification is mapping the food item names to a calorific value. This will be accomplished effectively by scratching the web for the average calories value will be considered of the food items things per unit weight[3]. The average calorie values are considered for the various classes of the food items[3].

VII. Conclusion

From the above results the transfer learning algorithms clearly improves the accuracy for the image classification. Since in transfer learning you do not need to train the classification model from scratch as it contains a pre-trained model which is not available with the basic SequentialNet 3- layer algorithm. Also, the number of layers is quite less in the SequentialNet algorithm which is a major factor resulting in less accuracy. The performance of CNNs depends heavily

on multiple hyper parameters like the number of layers, number of feature maps in each layer, the use of dropouts, batch normalization, etc. Hence training of the model mainly includes adjusting the model hyper parameters by conducting lots of experiments. Thus, this paper helps in identifying and understanding the best algorithm that can be used for food image recognition.

VIII. Future Scope

It is not always possible to implement each algorithm using transfer learning as some problems are dynamic in nature where the pre trained model would act as a disadvantage in that scenario. Here the SequentialNet would be the most appropriate choice for this type of scenario.

In this system the recommendation for the user works well until and unless there is a proper internet connectivity available. If the user lives in a rural area, the application "FoodNosh" will not work up to the expectation. Thereby, storing the data of the food items in the database will be difficult in that case of the user and this will stand as a drawback for the system. Acknowledgment

The success and final outcome of this project required a lot of guidance and assistance from many people and we are extremely privileged to have completed the project successfully.

We would like to thank everyone for their guidance. We sincerely thank our Principal, Dr. B. K. Mishra, Vice Principal, Dr. Deven Shah, Mentor Dean, Dr. Kamal Shah and HOD, Dr. Rajesh Bansode for always encouraging us to do our best. We are highly indebted to our guide Mr. Namdeo Badhe who supported and constantly supervised us through this project and helped us in not only completing this project but also provided us with sample amount of knowledge that was really beneficial to us. We also thank the project coordinators for arranging the necessary facilities to carry out our project work.

We are thankful to and fortunate enough to get constant encouragement, support and guide from all teaching staff of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their timely support.

We would like to express our gratitude towards our parents for their kind cooperation and encouragement which helped us in completion of this project.

Abstract— **"SQL using Natural Language Processing & Virtual Reality" is an Artificial Intelligence based system which uses modern AI tools such as Machine Learning, Natural Language Processing, Virtual Reality ,etc. to compute and perform various tasks and activities by using Intelligent agents that accept input from user in Natural Language and perform SQL related functionalities. The system works by creating a Virtual Environment using Unity 3D in which we create Artificial Intelligence ingrained bots that can take input from user as Speech and that input can be processed by using Natural Language Processing to convert speech to digital signals. Consequently, training the bots to perform various operations and manipulations on already created Databases to execute SQL queries just by speech recognition.**

Keywords—Natural Language Processing, Virtual Reality, Sequence to Sequence Model, Artificial Intelligence, SQL, Speech to Text, Unity 3D

I. INTRODUCTION

Setting up an organization requires a lot of resources including skilled manpower, but the risk of failure of a new organization creates a lot of insecurities. Artificial Intelligence has always been considered as a tool which can help to improve the society in various aspects. Artificial Intelligence, when integrated with other powerful technology like Virtual Reality helps to create such an environment, where we can preliminarily set up a virtual organization with least resources.

The project integrates intelligent agent system along with Virtual Reality (VR) to create a virtual environment which will be capable of performing real world organizational tasks by reducing the manpower as well as creating an easy-to-communicate interface. As a purpose of demonstration, Database commands will be executed, in the real world by providing commands in Natural Language (English), to the Virtual Reality hardware.

II. BACKGROUND

A Virtual Environment that can be used to perform various tasks on Databases and Data Warehouses by using Natural Language Processing and Artificial Intelligence Technology. While thinking for the idea we found ourselves digging around the problem of lack of cheaper and safer security solutions for our homes. Hence, we planned to use the latest technologies and expertise in the best way to make a project that would try to perform various SQL tasks on Databases by a naïve user. The proposed system uses advance machine learning and Natural Language Processing for Database Operations.

III. PROBLEM DEFINITION

Developing an Virtual Environment which can be used to compute SQL queries with the help of Artificial Intelligence integrated agents by using Natural Language Processing. The system uses Seq2Seq Model, also known as Encoder-Decoder Model to convert natural language to text which is later converted to executable SQL queries. The Virtual Reality medium provides an interactive user interface through which users can interact with intelligent agents and perform required SQL operations.

IV. NATURAL LANGUAGE PROCESSING

Natural language processing (NLP) is a subfield of linguistics, computer science, information engineering, and artificial intelligence concerned with the interactions between computers and human (natural) languages, in particular how to program computers to process and analyze large amounts of natural language data. NLP is an interdisciplinary field concerned with the interactions between computers and human natural languages (e.g: English) — speech or text. NLP-powered softwares help us in our daily lives in various ways, for example:

- Personal assistants: Siri, Cortana, and Google Assistant.
- Auto-complete: In search engines (e.g: Google, Bing).
- Spell checking: Almost everywhere, in your browser, your IDE (e.g: Visual Studio), desktop apps (e.g: Microsoft Word).
- Machine Translation: Google Translate. [4]

Setting up an organization requires a lot of resources including skilled manpower, but the risk of failure of a new organization creates a lot of insecurities.
Artificial Intelligence has always been considered as a tool which can help to improve the society in various aspects. Artificial Intelligence, when integrated with other powerful technology like Virtual Reality helps to create such an environment, where we can preliminarily set up a virtual organization with least resources.

Such an environment will eventually avoid a lot of risks, due to organization's failure and help to handle the entire network efficiently Artificial Intelligence has emerged as the most powerful technology in today's world which is utilized in various tasks such as Natural Language Processing (NLP), chat-bots, Object Recognition, etc.
The project integrates this technology along with Virtual Reality (VR) to create a virtual environment which will be capable of perform real world organizational tasks by reducing the manpower as well as creating an easy to communicate interface.

As a purpose of demonstration, Database commands will be executed, in the real world by providing commands in Natural Language (English), to the Virtual Reality hardware. [5]

V. INTELLIGENT AGENTS

In artificial intelligence, an intelligent agent (IA) refers to an autonomous entity which acts, directing its activity towards achieving goals (i.e. it is an agent), upon an environment using observation through sensors and consequent actuators (i.e. it is intelligent). Intelligent agents may also learn or use knowledge to achieve their goals. They may be very simple or very complex. A reflex machine, such as a thermostat, is considered an example of an intelligent agent. [6]

VI. ENCODER-DECODER MODEL

The encoder-decoder model is a way of using recurrent neural networks for sequence-to-sequence prediction problems. It was initially developed for machine translation problems, although it has proven successful at related sequence-to-sequence prediction problems such as text summarization and question answering. The approach involves two recurrent neural networks, one to encode the input sequence, called the encoder, and a second to decode the encoded input sequence into the target sequence called the decoder.

Following are some of the application of sequence to sequence models-

- Chatbots
- Machine Translation
- Text summary
- Image captioning

VII. VIRTUAL REALITY

Virtual Reality (VR) is the use of computer technology to create a simulated environment. Unlike traditional user interfaces, VR places the user inside an experience. Instead of viewing a screen in front of them, users are immersed and able to interact with 3D worlds. By simulating as many senses as possible, such as vision, hearing, touch, even smell, the computer is transformed into a gatekeeper to this artificial world. The only limits to near-real VR experiences are the availability of content and cheap computing power.

VIII. OBJECTIVE

The system works by creating a Virtual Environment using Unity 3D in which we create intelligent agents that can take input from user as Speech and that input can be processed through an Encoder-Decoder Model to convert speech to digital signals. Then, training the agents to perform various operations and manipulations on already created Databases to execute SQL queries just by speech recognition.

IX. LITERATURE SURVEY

Numbers of researches have been carried out as it has become very influential topic and has been gaining heights of increasing interest. Each paper used different method and algorithm to get good accuracy on SQL queries, Database Management, Reinforcement Learning, Virtual Reality and Artificial Intelligence.

REF NO.	PAPER TITLE	AUTHOR	YEAR	KEY FINDINGS	RESEARCH GAP
1	Natural Language Processing In VR Training Environments	Curry I. Guinn & R. Jorge Montoya	2014	It demonstrates the integration of spoken human-machine dialogue with visual virtual reality in implementing intelligent assistant and training systems. Increases retention.	Fusion of virtual reality, expert systems, and natural language processing may sometimes lead to errors.
2	VR for education and Workforce training	Daniel W. Carruth	2013	Measures user performance and user's experience. Completion time and accuracy can be easily recorded in a virtual environment at a level of detail and objectivity that is very difficult to achieve in the real-world.	Simulator sickness is a common issue with virtual reality. It is common to have dropout rates of 10% to 20% and we have observed dropout rates as high as 50%.
3	Creating Real Time Intelligent Interactive Virtual Environment	Weibin Liu, Liang Zhou & Baozong Yan	2010	Generates terrain from height map and smoothens through filtering.	Integration of autonomous virtual humans and virtual environment may lead to errors.

4	Generating Structured Queries from Natural Language using Reinforcement Learning	Victor Zhong, Caiming Xiong & Richard Socher	2016	Introduction to WikiSQL. Reinforcement learning generates higher quality WHERE clause. Also incorporates structures that reduces invalid queries. Improves execution and logical accuracy.	If the former query is provided as the ground truth, using cross entropy loss to supervise the generation would then wrongly penalize the latter query.
5	Application of Artificial Intelligence in Machine Learning	Sumit Das, Aritra Dey, Aakash Pal & Nabamita Roy	2015	Automatic Indexing for Boolean Information Retrieval Systems. Semantic Annotation of Ubiquitous Learning Environments.	Requires skill and practised labours for this task
6	Agent Supported Serious Game Environment	Theodouli Terzidou,	2016	This research study proposed and evaluated an agent supported serious game environment for a 3D collaborative game in the OpenSim platform involving university students. With regards to students' attitudes, results revealed that students provided with the agent supported game environment did not change their attitude towards the course and games.	Agent's representation: the pedagogical game agent was chosen to interact with the students in a conversational mode, without any embodied representation in order to reduce the cognitive overload and to operate in a discreet manner.

Artificial Intelligence has emerged as the most powerful technology in today's world which is utilized in various tasks such as Natural Language Processing (NLP), chat bots, Object Recognition, etc. [1]

Seq2seq takes as input a sequence of words (sentence or sentences) and generates an output sequence of words. It does so by use of the recurrent neural network (RNN). Although the vanilla version of RNN is rarely used, its more advanced version i.e. LSTM or GRU are used. This is because RNN suffers from the problem of vanishing gradient. LSTM is used in the version proposed by Google. It develops the context of the word by taking 2 inputs at each point of time. One from the user and other from its previous output, hence the name recurrent (output goes as input).

It mainly has two components i.e *encoder* and *decoder*, and hence sometimes it is called the Encoder-Decoder Network. [3]

The system contains agent bots that are trained by using Reinforcement Learning by using sequence to sequence algorithm and hence they learn through experience by providing them training data and then verifying the operations performed by them and rewarding the system with 0/1 reward based on the validity of the result and hence their performance increases by experience. [2]

Encoder: It uses deep neural network layers and converts the input words to corresponding hidden vectors. Each vector represents the current word and the context of the word.

Decoder: It is similar to the encoder. It takes as input the hidden vector generated by encoder, its own hidden states and current word to produce the next hidden vector and finally predict the next word.

Technologies used are:

- SQL for Database Management
- Unity for creation of Virtual Environment
- Reinforcement Learning by using Seq2Seq
- Natural Language Processing
- Python for Machine Learning

XII. CONCLUSION

The system works by creating a Virtual Environment using Unity in which we create bots that can take input from user as Speech and that input can be processed by using Natural Language Processing to convert speech to digital signals and then training the bots to perform various operations and manipulations on already created Databases to execute SQL queries just by speech recognition.

The system can help a user who has no previous knowledge about SQL and perform SQL queries on Database just by using speech-as-an-input methodology. This environment can help to reduce the load of tasks like Data entry, Data Manipulation in Corporate Offices and Educational institutes.

It works by creating a Virtual Environment using Unity in which we create bots that can take input from user as Speech and that input can be processed by using Natural Language Processing to convert speech to digital signals and then training the bots to perform various operations and manipulations on already created Databases to execute SQL queries just by speech recognition.

Our current system is capable of performing SQL queries on Databases by using Natural Language Processing in Virtual Reality and Artificial Intelligence.

System can be developed into an Interactive Virtual Environment that can be used to perform different tasks and activities and reflect the changes into the real world.

A Product Backlog is rarely finished. The soonest improvement of it spreads out the at first known and best-got prerequisites. The Product Backlog develops as the item and nature wherein it

will be utilized advances. The Product Backlog is dynamic; it continually changes to recognize what the item should be proper, aggressive, and helpful. On the off chance that an item exists, its Product Backlog additionally exists.

Item Backlog refinement is the demonstration of including point of interest, gauges, and request to things in the Product Backlog. This is a continuous procedure where the Product Owner and the Development Team work together on the subtleties of Product Backlog things. During Product Backlog refinement, things are audited and reexamined.

XIII. FUTURE SCOPE

Future Scope is to make a highly interactive Artificial Intelligence 3D Virtual Environment that can be used to achieve much more complicated tasks and creating more intelligent AI bots for computing and processing much more intricate data. This would help to complete demanding tasks by using Artificial Intelligence.

This system can be implemented for NoSQL, MongoDB. A module for implementing text auto-completion using Elastic-Search. We will be using solar as the searching algorithm which will counter problems such as identification of homo-sonic words, text recommendations and quick results.

The Future of Natural Language Processing explains that in NLP, machines are taught to read and interpret text as humans do. NLP is recognized as the "enabler of text analysis and speech-recognition applications." This human capability for interpreting text comes in handy for analyzing large volumes of text data. NLP is set to capture the voice of the customer. As an example of this use of NLP, think of Google Drive, where users can search documents via conversational input. With the exponential growth of multi-channel data like social or mobile data, businesses need solid technologies in place to assess and evaluate customer sentiments. So far, businesses have been happy analyzing customer actions, but in the current competitive climate, that type of customer analytics is outdated. Now businesses need to analyze and understand customer attitudes, preferences, and even moods – all of which come under the purview of sentiment analytics. Without NLP, business owners would be seriously handicapped in conducting even the most basic sentiment analytics.

Abstract **- In this technological era, the use of advance technologies are increasing day by day. Each and every day new discoveries are taking place which are satisfying the user's need. The main aim of the project is to provide an online platform for various users through which they can discuss and communicate their thoughts and ideas and thus transfer of knowledge would also take place. Technical Discussion Support System encourages reflection and deeper thinking and also focusses on peer to peer communication among the members in the form.**

Keywords—Web Technology, PHP, JavaScript

I. INTRODUCTION

Nowadays e-learning platform is becoming more and more famous. The project is also towards e-learning. It's a PHP based project named "Technical Discussion Support System" is the place where persons after creating their account can share their ideas and make discussions on various topics. In this project CSS, JavaScript, BootStrap and etc are used. This project aims to increase the interest of users regarding any particular topics. This project is on the perspective of students. Expert thinking about the topic can be modelled and learned and useful information is shared among the users. Database connectivity is also used which records the activity performed by the member in the forum. Discussion System motivates learners since active discussion forum have every minute new content and thus can be more would become more attractive to the users.

II. OBJECTIVE

A discussion system contributes to the development of an individual's cognitive and critical thinking skills, allows time for thoughtful, in-depth reflection on course topics, facilitates exploratory learning by allowing you to review and respond to the work of others and paves the way for you to approach your own learning in diverse ways. It provides a platform for users to spread knowledge and also provides an effective communication and discussion among the users. Effective forum topics are open-ended and designed to encourage students to take a position on issues.

III. BACKGROUND

In this technological era, the use of advance technologies are increasing day by day. Each and every day new discoveries are taking place which are satisfying the user's need. The main aim of this project is to provide an online platform for various users through which they can discuss and communicate their thoughts and ideas and thus transfer of knowledge would also take place between them. Online discussion system encourages reflection and deeper thinking and also focuses on peer to peer communication between the members in that forum. The main motive is to provide a wide platform for the users to explore the field of transfer of knowledge through which they would build interest in various topics and can discuss and communicate among themselves related to that particular topic. In future, some features will be added in the discussion forum to overcome the drawbacks in the previous year research papers.

IV. LITERATURE SURVEY

During this phase certain research papers are studied and some of the key findings, research gapes are obtained which can be overcome during the implementation of the project.

Neil Harris and Maria Sandor Developing online discussion forums as student centred peer e-learning environments. It deals with peer based approaches to learning in the e learning environment. Use of discussion board as an assessment. The gap which is observed is that it is limited to use by e learning environment and can be used in other fields also.

Alabo .H. Biriyai and Emmah .V. Thompson Online Discussion Forum a tool for effective teacher student interaction. They used PHP and javascript for creation of the forum. Moderators are used to grant access to the post and are also used to respond to the user's questions and control he content of the discussion forum. It is only limited for teacher and student interaction and is limited to a certain extent.

Ankita Singhal and Brij Mohan Karla Review of online discussion foum in e learning scenario. Web technology is the domain which is used for implementation of the forum. Novek method is proposed to determine post usage to evaluate quality of content in the forum. Removal of error URLs for efficient searching. The paper only suggests the methods of improving forum and does not implement any new feature in the forum.

Jenny McDougall A Study of online discussion forum and needs of adult learners. Concept of authenticity is used. The concept of authentic discussion in classroom study can be replaced by online discussion forum. The paper is only limited to the online discussion at the university level.

Ravi Seethamraju Effectiveness of using Online Discussion Forum for case study analysis. Quantity of responses, Quality of responses and improvement in overall learning. It is reduced structure but a bit complicated to use.

Suryakumari Lane Effective Online discussion forum as an effective learning space. The research methodology is theoretical and empirical. The paper discusses about majority of students having a good learning experience. The author suggest way forward for traditional universities to have blended learning.

V. METHODOLOGY

Technical Discussion Support System focuses on improving cognitive and critical thinking of an individual. Firstly the user needs to login if he/she is the member of the discussion system. If the user is not a member, then he needs to register himself in the forum. Once registered, a wide range of categories is displayed to the user through which he can discuss on his topic of interest. The user can post question and answers and can refer chatbot in case of query. The chatbot consists of predefined set of questions which would help user in case of any issue. User can also read the latest news from the news feed section. Admin has overall control of the activities that is performed by the user. Database connectivity is done which tracks or keeps the record of the activities that are performed by the user in the forum. Web technology is used as a domain and PHP used at front end.

Fig 1shows the flow of the system and various parameters that are considered in the system. Fig 2 displays the use case diagram of the system which involves various actors in the project along with their respective roles. Fig 3 represents the dataflow diagram of the admin which consists of various functions carried out by admin. Fig 4 represents the dataflow diagram of the question module. Fig 5. Represents the login module through which the user can access the system. Fig 6 shows the dashboard which consists of the pending questions. Fig 7 has the record of the user information which are the part of the forum. Fig 8 represents the various categories in the discussion forum. Fig 9 shows the questions that are asked by the registered user in the forum.

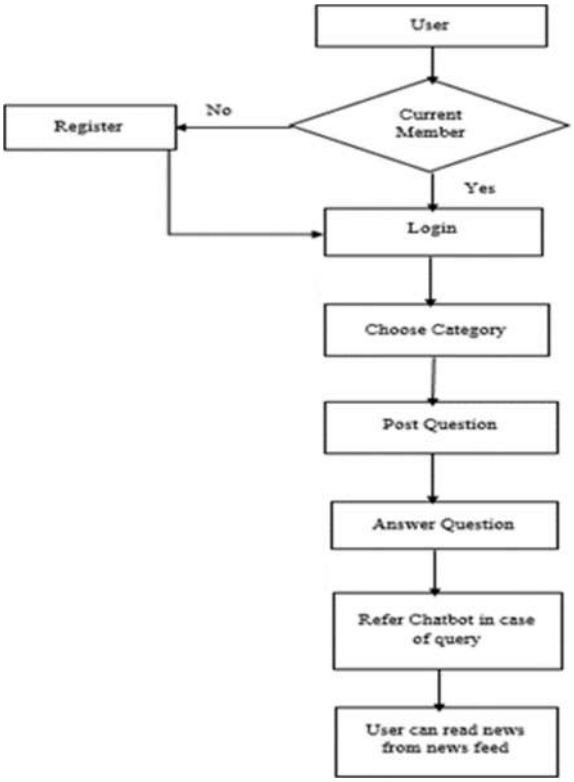

Fig 1: Flowchart of Technical Discussion Support System

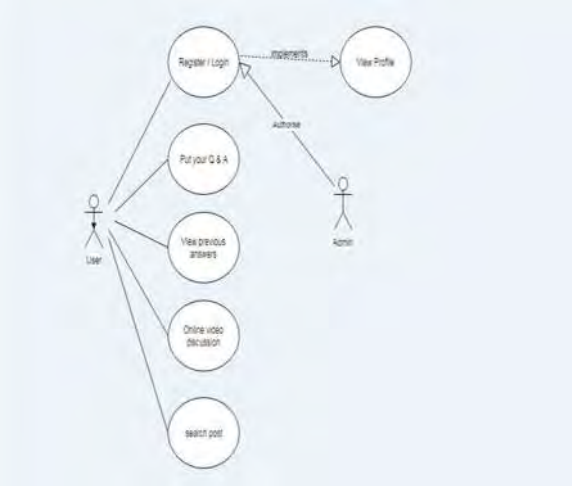

Fig 2: Use case diagram

The Use Case diagram consists of two actors and their respective functionalities.

User- User acts as an actor who firstly register via login and then become a registered user in the discussion forum. Following are the activities that are performed by user as an actor:

1. Register and login
2. Post Questions and answers
3. View Answers
4. Online video discussion
5. Search posts

Admin- Admin takes the control of the discussion forum.

1. Admin can check the question answers posted by user.
2. Has right to accept the post by the users or not

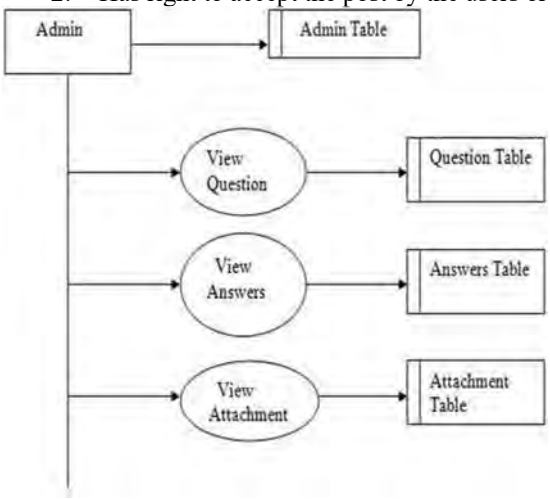

Fig 3: Block DFD diagram of admin module

The admin has the right to view the questions that have been asked, view the answers and also have a role in which he would decide whether the post is relevant or not. The questions that have been asked and answered is stored in the database.

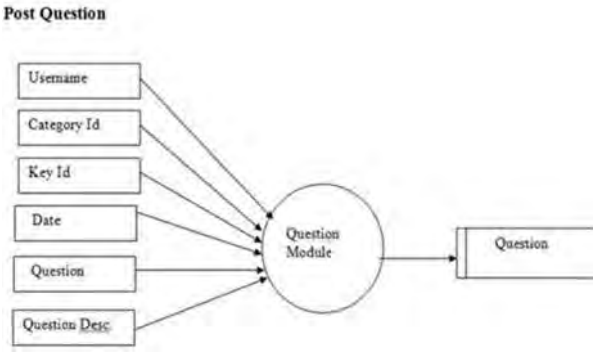

Fig 4: Block diagram of question module

Various category Ids are given based on the user's interest. When the member posts the question then his username ,date on which the question is posted is mentioned in the discussion forum.

VI. RESULT

Technical Discussion Support System focuses on providing an e learning platform for the users for interaction purpose. The main motive behind this project is to establish a knowledge transfer among the people. Firstly, the user needs to register in to the system to be the part of the forum. Once the user is registered a login page is generated which asks user to enter their email id and password for authentication purpose. Some strong crypto algorithms would be applied to ensure security of the technical discussion support system. Once the user would become the member of the forum then he has a right to post questions and answer related to the topic of interest and thus an effective interaction would be established among the members of the forum. News feed section is also provided through which the user would be aware of the daily happenings that are going all around in the world. Chatbot mechanism is going to be incorporated. If a user is having certain doubts while using the technical discussion forum, he can get it cleared via chatbot mechanism which consists of predefined sets of questions along with the answers.

Fig 5: Login Module

The figure represents the login module for the user once he becomes the registered member of the discussion system. The login module consists of email id and password for authentication purpose. Once the user is logged into the forum he can discuss about a particular topic either by posting question or answering the questions.

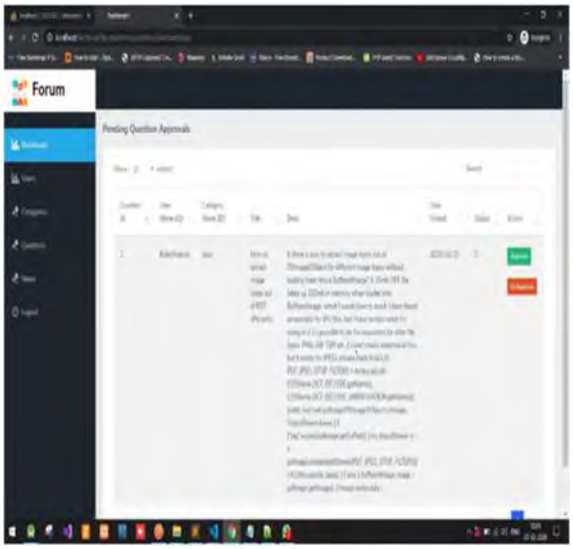

Fig 6: Dashboard Portal

The figure represents the dashboard portal of the discussion system. It consists of some of the pending questions asked by the users along with the user name, category id, title and the date on which it was posted. The admin can take action whether to approve or unapproved.

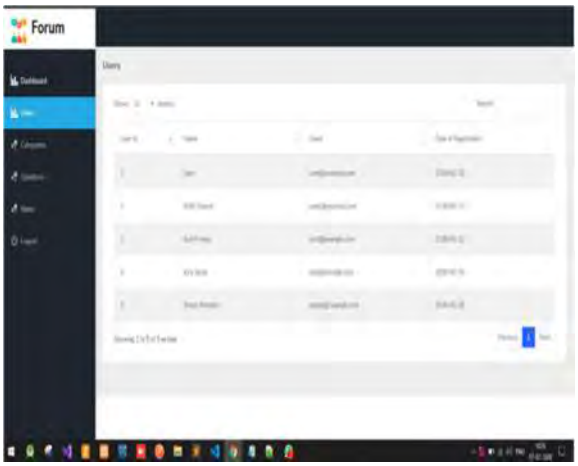

Fig 7: User Information Portal

The figure represents the information of the registered users that is stored in the technical discussion system. The information portal consists of the user id, name of the user, email address of the registered user and the date of registration of the user.

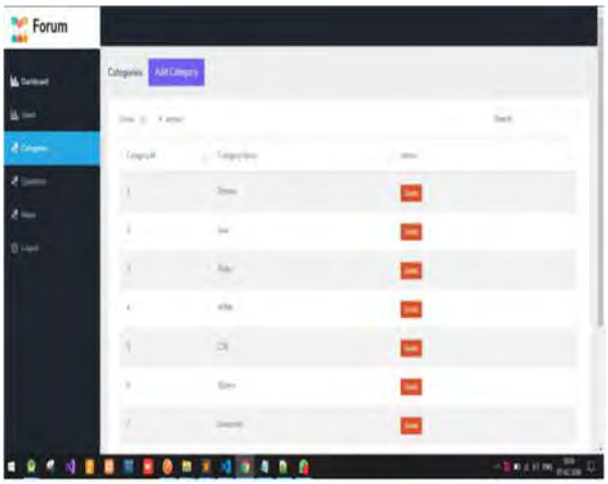

Fig 8: Category Portal

The category portal consists of various categories in the technical discussion system. It has category id, Category name and the action that needs to be taken. Some of the category names are Python, Java, Ruby, HTML, CSS, JQuery, JavaScript.

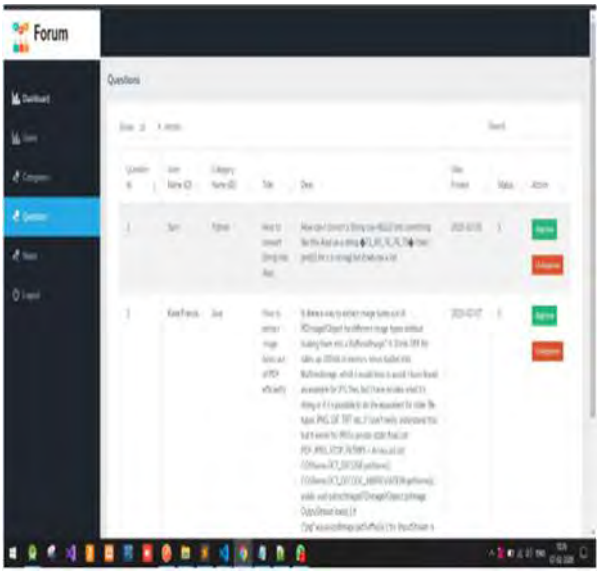

Fig 9: Question Portal

The above figure represents the question portal in the technical discussion support system. The question portal consists of the questions that are asked by the user in the forum. The format of the question portal has question id, user id i.e. the id of user who post question, category id, title, date on which the question is posted along with the status. The admin has right whether to approve the question posted by the user or to unapproved the post.

VII. CONCLUSION

Technical Discussion Support System acts as an interactive tool for knowledge sharing purposes. PHP and database connectivity is used and thus provide a wide platform for the users to explore the field of transfer of knowledge through which they would build interest in various topics and can discuss and communicate among themselves related to that particular topic. News feed section is also provided through which the user would be aware of the daily happenings that are going all around in the world. Chatbot mechanism is going to be incorporated. If a user is having certain doubts while using the technical discussion forum, he can get it cleared via chatbot mechanism which consists of predefined sets of questions along with the answers. A discussion system contributes to the development of an individual's cognitive and critical thinking skills, allows time for thoughtful, in-depth reflection on course topics, facilitates exploratory learning by allowing you to review and respond to the work of others and paves the way for you to approach your own learning in diverse ways. It provides a platform for users to spread knowledge and also provides an effective communication and discussion among the users. Effective forum topics are open-ended and designed to encourage students to take a position on issues.

VIII. FUTURE SCOPE

Further planning involves introduction of video function and Google voice assistance in project so users can discuss the things online and it would be more convenient and working to make an app for it. Our aim is to make the application on current situations and demand.

IX. ACKNOWLEDGEMENT

The quality and ultimate outcome of this paper involved a great deal of support and expertise from many people and we are incredibly privileged to have successfully completed the paper. We take this opportunity to thank everybody for their support.We sincerely thank our principal Dr. B. K. Mishra, vice Principal, Dr. Deven Shah, Mentor Dean Dr. Kamal Shah and HOD Dr. Rajesh Bansode for always guiding us to paths that were right for us. We are grateful to our guide Mrs. Pranjali Kasture who supported and constantly monitored this work and helped us in not only completing this project but also providing us with basic knowledge with their practical aspect that really proved beneficial to us. We are forever thankful and fortunate enough to receive constant encouragement, support and guidance from all IT department faculties that helped us finalize our paper work successfully. We would also like to extend our sincere gratitude to all the laboratory support staff for their timely support. We would like to convey our heartfelt thanks to our parents for their kind cooperation and encouragement without which none of this was possible.

Interactive paper - Paper display using Projection Mapping

Krishna Madani, Shivani Nawal, Nandan Maurya, Kamal Shah
Thakur College of Engineering and Technology, Mumbai, India
krishnamadani@gmail.com, shivani.nawal1@gmail.com, nandanmaurya209@gmail.com

Abstract— **With advancement in technology especially in the field of virtual reality the user experience has become easy, interactive and interesting. We here are going to present the concept of Interactive paper i.e. Paper display using projection mapping. The traditional way calibrates the projector to display the content. Calibration is the process to setting up the connection between the device that projects and the one on which it is projected. The overall process of calibration consumes a lot of time and if there is a little mishandling it can cause disturbance in the projection. Our project overcomes this issue. Our project's main aim is to provide an interactive platform for users to implement and understand things in a better way. The Object that is to be interacted with is 3D designed in a Virtual environment with the help of computer software like Unity, AutoCAD etc. It is then projected on the paper and mapped accordingly by means of specialized software. This is where the Projection mapping is implemented as well as restricted because of required stillness of real object but it is extended further printing a pattern on the paper and tracking it by software by means of a camera. So real-time scenes of the paper are fed to the software by the camera and accordingly, updates are made if the paper is moved from its original position. This concept has been in existence from past 3-4 years, but it is not implemented or used widely. This concept models the e -light emitted by projectors and reflected into cameras, and to consider the displayed content as additional information useful for direct alignment and to provide the projection accurately.**

The projection mapping on paper is going to be achieved by combining hardware with software to produce the result accuracy. We here are displaying the pattern on the paper in 3D format to make it interactive. This can be widely used in the field of education and medical science.

Key words: Projection Mapping, Augmented Reality, VR.

I. INTRODUCTION

Nowadays Virtual reality and Augmented reality have taken over the world. With these two powerful field of domains we are able to experience a lot of new things. The most common examples of these are : broadcasting messages through VR , Playing sports game is the most trending one , Pokémon Go game is one the examples for AR. The point here is that these fields are applied to the gaming and entertainment purpose so effectively why not use it for Educational purposes.

In this project projection of objects / patterns are done on the paper. The projection of Virtual objects will be done on a sheet of paper which will be having a specific pattern printed in it for tracking i.e. by tracking the pattern we can have the virtual effect of the object/pattern. Increase in technology is rising highly and with them new concepts need to be adapted and implemented to efficient use. This concept is an upcoming technology in the field of virtual reality which can be helpful in various fields. In the end this project is just a start towards the new technology to be used in education institutes and medical science.

In education there are various ways such as explaining science topics to students so that their understanding of subjects improves. In medical science Doctors can explain to students as well as the patients each part of body in 3D, which can actually give the feeling of an actual object.

II. OBJECTIVES OF THE PROJECT

The aim is to make the conventional paper using a unique experience by interacting with it with the help Augmented Reality and a concept known as Projection Mapping.

1. The Object that is to be interacted with is 3D designed in a Virtual environment with the help of computer software like Unity, AutoCAD etc.
2. It is then projected on the paper and mapped accordingly by means of specialized software. This is where the Projection mapping is implemented as well as restricted because of required stillness of real object but it is extended further printing a pattern on the paper and tracking it by software by means of a camera.

So real-time scenes of the paper are fed to the software by the camera and accordingly, updates are made if the paper is moved from its original position

III. RELATED WORK

There has been vast work on permitting augmented truth eventualities using projection mapping. Whilst recent work has captured lots press interest, there has been much work over the last many years. Since this early paintings, which explored the use of big and

curved projection surfaces that would be semi-automatically calibrated, there was tons work on projection systems, calibration strategies, and camera-projector structures. Systems have looked at the problem of projecting and interacting across more than one flat surfaces, even the usage of a moving hand-held projector. One particular trouble explored is the mixing of a couple of projections on flat or pseudo-flat surfaces. These systems borrow from the big literature on image-based totally rendering and mixing techniques. However, these structures have no longer explored complicated geometry or moving surfaces. More recently, with the arrival of actual-time depth cameras, projector systems have all started to cope with greater complex geometries. IllumiRoom explored projecting across the periphery of a tv display, and RoomAlive explores multiple projections inside an entire room. However, neither of those systems deal with moving projector/cameras or moving scenes. One instance of a transferring hand-held projector gadget which is used to render content onto real-world geometry of arbitrary form, captured the usage of the KinectFusion gadget. However, this machine did no longer scale to transferring gadgets, nor more than one projectors. Other work has focused at the problem of correcting the projected photograph because of inherent shade and visual artifacts the usage of various radiometric repayment strategies, or by using modeling the inverse light shipping of the projector. Some projector structures compensate in actual-time for shade modifications on dynamic projection surfaces. Other structures compensate for environment lighting fixtures modifications or maybe the cloth houses of the scene. These structures but frequently do now not deal with complicated geometries or assist motion of the floor or projector/digicam device. However, a time-eating static calibration approach changed into finished by manually moving a go hair within the projector view to highlight pixels that light up known object factors. In comply with-up work, used fiber optic sensors embedded inside the object to localize a shifting object, but now not in actual-time. There has been comparable research which demonstrated projecting on a moving item, however required infrared markers and/or magnetic sensors at the object, and best a small working extent. DisplayObjects extensively utilized a marker-based totally monitoring gadget, to music the display objects. In those structures the projector and sensor device are assumed to remain static. Researchers supports a moving projector digital camera system, however does not scale to a couple of projectors modeling the light shipping to make sure accurate in keeping with-pixel projection rendering. Researchers have offered a projection mapping gadget this is able to dynamically task onto moving objects. They use a 1000fps digital camera and galvanometer mirrors to tune and illuminate the object with a single projector. The ensuing monitoring is extraordinarily fast and dazzling effects are performed. Note that this monitoring method is orthogonal to our contribution and could be used to seriously reduce the latency of our machine.

IV. BACKGROUND

PROJECTION MAPPING

Projection mapping, similar to video mapping and spatial augmented reality, is a projection technique used to turn objects, often irregularly shaped, into a display surface for video projection. These objects may be complex industrial landscapes, such as buildings, small indoor objects or theatrical stages. By using specialized software, a two- or three-dimensional object is spatially mapped on the virtual program which mimics the real environment it is to be projected on. The software can interact with a projector to fit any desired image onto the surface of that object. This technique is used by artists and advertisers alike who can add extra dimensions, optical illusions, and notions of movement onto previously static objects. The video is commonly combined with, or triggered by, audio to create an audio-visual narrative.

AUGMENTED REALITY

Augmented reality (AR) is an interactive experience of a real-world environment where the objects that reside in the real world are enhanced by computer-generated perceptual information, sometimes across multiple sensory modalities, including visual, auditory, haptic, somatosensory and olfactory. AR can be defined as a system that fulfills three basic features: a combination of real and virtual worlds, real-time interaction, and accurate 3D registration of virtual and real objects. The overlaid sensory information can be constructive (i.e. additive to the natural environment), or destructive (i.e. masking of the natural environment). This experience is seamlessly interwoven with the physical world such that it is perceived as an immersive aspect of the real environment. In this way, augmented reality alters one's ongoing perception of a real-world environment, whereas virtual reality completely replaces the user's real-world environment with a simulated one. Augmented reality is related to two largely synonymous terms: mixed reality and computer-mediated reality.

The traditional and mostly used method to experience the VR is via the Head Mounted Devices and if we are talking sharing this experience with Group of people than it would be CAVE or using the PC so as to view the orthographic projection of VR. In both the cases user has to wear some type of gadget / device to operate and sharing it would mean that many devices and complexity or only one person controlling the environment and other are just passive viewers which is not very interactive and feature rich method. So as to provide the user/s a featured experience without any need of wearable devices and to be able to share this with a group with ease, this system is proposed.

V. PROPOSED SYSTEM

Purpose –The aim is to make the conventional paper by interacting with it with the help Augmented Reality and a concept known as Projection Mapping.
Process –Paper is tracked, via the pattern made on it, by a camera and feedback is provided to the application which calculates the relative coordinated with respect to the surface on which paper is to be placed and mapped to the correct content and projected so as to give a feeling of a interactive paper display. So real-time scenes of the paper are fed to the software by the camera and accordingly, updates are made if the paper is moved from its original position.

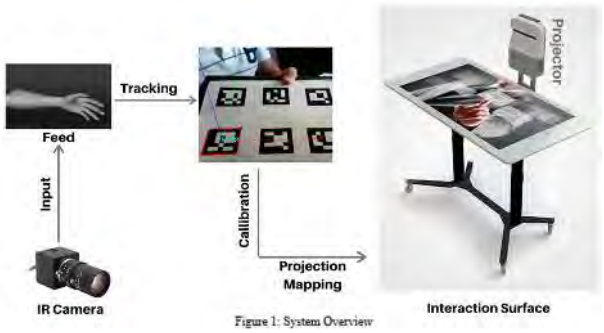

Figure 1: System Overview

VI. METHODOLOGY

Our project is AR based and involves both hardware and software. This project combines both the technologies of projection mapping and augmented reality to get the results. The following are the steps involved to get the result.

Step 1: The paper is kept on the surface which on which the projected content will be displayed.

Step2: Using the marker technology and camera the coordinates of paper are captured.

Step 3: This is then sent to the system to process the data and then it is projected.

Step 4: When the user moves the paper the camera again captures the coordinates again as a feedback and then accordingly it changes the projection.

VII. FLOWCHART

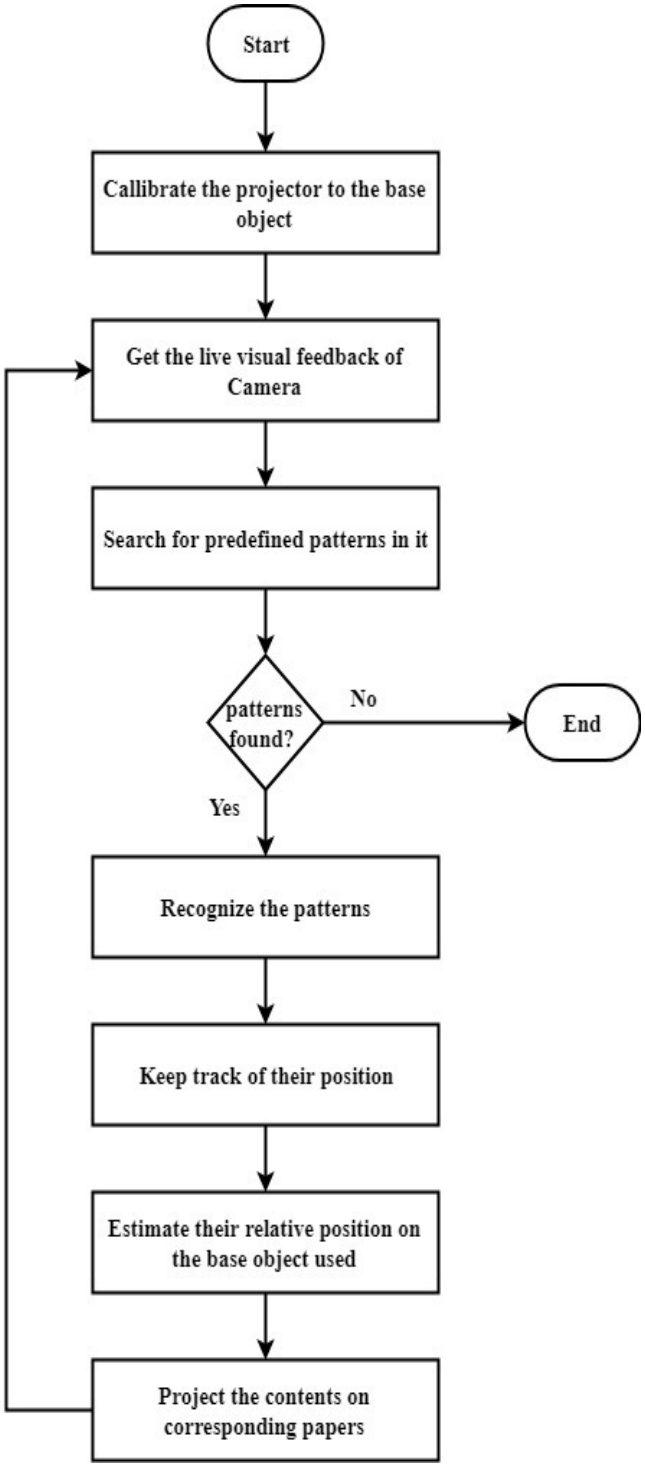

Figure 2: Flow of the System

VIII. RESULT

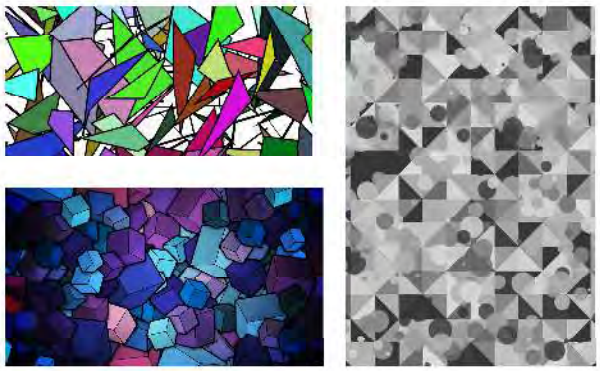

Figure 3: Markers to be tracked

The above image has the markers which are going to be tracked with the help of a software. These patterns are numbered and their relative distance is calculated.

Figure 4: tracking the markers

The application on start searches for the marker printed on the paper. It detects it gives them numbering. After the numbering is done it tracks the marker when it is moved.

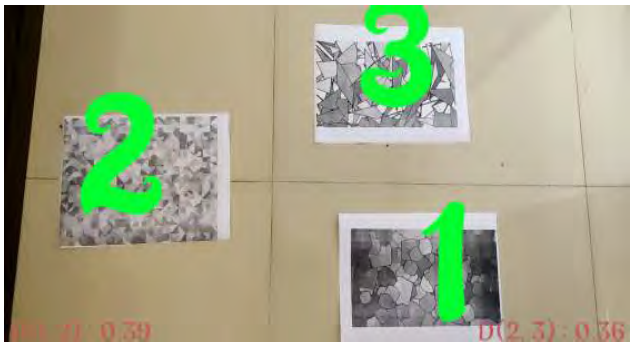

Figure 5: Showing distance between papers

Figure shows a sample testing program which tracks several markers printed on papers and calculated a relative difference of positions in terms of actual distance which will be used for calibrating and mapping the projection accordingly. Here, the distance between marker 1 and 2 is 0.39 and that of 1 and 3 is 0.36

IX. CONCLUSION

Our project is an AR system that uses the concept of projection mapping to display the object on a paper. The Object that is to be interacted with is 3D designed in a Virtual environment with the help of computer software like Unity, AutoCAD etc. It is then projected on the paper and mapped accordingly by means of specialized software. This is where the Projection mapping is implemented as well as restricted because of required stillness of real object but it is extended further printing a pattern on the paper and tracking it by software by means of a camera. Real-time scenes of the paper are fed to the software by the camera and accordingly, updates are made if the paper is moved from its original position. Here we will be able to make a fully efficient system when the implementation starts as of now we have just completed 2 phases of the waterfall model i.e. requirements gathering and system design.

X. FUTURE SCOPE

This project has tremendous development scope which is only limited by a person's imagination.

It can be improved and used in various ways such as:-

1. The pattern on the paper can be made with infrared ink so that the paper can be tracked in low luminous conditions such as closed areas or in the night and it also improves the contrast of the projection.
2. Hand or Body tracking machines can be used to implement body gestures, so as to better interact with the projection and make the experience as equipment free and natural as possible.

XI. ACKNOWLEDGMENT

We sincerely thank our guide Dr. Kamal Shah for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

We thank the HOD, Dr. Rajesh Bansode, the Principal, Dr. B. K. Mishra, and the college management for their support.

Abstract— **Data Mining is a technique which focuses on large data sets to extract information for prediction and discovery of hidden patterns. Data Mining is applicable on various areas like healthcare, insurance, marketing, retail, communication, agriculture. Agriculture is the backbone of country's economy. It is the important source of livelihood. Agriculture mainly depends on climate, topography, soil, biology agricultural. The current study presents the different data mining techniques and their role in context of soil fertility, nutrient analysis. Decision tree is a well-known approach for classification in data mining. C4.5 and Classification and Regression Trees (ID3) are two widely used decision tree algorithms for classification. The main drawback of C4.5 algorithm is that, it is biased towards attributes with more values while ID3 algorithm produces misclassification errors when the domain of the target attribute is very large. In view of these limitations, this paper presents a modified decision tree algorithm. The model is tested with test data set of soil samples. The test proves that the modified decision tree algorithm has higher classification accuracy when compared to C4.5 and ID3 algorithms. Classification of soil is the separation of soil into classes or groups each having similar characteristics and potentially similar behavior. Classification of soil is needed so that farmer can know the type of soil and can plough the crops depending on the type of soil.**

Keywords— DecisionTree, C4.5,ID3

I. INTRODUCTION

Globally, day to day the need for food is escalating, therefore the agricultural scientists, farmers, government, and researchers are trying and using varied techniques in agriculture for improvement in production. As an impact, the information generated from the agricultural data is increasing day by day. Because the volume of information enlarged, it needs a spontaneous method for this information to be mined and analyzed once required. Data Mining techniques will be used for prediction the longer term trends of agricultural processes.

Data Mining techniques are of two types, one is descriptive which considers the existing data and another is predictive which depends on probability for future analysis. Data Mining process involves

a) Collect, clean and load the data into data warehouse system
b) Stores the data in multidimensional format
c) Provides information access to analysts and decision makers
d) Analyzation of data using different applications
e) Presents the data using different patterns

II. BACKGROUND

Agricultural researchers and farmers deploy sensors at their remote agricultural-fields to obtain the data of temperature, humidity, soil moisture and so on. Automatic collection of those data greatly helps their analytical works. Currently, they are relying on network providers, for example, cellular phone network to achieve such automatic collection from their remote sites, which is not feasible for most of the farmers due to operational cost. The review and meta-analysis of yield data comparing organic and conventional agriculture showed that currently organic yields of individual crops are on average 80% of conventional yields The analysis of 362 datasets also showed a high variation of the yield gap of organic agriculture (standard deviation 21%). Some of this variation seems systematic.E.g. soybean, some other pulses, rice and corn score higher than 80% and wheat, barley and potato scoring lower than 80%. Most regions have relative yields fairly close to the overall average.

III. PROBLEM DEFINITION

In current scenario, there are no such recommendation system available online. And also farmer has to physically go and get recommendation based on their soil report by quality executives. In this project, we've got suggested an analysis of the soil information using Decision Tree algorithms and prediction technique. By using Decision tree algorithm, we recommend farmers about their field soil quality and suggest crops which are suitable to grow in that soil.Use of information technology in agriculture can change the scenario of decision making and framers can yield in a better way.

IV. OBJECTIVE

The objectives of this study were to characterize and classify the soil to provide more details about the quality information of soil. An additional objective of this study was to seek out approximate crops can be growing on that field. This study were to characterize and classify the soil to provide more details about the subsurface morphological information. An additional objective of this study was to seek out an approximate value of soil loss from the Lower Moshi Irrigation Scheme using the Universal Soil Loss .

V. LITERATURE SURVEY

We have undergone certain research papers based on the Experimental Analysis Of agricultural Data Using DataMining and found out certain methodology and key findings. During the process, we have .also identified certain research gaps which we can overcome while implementing our project.

Ref no.	Paper Title	Author	Year Of Publication	Key Findings	Research Gaps
1	Analysis Of agriculture data Using Data Mining	Lucinda Edwards & Carolina Eriksson	2017	Various data mining techniques are implemented on the input data to assess the best performance yielding method. The present work used data mining techniques PAM, CLARA and DBSCAN to obtain the optimal climate requirement of wheat like optimal range of best temperature, worst temperature and rain fall to achieve higher production of wheat crop.	Clustering is considered as an unsupervised classification process. A large number of clustering algorithms have been developed for different purposes. Clustering techniques can be categorised into Partitioning clustering, Hierarchical clustering, Density-based methods, Grid-based methods and Model based clustering methods.
2	Analysis Of Soil Behaviour and Prediction of Crop Yield using data mining approach	Supriya Dm , Karnataka	2016	The researcher express that large amount of data which is collected and stored for analysis. Making appropriate use of these data often leads to considerable gains in efficiency and therefore economic advantages.	The researchers implemented K-Means algorithm to forecast the pollution in the atmosphere, the K Nearest Neighbour is applied for simulating daily precipitations and other weather variables and different possible changes of the weather scenarios are analyzed using Support Vector Machines.
3	A Survey On Predictive Analysis in	A. Agrawal J. Basak	2018	Soil classification was measured serious to study due to depending upon	suggested an analysis of the soil data using different
	Agricultural soil data to predict the best fitting crop	V. Jain R. Kothari		the fertility class of the soil domain knowledge experts determines which crops should be taken on that particular soil and which fertilizers should be used for the same.	algorithms and prediction technique.
4	Data Mining Technique to Predict the Accuracy Of the Soil fertility	Dr. S. Hari Dr.Jayashree	2017	The research studies on application of data mining techniques in the field of agriculture. Some of the techniques, such as ID3 algorithms, the k-means, the k nearest neighbour, artificial neural networks and support vector machines applied in the field of agriculture were presented.	This article explores the applications of data mining techniques in the field of agriculture and allied sciences. Historical crop yield information is important for supply chain operation of companies engaged in industries that use agricultural produce as raw material.
5	Data Mining in Agriculture prediction soil fertility	Dr.Shrinivashan , Dr.Mailthili M.	2017	A soil test is the analysis of a soil sample to determine nutrient content, composition and other characteristics. Tests are usually performed to measure fertility and indicate deficiencies that need to be remedied.	In this paper demonstrated acomparative study of varied classification algorithms i.e. Naïve bayes, J48 (C4.5), JRip with the assistance ofdata mining tool .J48 is incredibly easy classifier to form a decision tree.

VII. ALGORITHM IMPLEMENTED

Decision Tree Algorithm

In this project, we've got suggested an analysis of the soil information using Decision Tree algorithms and prediction technique. By using Decision tree algorithm, we recommend farmers about their field soil quality and suggest crops which are suitable to grow in that soil.

Regression Tree Algorithm

It models a target prediction value based on independent variables. ... Linear **regression** performs the task to predict a dependent variable value (y) based on a given independent variable (x).We have used the

algorithm to predict rainfall based on the previous year rainfall data.

The main drawback of C4.5 algorithm is that, it is biased towards attributes with more values while ID3 algorithm produces misclassification errors when the domain of the target attribute is very large**.**

VIII. RESULT AND DISCUSSION

This project is fundamentally related to use of information technology in agriculture can change the scenario of decision making and framers can yield in a better way. For decision making on overall issues related to agriculture field; data mining plays a vital role. The survey discussed the role of data mining in terms of agriculture field. We have also discussedvarious types of soils, several data mining techniques in agriculture and soil containment.

IX. CONCLUSION

In this project, we've got suggested an analysis of the soil information using Decision Tree algorithms and prediction technique. By using Decision tree algorithm, we recommend farmers about their field soil quality and suggest crops which are suitable to grow in that soil. Agriculture is the utmost important area especially in the mellowing country like India. Use of information technology in agricultre can change the scenario of decision making and framers can yield in a better way. For decision making on overall issues related to agriculture field; data mining plays a vital role. The survey discussed the role of data mining in terms of agriculture field. We have also discussed various types of soils, several data mining techniques in agriculture and soil containment.

X. FUTURE SCOPE

The system “crop prediction using data mining technology” is developed and tested successfully and satisfies all the requirement of the client. The goals that have been achieved by the developed system are: • Simplified and reduced the manual work. • Large volumes of data can be stored. • It provides Smooth workflow. We can add device to get values directly from soil testing lab to server. We can add module if any queries is there, the staff can directly interact with the administrator very easily.

XI. ACKNOWLEDGEMENT

The success and final outcome of this project required a lot of guidance and assistance from many people and I am extremely privileged to have completed the project successfully. I would like to thank everyone for their guidance.

We sincerely thank our principal, Dr.B.K.Mishra , Vice Principal Dr. Deven Shah and HOD Dr.Rajesh Bansode for always encouraging us to do our best. We highly indebted to our guide **Mr.Vijay Kumar Yele,** who supported and constantly supervised us throughout the project and helped us in not only completing this project but also provided us with ample amount of knowledge that was really beneficial to us.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staffs of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their timely support.

We would like to express our gratitude towards our parents for their kind co- operation and encouragement which helped us in completion of this project.

donadarji24@gmail.com, himanimehta20@gmail.com, priyankaiyer98@gmail.com

Abstract—**Crime analysis and prevention is a systematic approach for identifying and analyzing patterns and trends in crime. Our system can predict regions which have high probability for crime occurrence and can visualize crime prone areas. The objective of this project is to analyze dataset which consist of numerous crimes and predicting the type of crime which may happen in future depending upon various conditions. In this project, we will be using the technique of machine learning and data science for crime prediction of India crime data set. The crime data is extracted from the official portal of the Indian government. It consists of crime information like location description, type of crime, date, time, latitude, longitude. Before training of the model data preprocessing will be done following this feature selection and scaling will be done so that accuracy obtained will be high. The Naive Bayes classification and various other algorithms will be tested for crime prediction and one with better accuracy will be used for training. Visualization of dataset will be done in a graphical manner and in a way that can be easy to understand for the concerned authorities. This information can be used to determine a number of characteristics such as the time at which the criminal rates are high or at which month the criminal activities are high according to the locality specified. With the increasing advent of computerized systems, crime data analysts can help the Law enforcement officers to speed up the process of solving crimes. Using the concept of data mining we can extract previously unknown, useful information from an unstructured data. Here we have an approach between computer science and criminal justice to develop a data mining procedure that can help solve crimes faster. Instead of focusing on causes of crime occurrence like criminal background of offender, political enmity etc we are focusing mainly on crime factors of each day. The soul purpose of this project is to give a basic idea of how machine learning can be utilised by the law enforcement agencies and intelligent forces to identify patterns in commited crimes, predict crime prone regions and unsafe time periods and hence solve crimes at a much faster rate and thus reduce the crime rate. It is not restricted to our Country; this can be used in other states or countries as well depending upon the availability of the dataset.**

Keywords—Crime analysis, Criminal prediction, Naı̈ve Bayes

I. INTRODUCTION

Violations are the basic peril to humankind. Crimes can't be anticipated since it is neither precise nor arbitrary. Infringement happens from town to enormous urban zones. Infringement are of different sort robbery, murder, ambush, assault, battery, counterfeit confinement, stealing, crime. Since infringement is extending there is a need to light up the cases in a significantly snappier manner. Every day the crime rate is expanding fundamentally. It is growing and spreading at a snappy and colossal rate.

It is the commitment of the police office to control and lessen the crime rates. The desire to commit an offence and criminal unmistakable confirmation are the significant issues to the police office as there are enormous proportion of crime data that exist. There is a need for advancement through which the case settling could be speedier. Conjointly the advances and modern ways encourage culprits in accomplishing their wrongdoings. As indicated by Crime Records Bureau wrongdoings like lawful offense, incendiarism and so on are wilted though violations like homicide, sex misuse, assault and so on are amplified.

Regardless of whether we are not ready to realize who are the exploited people we can in any case anticipate the spot that crime may occur.The anticipated results can not be guaranteed of 100% exactness anyway the outcomes shows that our application causes in lessening rate to a specific degree by giving security in wrongdoing delicate regions.

There should be an ideal crime analysis tool that should be able to identify crime patterns quickly and in an efficient manner for future crime pattern detection and action. However, currently, there are a number of major challenges that are encountered. Increase in the size of crime information that has to be stored and analyzed, Problem of identifying techniques that can accurately and efficiently analyze this growing volumes of crime data, Different methods and structures used for recording crime data, The data available is inconsistent and are incomplete thus making the task of formal analysis a far more difficult. Investigation of the crime takes longer due to the complexity of such issues.

Therefore, there is a need for building a system that can if not overcome, limit the challenges that are faced by the existing systems. The main features it should contain should be identifying crime patterns and analysing them, determining crime prone regions of a specific location, providing information to formulate strategies for crime prevention and reduction. So, for building such an amazing crime examination instrument we've to assemble crime records and judge it. Finding the examples and patterns in wrongdoing is a troublesome issue. To detect an example, crime experts take a lot of your time, looking over data to see whether a particular crime fits into a superior known example. In the event that it doesn't work into a partner degree existing example, at that point the data ought to be named another example. When an analyst works as an example, it will be utilized to foresee, envision and stop crime.

The purpose of this is to make crime gauge using the features present in the dataset. The dataset is

expelled from the official regions. With the help of AI computation, using python as focus we can envision the kind of crime which will occur in a particular territory. The target is to prepare a model for desires. Building the model will be finished using better count depending on the precision. The Naive Bayes course of action and other computation will be used for wrongdoing desires. Impression of dataset is done to separate the infringement which may have occurred in the country. This work helps the law prerequisite workplaces to predict and recognize infringement in the district with improved exactness and thus diminishes the crime rate.

II. BACKGROUND

The job of PCs has been expanded in varying backgrounds from the fund division to general stores. As of late police powers have been improving their customary technique for wrongdoing revealing with new innovative progressions to expand their yield by productively recording violations to help their examination. Information isn't only a record of wrongdoings, it additionally contains significant data that could be utilized to interface wrongdoing scenes dependent on the business as usual of the offender(s), recommend which guilty parties might be liable for the wrongdoing and furthermore distinguish those guilty parties who work in groups (wrongdoer systems) and so forth. In this day and age, computers are assuming a significant job in the examination of a wide range of crime from those that are considered as volume wrongdoing (thievery, vehicle related crimes and so on.) to significant wrongdoing, for example, extortion, tranquilize dealing, murder etc.It isn't a simple errand for a Police expert to physically unwind the inalienable complexities inside police information and this issue is exacerbated when the investigation is attempted by a group. The appropriation of the information to the group may cause huge data, which could be valuable to tackle the violations, to be missed as every part isn't in control of every single pertinent truth. For quite a while, criminologists and analysts have been applying their aptitudes and information attempting to anticipate when and where the following arrangement of wrongdoings will happen, with changing degrees of achievement. The crime rate and the more prominent familiarity with present day crooks put a strain on the current techniques. Human thinking bombs when given a great many records. In this manner, there is obviously a necessity for a toolbox to help with breaking down the information which will utilize constrained assets. Information Discovery in Databases (KDD) procedures can be utilized to uncover information which is past instinct.

III. LITERATURE REVIEW

Crimes are a significant threat to humankind. There are many crimes that happen regularly. Perhaps it is increasing and spreading at a fast and vast rate. Crimes happen from small villages, town to big cities. Crimes are of different type robbery, murder, rape, assault, battery, false imprisonment, kidnapping, homicide. Since crimes are increasingly there is a need to solve the cases in a much faster way. The crime activities have been increased at a faster rate and it is the responsibility of police department to control and reduce the crime activities. Crime prediction and criminal identification are the major problems to the police department as there is a tremendous amount of crime data that exist. There is a need for technology through which case solving could be faster. The aim is to make crime prediction using the features present in the dataset. The dataset is extracted from the official sites. With the help of machine learning algorithms, using python as core we can predict the type of crime which will occur in a particular area. Developing a crime analysis tool using different data mining techniques can help law enforcement department to efficiently handle crime investigation. The proposed tool enables agencies to easily and economically clean, characterize and analyze crime data to identify actionable patterns and trends. The criminal forecast turns out to be significantly more confused when the criminal-related information, for example, criminal profile and criminal interpersonal organization, and the geographic information than can be any information related with the date and area where the incident occurrence, are considered.
episodes, for example, geographic profile, are considered.
[1]. Various criminal activities can show the criminal's characteristics and his/her intentions to a great extent. Hence, analysing the crime and predicting it based on the characteristics of the criminal activity is of paramount importance. Therefore, analysing the criminal's behaviour has been proven to play a significant role in criminal behavior analysis [6]. This research work suggests that linear regression algorithm is the most effective Machine learning algorithm to analyze crime patterns and can work with randomness to an extent as opposed to decision stump algorithms which have a relatively poor performance which only discusses algorithms to analyse crime patterns [5].

IV. OBJECTIVE

As we realize that the quantity of bodies of evidence recorded against various violations have expanded in the previous 3-5 years.There is a need to examine the quantity of wrongdoings carried out, the sort of wrongdoing perpetrated, recognize the locales where there is the most extreme crime rates. There is a need to build up a framework that can anticipate districts which have high likelihood for criminal events and can imagine crime inclined zones. With the expanding appearance of automated frameworks, crime information examiners can help the Law requirement officials to accelerate the way toward understanding violations and can likewise encourage overwhelming watching in those districts as to anticipate wrongdoings.

We can apply distinctive measurable examination calculations to the info datasets i.e, the quantity of crime rates in a specific interim of time, the districts where most extreme crime rates have been recorded and different variables can be considered to foresee

future crimes.Therefore, important advances can be taken to forestall the crimes specifically region.Thus, the goal is to train a model for forecast. The preparation would be finished,utilizing the preparation informational index which will be approved utilizing the test dataset. Building the model will be done

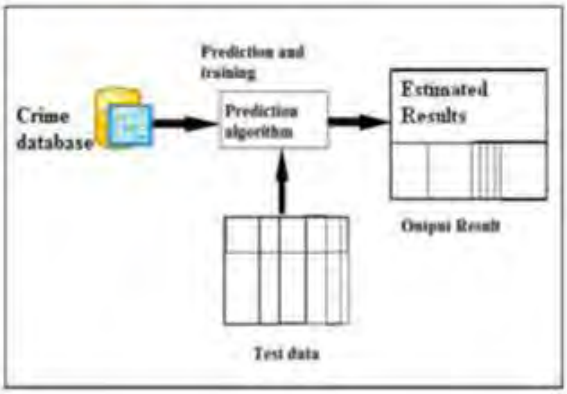

Fig.1 Proposed Architecture

utilizing better calculation relying on the exactness. Representation of dataset is done to break down the wrongdoings which may have happened in the nation.Generated model can be used in many ways and can be integrated with multiple applications like in intelligent investigative systems, crime analysis systems etc or can be used as an independent system. It has a wide range of applications. Resources and funding provided by respective stakeholders can be used in scaling the computing power i.e. renting or purchasing the GPUs, which will help us to develop a better model.

V. METHODOLOGY

Utilizing Machine Learning Technology, different calculations can be utilized to :- 1. Examine criminal patterns, Predict future spots for criminal activity. 2. Determine the perilous time frames of different regions.3. Predict the sort of violations that could occur in various locales dependent on notable information and patterns.4. Come up with measures to counteract those violations.

Python library Scikit-learn (sklearn) is used for preprocessing the dataset. Some attributes in the csv files contain string values and others are numeric values. In order to use this dataset in machine learning models, the text features need to be converted into a numeric value. Python library numpy is used to contain both features and label of the dataset after converting them into numeric values. Attributes with string data type are “Day”, “Category”, “Address” columns. Scikit-learn has a preprocessing package that converts string data into numeric data. This package gives an integer value to each unique item after sorting items in ascending alphabetical order. Datetime attribute is also a string data type, however this is converted into a datetime object and four different attributes are obtained from it: “Hour”,”Date”,”Month” and “Year”.

To avoid overfitting and getting more realistic accuracy, the dataset is divided into two portions: testing dataset and training dataset. Training dataset contains all features along with the target label. Testing dataset only contains the features from which a machine learning model predicts the target label. Scikit-learn’s model_selection package contains a class test_train_split that splits the original dataset into testing and training dataset. The default value of the test dataset size is 25% of the original dataset. This default value is used in the conducted experiments.

While the given features give sufficient information about a crime incident, new features can be extracted from the given features which might prove to be useful.

One assumption is made before using any predictive model is, some features might be more useful than others. While more features describe the data better, too many features can make classification complicated and cause overfitting. sklearn.feature_selection module uses univariate statistical tests to find features that are best related to the target label. select_percentile class of this module takes a percentage input and returns that percentage of best features. For classification problems f_classif function of this class is used. Different percentages of features are used in different models to see using how many features gives better performance. Supervised classification models are applied on the Dataset to predict the category of a crime incident.

V. THE PROPOSED MODEL

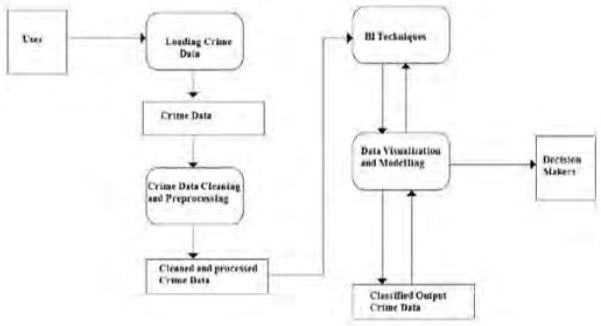

Fig.2 Flow of the process

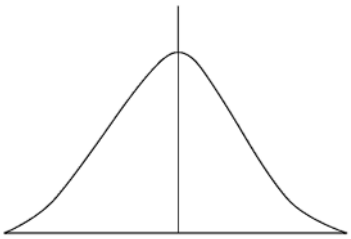
The first step is to upload the dataset and then pre-process and then clean the data so that it is ready for the analysis. Noisy data will adversely have an effect on the results of any data mining analysis therefore it's of essence to clean up the data.The data flow diagram illustrates how data flows from process to process.The performance of different classification models is calculated and the best one is then selected.

1. Decision Tree: Sklearn.tree module provides DecisionTreeClassifier class. Among many parameters of this class, two parameters are useful in this case: min_samples_split indicates the number of splits to make at each step of building a decision tree and criterion indicates the function to measure the quality of split. As discussed above, there are two types of function to measure quality of split: information gain and impurity. In this class information gain is indicated with entropy and impurity is indicated with gini.

2. Gaussian Naive Bayes: In Gaussian Naive Bayes, continuous values associated with each feature are assumed to be distributed according to a Gaussian



distribution. A Gaussian distribution is also called Normal distribution. When plotted, it gives a bell shaped curve which is symmetric about the mean of the feature values as shown below:

Fig.3 Gaussian Naive Bayes Graph

The likelihood of the features is assumed to be Gaussian, hence, conditional probability is given by:

$$P(x_i|y) = \frac{1}{\sqrt{2\pi\sigma_y^2}} exp\left(-\frac{(x_i-\mu_y)^2}{2\sigma_y^2}\right)$$

Sklearn.naive_bayes provides GaussianNB class.

3. KNearestNeighbors: The *k*-nearest neighbors algorithm (*k*-NN) is a non-parametric method used for classification and regression. In both cases, the input consists of the *k* closest training examples in the feature space. The output depends on whether *k*-NN is used for classification or regression: In *k-NN classification*, the output is a class membership. In *k-NN regression*, the output is the property value for the object. *k*-NN is a type of instance-based learning, or lazy learning, where the function is only approximated locally and all computation is deferred until classification. Both for classification and regression, a useful technique can be to assign weights to the contributions of the neighbors, so that the nearer neighbors contribute more to the average than the more distant ones. A peculiarity of the *k*-NN algorithm is that it is sensitive to the local structure of the data. KNearestNeighbors class in sklearn.neighbors module provides supervised nearest neighbors classification models using k nearest neighbors. Among different parameters of the class, n_neighbors indicates the value of k, metric indicates the metric used to measure the distance of neighbors. An equivalent of Euclidean distance is used as default.

4. Logistic Regression Classifier: Logistic regression measures the relationship between the categorical dependent variable and one or more independent variables by estimating probabilities using a logistic function, which is the cumulative distribution function of logistic distribution. Thus, it treats the same set of problems as probit regression using similar techniques, with the latter using a cumulative normal distribution curve instead. Equivalently, in the latent variable interpretations of these two methods, the first assumes a standard logistic distribution of errors and the second a standard normal distribution of errors. Logistic regression can be seen as a special case of the generalized linear model and thus analogous to linear regression. sklearn.linear _model.LogisticRegression class is used for this model. The parameter multi_class is set to ovr which provides one vs the rest scheme,as a multi class model is needed. Class_weight parameter makes classes balanced in case of imbalanced classes.

5. Random Forest: Parameters of RandomForestClassifier class that are used are: n_estimator, min_samples_split, criterion, where min_samples_split and criterion are the parameters of decision tree of the random forest. N_estimator indicates the number of trees to build. There are a lot of benefits to using Random Forest, but one of the main advantages is that it reduces the risk of overfitting and the required training time. Additionally, it offers a high level of accuracy. Random Forest runs efficiently in large databases and produces highly accurate predictions by estimating missing data.

Our methodology consists of steps, data collection, data pre-processing, classification model building using training data and model evaluation using test data. It then uses a trained and tested model to score incoming data.

Finding crime patterns can be a very difficult task as we have to scan through a large amount of data, look for a pattern and then find if a particular crime fits the pattern. This process is very time consuming. If it doesn't fit, then the information should be classified as a new pattern.These reasonable results are going to be obtained once underneath going varied processes that return under machine learning.The first step would be to appear for an applicable information set for the system supported that the algorithms can offer India the output. These information sets are going to be correct data sets that are extracted from actual crimes that have taken place everywhere on the planet. A number of this information is going to be utilized in the coaching set and also the remaining will be used in the take a look at set.After this, we do the preprocessing of data. Here we can delete unwanted rows and convert improper information. For example we convert infinity to a numerical value or string into numerical.

The dataset that is considered for this project has been obtained from the official portal of the government of India. It consists of crime data related to all the states of India and also their respective districts. The collected data ranges across several years since having a good amount of historic data would help train the machine learning model to predict future crimes. There are several parameters in the data set like the name of the state, district, year, different types of crimes (Murder, Rape, Theft etc), total count. The dataset can be cleaned and processed as per the requirements of the project.

Fig.4 Crime Dataset of India

After this,we represent the information with the help of a diagram called a heat map. Dark colors are used to show more activity of crime and light shades are used to show less occurrence of crime.The figures explains how it happens. After seeing where the most crime is occuring, proper preventive measures can be taken into account. Increasing the police patrolling, installing more cameras and installing burglar alarms help notifying the authorities faster and help in preventing crimes.Dangerous time periods of various locations can also be highlighted based on the result obtained.

Fig.5 Graphical Visualization of Crime prone regions

Fig. 5 shows the regions that have a high probability for crime occurrence. The advantages of using heat maps over other representational mechanisms are:

- Numeric and category based color images.
- Gradient color range.
- Analyze only the data we want.
- Out of range data is automatically discarded.

So by knowing about the probable regions we can prevent crimes by taking preventive mechanisms like night patrolling, fixing burglar alarms, fixing CCTV cameras etc.

VI. CONCLUSION

One of the biggest problems that all law-enforcement and intelligence- gathering organizations are facing is accurately and efficiently analyzing the growing volumes of crime data. With the advancement of technology, sophisticated data mining and artificial intelligence tools are becoming easily available to the law enforcement community. These techniques can help process thousands of instructions in seconds, saving precious time. In addition, installing and running software often costs less than hiring and training personnel. Computers are also less prone to errors than human investigators, especially those who work long hours.

The main focus through this research work is to develop a tool that uses different data mining techniques to help law enforcement officers carry out their task with maximum efficiency, accuracy and speed. The proposed tool will clean the data set, identify crime patterns and analyse it along with classifying it into various suitable class labels with minimal expenditure. With the assistance of AI innovation, it has gotten simple to discover the connection and examples among different information. The work in this venture essentially rotates around foreseeing the kind of wrongdoing which may occur and the area of where it has happened. Utilizing the idea of AI we will fabricate a model utilizing training dataset that will experience information cleaning and information change.

The information will be pictured utilizing diagrams like bar, pie, line and dissipate charts and so on, each having its own attributes. Diagrams will help in understanding violations datasets that can help in catching the components that can help in protecting society. In this project, using Machine Learning Technology, various algorithms will be used to :-

A) Breaking down crime patterns
B) Foresee future spots for crimes
C) Determine dangerous time periods of various regions
D) Predict the type of crimes that could happen in different regions based on historic data and patterns
E) Decide techniques to prevent those crimes.

Different data sets that have been extricated from genuine cases can be utilized to prepare the framework. The informational indexes can be isolated into preparing sets and testing sets.
The testing informational collections will be utilized to test the comprehension of the machine and the exactness of the calculations to do the counteractive action, examination and expectation of crimes.
For this research, only crime data has been used, but as many researches have shown that a particular area's socio-economic standard is also a key indicator of possible criminal activity. This machine learning agent could incorporate that data and might perform better.

This model can be also used for other geographic locations. This would also help to analyze crimes occurring in different locations and build a better understanding of different crimes and its relation with particular demography. Also, there are many advanced machine learning approaches that can be explored.
Deep Learning & Neural Networks can provide a more balanced understanding of criminal activities. As it has been seen on this research, imbalanced classes has been a major issue in dealing with the particular database. Advanced techniques to deal with imbalanced classes are also something that remains to be explored.

Smart Bag

Rishabh Chorasiya, Bobby Kalal
Thakur College of Engineering and Technology, Mumbai, India
rishabh.chaurasiya1@gmail.com, bobbykalal07@gmail.com

Abstract— **Smart Bag uses Internet of Things and provides solution to numerous things which includes giving an alert about the items left outside the luggage, allowing it to track its location if it goes missing. The concept of smart luggage was implemented to give the passengers to stop worrying about their luggage and rather enjoy their journey. It consists of various features such as remembering the belongings in the bag, tracking the location of the bag. These operations are carried out using mobile application.**

Keywords—Raspberry Pi, GPS, GSM, RFID Reader.

I. INTRODUCTION

Travelling has always been an important aspect of our lives. We travel to meet new people, have new and exciting experiences and explore the beautiful places that exist in this world. And to travel, everyone needs their stuff, i.e. their luggage, with them. But, in India, one of the biggest problems while travelling remains the theft of our luggage/bag. This has been a problem since long. Hence there is a need to keep our dear ones and our belongings safe. But no matter how much we try and no matter how many locks we put on our luggage, what would happen if this luggage gets lost or robbed in the middle of your journey? It would be a menace because it would contain all your important things or sometimes documents. Hence, to provide a solution to this problem would include introducing the concept of smart bags thereby providing a better security. It is one of the alternative solutions where instead of looking after your baggage every now and then, where the passengers follow the bag, the bag follows them. Also, if the bag is stolen, the passenger can always get its location with the GPS tracker in it. We have also tried to add some more features for better over-all user experience, such as time-table reminder, finger-print lock for better security, and some more features that will be useful in the future.

II. BACKGROUND

The Smart Bag using IOT provides solution to numerous things which include right from giving an alert about the items if left outside the luggage to allowing it to track its location if in case went missing with the help of the RFID Tags and Reader. The concept of smart luggage was implemented to give the passengers a relief from worrying about their luggage but to worry about their journey. It is used in tracking the location of itself in case if it went missing or if forgotten somewhere which would include the concept of GPS. Also, in case if their luggage got taken away by someone it provides us a facility for the locking of the bag immediately if required. This concept was further thought of narrowing to small bags of schools which would include the basic feature of just tracking the location for the children if required.

III. OBJECTIVE

The objective of this project is to provide security of the luggage inside the bag. The bag must be able to track and also provide alerts of the bag in real-time, if the bag is stolen or misplaced or forgotten by the owner. It should provide power backup for mobile devices and laptops for emergencies. It should also alert the owner if any book is missing from the scheduled time-table. Also, it should provide security to school-going children with security features, such as a panic button, which, when pressed, will send an alert to their parents.

IV. PROBLEM DEFINITION

The main objective of this project is to provide security and tracking of the luggage bag as well as the belongings of the bag owner through IoT. Also, it should provide power backup for mobiles and laptops. It should provide security to school-going children with security feature and alert their parents through message. The phases in which a part of problem will be solved is provided below:

- **Planning:** The project planning was done based on the need for the smart bag in the real world thereby giving importance to overcoming the drawbacks of it. This concept was selected by taking into consideration the actual need for it in daily travelling. The various features like location tracking, monitoring forgotten items, automatic lock and other features were planned and documented.
- **Analysis:** The analysis of the bag was done based on comparison with the features of other bags, which included the tracking of the location of the bag. By connecting the bag with the application enabled the users to automatically lock their bags just by providing them a minimum location. This location helped the user to realize that where is their bag and is the location of the bag moved ahead or the coordinates of the location changed which indicated the bag being taken somewhere. Also, analyzing helps understand various issues.
- **Design:** Construction of the bag according to the required specification is done in this phase. The bag is

made up of different hardware support. Also, there is a complete software support for the working of the bag. The hardware is connected to and used by the

software thereby making it easy to handle and use. The designing of the entire application and the required hardware setup is done in this phase. The block diagram for the hardware set up is done in this phase. The construction of the diagram helped in determining the placement of the components in the bag without affecting the overall usage of the bag. The application interface and the requirement specification along with the feature for the alert is designed in this phase.

- **Coding:** Writing the whole system app code and taking help of open source. The entire code for the application would be written in this phase and would be tested. Application development is can be done via different platforms available. The application thus developed should be user friendly and easy to use. The complete guidelines for its usage can be displayed at the beginning so as ease the customer for further usage. The whole hardware is connected to the bag which included of GPS, lock, the weighing component and other. An application was later built which would help in connecting to this hardware. The control of the hardware was given to this application. The application entire code was written using the basic languages. The hardware of the bag was setup as such not to increase the weight of the bag so as make it heavy. Also, the application was made user friendly as so the user was able to access it with ease.
- **Implementation:** Give the user for alpha testing and gathering centric analysis of performance, feedback and try to improve the quality of the result/output. In this phase the testing would be done for checking the hardware and the software support. Also feedback would be taken from customers and improvements would be made further if required. The testing of the bag was done which included checking and weighing the items of the bag and verifying whether it gave the desired results or not. The location tracking with automatic lock was tested by taking the bag to different locations and verifying whether the application was able to give an alert or not. The feedback from various customers was taken to improve the graphical user interface of the application.

V. ANALYSIS

The smart bag will help the owner be carefree of their luggage and focus on the journey and their work. It will also help the students to keep in check with their books and study better. Also, as they will only carry the required books, the burden on their shoulders will be less. Children and women security is a very critical feature in current date and time. It will also help the police authorities track the bag more efficiently and quickly, thereby, reducing their time and energy on such cases.

VI. PROPOSED SYSTEM

The proposed system uses the technique of Internet of Things in order to track the bags. In this, hardware would be created and installed which would be having the basic arduino board with a GPS module and an alarm being connected to it. A map has been created which would be synchronized in order to track the location of the bag. Furthermore, the map has the features that as soon as the bag gets lost or theft and it moves away from the owner and goes out of a particular range, the alarm would start ringing so that the owner gets notified where exactly the bag is. Also it would help the owner to track down the location of the bag which could be seen on the map as the markers would be dropped which gives us the location of the bag as it moves away from the owner.

VII. METHODOLOGY

The methodology that we chose for our project is Agile. While waterfall model is a tried and tested framework, it is not suitable for our project, due to the changeable nature and small team size. Agile allows us to be flexible, manage changing requirements, manage the ever-increasing scope as well as get consumer perspective. Agile has focus on customer satisfaction, which is a crucial aspect of any healthcare application. Patients need to be clued in to the process for the indispensable inputs they can provide.

Agile Methodology

Agile methodology mainly focuses on the incremental and the iterative development of the different project phases. It controls and determines how the various stages are implemented and what kind of environment is involved. The project is first divided into different phases, and then the responsibility of developing these phases is given in the hands of the various developers. At every stage of the project development it is continuously monitored and taken care of. These developers developing the phases have particular amount of time period and tasks involved with them. To remain in sync with the other members of the team they have to complete their task within the stipulated amount of time. Agile is considered to be a methodology that is ready to accept and work on any change that occurs during any phase of the project which can be from any side of the project. It is flexible methodology that welcomes change during any stage of the project. After the development phase each task or each developed phase is tested in different environment. This helps the team members to determine what would be the next phase of the project. Every iteration of the project involves a testing phase. It requires close communication with the project master along with team members and the product owner for the development of the project.

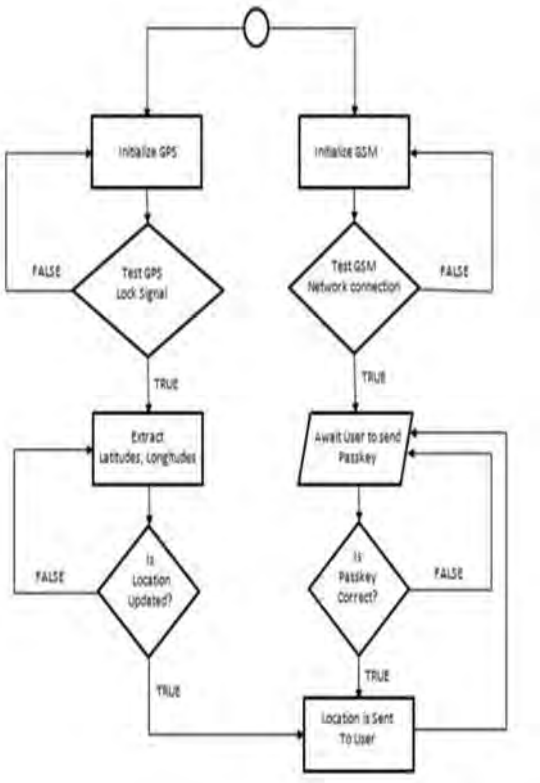

Fig 1: Methodology Flowchart of GPS of Smart Bag

VIII. FEASIBILITY STUDY

1. Executive Summary

Project is related to Smart Bags.

The project maintains two levels of users: -

- Administrator Level-Owner
- User Level-Data Entry Operator
- Main facilities available in this project are: -
- Maintaining the daily time-table.
- Providing GPS location tracking.
- Reminding customers of the luggage.
- Providing the weight capacity of the bag.
- User can set a reminder for his/her different requirements.

2. Define business problem or opportunity

The Software is for the automation of Smart Bags. It maintains one level of user:-

- User Level

The Software includes:-

- Maintaining customer details.
- Providing and maintaining all kinds of storage facilities for a customer.
- Reminding and giving an alert to the user as per requirements.

3. Requirements and purpose of the study

- Hardware Requirements
  - Raspberry pi
  - Bag
- Software Requirements
- Android Studio
- **Purpose**
- Delightful Bags provide following facilities like:-
- Taking orders from the customer.
- Delivering ordered meal timely
- Bill computation
- Record maintenance.

4. Description of the options assessed

Based on research conducted over the Internet we identified the following alternatives for the MMS:

- Continue to use the current system.
- Utilize a packaged solution. The bag providers who require this software can purchase the product and host them in their own environment. Less amount of programming and re- programming is required for customizing the system and implementing them.
- Develop a customized bag solution which meets all requirements satisfactorily and is also built with a scalable scope.

5. Assumptions used in the study

Every user should be:

- Comfortable bag usage.
- He/she must have proper internet connection.
- He/she must also have basic knowledge of English too.

6. Audience impacted

It can be used in anywhere as far the internet services are provided.

7. Financial obligation

The financial and the economic questions during the preliminary investigation are Verified to estimate the following:

- The cost to conduct a full system investigation.
- The cost of hardware and software for the class of application being considered.
- The benefits in the form of reduced cost.

The proposed system will initially give the minute information, as a result the performance is improved which in turn may be expected to provide increased profits.

IX. HARDWARE DESCRIPTION

The various components required for the development of the project Smart Bag using IOT along with their estimated budget is as shown below:

o RASPBERRY PI 4

o GPS module Ublox NEO 6mM GPS module

o SD card 64 GB Sandisk Ultra memory card

o Universal card Reader phone-PC smart card reader

o Bread Board 840 points solder less

o Female to Female Jumper wires

o Male to Male Jumper wires

o Berry GPS-GSM

o Passive RFID Tags and Reader

o Arduino Mega 2560 R3

o GSM module for SMS service

o Finger Print Scanner Module (R305)/ Fingerprint Scanner GT(511C1R)

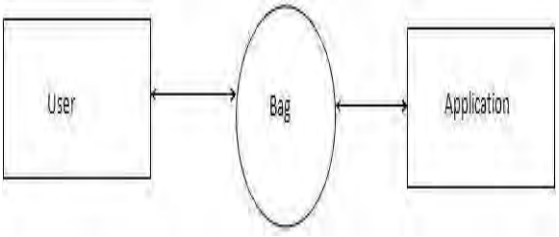
o Buzzer and Panic Button

o Douself Sola magnetic lock.

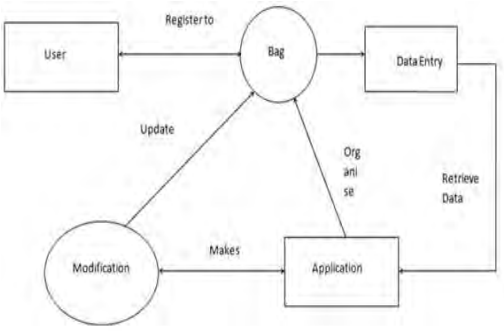
X. DESIGN AND IMPLEMENTATION

1. Data Flow Diagram (DFD)

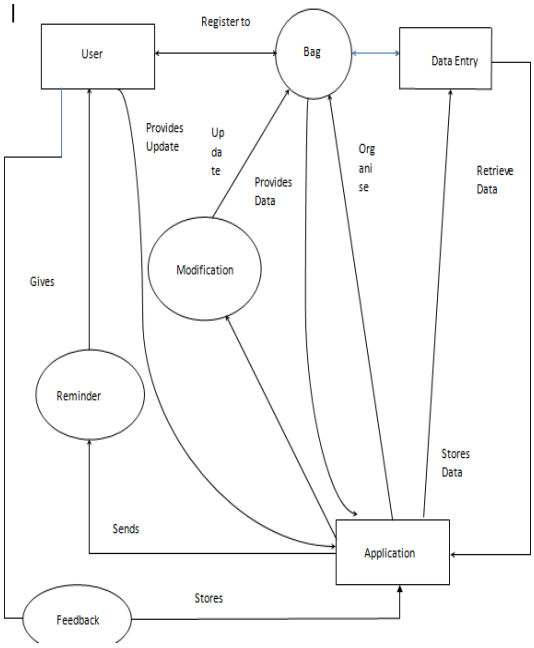
DFD level 0:



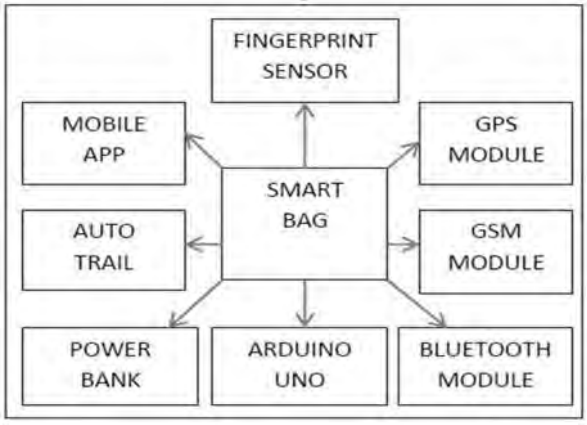
DFD level 1:

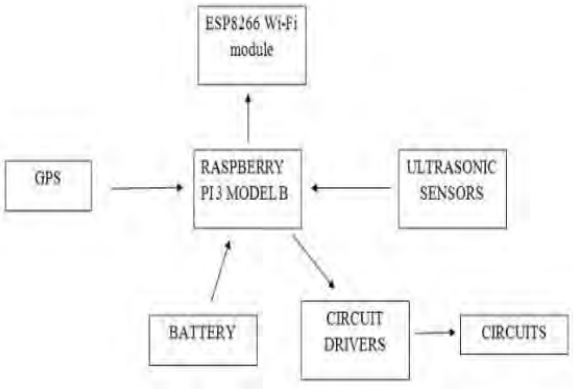


DFD level 2:



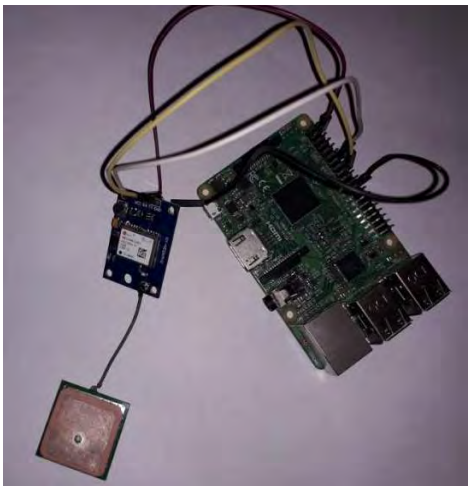
2. Block Diagrams





Implementation

This project idea shows the implementation of tracking the bags which are either lost or stolen using IoT. Certain procedures and techniques have been made and proposed in order to achieve the same. Experimentation has been done and maps have been created in order to track the location of the bags which are misplaced and lost. Experiment results further concludes that the bags can be easily tracked based upon the hardware installed in them and then by tracking that hardware and tracking the route, directions and location of the bag with the help of a map.



XI. RESULT

This smart bag consist of inbuilt circuit which provide location tracking and baggage remembering system to individual at cheapest cost. Additional feature has been added to facilitate Students not to miss textbook as per college/school time tables concept of Google Home mini and list of baggage (for backup) has been used to make sure all books are carried in the bag if any missing book from the time table will be notified.

XII. CONCLUSION

The progress in science & technology is a non-stop process. New things and new technology are being invented. As the technology grows day by day, we can imagine about the future in which thing we may occupy every place. The proposed system based on microcontroller is found to be more compact, user friendly and less complex, which can readily be used in order to perform several tedious and repetitive tasks. Though it is designed keeping in mind about the need for school kids, it can extended for other purposes such as commercial & research applications. Due to the probability of high technology (Android) used this system is well software controlled. The feature makes this system is the base for future systems.

Smart bag is an application-specific design that can be useful for almost everyone in the society. Smart means intelligent, the bag will be intelligent enough to carry out various features for everyday use .

XIII. FUTURE SCOPE

In future, we are planning to include some interesting features like automatic object avoidance, stair case climbing and some extra woman safety features. These extra features make the bag more powerful and user friendly. In future we can use this idea of smart bag to packing system in factories, shops, super markets etc.

Image Captioning Using Deep Learning

Rohan Arora, Meghanshu Bhatt, Akhil Daphara, Shridhar Kamble
Department of Information Technology,
Thakur College of Engineering and Technology, Mumbai,
rohanarora3434@gmail.com, meghanshubhatt@gmail.com, akhildaphara@gmail.com, shridhar.kamble@thakureducation.org

Abstract—**Image captioning, which aims to automatically generate a sentence description for an image, has attracted much research attention in cognitive computing. The task is rather challenging, since it requires cognitively combining the techniques from both computer vision and natural language processing domains. Existing CNN-RNN framework-based methods suffer from two main problems: in the training phase, all the words of captions are treated equally without considering the importance of different words; in the caption generation phase, the semantic objects or scenes might be misrecognized. In our work, we propose a method based on the encoder-decoder framework, named Reference based Long Short Term Memory (R-LSTM), aiming to lead the model to generate a more descriptive sentence for the given image by introducing reference information. Specifically, we assign different weights to the words according to the correlation between words and images during the training phase. We additionally maximize the consensus score between the captions generated by the captioning model and the reference information from the neighboring images of the target image, which can reduce the misrecognition problem. We have planned to conducted extensive experiments and comparisons on the benchmark datasets MS COCO and Flickr30k. By this approach we have try to outperform the state-of-the-art approaches on all metrics. We come to a conclusion that through the introduction of reference information, our model will learn the key information of images and generate more trivial and relevant words for images.**

I. INTRODUCTION

Benefiting from the significant advances of large-scale labelled datasets, such as ImageNet and deep learning, especially deep convolutional neural networks (CNN); the problems of image classification and object recognition have been studied thoroughly. As a result, computers even outperform humans at these tasks. Recently, automatically generating a sentence description for an image, has attracted much research attention in artificial intelligence. This problem, known as image captioning, plays an important role in computer vision, i.e., enabling computers to understand images, which can be exploited in wide applications, such as video tracking, cross-view retrieval, sentiment analysis, childhood education, and visual impairment rehabilitation. However, image captioning is a challenging task due to the coverage of both computer vision and natural language processing technologies. Apart from the need for identifying the objects contained in an image, the generator should also be able to analyze their states, understand the relationship among them, and express the semantic information in natural language. The early efforts on image captioning mainly adopt the template-based methods, which require recognizing the various elements, such as objects as well as their attributes and relationships in the first phase. These elements are then organized into sentences based on either templates or pre-defined language models, which normally end up with rigid and limited descriptions. As a typical transfer-based method, nearest neighbor (NN) is employed to retrieve a description from the corpus for a given image. Although this method cannot generate any novel sentence, it suggests that NN can indeed provide valuable information. Inspired by recent advances in machine translation, neural network-based methods have been widely applied in image captioning tasks and achieved great success. These methods are primarily based on the encoder-decoder pipeline, consisting of two basic steps. First, visual features are extracted using CNN to encode the image into a fixed length embedding vector. Second, recurrent neural network (RNN), especially long

short-term memory (LSTM) is adopted as the decoder to generate the sentence description by maximizing the likelihood of a sentence given the visual features. Thanks to the feature representation capability of CNN and the temporal modelling of RNN, the neural network- based methods are more flexible, which can generate new sentences coherently. On the other hand, motivated by the attention mechanisms, which have been proven to be effective in visual scene analysis, different attention mechanisms are proposed for image captioning, such as region-based attention, visual attention, semantic attention, global-local attention, and spatial and channel-wise attention.

A. Abbreviations and Acronyms

CNN: In neural networks, Convolutional neural network (ConvNets or CNNs) is one of the main categories to do images recognition, images classifications. Objects detections, recognition faces etc., are some of the areas where CNNs are widely used.

LSTM: The LSTM (Long Short-Term Memory) layer is nothing but a specialized Recurrent Neural Network to process the sequence input (partial captions in our case).

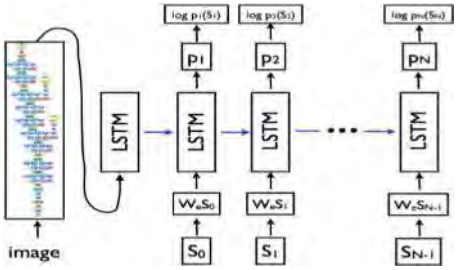
GRU: A gated recurrent unit (**GRU**) is part of a specific model of recurrent neural network that intends to use connections through a sequence of nodes to perform **machine learning** tasks associated with memory and clustering, for instance, in speech recognition.

II. Background

Generally, the existing image captioning algorithms can be divided into three categories based on the way of sentence generation: template-based methods, transfer-based methods, and neural network-based methods. The template-based methods either use templates or design a language model, which fill in slots of a template based on co-occurrence relations gained from the corpus, conditional random field, or web-scale n-gram data. The transfer-based methods are based on the retrieval approaches, which directly transfer the descriptions of the retrieved images to the query image. Some approaches took the input image as a query and selected a description in a joint image-sentence embedding space. The neural network-based methods come from the recent advantages in machine translation, with the use of RNN. A multimodal layer to connect a deep CNN for images and a deep RNN for sentences, allowing the model to generate the next word given the input word and the image. Inspired by the encoder-decoder model in machine translation, used a deep CNN to encode the image instead of a RNN for sentences, and then used LSTM, a more powerful RNN, to decode the image vector to a sentence. Many works follow this idea, and apply attention mechanisms in the encoder. With each feature representing a fixed-size region of the image, the model can learn to change the focusing locations. Employing a pre-trained CNN for object detection to analyse the hierarchically segmented image, and then ran attention-based decoder on these visual elements. Combining the whole image feature with the words obtained from the image by attribute detectors can also drive the attention model. Proposed a global-local attention mechanism by integrating local representation at object-level with global representation at image level. More recently, reinforcement learning has been integrated in the encoder-decoder framework. To address the deficiencies of exposure bias and a loss, which does not operate at the sequence level in traditional encoder-decoder frameworks, a novel sequence level training algorithm, named Mixed Incremental Cross Entropy Reinforce (MIXER), that directly optimizes the metric used at test time.

$$R = \arg\max_{R'} \mathcal{O}(R'|J;\theta^*), \quad (2)$$

III. IMPLEMENTATION DETAILS



Our goal is to generate a description sentence for an image. Suppose we have N training images I1, I2, ⋯ , IN , which also denote related visual features. For image In (n = 1, 2, ⋯, N), we have Mn correct description sentences Sn1, Sn2, ⋯, SnMn

Our task aims to maximize the likelihood of the correct descriptions given the training images by the following:

$$\theta^* = \arg\max_{\theta} \sum_{n=1}^{N} \sum_{m=1}^{M_n} \mathcal{L}(S_{\mathrm{nm}} | I_n; \theta), \qquad (1)$$

where θ are the parameters of our model and L() is a pre- defined likelihood function. In the next section, we will firstly describe the conventional likelihood function for image captioning used in previous works, and then we will introduce the proposed likelihood objective function.

After training, we can generate a sentence for a test image J by the following:

where O() is a pre-defined objective function. This objective function aims to generate the best sentence for the given image J.

Our model will have three main parts: a convolutional neural network (CNN) that extracts features from images, an attention mechanism that weights the image features, and an RNN that generates captions to describe the weighted image features. In the following sections, we will describe each in turn.

A convolutional neural network is a standard feed forward neural network, except that instead of computing the affine function f(x) = Ax + b, we restrict A to be a Toeplitz matrix. This is the same as saying that A is a convolution. This basic idea generalizes to images, where we have a 2D convolution over each of the K color channels. In the context of neural networks, we often follow these affine convolutional layers with a nonlinearity. In fact, f is an affine operator on x, and nonlinear itself. The most commonly used nonlinearity is the rectified linear unit (ReLU), which is nothing more than the hinge loss. While CNNs are adept at signal processing, they cannot easily express the idea of patterns in sequences.

Recurrent neural networks (RNNs) are similar to feedforward neural networks, except their outputs are fed back into the input. The networks maintain a hidden state that allows them to adjust their behavior throughout iterations of this feedback loop. RNNs are considered state of the art in machine translation and other tasks involving generating text, as they easily learn the patterns of human grammar. In this work, we leverage a powerful variant on the RNN idea called a Long ShortTerm Memory (LSTM) unit.

IV. RESULT

To understand how good the model is, let's try to generate captions on images from the test dataset (i.e. the images which the model did not see during the training)

No model in the world is ever perfect and this model also makes mistakes. Let's look at the example where the captions are not very relevant and sometimes even irrelevant.

As you can see the outputs, our model is not perfect but our objective is to further improve our model in future sprints by utilizing various deep learning techniques and to achieve the state of art.

A model can make lots of mistakes like wrongly identifying/classifying the object/entity/person, grammatical mistakes and not understanding the scenario of the given image. We must understand that the images used for testing must be semantically related to those used for training the model. For example, if we train our model on the images of cats, dogs, etc. we must not test it on images of airplanes, waterfalls, etc. This is an example where the distribution of the train and test sets will be very different and in such cases no Machine Learning model in the world will give good performance.

V. Future Scope

Of course, this is just a first-cut solution and a lot of modifications can be made to improve this solution like:

•Using a larger dataset.

•Changing the model architecture, e.g. include an attention module.

•Doing more hyper parameter tuning (learning rate, batch size, number of layers, number of units, dropout rate, batch normalization etc.).

•Use the cross validation set to understand overfitting.

•Using Beam Search instead of Greedy Search during Inference.

•Using BLEU Score to evaluate and measure the performance of the model.

•Writing the code in a proper object-oriented way so that it becomes easier for others to replicate.

VI. VI. CONCLUSION

We introduced a model that generates natural language descriptions of image regions based on weak labels in form of a dataset of images and sentences, and with very few hardcoded assumptions. Our approach features a novel ranking model that aligned parts of visual and language modalities through a common, multimodal embedding. We showed that this model provides state of the art performance on image-sentence ranking experiments. Second, we described a Multimodal Recurrent Neural Network architecture that generates descriptions of visual data. We evaluated its performance on both full frame and region-level experiments and showed that in both cases the Multimodal RNN outperforms retrieval

baselines. Although our results are encouraging, the Multimodal RNN model is subject to multiple limitations. First, the model can only generate a description of one input array of pixels at a fixed resolution. A more sensible approach might be to use multiple saccades around the image to identify all entities, their mutual interactions and wider context before generating a description. Additionally, the RNN receives the image information only through additive bias interactions, which are known to be less expressive than more complicated multiplicative interactions. Lastly, our approach consists of two separate models. Going directly from an image sentence dataset to region-level annotations as part of a single model trained end-to-end remains an open problem.

Abstract -**Machine Learning and Game Development have been correlated in a very compact manner since the second half of the 20th century. Historically, games have followed a specific script based on the ideology of the developer where various stages were predefined i.e. static in nature. Generally, games have always been comprised of a set of agents and objects that follow a certain set of paths determining cumulatively the state that the agent is in, in order to reach its goal defined by the developer without any learning component. Behavior of these agents and objects have always been based on simple rules and consecutively, the goals set for these agents and objects are very deterministic in nature. In modern times, game development fraternity has made great strides in integrating ML algorithms in order to make games more dynamic and ever evolving. The advent of ML algorithms has ushered in the inclusion of learning components. The proposed system aims to use ML algorithms to determine the behavior and decision-making process for NPCs (Non- player Character) and to train agents to adapt to the dynamic gaming environment.**

Keywords- ML (Machine Learning), NPC (Non-player Character) Artificial Intelligence (AI)

I. INTRODUCTION

Arcade was developed in the mid-20th century which was the first in a long line of games in the now ever-growing gaming industry. Gaming Industry has become one of the largest industries in terms of employment and revenue generation. From computers to consoles to mobile games to AR/VR technologies and to whatsoever the future might hold, the evolution of games has been directly proportional to the growth of the industry. Online Gaming has been a flagship breakthrough and a huge contributor to the gaming industry. MMORPG (Massively Multiplayer Online Role-Playing Games) is an example of the next generation of online gaming. ML is a subset of AI (Artificial Intelligence) that deals with teaching machines to self-train and grow. Algorithms are built by developers to self-improve by classifying patterns in the data provided.

ML is no stranger to Games and simulations there are many assets available to the Unity developer which are used to provide simulated machine intelligence. In modern times we do not need to fake or simulate intelligence rather, it can be created.

We have come far in the ML world; we can construct agents which learn from their environment to the extent that they beat their human builders. A complete system, for instance, may involve ML tools in-addition with more classic AIs like Behaviour Trees this is done to simulate a better, more unpredictable game. Most developers may use ML for gaming, it certainly helps game development in the following areas:

- Map/Level Generation
- Model Generation
- Artificial Players
- NPCs or Game AI

II. BACKGROUND

IN PAPER [1] which was a General Video Game AI for Evaluating Agents, Games and Content Generation Algorithms by Diego Perez-Liebana specifies the group of algorithms which is used for planning of the single-player using evolutionary algorithms (EA). The agents do not use the forward model to plan to execute the real game. Rather the game is played multiple times and in each play the game learns by itself and improvises in further turns.

IN PAPER [2] Deep Reinforcement Learning for General Video Game by Ruben Rodriguez Torrado published in 2018: In this paper the RL (Reinforcement Learning) agents get learning through trial and error interactions within an environment which is dynamic,

further in this paper the reward trade-off between long-term and short-term planning is balanced. Each and every algorithm mentioned in this paper is trained on one million frames of any particular game

IN PAPER [3] The Mastering Chess and Shogi by Self-Play paper published in 2017 by David Silver reuses the existing hyper-parameters for all games and does not actually specify the tuning of the game. A single Neural networks concept is used which updates continuously using Alpha Zero concept instead of waiting for the iteration to complete but neural networks failed to upstage the grandmaster in chess.

IN PAPER [4] The 2016 paper of Creating AI Characters for Fighting Games by Giovanna Mart, Richard Cant and David Woods states the Round Robin tournaments between the standard AI

characters and the general AI characters. This paper highlights that the evolutionary process was better than that of the hand coded ones. But the extensive experimentation was not much focused in it.

IN PAPER [5] Review of the Use of AI Techniques in Serious Games Maite Frutos- Pascual Deustotech published in 2015: This paper explains that the use of Fuzzy logic is based on approximate reasoning. It is greater than binary approximations, and was specifically designed in such a way so as to cope with areas that are gray i.e they go beyond true or false.

IN PAPER [6] Real-Time Monte Carlo Tree Search in Ms Pac-Man by Tom Pepels published in 2014: In this paper Selection, Expansion, Playout, Backpropagation are the four main steps of the algorithm which is explained in detail in the paper and applied on the MS Pac-Man game.

III. PROBLEM DEFINITION

Traditionally games were based on a fixed storyline and are very limited in terms of action and dynamic nature of the play. The proposed system ensures that the games developed with machine learning reacts and responds more dynamically and in more imaginative ways to the player.

The proposed system can be implemented in 2 phases as follows:

Phase 1: Develop a game using “unity beta” development environment.

Phase 2: Apply Machine Learning algorithms to the game that we had developed in the first phase in order to provide users with a better gaming experience.

IV. PROPOSED WORK

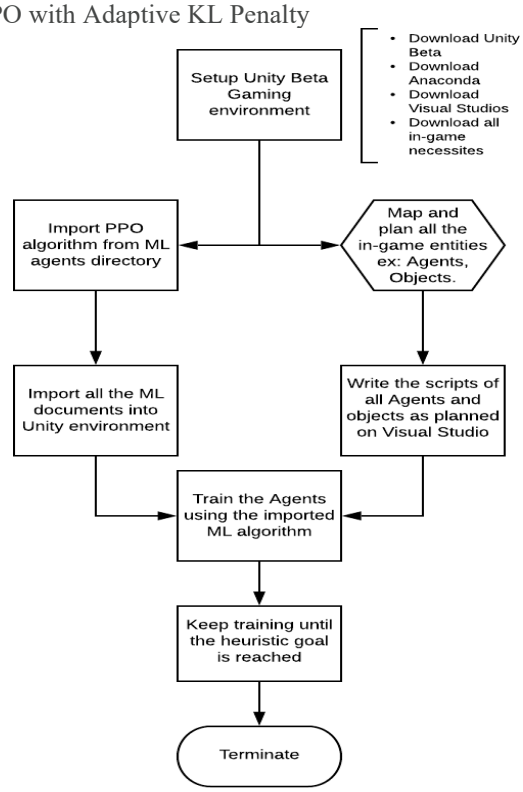
The proposed system uses unity ML agents to do ML and specifically reinforcement learning using Proximal Policy Optimization (PPO) algorithm to train agents that will try to learn and carry out certain actions based on the environment. PPO algorithm is extracted from the ML agents file which can be procured over the internet. This algorithm is used to train.

A Unity Beta game development platform is installed and studied. After the installation the ML agents are imported from the SDK assets directory. The scripts are written for the various agents that are required for the game using c- sharp. In the proposed system we made scripts for various agents and objects. Various 3D meshes of the agents and objects specifically required for the game are downloaded and these 3D meshes are imported from the asset’s directory. The meshes can be seen using the inspector view in unity. The positioning as well as the various other aspects of the agent, environment, object is designed according to the game. All the entities are placed in the area specified. Now an academy is created and the agent academy script is added to it. The agent learning brain is also added to the academy to broadcast the hub. In order to start the training a couple of configurations are setup. The trainer config DML is dragged in Visual Studio and the hyper parameters for machine leaning are set. A curriculum is set where the agent folder will have a text file called agent learning JSON which is an exact match to the name of the brain. Training of the agents can be done using Anaconda. The ML agent’s environment is setup on the Anaconda prompt and the agents are trained. Converting the brain type from player to heuristic in order to let the game learn by itself.

The PPO algorithm is an on-policy learning method which is used for navigating any game environment. The advantage of using the PPO algorithm is that it is compatible with the updates in the policies and thereby ensures less variance in training cost and also makes sure that the agent does not take any senseless actions.

Fig. Flowchart Of Project

PPO with Adaptive KL Penalty



Step 1. Input: initial policy parameters θ_0, initial KL penalty β_0, target KL divergence δ

Step 2. for k = 0,1, 2...do

Step 3. Collect set of partial trajectories Dk on policy $\Pi k = \Pi(\theta k)$

Step 4. Estimate advantages $\hat{A}$ $\pi k\tau$ using any advantage estimation algorithm

Step 5. Compute policy update

$\theta k+1 = \arg\max\theta \angle\theta\kappa (\theta) - \beta k \bar{D} KL (\theta||\theta k)$

By taking K steps of minibatch SGD(via adam)

Step 6. If $\bar{D}$ $KL(\theta k+1||\theta k)\geq 1.5\delta$ then

$\beta k+1=2\beta k$

else if $\bar{D}KL(\theta k+1||\theta k)\leq\delta/1.5$ then $\beta k+1=\beta k/2$

end if

Step 7. end for.

V. METHODOLOGY

This project aims at developing a ML trained game. The main advantage of using ML algorithms in game development is that it learns the goal-oriented moves on its own gets better and better at those moves the more it trains thereby providing an excellent and improvised gaming environment.

The process starts by setting up the gaming environment which includes downloading various tools namely Unity Beta, Anaconda, Python IDLE, Visual Studios and other in-game accessories. Making sure that all these tools and accessories have been correctly setup is very important to the project. After the setup process is complete the planning and visualization of the entire project needs to be accomplished by defining the entire game which encompasses the Environment, Features, Goal, Agents, Objects, etc, and also everything that is required to correctly define all these entities. Once the game is visualized a training or learning algorithm needs to be picked to be used in this game, for the purposes of this project PPO (Proximal Policy Optimization) algorithm is being used. The algorithm needs to be written in a python environment so that it can be used to train the agents in the game.

Once the algorithm is written, all the files made in the writing of the algorithm need to be imported in the Unity Beta gaming engine. To visualize all the planned Agents and Objects of the game a script must be written for each and every one of them. This script must be written in Visual Studio, it defines all the characteristics of the said agent or object. Similarly, the scripts of gameplay, area, environment must also be written. This will create an entire scene in the Unity Beta gaming environment. Once the scene is created the Agent is trained using the PPO algorithm. The training needs to be continued until the agent masters the game completely.

VI. TOOLS

Various tools used to implement the project:

1.Visual Studio 16.5.0: For writing scripts (in C sharp) in order to create the scene.

2.Anaconda 5.3.0: Used for importing python files into Unity.

3.Unity Beta 2019.1b: Cross platform gaming engine used to develop the game.

4.Python 3.6: Programming platform that is preferred in this project to write training algorithm.

VII. VII. RESULTS AND DISCUSSIONS

Initially while getting accustomed to unity engine environment and PPO algorithm, a small-scale game namely the racket game was developed in this project. In this game the racket agents where given a heuristic brain which used the PPO algorithm from the ml-agents directory to train in accurately hitting the ball at all times.

The PPO learning algorithm is observed to have run very smoothly while making this racket game as this game was done on a small scale with single agent and object environment. It remains to be seen how this algorithm fares for our large-scale project including multiple agents and objects in the coming months of this project.

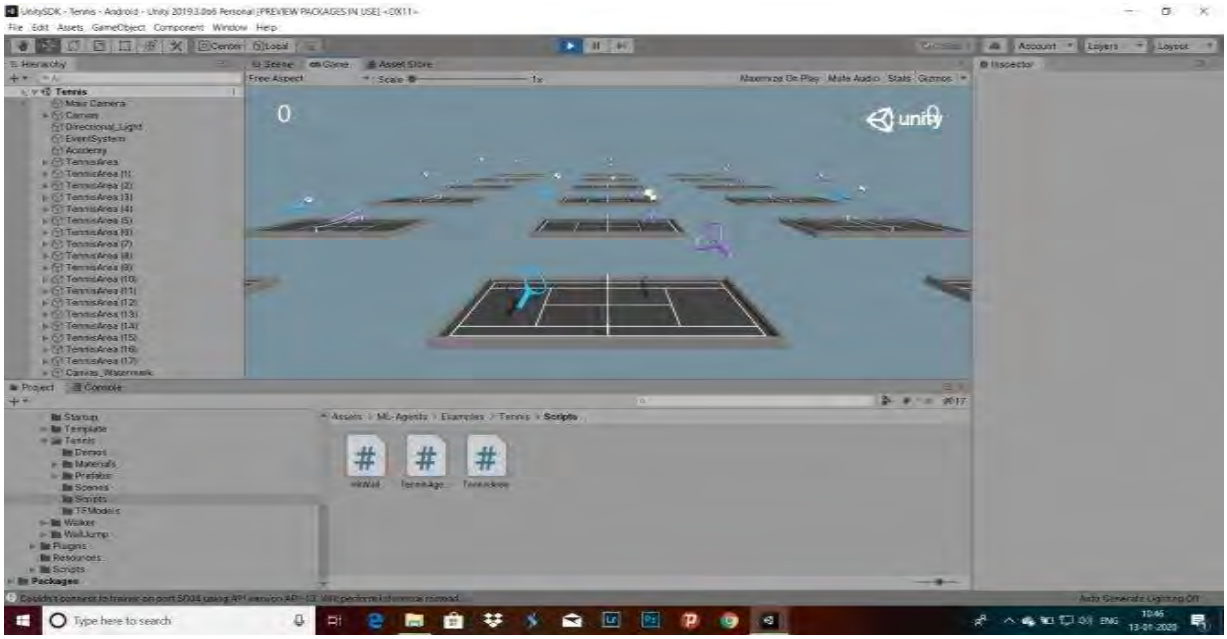


Fig. Racket Game

VIII. CONCLUSION AND FUTURE WORK

From the literature survey we observe that initial gaming models were based on storylines which made them static as there were fixed standard paths for each level. This made the games predictable and easy. In order to provide better gaming experience, the proposed system uses PPO (Proximal Policy Optimization) algorithm, method mapping, game stakeholder (end user) taxonomy and the player-game interaction loop. This analysis revealed dominant PPO (Machine Learning) algorithm within particular areas as well as in general areas has a room for exploration of new methods within the existing system. PPO algorithm is compatible with the updates in the policies and thereby ensures less variance in training cost and also makes sure that the agent does not take any senseless actions. But PPO algorithm finds it difficult to support GPU enabled implementations and to work on large scale projects and hence many updated versions of PPO namely PPO2 and ACER (Actor critic with experience replay) which claim to be 3 times faster than current PPO.

In future this project will deal with implementing a large-scale game with multiple agents and objects in an environment and training specific agents to play the game.

IX. ACKNOWLEDGMENTS

We sincerely thank our guide Mr. Namdeo Badhe for his guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

We thank the HOD, Dr. Rajesh Bansode, the Principal, Dr.B. K. Mishra, and the college management for their support.

Abstract---**Air Pollution and its precaution has been a scientific as well an industrial challenge since past few decades. And it still remains an endless global problem. Thanks to the growing population and increase in settlements in urban areas, the quantity of pollutants in air increase day by day. Affecting human's respiratory and circulatory system, they are the main cause for increased mortality and increased risk for diseases for the population. Many efforts are taken by the governmental bodies to know and predict the AQI (Air Quality Index) to further improve public health. The foremost important step in prediction, no doubt, is to develop a predictive model of air quality status, which can help in management of the environment and also to make a way of awareness among people. Air quality prediction is the most important factor for monitoring pollution.**

Keywords---Air pollution, SVM, Machine Learning, Prediction.

I. INTRODUCTION

Artificial Intelligence and machine learning have seen a sudden rise within the past few years. Regarding the field of artificial intelligence where the machine makes all the choices on its own instead of having to program the machine for each specific need of the user, has started integrating itself in every aspect of our life. AI and machine learning have become the key focus of each company and organization, from start-ups to documented vendors.

The procedure of machine learning is that the machine first senses the environment and therefore the factors associated with it. It then gathers information and makes appropriate decisions like a human mind does naturally. One among the most important reasons why machine learning was chosen to predict air quality index and other harmful pollutants was this ability of adapting of machine learning (ML) algorithms.

The air is crammed with pollutants which are present in different states like liquid, gaseous or solid. These pollutants have a varying concentration, which

could determine its hazardousness. If the concentration of some pollutants is high, it could severely affect citizenry, plants, animals and environment. There are multiple sources which contribute to tremendous increase of air pollutants like indoor activities as well as outdoor activities. Many domestic activities like cooking, burning of bio-fuels and heating produce indoor air pollutants. There are two sorts of outdoor air pollutants namely, primary and secondary air pollutants. The pollutants that are released by industrial activities and fuel combustion into atmosphere are primary pollutants, whereas the secondary pollutants are a result of reaction in atmosphere. The varied harmful air pollutants are Oxides of nitrogen, particulate, carbon monoxide gas and CO2.

AQI Category (Range)	PM_{10} 24-hr	$PM_{2.5}$ 24-hr	NO_2 24-hr	O_3 8-hr	CO 8-hr (mg/m^3)	SO_2 24-hr
Good (0-50)	0-50	0-30	0-40	0-50	0-1.0	0-40
Satisfactory (51-100)	51-100	31-60	41-80	51-100	1.1-2.0	41-80
Moderate (101-200)	101-250	61-90	81-180	101-168	2.1- 10	81-380
Poor (201-300)	251-350	91-120	181-280	169-208	10.1-17	381-800
Very poor (301-400)	351-430	121-250	281-400	209-748*	17.1-34	801-1600
Severe (401-500)	430+	250+	400+	748+*	34+	1600+

II. BACKGROUND

In the last decade, artificial neural networks (ANNs) and more recently support vector regression (SVR) have emerged as two attractive tools for nonlinear modelling especially in situations where the event of phenomenological or conventional regression models becomes impractical or cumbersome. In recent years, support vector regression (SVR) which may be a statistical learning theory based machine learning formalism is gaining popularity over ANN, thanks to its many attractive features and promising empirical performance. The most important difference between conventional ANNs and support vector machines (SVM) lies within the risk minimization principle. Conventional ANNs implement the empirical risk minimization (ERM) principle to attenuate the error on the training data, while SVM adheres to the Structural Risk Minimization (SRM) principle seeking to line up a boundary of the generalization error. This study is motivated by a growing popularity of support vector machines (SVM) for regression problems. This process results in better generalization than conventional methods. This paper presents a study of using the SVM model to research of air pollutants. The SVM was trained by was performed on data of the principal air pollutants Nitrogen Dioxide, Sulphur Dioxide, Suspended PM, RSPM.

III. LITERATURE REVIEW:

1. Chi-Man Vong et. al.[1] suggested that to effectively compare accuracy of the model, four error measures namely, mean absolute error (MAE), root mean squared error (RMSE), complementary Willmott's index of agreement (CWIA), and relative error (RE) should be used. Predicted and observed level of NO2 in 1-year experiment, SPM in winter experiment, and O3 in summer experiment were plotted. Although there were some lagging and underestimations, the predicted levels produced by Linear model and RBF model followed the trend of observed level of NO2 pretty well in 1-year experiment. The prediction results of Linear model and RBF model showed a relative good fit to the observed test set of over one year of data, particularly for SO2 and NO2.

2. Soawalak Arampongsanuwat et. al. [2] studied and presented the potential of applying SVM model in ambient air pollutant prediction in this paper. The model was developed by using a technique from support vector regression (SVR). Gaussian Radial Basis Kernel functions was used because it is more suitable for the estimation of function Parameters to define the C (Regularization Parameter) with the ε (Error-insensitive) supported by vector machine. Parameters of Gaussian Radial Basis Kernel functions (σ) from the experiment find for the most appropriate using the values in the ascending range 0.1 through 1.0. In the experiment, the model selected has the lowest mean squared error (MSE). The results of this research show the model that set with value C = 5,000, ε = 0.001 and σ = 0.1 work out most precise in forecasting over other tested models. Based on the test forecasting data, the mean squared error (MSE) was 1.0588×10-10, which means this model is very satisfactory. The model reports that support vector regression can be used in forecasting PM10 successfully.

3. Shahid Ali et. al. [4] conducted an empirical study of SVM approaches to assess the capability of SVM in handling air pollution data set. A real-time dataset was obtained from USA and carried out rigorous experiments with single SVM, and ensemble methods like Bagging and AdaboostM1. From experimental results, it can be concluded that, ensemble methods outperformed single SVM in both accuracy and efficiency. Experimental results on air pollution dataset indicated that the proposed SVM with AdaboostM1 algorithm performs better than other algorithms. The classification accuracy of single SVM method was 76.33%t whereas with Bagging algorithm it was 79.66%. However, through AdaboostM1 algorithm, classification accuracy of 91.28% was achieved and less time was required to build ensemble model.

4. Bedoui, S. et. al. [6] Analysed the dispersion of ozone and the suspended particles presented. In this paper, Support Vector Machines SVM has been performed to predict the concentrations of the ozone and particles. To achieve this goal, the SVM with the linear kernel, SVM with the polynomial kernel and SVM with the RBF kernel have been used. The concentrations of pollutants have been investigated by a discriminant analysis DA of the monthly average values measured at four, and then at two locations in Tunisia. In the case of four classes, regardless of either linear or quadratic no reliable classification is available, with an error rate of 37.78%. However, in the case of two classes, the quadratic DA produces a lower misallocation rate (0%) than the linear DA (4.35%). A thematic map was created using the MapInfo software enabling classification of the regions.

5. Z. Ghaemi et. al. [7] designed a spatio-temporal system using a LaSVM-based online algorithm. Pollutant concentration, meteorological data and geographical parameters are fed to the online forecasting system. Performance evaluation of the system is done by comparing the prediction results of the Air Quality Index with those of a traditional SVM algorithm. Results show an increase of speed while preserving the accuracy of the SVM classifier. Comparison of the hourly predictions for next coming 24 h, with those of the measured pollution data in Tehran pollution monitoring stations shows an overall accuracy of 0.71, root mean square error of 0.54 and coefficient of determination of 0.81. These results are indicators of the practical usefulness of the online algorithm for real-time spatial and temporal prediction of the urban air quality.

IV. SVM WORKING

Support vector machines (SVMs) are known as an excellent tool for classification and regression problems, producing good generalization. The basic principle of SVM applies linear model to convert nonlinear class boundaries through some nonlinear mapping of the input vector into the high-dimensional feature space. The concept of a maximum margin hyperplane only applies to classification. However, support vector machine algorithms have been developed for numeric prediction that share many of the properties encountered in the classification case: they produce a model that can usually be expressed in terms of a few support vectors and can be applied to non-linear problems using kernel functions. Similar with linear regression, the basic idea here is to find a function that approximates the training points well by minimizing the prediction error. The crucial difference is that all deviations up to a user specified parameter are simply discarded. Also, when minimizing the error, the risk of over-fitting is reduced by simultaneously trying to maximize the flatness of the function. Another difference is that what is minimized is normally the predictions' absolute error instead of the squared error used in linear regression. A user-

specified parameter defines a tube around the regression function in which errors are ignored.

V. PROBLEM DEFINITION

Air Pollution is considered to be a concerning issue for the people and the environment. Therefore, many countries develop a monitoring system to reduce the effects caused by the pollution. Monitoring help us to examine the presence of noxious pollutants in the air, such as CO, NOx and NO_2. Due to the severe impact of air pollutants on the environment, monitoring and prediction of air has become important. The existing air quality monitoring stations in urban areas continuously record high volumes of pollutant concentrations. These data need to be effectively utilized for analysis and prediction of the air quality indices. The Support Vector Machine (SVM) model will be used to monitor the concentrations of gases in air and further predict values for the same.

VI. METHODOLOGY

- **Data Sampling**

The raw air pollutants and meteorological data from year 2005 to year 2010 were obtained from the website (https://www.kaggle.com/shrutibhargava94/india-air-quality-data).

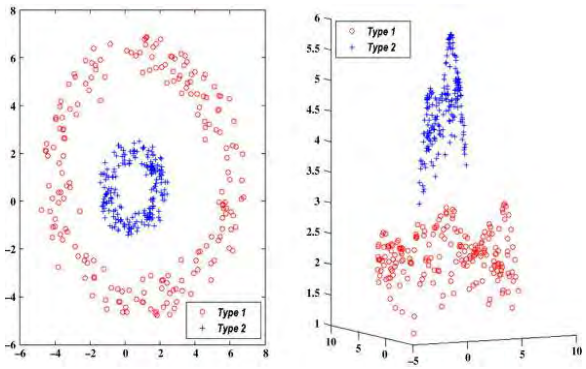
- **Data Normalization**

Prior to modelling, it is necessary to normalize all selected features into same range to avoid the domination by any feature with large values. This normalization process leads to more stable and accurate predicted results.

- **Modelling and Data Representation**

Air pollutants and meteorological data were used in this study to predict air pollutant levels. In order to apply SVM for pollutant level forecasting, the representation of a pollutant level is defined as a pair ($\mathbf{x}$, y).

The set of kernel functions is composed of variants in that they are all based on calculating inner products of two vectors. This means that if the functions can be recast into a higher dimensionality space by some potentially nonlinear feature mapping function, only inner products of the mapped inputs in the feature space need be determined without us needing to explicitly calculate ϕ. The reason that this kernel trick is useful is that there are many regression problems that are not linearly regressable in the space of the inputs, which might be in a higher dimensionality feature space given a suitable mapping function.



Then a data set that it not linearly separable in the two-dimensional data space is separable in the nonlinear feature space defined implicitly by this nonlinear kernel function known as radial basis function. Other popular kernels for classification and regression are the polynomial kernel.

In summary, in order to use an SVM to solve a regression problem on data that is not linearly separable, we need to first choose a kernel and relevant parameters which you expect might map the nonlinearly separable data into a feature space where it is linearly separable. This is more of an art than an exact science and can be achieved empirically, e.g. by trial and error. Sensible kernels to start with are the radial basis, polynomial and sigmoidal kernels. Therefore, the first step consists of choosing our kernel and hence the mapping function.

VII. CONCLUSION

Using observed meteorological and pollutant data, SVM models for forecasting ambient air pollutants were constructed. The prediction results of Linear model and *RBF model* showed a relative good fit to the observed test set of over one year of data, particularly for SO_2 and NO_2. It was evident that using Linear kernel and *RBF* kernel in SVM model for air pollutant forecasting produced superior results with

relatively lower errors. It is believed that SVM model with Linear kernel or RBF kernel can also produce good performance for air pollutant forecasting in other similar developing cities, or even other time series prediction in similar situation.

How to solve this problem to improve the accuracy of prediction model is the future works. Some literature attempted to integrate discrete wavelet transform (DWT) with SVM for a higher accuracy. Hence, we will attempt to integrate other machine learning methods, for example, genetic algorithm (GA), with SVM to improve the accuracy and efficiency of model in the future.

VIII. FUTURE SCOPE:

A much larger dataset can be used for better accuracy and prediction. Further, additional factors that might have affected the concentration of pollutants in a particular area can also be considered. More pollutants can be used as input to gain a great control over the pollution. Conventional methods such as the support vector machine (SVM) or artificial neural networks (ANN) show some inadequacy when enormous amount of data has to be analyzed for prediction. To overcome the limitations and improve the performance of prediction, a spatio-temporal system can be designed in the future. To predict the large dataset of pollutants provided by pollution control boards neural networks can be used. A better update into the SVM will result in advanced accuracy and efficiency.

Abstract- **Stock market is basically nonlinear in nature and the research on stock market is one of the most important issues in recent years. To predict the stock market prices people search such methods and tools which will increase their profits, while minimize their risks. There are various algorithms for predicting stock market in Machine Learning. Due to various limitations like over-fitting and non-relevant inputs in Artificial Neural Network (ANN), algorithms like PSO (Particle Swamp Optimization) and LS-SVM (least square support vector machine) are gaining importance. This project aims to develop a machine learning model that hybrids the PSO and LS-SVM model. The performance of LS-SVM depends upon the selection of free parameters – C (cost penalty), ∈(insensitive loss function) and γ (kernel parameter). PSO will be used together to find the best parameter combination for LS-SVM.**

I. INTRODUCTION

Stock market plays a really vital role in quick economic process of the developing country like Asian country. Therefore our country and different developing nation's growth could depend upon performance of stock exchange. If stock exchange rises, then countries economic process would be high. If stock exchange falls, then countries economic process would be down. In different words, we are able to say that stock exchange and country growth is tightly delimited with the performance of stock exchange.

Predicting however the stock exchange can perform is one amongst the foremost tough things to try and do. There square measure such a large amount of factors concerned within the prediction – physical factors vs. physiological, rational and irrational behavior, etc. of these aspects mix to create share costs volatile and really tough to predict with a high degree of accuracy. Broadly, stock exchange analysis is

split into 2 elements – basic Analysis and Technical Analysis, however our focus is on the technical analysis half. Fundamental Analysis involves analyzing the company's future profitableness on the premise of its current business setting and money performance. Technical Analysis, on the opposite hand, includes reading the charts and mistreatment applied math figures to spot the trends within the stock exchange. Artificial Neural networks (ANNs) is the most commonly used technique. In most cases ANNs suffer from over-fitting problem due to the large number of parameters to fix, and the little prior user knowledge about the relevance of the inputs in the analyzed problem.

Also, Support vector machines (SVMs) had been developed as an alternative that avoids such limitations. Their practical success can be attributed to solid theoretical foundations based on VC-theory. SVM compute globally optimal solutions, unlike those obtained with ANNs, which tend to fall into local minima [4].

Least squares –support vector machines (LS-SVM) method was reformulated the traditional SVM algorithm. LS-SVM uses a least squares function with equality constraints which lead to a linear system which meets the Karush-Kuhn-Tucker (KKT) conditions for finding an optimal solution. Although LS-SVM simplifies the SVM procedure, the regularization parameter and the kernel parameters play an important role in the regression system. Therefore, it is necessary to establish a methodology for properly selecting the LS-SVM free parameters, in such a way that the regression obtained by LS-SVM must be robust against noisy conditions, and it does not need prior user knowledge about the influence of the free parameters values in the problem studied.

II. BACKGROUND

There are various tries to predict stock worth with Machine Learning. The main target of every research varies a great deal in 3 ways. (1) The targeting worth modification will be near-term (less than a minute), short-run (tomorrow to some days later), and semi-permanent (months later). (2) The set of stocks will be restricted to but ten explicit stocks, to stocks during an explicit business, to typically all stocks. (3) The predictors used will vary from international news and economy trend, to explicit characteristics of the corporate, to strictly statistic information of stock worth.

Based on the works we discover, a lot of progress has been created in predicting near-term and semi-permanent worth changes. These well operating models usually accept explicit info of the corporate that is commonly laborious to access by general public and doesn't work with short-run prediction.

We set to focus our project on the domain that presently has the worst prediction accuracy: short-run worth prediction on general stock victimization strictly statistic information of stock worth. Most researches during this domain have solely found models with around fifty to sixty % accuracy and that they usually

work just for classification. When studied thoroughly, we tend to noticed that some papers that claim to possess higher result used problematic metrics to guage the model, though the graphs or numbers may look fancy but the particular model provides restricted meaty steering for mercantilism.

III. LITERATURE SURVEY

Paper[1] :- The model trained by SVM shows pretty good effect with a high accuracy rate of 96.15%. A lot of parameters fit the training data perfectly well therby increasing the probability. The work design for the stock prediction system includes major factors that includes performance of the stock, dataset to predict the future performance, use Support Vector Machine (SVM) and classify it further to stock classification. Over-fitting in classifications and exaggerating minor fluctuations in the training data might decrease the subsequent predictive ability

Paper[2] :- This paper is based on the preliminary work that includes data preprocessing, data alignment and the use of Extreme Learning Machine algorithm which achieves good generalization performance at an extreme rate. The experiments are run with MATLAB R2010a in a PC machine which gives the prediction speed (running time) of each model at each time point (numbers in bold font indicate the best results at the given time point and the second best results are underlined). The bottleneck of any kernel based method is the definition of kernel 'k' that accurately reflects the similarity amongst all the data samples taken into consideration.

Paper[3] :- The proposed methodology can be summarized in the following modules – Data Collection, Feature Extraction Module , Training Module, Prediction Module . Support Vector Machine proved to be the most efficient and feasible model in predicting the stock price movement, in favour of the sentiments of the tweets. Through Machine Learning techniques for prediction purposes is inexpensive compared to the complete other survey that would have been conducted otherwise to gauge the public mood. Historical Twitter data cannot be obtained, unless it is saved by someone, so data has to be collected over a duration of a fixed number of months starting from the present date and time

Paper[4] :- In this research the stock market is tried to be predicted by three variants of Artificial Neural Network and by the Support Vector Machine algorithm which are Single Layer Perceptron, Multi-Layer Perceptron, Radial Basis Function, Support Vector Machines. It is evident from the result that SVM performed best on training set while the MLP algorithm did well on test data set. Conventionally, the prediction model works on test data set for the verification of the model that was built using the training data set.

IV. PROBLEM DEFINITION

Counting on one dataset might not be decent for the prediction and provide a result that is inaccurate conjointly having lower accuracy and taking longer for prediction. The previous projects existing provide lower accuracy with datasets not been taken from stock brokers.

Hence, we tend to take a collaborative approach towards this problem by integrating 2 hybrid models of Machine Learning- PSO-LSSVM (Particle Swamp Optimization and Least Square Support Vector Machine). Since PSO is straightforward to implement with larger accuracy and potency, once combined with LSSVM provides with shorter procedure time and can be ready to run on parallel computation

V. OBJECTIVE

The aims of this project square measure as follows: 1. to spot issue moving share market. 2. To come up with the pattern from giant set of knowledge of exchange for prediction. 3. To predict associate degree approximate worth of share value. 4. To produce analysis for users through net application.

The project are going to be helpful for investors to speculate available market supported the varied factors. The project target is to make net application that analyses previous stock knowledge of firms and implement these values in data processing rule to work out the worth that exact stock can have in close to future with appropriate accuracy. These foreseen and analyzed knowledge may be discovered by individual to grasp the money standing of firms and their comparisons. Company and business will use it to breakdown their limitation and enhance their stock values. It may be terribly helpful to even researchers, stock brokers, market manufacturers, government and general individuals.

VI. METHODOLOGY

AGILE methodology is a practice that promotes continuous iteration of development and testing throughout the software development lifecycle of the project. Both development and testing activities are concurrent. The following will be the system architecture:

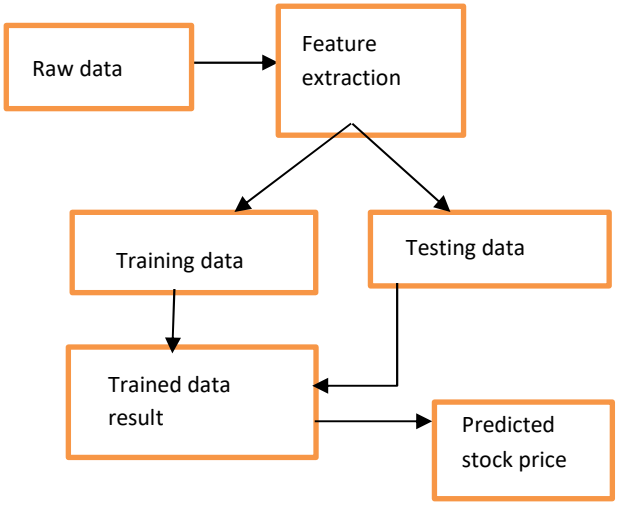

Figure No. 1: Basic Block Diagram

The training and test data will then be going through the hybrid module of PSO-LSSVM where the data goes through a technique of reaching more and more accuracy considering one head point. LSSVM algorithm is used for setting parameters for further processing.

LEAST SQUARE SUPPORT VECTOR MACHINE

Least squares support vector machines (LS-SVM) square measure statistical method versions of support vector machines (SVM), that square measure a group of connected supervised learning strategies that analyze knowledge and acknowledge patterns, and that square measure used for classification and multivariate analysis. During this version one finds the answer by finding a group of linear equations rather than a gibbose quadratic programming (QP) downside for classical SVMs. statistical method SVM classifiers, were planned by Suykens and Vandewalle..

Let X is n*p input data matrix and y is n*1 output vector. Given the {xi,Yi}i=1n,{ □ training data set, where xi E Rp andyi E R , the LS-SVM goal is to construct the function f(x)=y , which represents the dependence of the output i y on the input i x . This function is formulated as:

$$f(x)=Wt(x)+b$$

Where W and (x): Rp Rn are n*1 column vectors, and b E R. LS-SVM algorithm computes the function from a similar minimization problem found in the SVM method. But the main difference is that LS-SVM algorithm involves equality constraints instead of inequalities, and this algorithm is based on a least square cost function. In addition, the LS-SVM method solves a linear problem while conventional SVM solves a quadratic one.

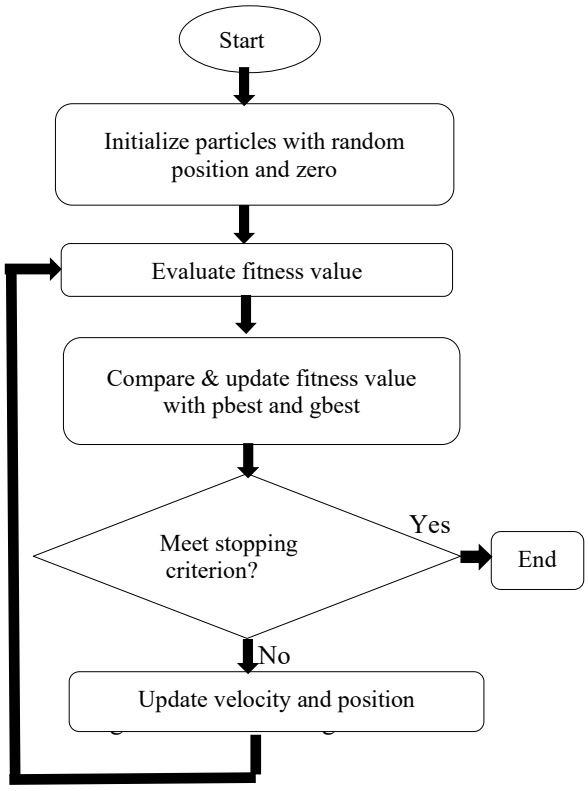
PARTICLE SWARM OPTIMIZATION ALGORITHM

PSO may be a comparatively recent heuristic search methodology that comes from the behavior of social teams like bird flocks or fish swarms. PSO moves from a group of points to a different set of points in an exceedingly single iteration with possible improvement employing a combination of settled and probabilistic rules. The PSO has been well-liked in academe and business, in the main as a result of its intuitiveness, simple implementation, and therefore the ability to effectively solve extremely nonlinear, mixed number optimization issues that area unit typical of complicated engineering systems. Though the "survival of the fittest" principle isn't utilized in PSO, it's typically thought-about as AN organic process algorithmic program. Optimization is achieved by giving every individual within the search house a memory for its previous successes, data concerning successes of a group and providing the simplest way to include this information into the movement of the individual .Therefore, every individual (called particle) is characterized by its position xi, its rate vi , its personal best position pi and its neighborhood best position pg. the weather of the speed vector for particle area unit updated as:

Vy□WVy+c1q(Xypb-Xy)+c2y(Xjsb-Xy),j=1,…,n

Where w is the inertia weight, xipb is the best variable vector encountered so far by particlei, and xsb is the swarm best vector, i.e. the best variable vector found by any particle in the swarm, so far 1 c and 2 c are constants, and q and r are random numbers in the range (0, 1). Once the velocities have been updated, the variable vector of particle i is modified according to:

xy□xy+vy,j=1,...,n.



VII. THE PROPOSED MODEL

The proposed system is based on the study of historical data, technical indicators and optimizing LS-SVM with PSO algorithm to be used for the prediction of daily stock prices. Levenberg-Marquardt (LM) algorithm is used as a standard benchmark for comparison with LS-SVM and LS-SVM-PSO algorithm. The proposed model contains six inputs vectors represent the historical data, derived technical indicators and one output represents next price.

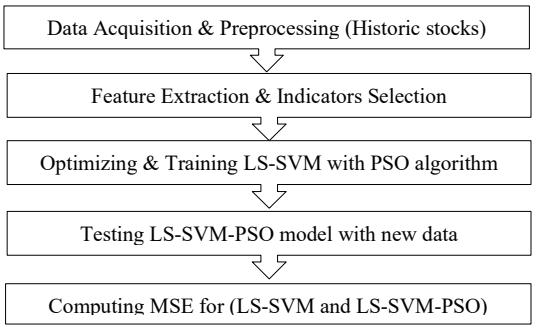


Figure No. 3: Proposed Model

The five technical indicators can be calculated from the raw datasets:

1. Relative Strength Index (RSI): A technical momentum indicator that compares the magnitude of recent gains to recent losses in an attempt to determine overbought and oversold conditions of an asset. The formula for computing the Relative Strength Index is given as follows.

$$RSI = 100- [100 / (1+RS)]$$

Where RS = Avg. of x days' up closes / Average of x days' down closes.

2. Money Flow Index (MFI): This one measures the strength of money in and out of a security. The formula for MFI is as follows:

Money Flow (MF) = Typical Price * Volume.

Money Ratio (MR) = (Positive MF / Negative MF).

MFI = 100 – (100/ (1+MR)).

3. Exponential Moving Average (EMA): This indicator returns the exponential moving average of a field over a given period of time. EMA formula is as follows.

$$EMA = [\alpha *T\ Close] + [1-\alpha* Y\ EMA].$$

Where T is Today's close & Y is Yesterday's close

4. Stochastic Oscillator (SO): The stochastic oscillator defined as a measure of the difference between the current closing price of a security and its lowest low price, relative to its highest high price for a given period of time. The formula for this computation is as follows:

%K = [(Close price – Lowest price) / (Highest Price – Lowest Price)] * 100

5. Moving Average Convergence/Divergence (MACD): This function calculates difference between a short and a long term moving average for a field. The formula for calculating MACD and its signal is given as follows.

MACD = [0.075*EMA of Closing prices] – 0.15]*EMA of closing prices]

Signal Line = 0.2*EMA of MACD

VIII. CONCLUSION

Machine learning is continually evolving with new strategies being developed each day. It's crucial that we tend to update our data perpetually and also the best thanks to do thus is by building models for fun comes like stock value prediction. Though the LSTM model higher than isn't adequate to be employed in live commerce, the foundations engineered by developing such a model will facilitate U.S.A. build higher models which may someday be employed in our commerce system.

Time series prediction could be a terribly intriguing field to figure with, as I actually have completed throughout my time writing these articles. There's a perception within the community that it's a posh field, and whereas there's a grain of truth in there, it's not thus tough once you get the suspend of the fundamental techniques.

Apart from Neural Networks, there is a unit several different machine learning models that may be used for commerce. The bogus Neural Network or the other Deep Learning model are simplest once you have over one hundred, 000 information points for coaching the model. This model was developed on daily costs to form you perceive the way to build the model. It's well to use the minute or tick information for coaching the model, which is able to offer you enough information for a good coaching.

IX. FUTURE SCOPE

The limitation of the proposed model is its computational speed, especially w.r.t. its sliding-Window validation as the computational cost increases with the number of forward day predictions. The proposed system does not predict well for sudden changes in the trend of stock data. This occurs due to many external factors and real-world changes affecting the stock market. We can although overcome this problem by implementing Sentiment Analysis and Neural Networks to enhance the proposed system. We can modify the same system to an online-learning system that adapts in real-time.

X. ACKNOWELEGMENT

We sincerely thank to our guide Mr. Sudhir Dhekane for his guidance and support for carrying out our project work and giving us new ideas to develop our project well. We also give our sincere thanks to our Principal Dr. B. K. Mishra, Vice-Principal Dr. Deven

Shah, HOD-IT Dr. Rajesh Bhansode, our project coordinators for arranging the necessary facilities to carry out the project work. We thank Thakur College of Engineering and Technology for their support and providing us a platform to explore new trending technologies in the world.

Supervising heart disease using machine learning Algorithm

Amish Punmiya, Ketan Samrit, Saish Shetty, Shridhar Kamble
Thakur College of Engineering and Technology, Mumbai, India

Abstract - **Recent studies have shown that the world is encountering a high rate of heart ailments. Heart diseases have become one of the leading causes of death, and World Health Organization (WHO) states that cardiovascular diseases are the world's largest killers, which claimed 17.1 million lives a year. India having a population of approximately 1.33 billion people, more than one sixth of the world's population, experiencing heart disease as the single largest cause of death in the country with heart attacks being responsible for one-third of all death caused by heart diseases. Monitoring person's behaviour at some stage in sleep, specially heart rate and breathing fee has obtained greater attention from the last few years. Many systems have been advanced to display, discover chance of coronary heart failure below sure situations. Most of these structures screen important signs and symptoms with the aid of measuring one or greater components of the ballistic pressure during a heartbeat pulse, ranging from force magnitude, stress, to the ensuing function trade. Even though they may be able to carry out correct tracking, most of them are pretty bulky to put in or are inconvenient to the customers. Advanced technology like this system makes it possible for the doctors to get information about the patient's heart beat using it without interrupting their life. Continuous heart monitoring is useful for capturing irregular heart beat that happen infrequently. This may then be useful for performing further actions which are necessary to keep the heart beat at regular level.**

Keywords - IOT, ML, Health Monitoring, Arduino, Node MCU, Heart disease prediction, Heart rate sensors, Health diagnosis.

I. INTRODUCTION

The Internet of Things (IoT) is a communication of embedded devices using networking technologies. IoT will be one of the important trends in the upcoming years. It will affect the networking, communication and business. By keeping all these things in minds, technology really proves to be helpful for an individual. With new technological advancement, lots of smart sensors or medical sensors have been introduced that continuously analyse individual user activity and automatically predict a heart attack before the individual feels sick. Therefore, identifying the appropriate sensors is important. Nowadays patient is more concerned and takes actively part in collecting and reviewing his reports.

In today's world, various wireless communication standards have enabled the sensor to develop from traditional forms i.e. require active patient involvement to passive form i.e. require no involvement from user. Elderly people got to make regular visit to the doctor for his or her health signs test results. Observing on regular basis of essential signs is compulsory as they're main signs of well-being of one's individual health. These vital signs include,

a. Pulse rate

b. Body temperature [1]

The goal is to develop a low power, more reliable technology that analyses essential signs, and continually monitors users by gathering information from the body and send the parameters through wireless technology. There must be a specified method of transmission and to display the signal after the data is recorded.

There are many technologies which help us to monitor the patients who are not in reach of common clinical settings, which will increase the access to care and reduce the cost of delivering human healthcare. In many developing countries, Human Healthcare is usually defined as a serious problem i.e. almost as much as 8% of the population who can has access to 20% of the country's medical resources. This inability to access proper Human Healthcare for rural populations paired with rapidly increasing disorder rates poses a significant problem. This paper proposes a remote monitoring and sensing parameter of the human body which consists of pulse and temperature. The parameters that are used for sensing and observing will send the data through wireless network using firebase as database. Adding a web-based observing helps to keep track of the regular health status of a patient. The sensing data will be collected in database continuously and will be used to inform the doctor and the patient about the current trend in health. [1]

II. BACKGROUND

There are about 55 million annual deaths due to cardiovascular diseases in India every year. These are mainly due to the lack of knowledge among the masses. The Indian people tend to take things too lightly in context of diet and maintaining fitness. Hence there is an above average rate of people falling prey to heart diseases. Nowadays better technologies and better guidance from physicians is resulting in a control on the resulting deaths from cardiovascular diseases.

Many heart rate sensing devices are available in the market, and they give high accuracy rate in providing the pulse rate. Fitbit Versa is a wrist band watch used for sensing the heart rate and pulse rate of the body and it also tracks other activities, for instance while jogging it counts the kilometres and the footsteps of the user. Secondly, Fitbit band also plan the user daily activity which has to be performed. This activity is based on the past records. Apple Watch Series 1 is a kind of the wrist watch which sense the heart rate, maintain some diagnostics and integration to this

it is also used for picking up the call and showing content of the iPhone, iPad, and iMac on the watch. These devices are used only for sensing the heart rate while the device is on the hand but our system which can sense the ballistic force with the help of the sensors.

III. Objectives and scope of project

The project aims at creating a system which is able to sense the heart rate using IR sensor and Pulse Sensor and the pulse band sensor intelligent but lightweight healthcare assistant. This application will be able to help healthcare and other user suffering from heart diseases. This also aims at having a basic machine learning capability for heart attack prediction. In an era where medical diagnosis and treatment has made massive leaps, it is unfair to deny anyone proper healthcare owing to a lack of means.

One often sees a lack of a proper software to help it out in such cases. Software can avoid the necessity of having to revisit doctors, or to spend hours self-researching complex medical terms and appendices, as many diagnosed patients tend to do. The use of a band here can calculate the rate every minute and pass the data to the database. [2] This system can be used for providing enhanced healthcare services to the rural areas of the developing countries which are facing shortage of efficient specialized doctors. Thus, the cardiovascular disease causing the death of patient can be reduced immensely by the implementation of this proposed system, in both rural and urban areas.

1) Heart hate monitoring will help patient understand the nature of the body system.
2) Cost Effective system with multiple features embedded on a single unique system.
3) Wristbands and geophones help in early detection of the heart attack or stroke and help save lives.
4) It helps in alerting you and your near ones about sudden changes and help can be provided in medical emergency.

Besides the features above, we also aim to make the software robust, accurate and fast.

IV. Working of the project

The proposed system consists of sensors which are used to sense bed vibrations caused by the ballistic force. The sensors help in monitoring person's heart rate during sleep. This mechanism for heart rate monitoring does not require a special kind of bed. These sensors are placed at the side of the bed, which allows person to sleep in a comfort manner as well as person can move around and change position freely during sleep. The sensors are integrated with Arduino, which connected to the ac amplifier. The vibrations sense by the vibration sensors are converted from digital signal to analog signal which is to be displayed on to the monitoring screen.

This system can be used for providing enhanced healthcare services to the rural areas of the developing countries which are facing shortage of efficient specialized doctors. Thus, the cardiovascular disease causing the death of patient can be reduced immensely by the implementation of this proposed system, in both rural and urban areas. Heart hate monitoring will help patient understand the nature of the body system. Cost Effective system with multiple features embedded on a single unique system. [7] Wristbands and vibration sensor help in early detection of the heart attack or stroke and help save lives. It helps in alerting you and your near ones about sudden changes and help can be provided in medical emergency. Besides the features above, we also aim to make the software robust, accurate and fast.

The project basically consists of two modules. The modules are developed separately to be kept at the doctor's side and patient's side. The first module would be placed at the doctor's side, when a patient approaches the doctor when he feels unwell, the doctor would need to examine the possible reason for illness. The proposed system would prove of major help for the doctor in doing so.

The module 1 of the system would consist of a pulse sensor and a temperature sensor that would be mounted on an Arduino board and would send the data to firebase database. The data from firebase would be retrieved by a healthcare management system which the doctor can access. The doctor can add the patient data for a specific patient in the online system. The module 2 would be a patient side system that would consist of a wearable pulse sensor mounted on a node MCU. The node MCU would be connected to the internet and used to send the pulse data to the firebase database, the data from firebase would be displayed on an android application. [4]

This android application would also have an option to set the lower and higher acceptable value of the heartbeat. If the heartbeat gets out of the specified range the IFTTT URL would be triggered. This would send a notification and an email to the concerned people like the doctor and the closest relatives of the patient. The second part in module 2 would be deployment of vibration sensors to the bed of the patient having chances of heart attack. It is based on the study that generally before a probable heart attack, the body generates vibrations at a specific frequency. These vibrations would be detected by the vibration sensors and a buzzer would be sounded to alarm the patient so that preventive steps could be taken. [3]

V. Summary

Healthcare, though a new venture for the Artificial intelligence/ Machine learning domain, remains one of the most crucial domains of public service. With big data growth in biomedical and healthcare communities, accurate analysis of medical data benefits early disease detection, patient care, and community services. It is pertinent that we utilize mathematical modelling to iron out any imperfections and aberrations, so that we have the rigorous standards of accuracy that the medical diagnosis field requires.

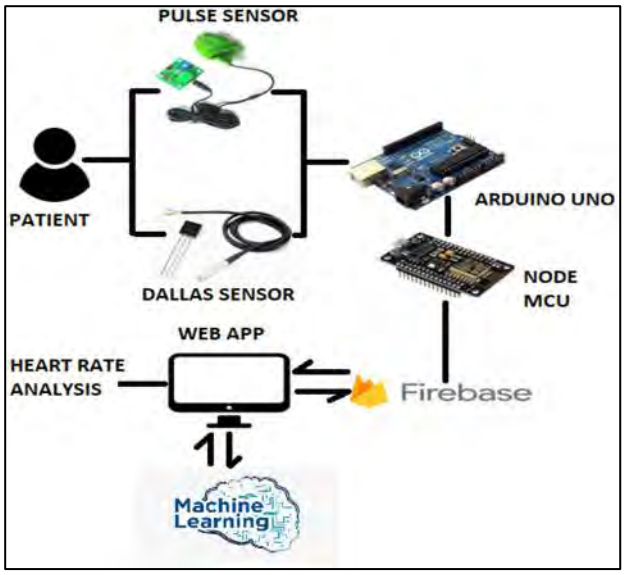

Figure 6.1 Heart Monitoring & Analysis

Many virtual assistants are available on the market, and they give high accuracy in handling input, particularly Siri and Google Assistant. Although not anywhere close in accuracy, the application understands most commands with enough accuracy to extract results through them.

The project aims at creating an intelligent but lightweight healthcare assistant. In an era where medical diagnosis and treatment has made massive leaps, it is unfair to deny anyone proper healthcare owing to a lack of means. This project aims to make healthcare less exclusive than it currently is and make it easier to find and avail services. This application will be able to help healthcare and other hospital staff work efficiently.

Stakeholder perspective is crucial to the success of this project. It is also vital to involve the patients, as the patients being comfortable with the equipment, both hardware and software, is necessitous to the smooth working of the technology. Potential users seemed open to the idea, as anticipated. Stakeholders here include - Doctors and nurses, Health insurance companies, Hospitals, Health department (State as well as National/Federal), Biotechnology manufacturers and even patients.

This application will be able to help healthcare and other hospital staff work efficiently. This also aims at having a basic machine learning capability for disease prediction.

The main objective is to offer a way for doctors and patients alike to easily perform mundane healthcare activities as well as advanced prediction services.

VI. Design and Implementation

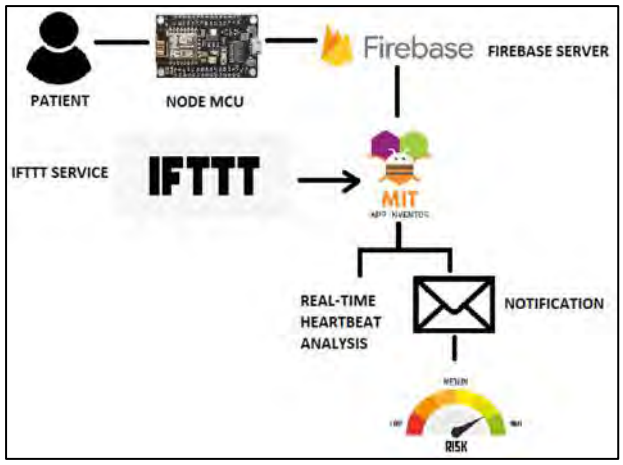

Figure No 6.2 Heart Rate Detection and Monitoring using Pulse Sensor Band.

VII. Deployment

Deployment is a major challenge in software and hardware which involves machine learning and software which will help in detecting the early heart attack from the given pulse rate and heart rate which is collected by vibration sensor and wrist pulse band. Huge amounts of processing are required just to get it up and running. Data generated in the process is humongous as well. The first module of the project would be deployed on the doctor's side. It would not be much of a task. The second module would be deployed individually at the customers end and hence would require some technical work like setting up the firebase database for every customer etc.

The GUI by itself is not very difficult to deploy. We have multiple ways of offering interfaces, such as web interfaces and command line interfaces. It will expand to

Figure No 6.3 Pulse sensor mounted on Node MCU

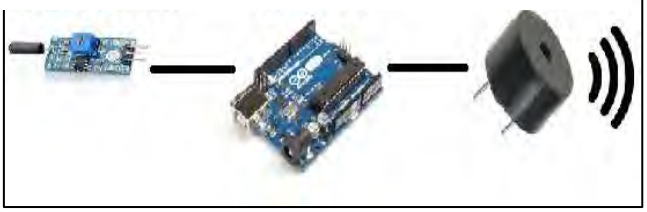

Figure No 6.4 Vibration Sensor Based Heart Attack Detection.

a desktop GUI in the future as well. The Web interface will be deployed using Somee.com, depending on the relative cost of hosting.

The command line can be used as a windows executable file. Users can simply download it and run it natively on their windows PCs.

Maintenance of the system is also a major challenge for the developer. As the system would continuously gather and store data the storage would be a major concern in case of online database.

VIII. FLOWCHART

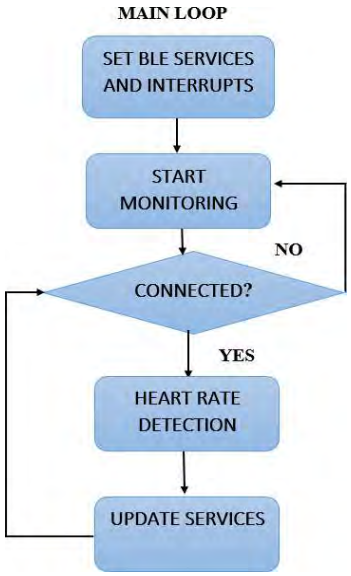

Figure No 8.1 Flow Chart for Heart rate detection.

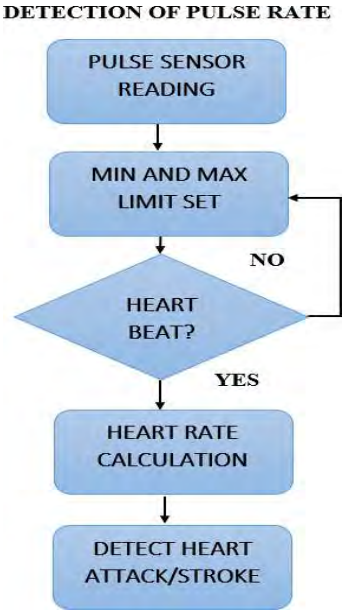

Figure No. 8.2 Detection of pulse rate

IX. RESULTS AND DISCUSSION

A. Output

We were able to build a pulse sensing wristband which is able to sense the pulse rate of the body. Besides this, we were also able to add some basic features such as transferring that data to the Node MCU and uploading the data to firebase server. The data from firebase would be displayed on the webpage hosted on the internet. The data from firebase can also be displayed on an android application for the user's convenience.

B. Outcomes

The project correctly analyses the pulse rate using pulse band sensor and displaying it on the screen. It uses Node

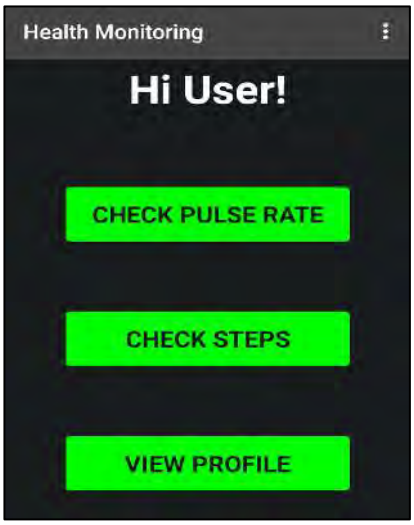

Figure No 9.1 Application Interface

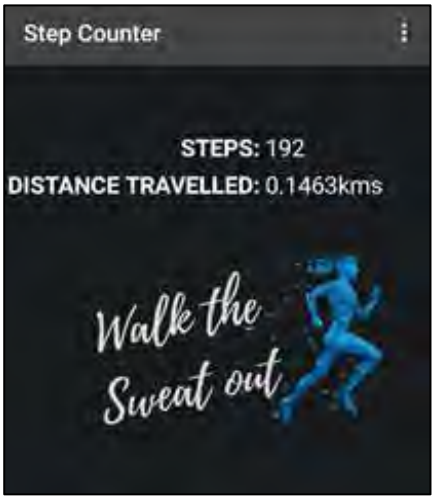

Figure No 9.2 Step counter

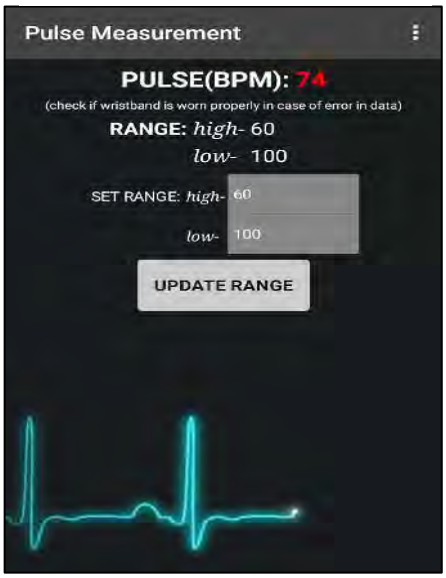

Figure No 9.3 Pulse Measurement

MCU which is for transferring data from the sensor to the

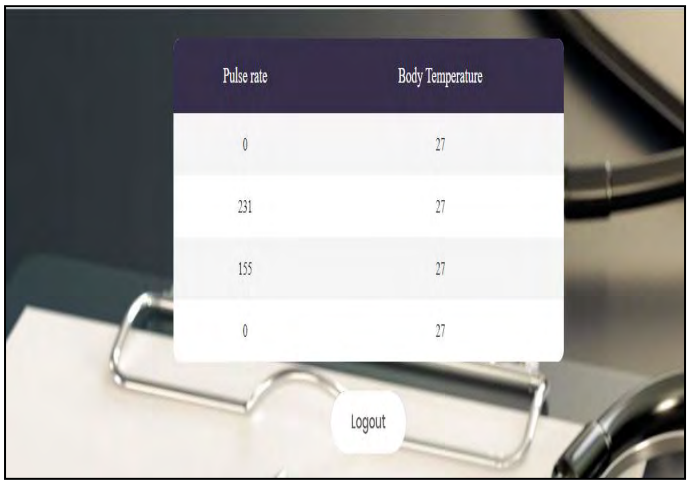

Figure No 9.5 Firebase data

device. The data is stored in firebase database. Data is retrieved from firebase and displayed on the doctor's dashboard. This data can be used for further analysis by the doctor in predicting the disease of the patient. The dataset that would be available would be tested using pretrained data and would be used for drawing important conclusion useful for the doctor. The continuous monitoring of the patient and availability of historic data would enable the doctor to make a better study of the patient's health condition.

We were able to build a pulse sensing wristband which is able to sense the pulse rate of the body. Besides this, we were also able to add some basic features such as transferring that data to the Node MCU and uploading the data to firebase server. The data from firebase would be displayed on the webpage hosted on the internet. The data from firebase can also be displayed on an android application for the user's convenience.

C. Discussion

AI systems are now a part of a variety of specializations from stock trading to the setting of real estate prices; from fraud detection to translation of vernacular languages; from designing our daily shopping lists to forecasting which movies we might like and diagnosis of medical condition. AI is gradually replacing the work that would require about hundreds of workers for its completion and hence is proving a major threat to jobs in future.

This is merely the beginning. Not long from today, AI will be used to advance our understanding of biological phenomenon through analysis of highly dense and huge datasets, help us invent new drugs and make treatments more thorough and personal. Self-driving vehicles can revolutionize transportation and allow new paradigms in planning of architecture. Machines will automate our homes more efficiently, make businesses more productive and help predict risks to society.

Before Artificial Intelligence systems can be deployed in healthcare applications, they need to be 'trained' through datasets that are generated from clinical activities, such as screening, diagnosis, treatment assignment and so on, so that they can learn similar groups of subjects, link between subject features and outcomes of interest. Use of AI in future would gradually lead to increase in accuracy and efficiency of the system.

The main focus in an AI application should be its accuracy in predicting the result. If the system has a good idea but has poor accuracy, it is of no use. The system especially if being used in healthcare field, must have an accuracy of over 95 percent. The accuracy of the system can be increased by training the system using large datasets.

X. CONCLUSION

Our system helps to detect the heartbeat of the patient who will be sporting/wearing the sensors. Whenever there is an irregular heart rate detect by the sensor it will be alerted to the patient, doctor and their relative via the IFTTT notification. Through which further actions can be taken to restore the normal heart beat of the patient. We developed a system that measures and detect heartbeat and body temperature of the patient, sends the info to user or server end by using microcontroller with reasonable cost and great effect. Use two different sensors (pulse sensor and Dallas temperature sensor) and these are mainly under the control of microcontroller. For Human Heartbeat measurement use fingertip, it's in bpm (beats per minute). These calculated rates will have stored in server by transferring through Wi-Fi module via internet. To measure the human body temperature, used a Dallas temperature sensor, the measured data is given to transmitter module, it in turn transfer these data to firebase database through wireless system due to this notice avoided use of wires.

Finally, the stored data in server will be displayed for further analysis by physician or specialist to provide better

aid. The data would be continuous and would be stored at 30 second time intervals. The data would also be available in its historic form and would provide the physician a better idea of the patient's overall condition. All the data would be available at the doctor's dashboard that can be accessed from anywhere and anytime. Also, machine learning is applied on the dataset for automation of the process.

XI. Future Scope

Currently the project focuses on gathering a structured authentic data. As medical data and analysis is a sensitive field, the project intends to find an assimilation of the results of various algorithms and compare the accuracy. It's a challenging task for monitoring and detect heart rate and predict heart attack/ stroke from pulse rate itself. There are other parameters also by which heart attack/ stroke may occur such as patients diabetic, blood pressure history and all. So, we can consider these parameters also to develop enhanced health monitoring system.

The project aims at creating a system which is able to sense the heart rate using IR sensor and the pulse band sensor which is intelligent but lightweight healthcare assistant. This application will be able to help healthcare and other user suffering from heart diseases.

Our system helps to detect the heartbeat of the patient who will be sporting/wearing the sensors. Whenever there is an irregular heart rate detect by the sensor it will be alerted to the patient, doctor and their relative via the IFTTT notification. Through which further actions can be taken to restore the normal heart beat of the patient.

Proposed health monitoring system will monitor the heart beat fluctuation using sensors and monitoring, detection and analysis will be done using pulse-wrist-band which is equipped with Node MCU, Pulse Sensor**.**

This system will help the patient to detect the irregular heart beat within stipulated time. The real time monitoring will avoid any fatality depending on the further actions taken.

XII. Acknowledgment

The success and final outcome of this project required a lot of guidance and assistance from many people and I am extremely privileged to have completed the project successfully. I would like to thank everyone for their guidance.

We sincerely thank our principal, Dr. B.K. Mishra and HOD, Dr. Rajesh Bansode for always encouraging us to do our best. We highly indebted to our guide Mrs. Shridhar Kamble, who supported and constantly supervised us throughout the project and helped us in not only completing this project but also provided us with ample amount of knowledge that was really beneficial to us.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all teaching staffs of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their timely support.

Abstract - **Student discussion portal are considered an extension of traditional learning that promotes dialogue, reflection, knowledge construction and self-assessment. This project represents the design and development of student discussion portal in which the community is limited to students studying in particular college registered students can raise discussions and topics and students can reply to that discussion with remark, comment or a rating and based on that rating the trending discussions will be displayed in the timeline. Now students can reply to particular registered user privately. Addition to that students can upload documents related to particular topic and any registered intended user can download it. Students can login whenever they want and upload/raise a discussion. Users can search according to tags on discussions.**

Keywords – extension of traditional learning, Timeline, tags

I. INTRODUCTION

Discussion forum also commonly referred in many kinds of the terms like web forums, message boards, discussion boards and discussion groups. Members can organize the discussions and gather the suggestions through online around various people. The discussion is initiated through any one member by posting a topic and other members of the group cam make reply. The authorized members of the same group can able to share information, suggestions and ideas among the group. The features in online course were that gives the instructor the opportunity to post topic for discussions and providing the students a tool for responding each topic is referred to as "thread". Technology wherever users will move with different user by exchanging messages generally referred to as post, and discussing a given subject (topic). A connected cluster of written conversations in a web setting. A forum might even be a neighborhood, situations, or group in which people exchange ideas and discuss issues, especially important public issues. A discussion board forum contributes to the event of your psychological feature and necessary thinking skills, permits times for thoughtful, thorough reflection on the right track topics, facilitates searching learning by allowing you to review and respond to the work of others and paves the way for you to approach own learning.

An online discussion forum is the based communication tool (or activity) that enables is participants to post messages and to reply to others messages asynchronously. Over time discussion become increasingly user friendly. Forum usually organized messages by thread topic, date, and time and allowed users to retort to determine message or a produce be a replacement message, of their own. in order to become part of a forum, many sites required web as to register for a user id and password. College professors began utilizing these forums as teaching tools. Students were encouraged to use specific forums set up by the college or professor to discuss the topics. The largest cluster of dialogue forum users, however, was created from people seeking information. Online discussion forum (ODF) is a web-based application that has been used extensively to bring people together with shared interest and mind-set. The use of online discussion forum (ODF) has emerged as a common tool and an effective way of engaging students outside the classroom [1]. ODF is an e-learning platform that permits students to post messages to the discussion threads, interact and receive feedback from other students and instructor, and foster deeper understanding towards the subject under study. In education, they have been deployed to complement traditional techniques such as lectures and tutorials [2]. Online discussion forums (ODFs) harmonize with the educational philosophy that considers communication a necessary and fundamental mechanism for effective learning. It was discovered that learners' interaction with both human and inanimate objects, and their participation in technology mediated education, were essential for the standard of their learning experience, which can enrich the process of knowledge exchange among participants and has positive effects on the students' performance [10]. Consequently, online discussion forums (ODFs) can be successful in enhancing collaborative learning by attracting students to participate and interact [8].

II. PROBLEM DEFINITION

With extremely growing of the telecommunication infrastructures, like net and also the development of the

high performance has led to new era of fast advances in data technology. Internet has become associate ocean of knowledge associated with each side that has existence during this world. The main purpose of this web site is to develop a 1 roof platform for the effective interaction, effective exposure, and a right direction toward communication. Main aim is to provide our students an opportunity to enhance their knowledge by sharing their views on this platform by having discussions with other users. This web portal will act as a healthy questionnaire which helps to give and get effective solutions with best of their experience.

III. BACKGROUND

The online student discussion is one of the key assessment components and requires students to answer the questions. The objective was to help students demonstrate their ability to work collaboratively using online discussion forum moderated by the lecturer and resolve their differences in developing an optimal solution collecting via synergies generated from collective wisdom and peer-to-peer learning. It requires students to participate in an online discussion forum on a weekly basis in a semester. During this time, they are expected to demonstrate their individual ability to apply the concepts and theories of enterprise systems to a business organization and suggest workable solutions to the problems/issues raised in a comprehensive case study. A tutorial may be a period of sophistication outside the 'regular lecture classes' where lecture material is discussed between students and an educator assistant or a professor. Communication in the electronic tutorial was asynchronous. No between-group differences were found regarding grades. From his assessment, students seemed to prefer the electronic tutorial due to the flexibility it offered and the fact that a permanent record was available for future reference. A study of online forum usage during a graduate science education course showed that contributions by students, were more detailed and deliberate when interacting online compared to face-to-face interactions [7]. Online forums provide an avenue where class material can be reviewed, discussed and reinforced. The underlying presumption is that knowledge is often constructed by a web asynchronous dialogue of sophistication material. The conversational model of learning – Laurillard [9] – stipulates that it'll enhance learning, including increased motivation, engagement, and deeper levels of understanding. Communications technologies – like online forums – enable students to debate class material in an asynchronous manner. This channel supports discussion outside the classroom and is flexible for college kids that employment full-time. [5] used a constructivist interaction analysis model to evaluate learning in an online community. However, their analysis revealed that most of the online interactions were limited to the social interchange rather than the creation of knowledge. The authors indicate that this finding was a product of their choice of forum – an information-share forum was used rather than an academic forum.

IV. SIGNIFICANCE

Personal responses to forum topics aren't restricted in time or the length. Students have the freedom to continue dialogues about the topics that interested them most. Effective forum topics are open-ended and designed to encourage students to require a grip on problems. To respond to a forum topic needs organized thought and synthesis of ideas introduced in school. If a view of student is challenged, he or she typically adds carefully considered reasons to back up previous comments. Students have the flexibleness to mirror on their thoughts and skim the responses of others. Many students have declared that they habitually mentioned the forum topics with friends, family and colleagues outside of sophistication before golf stroke their comments on-line. Students have long been want to class discussions within the confines of a brick-and-mortar classroom. albeit a proper discussion doesn't occur, there's always a touch of informal time with their teacher and classmates to debate and gauge their understanding of the category material. Understandably, discussion forums are an integral a part of a web class; however, students routinely voice their annoyance with- or downright hatred of- these forums. While some students would rather add isolation and just get their work done, most students would really like to urge more out of their class. Why do they resent discussion forums? Could it's that they sense the shortage of authentic and meaningful interaction? Could it's that they view it as just another assignment with a "right" and "wrong" answer? In some instances, they might be spot on. While it's important to possess forums for discussion, it's even as important to line them up during a meaningful way. A successful class discussion format creates a way of community, enabling students to attach with each other. This connection not only helps students better enjoy the web experience; it also leads to a deeper investment within the class. This intrinsic motivation is vital to overall success. Additionally, a carefully-constructed student discussion allows the teacher to select abreast of misunderstandings or weaknesses

which will be proactively addressed with the whole class.

V. PROPOSED SYSTEM

In student community portal a student is fundamentally an understudy who will utilize the dialog entrance for setting up any inquiries or questions he/she may experience. On the off chance that an understudy is new to the portal, at that point he/she needs to enroll first before making any talk they need or else they are just permitted to see the exchange of different understudies however can't reply to that dialog except if registered. Once getting themselves registered, they can just login to the community portal from at whatever point next time they need to start the discussion. Client credential (Id and secret phrase) are along these lines put away into the database while enlisting and cross-checked from a similar database while signing in. Aside from this, administrator can affirm/erase the dialog dependent on content against network rules being utilized.

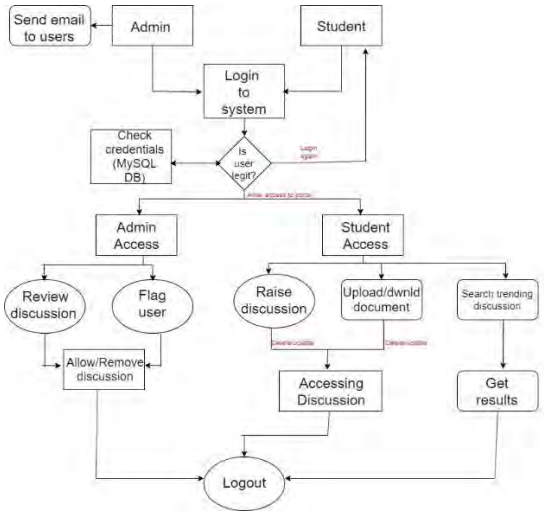

Figure 1. Work-Flow

Data Flow

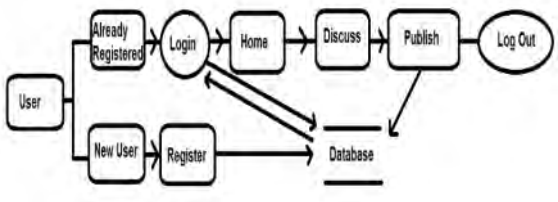

Figure 2. Data Flow

A User of the portal is basically a student who will be using the discussion portal for putting up any questions or doubts he/she might encounter. If a student is new to the system then he/she needs to register first before creating any discussion they want or else they are only allowed to view the discussion of other students but cannot answer to that discussion unless registered. Once getting themselves registered, they can simply login to the system from whenever next time they want to access the portal. User credentials (Id and password) are subsequently stored into the database while registering and cross-checked from the same database while logging in. Apart from this, admin can approve/delete the discussion based on content against community guidelines being used.

Some of the common features of forums are discussed below:

- Private message: a personal message, or PM for brief , may be a message sent privately from a member to at least one or more other members. the power to send so-called carbon copies is sometimes available. When sending a carbon (cc), the users to whom the message is sent directly won't remember of the recipients of the carbon or maybe if one was sent in the first place.
- Attachments: An attachment are often almost any file. When someone attaches a file to a post they're uploading the file to the forums' server. Forums usually have very strict limit on what are often attached and what cannot (among which the dimensions of the files in question). Attachments are often a part of a thread, group, etc.
- Emoticons: An emoticon or smiley may be a symbol or combination of symbols want to convey emotional content in written or message form. Forums implement a system through which a number of the text representations of an emoticons (e.g. xD, :p) are rendered as a little image. counting on part the planet the forum's topic originates (since most forums are international) smilies are often replaced by other sorts of similar graphics, an example would be kaonic(e.g. *(^O^)*, (^-^)b), or maybe text between special symbols (e.g. :blink:, :idea:).
- Poll: Most forums implement a poll system for threads. Most implementations leave single-choice or multi-choice (sometimes limited to a particular number) when selecting options also as private or public display of voters. Polls are often Electronic copy. Members choose a poll and a statistic is displayed graphically.

VI. OBJECTIVES

The aims of this project are as follows: Developing a closed student community web portal which is limited to specific student group or particular college. To achieve a flexible audacious student level network. Enable students to raise currently trending topic related to activities happening in college. Online discussion forum (ODF) could be a web-based application that brings individuals along with shared interest and mind-

set. The use of online discussion forum (ODF) way of engaging students outside the classroom1. ODF is associate degree e-learning platform that has students with privilege to post messages to the discussion threads, interact and receive feedback from other students. Online forums offer associate degree avenue wherever category material is reviewed, discussed and reinforced. The underlying presumption is that knowledge can be constructed by an online asynchronous dialogue. The main feature of the project is a web portal where students can raise discussions, privately message other users, upload files and documents limited to college and expect a secured layer gateway to enter the portal. An online discussion forum is the based communication tool (or activity) that enables is participants to post messages and to reply to others messages asynchronously. While we tend to consider discussions as face-to-face activities, online discussions provide benefits sometimes not available in the classroom.

For example:

- More students are able to participate in online forums than in large group classroom discussions.
- It provides the platform for students who do not participate during class discussions to become “vocal” during online discussion.
- Online interaction allows for further discussion of a topic. It also provides students with enough time to think and reflect on the course material and hence post more thought-out comments to the discussion board.
- Students and instructors often think of comments or questions after the lecture and can post them and discuss these inquiries online.
- The online environment lets you easily create small discussion groups within a large class.
- The online format is a convenient way to archive and preserve your course discussions.
- Online discussions can give you feedback prior to or after a class; this feedback may indicate what content students understand and what requires further clarification.

VII. METHODOLGY

AGILE methodology could be a apply that promotes continuous iteration of development and testing throughout the software system development lifecycle of the project. Both development and testing activities are concurrent. The agile software system development emphasizes on four core values. Individual and team interactions over processes and tools two. Working software over comprehensive documentation. Customer collaboration over contract negotiation. Responding to change over following a plan. Agile development with Scrum is the light at the end of the tunnel.

Scrum is a subset of Agile. It is a lightweight procedure structure for light-footed improvement, and the most generally utilized one. A "process system" is a specific arrangement of practices that must be followed all together for a procedure to be predictable with the structure. (For instance, the Scrum procedure system requires the utilization of improvement cycles called Dashes, the XP structure requires pair programming, etc.) A Scrum procedure is recognized from other coordinated forms by explicit ideas and practices, isolated into the three classes of Jobs, Ancient rarities, and Time Boxes. These and different terms utilized in Scrum are characterized beneath. Scrum is regularly used to oversee complex programming and item advancement, utilizing iterative and gradual practices. Scrum essentially expands profitability and diminishes time to benefits comparative with exemplary "cascade" forms. Scrum forms empower associations to alter easily to quickly evolving prerequisites, and produce an item that meets advancing business objectives.

VIII. RESULTS ACHIEVED

Students are now able to understand WordPress Framework and its fundamentals. This will help them to understand more of the development side of website and technologies being used to connect to database and retrieve from the same to check credentials of registered students. Apart from this, students also enable themselves to understand fundamentals of a discussion forum where they can raise a discussion based on the query they have and other student who had already registered can view the discussion and answer to discussion of other students. This ultimately facilitate them to urge their queries resolved, get discovered by different students, share their thoughts and additionally ping one another (if each have accepted friend request of every other) and additionally transfer study materials in style of document. More students are able to participate in online forums than in large group classroom discussions. It provides the platform for students who do not participate during class discussions to become “vocal” during online discussion. Online interaction permits for additional discussion of a subject. It also

provides students with enough time to think and reflect on the course material and hence post more thought-out comments to the discussion board. Students often think of comments or questions after the lecture and can post them and discuss these inquiries online. The online environment lets you easily create small discussion groups within a large class. The online format may be a convenient thanks to archive and preserve your course discussions. Online discussions can give you feedback prior to or after a class; this feedback may indicate what content students understand and what requires further clarification.

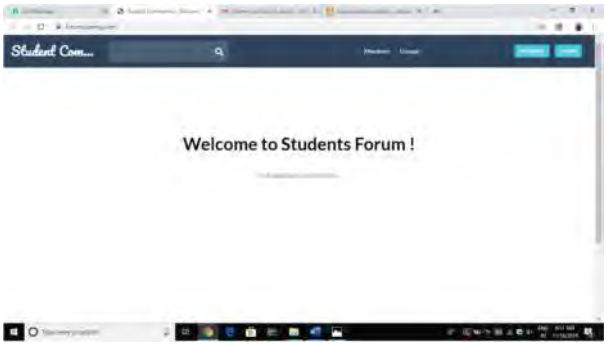

Figure 1. Home Page

Figure 2. Registration Page

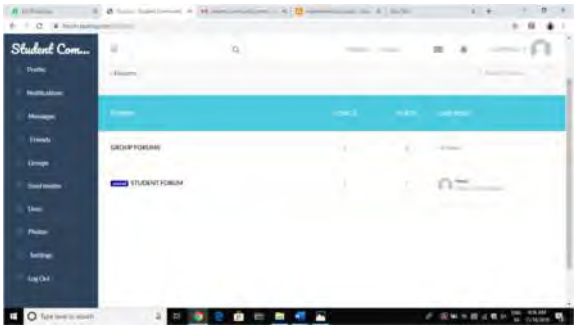

Figure 3. Discussion Page

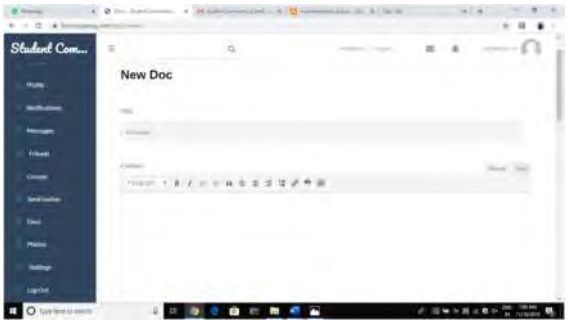

Figure 4. Document Upload Page

IX. FUTURE SCOPE

This Forum can easily support any browser. Various updates may be performed during this forum in returning future. This forum will result in minimizing the gap amongst different users. This forum gives a platform which results in an easy way of communication amongst different people from different areas. Every application has its own merits and demerits. The project has covered almost all the requirements. Further necessities and enhancements will simply be done since the secret writing is principally structured or standard in nature. Changing the present modules or adding new modules will append enhancements. Further enhancements can be made to the application, so that the student community web portal functions very attractive and useful manner than the present one.

X. CONCLUSION

With the proliferation of new computer technologies and Information Technology related innovations, learning and interaction of individuals are gradually taking advantage of these technological developments. Having discussed the structure and some of the features that are present in a forum which makes it a better choice for effective communication among members, it is therefore important that lecturers and students who have regular discussions be advised to require advantage of the pliability that forums provides. With the introduction of forum for student-lecturer interaction, communication between these groups of people become easier as students will be able to participate in the online discussion and contribute their opinion in any material of their choice without being shy or scared of making contributions to topics of dialogue.

XI. ACKNOWLEDGEMENT

We sincerely thank our guide Mrs. Vandana Munde for his guidance and constant support and also for the

stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. Rajesh Bansode, the Principal, Dr. B. K. Mishra, and the college management for their support.

Machine Learning Based Efficient Rain Prediction

Nadeem Choudhary, Manohar Jaiswar, Ganesh Jha
Information Technology, Thakur College of Engineering and Technology
Mumbai, India
ahmedinadeem@gmail.com, jaiswarmanohar3@gmail.com, 29051198gnj@gmail.com

Abstract— **Forecasting of weather always remained the most important part of human life. Rain forecasting always helped human in natural disaster management which helps in saving precious lives, limited resources and lot of important parameters of existence of livings on the earth. Because of the change in the climate during last 50 years now it has became very important to gather and predict the future events in the weather which helps in flood management agriculture planning and many more disasters . In Traditional methods of weather forecasting, the meteorological departments use verity of tools to gather information about weather and climate, tools include thermometers which measure air temperature, anemometers which gauge wind speeds, and barometers which provide information on air pressure etc. By collecting as much data as possible about the current state of the atmosphere (particularly the temperature, humidity and wind) and using understanding of atmospheric processes (through meteorology) to determine how the atmosphere evolves in the future. However most of the time this method does not provide correct predictions. Additionally weather forecasting using this method requires a good amount of knowledge in the field of meteorology. The proposed system provides a platform which predicts the amount of rainfall can occur in the future based on the historical data available with more accuracy. The methodology used in the proposed system is multiple-linear regression algorithm of machine learning. It requires some independent factors based on which it predicts the dependent factors. The independent factors may include Temperature, Dew point, Sea-level pressure, Visibility, Wind etc and these factors decide the level of precipitation can occur that is rainfall will happen or not? It gives the predictions of rainfall for any point of time for which the temperature, pressure and other required values are known. It does not require any high level knowledge related to meteorology to predict the future events. It also gives graphical representation between various parameters of climate.**

Keywords— Multiple-Linear Regression

I. INTRODUCTION

Climate guaging is an imperious and requesting task that is done by different climate divisions from around the globe so as to advise the ordinary citizens such as ourselves about the climate. It is a complicated system that incorporates different particular fields. This particular objective in this area is convoluted because of the idea of taking choices in a dubious way. An assorted gathering of researchers from everywhere throughout the world has created stochastic climate models with the assistance of Random Number Generator, which can deliver a yield that looks like the climate information, supporting them to fabricate a tremendous dataset with no need of manual recording. India is a nation that comprises of something else than a billion people and over 60% of this populace are reliant upon farming professionally. the uncommon field of precipitation forecast, which is important for all the individuals. Precipitation forecast plays a fundamental in anticipating causalities caused because of catastrophic events. It additionally encourages us to keep up our water assets appropriately. Profoundly precise precipitation forecast is helpful if there should arise an occurrence of substantial precipitation which might cause flood and no precipitation which may cause dry spell to keep up our water assets. In the nation like India where yields are reaped dependent on the storm season. In this way, having propelled information in forecast is significant. A few states are influenced by dry seasons while some with floods. This forecast model can assist us with taking required precautionary measures to spare lives by giving transport and nourishment. Machine learning is the scientific study of algorithms and statistical models that computer systems use to perform a specific task without using explicit instructions, relying on patterns and inference instead. It is seen as a subset of artificial intelligence. It has number of algorithms which is used to make a model which can be trained using a dataset. This model can be used to predict the result in the future without any explicit instructions. The process of learning begins with observations or data, such as examples, direct experience, or instruction, in order to look for patterns in data and make better decisions in the future based on the examples that we provide. The primary aim is to allow the computers learn automatically without human intervention or assistance and adjust actions accordingly.

II. RELATED THEORY

Weather plays a very vital role in day to day life, from centuries scientists and meteorologists are trying to predict the change in the events of environment in advance which helps in different aspects of human life, this era is of machine learning which allows us to predict the future events based on the historical data without having a lot of knowledge in that field. There are researches done by numerous researchers on rainfall prediction. We have studied different research papers written by different researchers thus understanding the basic work carried out on this project. We have gone through these papers of different researchers and understood the objectives of these research paper and the research gaps observed. While reading the paper we found that This paper proposes a strategy for selecting the best linear prediction model for Indian monsoon rainfall. This paper results cannot eliminate the possibility that dynamically based, coupled ocean–land–atmospheric models might predict monsoon rainfall with higher skill than linear models. In the next

paper we studied and observed that the present paper analyses the monthly rainfall data. Multiple linear regression is used to predict the average summer-monsoon rainfall using the previous years' data from the corresponding time period. The approach for predicting the rainfall is optimum according to the available data. Although overall prediction error is found to be 26.46%. When reading the next paper we found out that this paper proposed different methods to estimate rainfall. The methods include Autoregressive Integrated Moving Average (ARIMA), Multiple Linear Regression (MLR). However this paper reports a detailed survey on rainfall predictions using different rainfall prediction methods. Although there is a significant limitation in the prediction. The next paper we studied had uses multiple linear regression to predict the monsoon rainfall by using outgoing long wave radiations, global temperatures and sunspots. Although we found out the gap as this paper presents the use of statistical techniques: multiple linear regression method in modeling the rainfall prediction. Though it was efficient but the percentage error was around 15%. When studying this paper we found that This paper presents a case study of using SPSS 13.0 in weather prediction, and the gap we found out was that the present application can forecast an unknown value, using techniques that don't use too many scientific details, thus the precision is not that adequate.

DIFFERENT METHODS OF RAINFALL PREDICTION **:**

MULTIPLE LINEAR REGRESSION

Regression is a statistical measure that attempts to determine the strength of the relationship between one dependent variable usually denoted by Y and a series of other changing variables known as independent variables. Regression model which contain more than two predictor variables are called Multiple Regression Model. Multiple regression model is of the form: Y=b0+b1x1 +b2x2 +b3x3+ b4x4+...e where b0,b1,b2,b3,b4 are regression coefficient e is unexplained portion of dependent variable with zero mean and constant variance. Multiple regression fits a model to predict a dependent (Y) variable from two or more independent (X) variables

AUTOREGRESSIVE INTEGRATED MOVING AVERAGE (ARIMA) MODEL ARIMA

is used to predict a value in a response time series as a linear combination of its own past values, past errors, and current and past values of other time series. The ARIMA procedure provides a comprehensive set of tools for uni-variate time series model identification, parameter estimation, and forecasting, and it offers great flexibility in the kinds of ARIMA or ARIMAX models that can be analyzed. The ARIMA procedure supports seasonal, subset, and factored ARIMA models; multiple regression analysis with ARMA errors; and rational transfer function models of any complexity. In general, the ARIMA procedure can be subtle as follows :

Step 0) A class of models is formulated assuming certain hypotheses In this step, a general ARIMA formulation is selected to model the rain fall data. This selection is carried out by careful inspection and selection of the main characteristic of the daily rain fall and other meteorological data.The corresponding data are: humidity, air pressure, surface land temperature and wind velocity (corresponding to daily respectively), among others.

Step 1) A model is identified for the observed data. A trial model must be identified for the rain fall data. First, in order to make the underlying process stationary (a more homogeneous mean and variance), a transformation of the original rain fall data and the inclusion offactors of the form trial model must be identified for the rain fall data. First, in order to make the underlying process stationary (a more homogeneous mean and variance), a transformation of the original rain fall data and the inclusion offactors of the form may be necessary. In this step, the checking process can be done using Autocorrelation function (ACF) or unit root test. A further check for lag residual and lag dependent tested from partial ACF.

Step 2) The model parameters are estimated. After the functions of the model have been specified, the parameters of these functions must be estimated. Good estimators of the parameters can be computed by assuming the data are observations of a stationary time series (Step 1). If a Moving Average (MA) pattern is identified then further optimization process needed by using maximum likelihood or least square estimation. A conditional likelihood function is selected in order to get a good starting point to obtain an exact likelihood function. Also, an option to detect and adjust possible unusual observations is selected. As these events are notinitially known, a procedure that detects and minimizes the effect of the outliers is necessary. With this adjustment, a better understanding of the series, a better modeling and estimation, and, finally, a better forecasting performance is achieved.

Step 3) If the hypotheses of the model are validated, go to Step 4, otherwise go to Step 1 to refine the model. In this step, a diagnosis check is used to validate the model assumptions of Step 0. This diagnosis checks if the hypotheses made on the residuals (actual prices minus fitted prices, as estimated in Step 1) are true. Residuals must satisfy the requirements of a white noise process: zero mean, constant variance, uncorrelated process and normal distribution. These requirements can be checked by taking tests for randomness, such as the autocorrelation and partial autocorrelation plots. If the hypotheses on the residuals are validated by tests and plots, then, the model can be used to forecast prices. Otherwise, the residuals contain a certain structure that should be studied to refine the model in Step 1.

Step 4) The model is ready for forecasting. In Step 4, the model from Step 2 can be used to predict future values of daily rainfalldata. Due to this requirement, difficulties may arise because predictions can be less certain as the forecast lead time becomes larger. Based on the natural of data, time series forecasting is suit to short term forecasting (hourly or daily). For a long term period, a structural forecaster is more comply for the situation.

GENETIC ALGORITHM

Genetic algorithms are algorithms that attempt to apply an understanding of the natural evolution in problem-

solving tasks (problem solving). The approach taken by this algorithm is to combine a wide selection of solutions randomly within a population and then evaluate them to get the best solution By doing this process repeatedly, these algorithms simulate the process of evolution as the desired number of generations. This generation will represent improvements on previous population. In the end, we will get the best solutions appropriate to the problems faced. To use a genetic algorithm, solutions to problems represented as a set of genes that make up chromosomes. This chromosome was randomly based coding techniques are used. The entire set of chromosomes is observed representative of the population. Chromosomes will be evolved in several stages iterations called generations. The new generation is obtained By cross breeding techniques (crossover) and mutation (mutation). Crossover includes cutting two pieces of chromosomes based on the desired number of points and then combine half of each chromosome with other couples. While mutations include the replacement value of the gene in a chromosome with the value of other genes from other chromosomes become partner. The chromosomes are then evolved to a suitability criterion (fitness) and the set will be selected the best results while others are ignored. Furthermore, the process repeated until you have a chromosome that has the best fit (best fitness) to be taken as the best solution of the problem. On Genetic Algorithms, the bestsolution search techniques performed simultaneously at a number of solutions known as population. Individuals in a population are referred to as chromosomes. This chromosome is a solution that is shaped symbol. Initial population is built randomly, while the next population is the result of the evolution of chromosomes through iterations called generations. In each generation, the chromosomes will go through an evaluation process using a measurement tool called the fitness function. Fitness value of a chromosome will show the quality of the chromosomes in the population. The next generation is known as the child (offspring) are formed from the combination of two generations of chromosomes that act as the parent (parent) using the crossover operator. Besides crossover operator, a chromosome can also be modified by using mutation operators. The population of the new generation is formed by selecting the fitness value of parent chromosome and the fitness value of the chromosomes of children, and discard the other chromosomes so that the population size (the number of chromosomes in a population) constant. After several generations, the algorithm will converge to the best chromosome.

Genetic Algorithms steps for generating initial weight as follows:

1.Create an initial population randomly of meteorological data.

2. Evaluate each individual in the population.

3.Generate new population using genetic operations.

4.Determine the final result at the time of termination criteria.

ADAPTIVE SPLINES THRESHOLD AUTOREGRESSIVE (ASTAR)

Modelling In modelling ASTAR several software are used and integrated to process the ASTAR result, i.e.Microsoft Excel, SPSS 16 and MARS 2.0 are the software for ASTAR planning system.Rain fall forecasting, as response variable (Y), Input variable, as predictor variable (X), is wind speed, humidity and temperature withX1, X2, and X3 respectively. All of predictor variables are applied to attain the best model of rainfall forecasting.The significant variable, influenced the next day condition with importance variable, is processed using MARS 2.0 Software. Function Base A Basis Function is distance between sequence knots. In ASTAR, Basis Function is a set of function to describe information that consist of one or two variables. Max(0, x − t) or Min (0, t − x) is Basis Function value with t as a value to illustrate knot position and x as predictor variable. Every 1 knot will produce a couple of Basis FASTAR Methods as data analysis technique to find the best model from a set of data. It is using past and present data to predict the short-term forecasting.

Modelling Stage of ASTAR

1.Determine maximum Basis Function, maximum interaction numbers and minimum observation numbers between knots.

2.Forward Stepwise Processing to obtain maximum number of Basis Function using MARS 2.0

3.Backward Stepwise Processing to obtain Basis Function numbers from forward stepwise by minimizing the least GCV (Generalized Cross Validation) value.

4.Knots selection using forward and backward algorithm. 5.Estimating the coefficient of chosen Basis Function as a stage of response variable (Y) prediction (Y) to predictor variable (X).

SUPPORT VECTOR MACHINE (SVM)

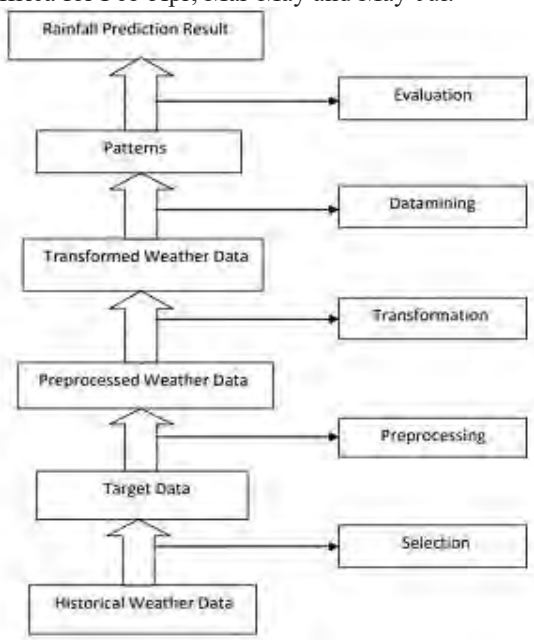
A Support Vector Machine (SVM) is a computer algorithm that learns by example to find the best function of classifier hyperplane to separate the two classes in the Input space.The SVM analyzed two kinds of data, i.e. linearly and non- linearly separable data .The example of linearly separated data is shown in fig. below. Best hyperplane betweentwo classes can be foundby measuring the hyperplanemargin and find out the maximum points.Margin is defined as the distance between hyperplane and the closest pattern of each class, which is called support vector.The best hyperplane is defined by the following equation f(x) = w x+ b(1) T Where x refers to a training pattern, w is referred to as the weight vector and b as the bias termSupport Vector Machine is one of the important category of perceptrons and radial basis function networks, support vector machines can be used for pattern classification and nonlinear regression. Support Vector Machines (SVMs) developed by Vapnik and his co-workers has been used for supervised learning due to – (i) Better generalization performance than other NN models (ii) Solution of SVM is unique, optimal and absent from local minima as it uses linearly constrained quadratic programming problem (iii) Applicability to non- vectorial data (Strings and Graphs) and (iv) Few parameters are required for tuning the learning m/c. Kernel Methods are a set of algorithms from statistical

learning which include the SVM for classification and regression, Kernel PCA, Kernel based clustering, feature selection, and dimensionality reduction etc . SVM is found to be a significant technique to solve many classifications problem in the last couple of years. Very few researchers of this field used this technique for rainfall prediction and got satisfactory result.

WEATHER RESEARCH AND FORECASTING MODEL The Weather Research and Forecasting (WRF) model is a numerical weather Prediction (NWP) and atmospheric simulation system desined for both research and operational applications. The development of WRF has been a multi-agency effort to build a next-generation forecast model and data assimilation system to advance the understanding and prediction of weather and accelerate the transfer of research advances into operations. The geogrid defines model domains and interpolates static geographical data to the grids. ungrib extracts meteorological fields from GRID formatted files. The metagrid horizontally interpolates the meteorological fields extracted by by ungrib to the model grids defined by geogrid. Each of the WPS programs reads parameters from a common name list file, as shown in the figure. This name list file has separate name list records for each of the programs and a shared namelist record, which defines parameters that are used by more than one WPS program The ungrib program reads GRIB files degribs the data, and writes the data in a simple format, called the intermediate format.GRIB (Gridded Binary or General Regularly distributed Information in Binary form) is a mathematically concise data format commonly used in meteorology to store historical and forecast weather data.

Seasonal Climate Forecasting

The CGCM is run by the BoM out for 9 months every day. Forecast products are generated from dynamical model output using data analysis software. The resulting derived forecast products are persisted in self describing files with additional metadata to support the clients that deliver the outlooks. Forecast data is exposed via a data server. Scheduled processes access and reformat the data for SCOPIC (Seasonal climate outlooks for pacific island Countries) access. Custom web services use the data server's interface to the forecast data to provide maps, data, and line plots. The Pacific Adaptation Strategy Assistance Program (PASAP) Portal consumes the outputs of the custom web services, and displays model based outlooks as overlays on dynamical maps and standard plots. The high predictability of seasonal climate in the tropical Pacific provides opportunities for using seasonal forecasts to improve the resilience of climate sensitive sectors throughout the region. An enhanced probability for below-normal precipitation is forecast for Feb-Apr and Mar-May in parts of Indonesia, northern Australia, and for Feb-Apr in part of southeast Africa. Below-normal is also favored for Feb-Apr through Apr-Jun in the Philippines, for Feb-Apr in scattered portions of interior Asia, and for May-Jul in central Chile and coastal northeast Brazil. Enhanced chances for above-normal precipitation are predicted for Feb-Apr in coastal northeast Brazil, northeastern Scandinavia, and northeast Asia, and for Feb-Apr and Mar-May in far northern North America. A tilt of the odds toward above-normal is also forecast in eastern equatorial Africa for Feb-Apr, Mar-May and May-Jul.



Since 2004 the Pacific Island-Climate Prediction Project (PI-CPP) managed by the Australian Bureau of Meteorology (BoM) has built seasonal prediction capabilities within National Meteorological Services (NMS) of Pacific Island countries through the development and provision of decision support software

GENERAL DATA MINING RAINFALL PREDICTION MODEL: In general data mining prediction model first we collect the historical weather data. Data were collected from Indian metrological department pune. the collected data consist of different features including daily dew point temperature (Celsius), relative humidity, wind speed (KM/H), Station level pressure, Mean sea level, wind speed, pressure and rainfall observation. Creating a target data set selecting a data set or focusing on a subset of variables or data samples on which discovery is to be performed. Then important step in the data mining is data preprocessing. One of the challenges that face the knowledge discovery process in meteorological data is poor data quality. For this reason we try to prepare our data carefully to obtain accurate and correct results. First we choose the most related attributes to our mining task. purpose we neglect the wind direction. Then we remove the missing value records. In our data we have little missing, because we are working with weather data. Then finding useful features to represent the data depending on the goal of the task.

After preprocessing and transforming the weather data choosing the data mining task i.e. classification, regression and decision tree. Then applying different data mining techniques i.e. K-NN, Naïve Bayesian, Multiple Regression and ID3 on weather data set and makes the rainfall prediction i.e. Rainfall Category or No Rainfall Category.

III. PROPOSED METHODOLOGY

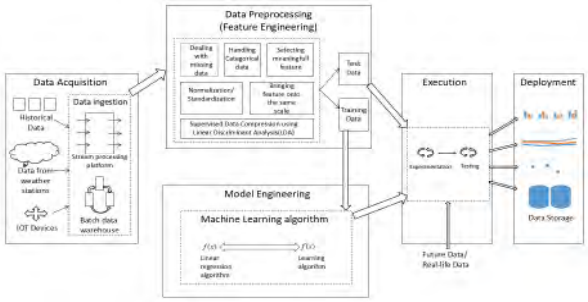


Fig. Proposed Methodology Architecture

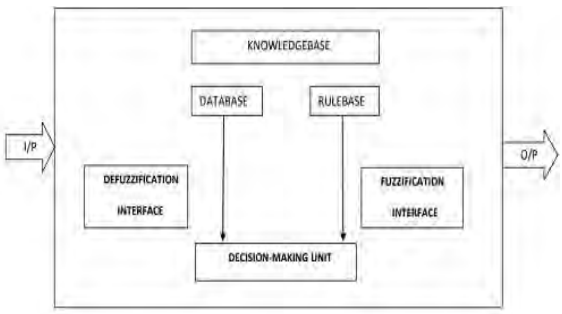
In this project we have tried to predict the rainfall using machine learning concept. The methodology is undertaken into different steps , basically three stages. Data Acquisition, Data pre-processing and Data Execution. In the first step we try to acquire as many data available which are relevant to our project from different resources. To build a prediction model we need an efficient dataset to train our model for the required output, so to have efficient and relevant data is very necessary before developing a prediction model. We can have different resources for these data, such as historical data which are already recorded and stored from past, or data which are real time like weather factors such as temperature , pressure etc. Also sometime the data is acquired from different sensors, relative to the system. As all these data are acquired from different sources, there is a possibility of this data being in unstructured format, also it maybe a noisy too. Thus to make this data usable and suitable for the model, we need to preprocess the data. We have to remove any anomaly or discrepancies from these datasets to make it system dependent. Also a machine learning model will be implemented in which this acquired data will be feeded to, for training the model and then performing a testing of the accuracy of this model with the help of remaining data.

WEATHER RESEARCH AND FORECASTING MODEL The Weather Research and Forecasting (WRF) model is a numerical weather Prediction (NWP) and atmospheric simulation system desined for both research and operational applications. The development of WRF has been a multi-agency effort to build a next-generation forecast model and data assimilation system to advance the understanding and prediction of weather and accelerate the transfer of research advances into operations. The geogrid defines model domains and interpolates static geographical data to the grids. ungrib extracts meteorological fields from GRID formatted files.The metagrid horizontally interpolates the meteorological fields extracted by by ungrib tothe model grids defined by geogrid. Each of the WPS programs reads parameters from a common namelist file, as shown in the figure.This namelist file has separate namelist records for each of the programs and a shared namelist record, which defines parameters that are used by more than one WPS program The ungrib program reads GRIB files degribs the data, and writes the data in a simple format, called the intermediate format.GRIB (Gridded Binary or General Regularlydistributed Information in Binary form) is a mathematically concise data format commonly used in meteorology to store historical and forecast weather data.

GLOBAL DATA FORECAST SYSTEM

A new Global Forecast System (GFS) has been implemented at Northern Hemisphere Analysis Center of IMD on High Power Computing Systems (HPCS). The new GFS is running in experimental real-time model since 15th January 2010. This new higher resolution global forecast model. The GFS at IMD Delhi involves 4 steps as given below: Steps 1 - Data Decoding and Quality Control: First step of the forecast system is data decoding. It runs 48 times in a day on half-hourly basis, as soon as GTS data files are updated at regional telecom hub (RTH) of global telecom system (GTS) at IMD New Delhi. Steps 2- Preprocessing of data: (PREPBUFR): Runs 4 times a day at 0000, 0600, 1200 & 1800 UTC. Step 3 - Global Data Assimilation (GDAS) cycle: The Global Data Assimilation cycle runs 4 times a day (00, 06, 12 and 18 UTC). The assimilation system is a global 3-dimensional variational technique, based on NCEP's Grid Point Statistical Interpolation (GSI) scheme, which is the next generation of Spectral Statistical Interpolation (SSI). Step 4 – Forecast Integration for 7 days: The analysis and forecast for 7 days is performed using the HPCS installed in IMD Delhi. One GDAS cycle and seven dayforecast (168 hour) run takes about 30 minutes.

FUZZY LOGIC (FUZZY) Fuzzy Logic is a type of reasoning based on the recognition that logical statements are not only true or false (white or black areas of probability) but can also range from "almost certain" to "very unlikely".Fuzzy logic has proven to be particularly useful in expert system applications. Fuzzy inference system is shown in diagram below. They are composed of five conventional blocks a rule-base containing a number of fuzzy if-then rules, a database which defines the membership functions of the fuzzy sets used in the fuzzy rules, a decision making unit which performs the inference operations on the rules, a fuzzification interface which transform the crisp inputs into degrees of match with linguistic values, a defuzzification interface which transform the fuzzy results of the inference into a crisp output.



IV. RESULT&DISCUSSION

The Amount Of Rain That Can Happen In Near Future Can Be Predicted Using Historical Data Available On Kaggle. The Expected Result Is Represented In The Graphical Format.

V. APPLICATION

Rainfall plays a very critical role in every aspects of life. The rainfall can either boost the society growth or destroy the society. It is thus very important to consider the rainfall as the main aspect for deciding other event. India being an agricultural country, extensively depends on Rainfall for its prosperous growth. Thus this project a wide range of spectrum for application in real life. From stepping out of our home, to economy of this country it mostly depends on rainfall, thus it is becomes very important to know wether there will be a rain or not, or how much rainfall is estimated. Thus this project has various application scope in the real-life.

VI. CONCLUSION

In this project, we've got suggested an analysis of the soil information using Decision Tree algorithms and prediction technique. By using Decision tree algorithm, we recommend farmers about their field soil quality and suggest crops which are suitable to grow in that soil. Agriculture is the utmost important area especially in the mellowing country like India. Use of information technology in agriculture can change the scenario of decision making and framers can yield in a better way. For decision making on overall issues related to agriculture field; data mining plays a vital role. The survey discussed the role of data mining in terms of agriculture field. We have also discussed various types of soils, several data mining techniques in agriculture and soil containment.

Abstract – **A career guidance system where students can see various career opportunities, the system shows different fields available after the 10th, 12th for graduation and after graduation fields are available. It also lists several universities available where students can search for universities for their courses. Subsequently, the system allows users to perform a test. The tests have two levels. The first level has questions that help us identify which field the student is interested in and, depending on this, the second level will ask questions from their field of interest. The first level has the same questions for all standards, since it is not based on knowledge but on interests. The second level questions will come from the field in which the student is most interested, together with the questions from other fields. After successfully completing both levels, the student will receive the results along with a detailed explanation and advice from us. The explanation will indicate why we believe a certain career is better for him and why not the other.**

I. INTRODUCTION

Choosing a right career for our self has been one of the most important decision of our lives from a very early age. This decision always keeps tricking our mind as to what our interest lies in. The tension starts to mount gradually as we grow up and realise that we have reached a point where we need to decide what has to be done next in life, but are still confused with the idea.

Career guidance system is designed by keeping in mind the seriousness of one's career. Our website is a relief for the students as it will clear a lot of their confusion and save time. Our system will guide the students after ssc,hsc and graduation who are looking for best career opportunities.

This system is designed in such a way that students will be able to easily rectify their area of interest and move further with the process of selecting a career for themselves. Student will have to first register with our website. Then they will have to login to the system with their id which will be given to them by the system. The first step will be that the student will have to select his/her standard to move further.

Student will then enter his/her data and this data will analysed by the system to give accurate results. This system will be connected to the database where all the information of the student will be stored.

Career guidance system will work as a guide for students and help them in analysing their interest and in making the right choice for the future. This system will show various career opportunities to the students based on the data entered by them.

Students can see suitable streams available after 12th or graduation. Students will be able to pick or select only one stream from science /commerce/arts. Based on the data entered by the student, their area of interest will be analysed by the system.

An online aptitude test will be taken to help the student in making a suitable choice. This aptitude test will be available for the students to make choices based on their knowledge. The result of the test will be given to the student and based on the marks scored by the student, career choice will be given to the student. E-books will be made available via hyperlinks for students who are looking for more information on certain fields. The system will generate a list of available fields and courses for the students based on their academics and interest. With the help of the guidance provided by this system, career selection will become easier for the student. Best colleges/universities will be marked based on their score. Students can also view this list of colleges based on the courses selected by them. This system will help students in selecting the right streams based on their performance. With the help of our system, confusion of selecting the right path for future will be solved and time and cost will be saved overall.

II. Literature Survey

The traditional approach to career guidanceis a manual method that is ineffective and inefficient. The electronic approach provides an effective and efficient career guidance. The intelligent system uses direct parameters from the students, such as the combination of preferred scientific subjects, the result of the analysis of the inventory of professional interests and the result of the intelligent quotient test for the professional recommendation. The web-based intelligent system was designed and implemented with the principle of a rule-based expert system using the fasttree algorithm, the client / front-end pages were designed using the "Bootstrap 3" frontend

framework containing: HTML5, CSS3 and JavaScript SSMS 2018 was used for the back end.

III. METHODOLOGY

The methodology that we chose for our project is Agile. While waterfall model is a tried and tested framework, it is not suitable for our project, due to the changeable nature and small tea size. Agile allows us to be flexible, manage changing requirements, manage the ever-increasing scope as well as get consumer perspective.

Student :
This module provides functionality for student. Applicants/students can give online Aptitude test System will automatically predict career option and courses for student based rest result. the applicant cans also browse through courses and colleges available. A student registration page will be created for the students who are looking for career guidance. Students will have to register themselves on the website in order to avail the facilities. Registered students will get a login id and password. They can use the website by logging in using the generated login id and password.
displayed.

Available courses: Students looking for certain courses can view it on the website. Also, the available courses after 10th, 12th or graduation will be displayed. Courses available for the student based on the marks will also be displayed. **Streams/fields:** Student can directly select courses according to their interest or available streams will be listed to the students based on their performance.

Suggestion: Streams will be suggested by the system to the students based on their performance

IV. PROJECT PROTOTYPE

PROTOTYPE DEVELOPMENT

The traditional approach to career guidance is a manual method that is ineffective and inefficient. The electronic approach provides an effective and efficient career guidance. The intelligent system uses direct parameters from the students, such as the combination of preferred scientific subjects, the result of the analysis of the inventory of professional interests and the result of the intelligent quotient test for the professional recommendation. The web-based intelligent system was designed and implemented with the principle of a rule-based expert system using the fasttree algorithm, the client / front-end pages were designed using the "Bootstrap 3" frontend framework containing HTML5, CSS3 and JavaScript SSMS 2018 was used for the back end.

3.2 Product Backlog or Sprint Backlog

The backlog of the project is given as follows:

To do

- Make GUI for fringe features
- Add a option for Sender to send type of data
- Add an archiving feature
- Providing Estimating transfer time
- Make a checklist database for users
  Ongoing
- Information catalogue building
- Dataset training
- GUI building
- Procurement of data for higher accuracy Done
- Analysis

Design

- Modelling
- Literature survey
- Budgeting and scheduling
  Feasibility analysis

3.3 Project planning (Resources, Tools used, etc.)

IT projects require resources in terms of money, time, human resources, infrastructure and technology, both hardware and software. Resources are not just a mean, but also an approximation of constraints. Project planning is essential to managing the scope, schedule and budget of the project. For this, we used tools such as MS Excel, MS PowerPoint, online MS project as well as various modelling tools, such as draw.io. Thus, we made it a necessity to search for user consensus before we planned for features to be built in our project. This was done by researching search

interest on search engines, visiting forums pertaining to QR code. We divided our project into various phases and sub-phases, and allocated date ranges from a week to 3 weeks to every sub-phase. This was done using the timeline chart feature of online MS project. We then used a Gantt chart to model schedule dependencies and fine tune the scheduling. The Gantt chart was created using the Gantt chart feature available in MS Excel. Using these two, we further planned our sub-phases.

The modelling included charts and diagrams such as UML diagram, GUI modelling, dependencies and other diagrams. These were done using free tools like draw.io. Drawing these models helped to incisively assess our requirements and features.

V. FUTURE SCOPE

In the knowledge economy and society, the trend towards aligning higher education with the needs of the working world has received considerable attention, turning concepts such as
'evaluation', 'accountability', 'knowledge society', 'knowledge economy', 'employability', and 'internationalisation' or 'globalisation' into some of the main recurring dimensions of the debate about the relationships between higher education and the world of work.In this context, a diverse range of support services geared towards helping students with the transition to employment has become increasingly common among higher education providers in recent decades. As graduation from higher education does not guarantee the transition to employment or professional success, higher education is considered an imperfect source of training for the world of work. The transition from one sphere to the next is a process influenced by a wide range of internal and external factors affecting professional development. In this context, a diverse rangeof support services geared towards helping students with the transition to employment has become increasingly common among higher education providers in recent decades. As graduation from higher education does not guarantee the transition to employment or professional success, higher education is considered an imperfect source of training for the world of work. The transition from one sphere to the next is a process influenced by a wide range of internal and external factors affecting professional development.

VI. CONCLUSION

The career guidance system is an innovative idea. The opportunities offered by this electronic medium are immense and many students can take advantage of this medium to choose a career more suited to their abilities. In today's competitive and technological world, with countless options available, the student is generally confused in choosing the right or most appropriate career. The world these days is moving towards "information flows". The information is released to the user instead of the user learning the information. In light of the above, it is believed that the proposed system has the ability to connect with different students and help them connect with the most appropriate career.

Abstract - **A stock market is a public market for the trading of company stock. It is an organized set-up with a regulatory body and the members who trade in shares are registered with the stock market and regulatory body SEBI. Since stock market data are highly time-variant and are normally in a nonlinear pattern, predicting the future price of a stock is highly challenging. Prediction provides knowledgeable information regarding the current status of the stock price movement. Many researches have carried out for predicting stock market price via various data mining techniques. This focuses on use of Artificial Neural Network techniques to predict the stock price. The past data of the selected stock will be used for building and training the models. The results from the model will be used for comparison with the real data to obtain the accuracy of the model.**

Predicting financial market changes is an important issue for time series analysis, receiving an increasing attention in past years.

The mean square error (MSE) measure was used to evaluate the performances of proposed model. The experimental output lead to the conclusion that the proposed model can be successfully used as an alternative method to standard statistical techniques for financial time series forecasting.

I. INTRODUCTION

In modern world financial time series prediction is an important subject for many financial analysts and researchers as accurate forecasting of different financial applications play a key role in investment decision making. Stock market prediction is one of the most difficult tasks of time series analysis since the financial markets are influenced by many external social-psychological and economic factors. Efficient market hypothesis states that stock price movements do not follow any patterns or trends, and it is practically impossible to predict the future price movements based on the historical data. However, financial time series are generally non-stationary, complicated and noisy, it is possible to design mechanisms for prediction of financial markets. Technical analysis with statistical and machine learning techniques have been applied to this area in order to develop some strategies and methods to be helpful for financial time series forecasting. The statistical methods include Recurrent Neural Network (RNN) and Long Short Term Memory (LSTM), area of stock prediction, feature selection plays a significant role in forecasting accuracy and efficiency.

RNN:- Recurrent Neural Network(RNN) are a type of Neural Network where the output from previous step are fed as input to the current step. In traditional neural networks, all the inputs and outputs are independent of each other, but in cases like when it is required to predict the next word of a sentence, the previous words are required and hence there is a need to remember the previous words. Thus RNN came into existence, which solved this issue with the help of a Hidden Layer. The main and most important feature of RNN is Hidden state, which remembers some information about a sequence. RNN have a "memory" which remembers all information about what has been calculated.

RNN converts the independent activations into dependent activations by providing the same weights and biases to all the layers, thus reducing the complexity of increasing parameters and memorizing each previous outputs by giving each output as input to the next hidden layer. Hence these three layers can be joined together such that the weights and bias of all the hidden layers is the same, into a single recurrent layer.

II. OBJECTIVE AND SCOPE

The aim of the project is to examine a forecasting technique to predict future stock returns based on past returns We do this by applying Neural network methods like RNN (Recurrent neural network) and LSTM(long short term memory) for stock price forecasting by interpreting the seemingly chaotic market data.

The stock market prediction task is interesting as well as divides researchers and academics into two groups those who believe that we can devise comes mechanism to predict the market is efficient and whenever new information comes up the market absorbs it by correcting itself, thus there is no space for prediction.

We are going to predict market price (index) of each individual company's share with help of historical data of that particular company,Similarly we can implement many of the company's share price individually and merge them in to a particular User interface, also we would check the accuracy on with the help of historical data which will not be present In trained.

III. PROBLEM DEFINITION

The uncertainity of the stock market and the unstable growth of any stock exchange creates challenges among investors to choose the right stock as per the market behaviour, to overcome these challenges stock market prediction models play a very critical role in influencing the investing behaviours of investors. There are a lot of

complicated financial indicators and also the fluctuation of the stock market is not very stable. But as the technology is getting advanced, the opportunity to gain a steady fortune from the stock market is increased and it also helps experts to find out the most informative indicators to make a better prediction. The prediction of the market value is of great importance to help in maximizing the profit of stock option purchase while keeping the risk.

The stock market prediction task is interesting as well as divides researchers and academics into two groups those who believe that we can devise comes mechanism to predict the market is efficient and whenever new information comes up the market absorbs it by correcting itself, thus there is no space for prediction.

We are going to implement a system in such a way so that all the problems which previously have been occured will be solved by using LSTM and RNN techniques of neural networks by taking a particular stock company data and train them as time series analysis based solution.

IV. METHODOLOGY

The prediction of the market value is of great importance to help in maximizing the profit of stock option purchase while keeping the risk low. Recurrent neural networks (RNN) have proved one of the most powerful models for processing sequential data.

Long Short-Term memory is one of the most successful RNNs architectures. LSTM introduces the memory cell, a unit of computation that replaces traditional artificial neurons in the hidden layer of the network. With these memory cells, networks are able to effectively associate memories and input remote in time, hence suit to grasp the structure of data dynamically over time with high prediction capacity.

In our LSTM model for stock prediction, one sequence was defined as a sequential collection of the daily dataset of any single stock in a fixed time period (N days). The daily dataset describes the performance of the stock with sequence learning features like closing price, trade volume on one particular day in these N days.

Our model is composed of (1) a single input layer with the number of memory cells as that of the sequence learning features one sequence may hold, followed by 2) multiple LSTM layers and (3) a dense layer and (4) a single output layer.

This section we will discuss the methodology of our system. Our system consists of several stages which are as follows:-

- Stage 1: Raw Data: In this stage, the historical stock data is collected from Google Finance and this historical data is used for the prediction of future stock prices.
- Stage 2: Data Pre-processing:

The pre-processing stage involves,

a) ***Data discretization***: It is a part of data reduction but with particular importance, especially for numerical data

b) ***Data transformation***: Normalization.

c) ***Data cleaning***: Fill in missing values.

d) ***Data integration***: Integration of data files.

After the dataset is transformed into a clean dataset, the dataset is divided into training and testing sets so as to evaluate. Here, the training values are taken as the more recent values. Testing data is kept as 5-10 percent of the total dataset.

Stage 3: Feature Extraction: In this layer, only the features which are to be fed to the neural network are chosen. We will choose the feature from Date, open, high, low, close, and volume.

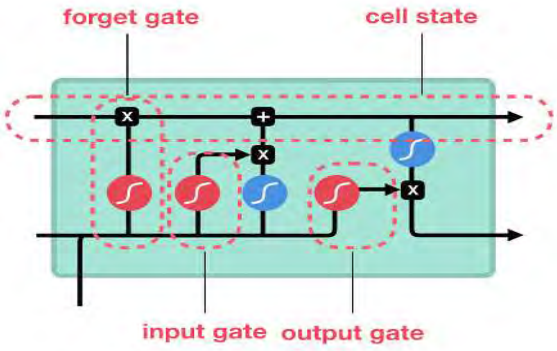
Stage 4: Training Neural Network: In this stage, the data is fed to the neural network and trained for prediction assigning random biases and weights. Our LSTM model is composed of a sequential input layer followed by 2 LSTM layers and dense layer with ReLU activation and then finally a dense output layer.

Stage 5: Output Generation: In this layer, the output value generated by the output layer of the RNN is compared with the target value. The error or the difference between the target and the obtained output value is minimized by using back propagation algorithm which adjusts the weights and the biases of the network.

LSTM recurrent unit tries to “remember” all the past knowledge that the network is seen so far and to “forget” irrelevant data. This is done by introducing different activation function layers called “gates” for different purposes. Each LSTM recurrent unit also maintains a vector called the Internal Cell State which conceptually describes the information that was chosen to be retained by the previous LSTM recurrent unit. A Long Short Term Memory Network consists of four different gates for different purposes as described below:-

Forget Gate(f): It determines to what extent to forget the previous data.

Input Gate(i): It determines the extent of information to be written onto the Internal Cell State.



Output Gate(o): It determines what output(next Hidden State) to generate from the current Internal Cell State.

The first step in our LSTM is to decide what information we're going to throw away from the cell state. This decision is made by a sigmoid layer called the "forget gate layer." The next step is to decide what new information we're going to store in the cell state. This has two parts. First, a sigmoid layer called the "input gate layer" decides which values we'll update. Next, a tanh layer creates a vector of new candidate values that could be added to the state. In the next step, we'll combine these two to create an update to the state.It's now time to update the old cell state into the new cell state.Finally, we need to decide what we're going to output. This output will be based on our cell state, but will be a filtered version. First, we run a sigmoid layer which decides what parts of the cell state we're going to output. Then, we put the cell state through tanh (to push the values to be between −1 and 1) and multiply it by the output of the sigmoid gate, so that we only output the parts we decided to.

V. EXPECTED RESULT

Stock market Prediction techniques will obvious make an improvement of Commercial sector of Business. With the use of LSTM (Long Short Term memory) algorithm of machine learning we analyzed the result of predictive stats of a particular Company's Stock. with the help of historical data such as Date, Open, close ,Volume, high, low,respectively. And with the help of these attribute we predicted the similar result of previous day stock which was not considered for dataset.

VI. CONCLUSION

This prediction model will help to develop neural network as another forecasting tool for highly volatile Indian market. In this paper, we attempted to find an optimal architecture of the neural network to predict the direction of the CNX S&P Nifty 50 Index with a high level of accuracy.

This method has considered most of the issues and critical factors for designing the neural network model and has tested the performance of each of the structures at various historic periods of the trading sessions of the Indices. A rigorous trial and error method is employed in selecting each of the features of the network structure. A three layer feed-forward back propagation neural network with 10 input neurons, a hidden layer with 5 neurons and 1 output neuron with tan sigmoid and linear transfer function in the hidden and output layer respectively is considered as the optimal network structure.

The structure is tested with the most recent trading data set. The input data used in the model is the preprocessed historic closing values of the index. The model predicts the next trading days closing value of the index. The training data set comprises of the historic data previous to the prediction day of prediction.

Abstract: **It is a common sight to witness garbage spilled out in and around the dust bins. The area around an improperly maintained dustbin can house disease spreading insects like mosquitoes, flies, bees and driver ants. The proposed system has smart dustbins that constantly monitor and send the level of dustbins on the cloud server where each dustbin is uniquely identified. Ultrasonic sensors are used to calculate the level of waste in the dustbin, which are transmitted via Node MCU. The dustbins are connected to the internet using Wi-Fi. Upon transmission, if the level of waste in the dustbin is more than some threshold limit, the dustbin becomes a node. Only after some nodes are formed, the route for garbage truck is formed using Shortest Path Algorithm and sent to the truck driver for garbage collection. The whole system is accessed using an Android Application. The truck drivers are notified and shown the optimized route within the application. The system is proposed for the efficient garbage collection in smart cities, with the help of smart dustbins for waste monitoring with most optimized routes based on several parameters for the truck drivers for smart garbage collection.**

Key words: Waste management, route optimization, smart dustbin, Node MCU, IOT, Cloud, Wi-Fi, Wireless, Ultrasonic sensors, Static & Dynamic Routing, Android application

I. INTRODUCTION

Today's waste management systems involve a large number of employees being appointed to attend a certain number of dustbins. This is done every day periodically. This leads to a very inefficient system in which some dumpsters will be overflowing and some dumpsters might not be even half full. This is caused by variation in population density in the city or some other random factor which makes it impossible to determine which dustbin needs immediate attention. The introduction of the sensor-based garbage dustbins is highly effective system to control the waste management in the cities. Dustbins will be embedded with ultrasonic sensors at the top, the ultrasonic sensor is used for measuring distance. This makes it possible to measure the amount of waste in the dustbin. If specific number of dustbins get full above the threshold level then an alert message will be sent to the corresponding personal. We are proposing a system for the efficient garbage collection in smart cities, with the help of smart dustbins for waste monitoring and an android app for managing the whole system by generating the most optimized routes based on several parameters for the truck drivers for smart garbage collection, and providing the GUI for other users. The smart dustbins use Node MCU and Ultrasonic sensors for monitoring the level of waste in the dustbin and uploading real-time the data on the server. Using the shortest path algorithm, will find the optimized path/route that the driver should take for emptying the dustbins considering the level of waste in dustbin.

II. BACKGROUND

Due to increase in the amount of garbage and a need to manage it, many researches have been done on waste management using Internet of things to look after the issues related to cleanliness which in turn result into bad health. Each paper has adopted a different approach and methodology. The information provided by every paper is very beneficial and helpful in taking our application to the next level.

The use of Arduino UNO brings in the need for an external Wi-Fi module which can be avoided in Node MCU along with cost saving. Node MCU is cheaper and the built-in Wi-Fi module further reduces the cost of external device.[1][2][3]

Some of the existing systems, are run entirely on solar panels. Therefore, availability of sunlight is needed most of the time. The cost of such a system is quite high since it uses solar panels and elevated assembly.[10] Piston can be attached to put additional pressure to accommodate more garbage. Elevated assembly collects the waste thrown outside and put it back in the dustbin properly.[4]

LCD module has been used to display the level of garbage in the dustbin. When dustbin is full, it sets timer. If the dustbin is not emptied within the given time, higher authorities will be informed via SMS. No route optimization is done which leads to increased fuel consumption.[5]

Algorithms like Dijkstra's shortest path algorithm, Genetic algorithm can be implemented for static and dynamic routing network. When compared, Dijkstra's algorithm takes more time in finding the optimum path as compared to Genetic algorithm.[6]

III. PROBLEM DEFINITION

To develop an android application for smart cities using smart dustbins and route optimization which will provide the following:

1. Optimized route for drivers for garbage collection
2. Real time monitoring of dustbin level

The main objective of this project is to design an effective and efficient garbage collection system for the smart cities. Other objectives of the project are: To provide dynamic routes for the truck drivers based upon traffic, road availability. To make the system fast, efficient and affordable. To connect the system over the internet for real-time monitoring and increasing efficiency. To make use of latest technologies for improving accuracy and other factors of system like cloud computing, machine learning. To minimize human efforts. To lessen the consumption of fuel, time, data, storage, etc. To spread awareness about cleanliness, hygiene and sensible use of energy and resources. To

give the citizens a clean and healthy environment to live in.

This project has huge scope in present as well as future. It can be expanded in terms of hardware, software, network and many more parameters. Time prediction can be incorporated in the system to predict dustbin filling time so as to make the system more efficient. The presence of spare digital and analog pins on the Node MCU in the smart dustbin gives the chance of adding more devices or sensors like fire sensor, temperature sensor, gas sensors, etc.

IV. RELATED WORK

Smart city can be defined as the utilization of the information and communication technologies, and recently IoT, to transform the cities from simple to smart. Such goal is achieved by exploiting different smart services of such as smart infrastructure, smart transportation, smart energy. The basic project idea is to design a smart waste detection system which would automatically notify the officials about the current status of various garbage bins in the city, would have real-time monitoring capabilities, which would be remotely controlled using IoT techniques. It can also be seen that it is mentality of some peoples that they will throw the waste into such places in spite of dustbins. The best example of this was canteen or work place like schools, colleges, government offices etc, where peoples took something and they throw them somewhere or remain them at their table where they were taking them. Most of them do same things but they didn't throw those wastes into dustbins. It is the mentality of the people's especially Indian peoples, if they will get something new which is related to technology or autonomous they feel tickle to look forward it. So, keeping all things in mind a proposed dustbin model is prepared, which is a Smart Dustbin.

Fig 1. Existing waste management system

Smart dustbin development in India: Four young men from Nashik came up with a unique idea in a bid to further their efforts to keep the country litter-free. They built smart automated waste-bins called the KRRYP Garbage ATM. The system actually has two dustbins and one LCD screen. Users will be provided with a card that has to be swiped for the dustbins to work. Once they have swiped it, the LCD screen will automatically ask the user a general knowledge question with two options as answers (for either of the bins). For instance, if the user thinks the right answer is Option B, then they will dispose their waste in the bin marked B. Depending on whether their answer is accurate, they will collect points in their smart cards, which they can later trade for coupons or cash.

An engineering student from Rampur**,** UP, has developed a dustbin with built-in sensors that would go off if garbage is thrown around the 'Smart Dustbin', compelling passersby to put it in the dustbin. The developer, has inducted a sensor instrument which is capable to catch the smell of garbage not dropped in the dustbin. It can sense the household wastes thrown on the roads. Inspired by India's Swachhata Abhiyan, the young research scholar informed media that an infra-red receiver, buzzer, transistor and a battery has been used and it took five months' time to complete the project named 'Smart Dust Bin'.

An enterprising group of students from Mysuru has come out with the solution to address the overflowing problem of garbage containers across the city. The students' team has developed a concept of smart dustbins that will enable the civic officials concerned to monitor storage level of garbage containers on their android phones through an application.

In a first in Rajasthan, three smart dustbins will be installed by the Jodhpur Municipal Corporation at different places in Jodhpur. The civic body plans to install 35 such dustbins across the city soon.

In North and South Delhi bins are installed which is fitted with sensors that send signals once the bin is full. The initiative aids in reducing hazards such as bad odor and harmful gases. Steel Authority of India Ltd (SAIL) has launched Internet of Things (IoT)-driven garbage bins across South and North Delhi Municipal Corporation area, which automatically sends a signal to the waste collection authority once the bins are full.

Kathmandu has become the first city in Nepal to install smart solar dustbins in major streets of the metropolis. Taking a major leap toward the waste management in the city, the Kathmandu Metropolitan City (KMC) has initiated the campaign to install 100 smart dustbins in the metropolis.

V. METHODLOGY

This proposed system does real time monitoring of the dustbin. The ultrasonic sensor will detect the level of garbage in the system. This data will be uploaded on the Firebase cloud using the Node MCU. The Node MCU has an inbuilt Wi-Fi module. Once, the threshold limit is reached, dustbin becomes an active node. When a specified number of dustbins become active nodes, they form a network. Then the system applies route optimization and provides optimized route for drivers to collect the garbage. This reduces overall time, fuel and cost.

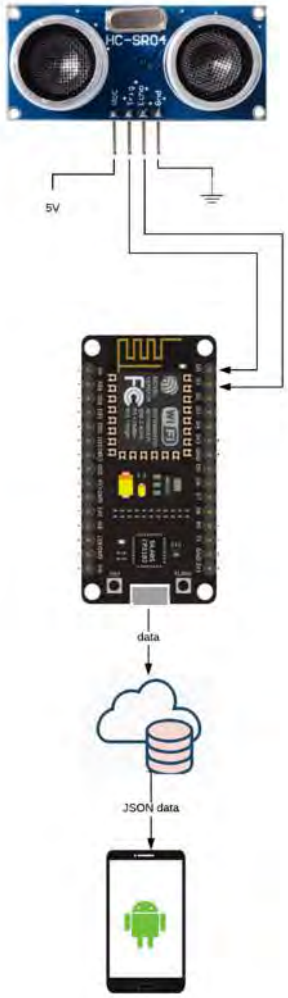

Fig 2. Block Diagram

The figure 1 explains the methodology for the implementation process.

VI. PROPOSED ARCHITECTURE

Proposed system has been implemented using following hardware:

i. Node MCU
ii. Ultrasonic sensor
iii. Jumper wires
iv. Breadboard

Fig 3. Outside the dustbin

Fig 4. Inside the dustbin

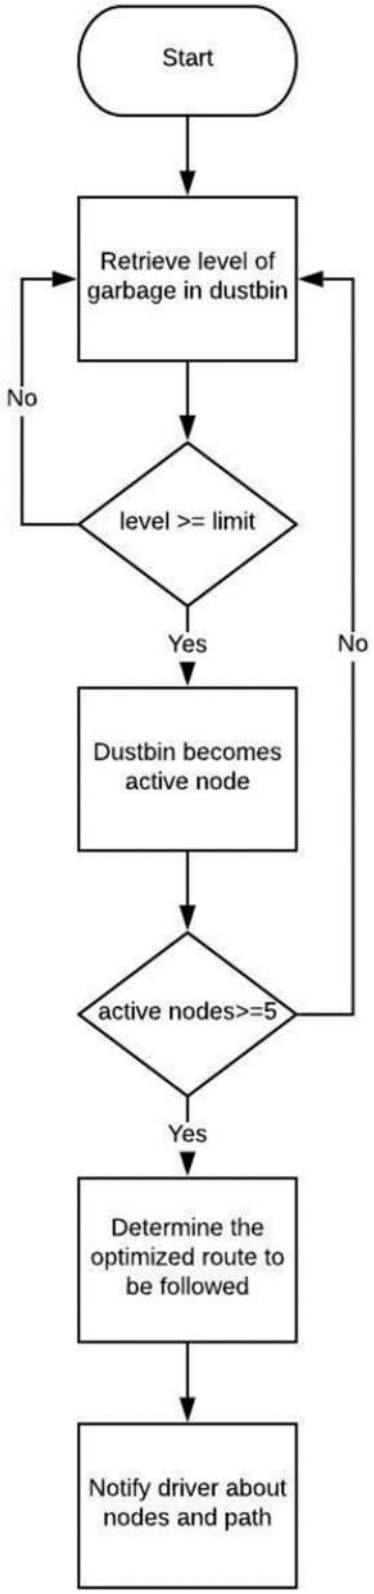

Fig 5. Flowchart

The proposed system retrieves the level of dustbin from a real-time database on periodic basis and checks whether it has reached a minimum threshold. If a certain threshold is reached, dustbin becomes an active node. When the count of active nodes is up to certain limit then optimized route is sent to the driver including all the active nodes for efficient garbage collection.

VII. FUTURE SCOPE

Fire sensor can be used to prevent any accidents

- Gas sensor can be used to detect any presence of poisonous gases in dustbins
- Time prediction: Time prediction can be incorporated in the system to predict dustbin filling time so as to make the system more efficient
- The new gen technologies and algorithms can be used in the system like artificial intelligence, future prediction and analysis, robotics, etc.

VIII. RESULTS AND DISCUSSION

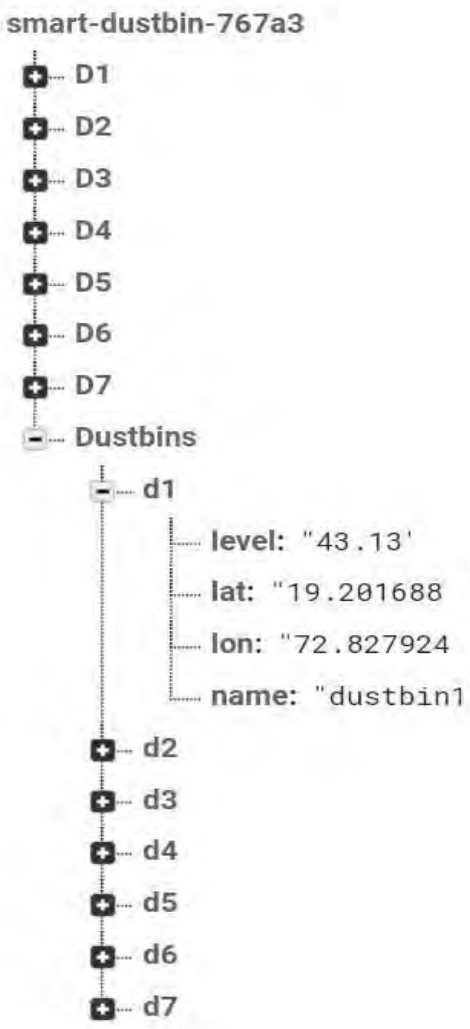

Fig 6. Firebase Cloud Database

This system uses NoSQL database for storing the data from dustbins. NoSQL databases offer storage for non-structured data and thus are flexible to query for information. The data is brought to app in JSON format which is very lightweight and compatible with various platforms along with having good amount of security. Each dustbin has level of dustbin name, latitude and longitude as child nodes.

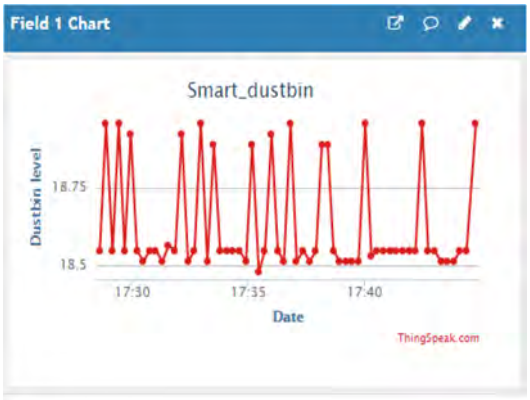

Fig 7. Graphical representation of level of dustbin

Fig 8. Locations of dustbins on the map

This image shows the locations of various dustbins in a locality. The application retrieves the coordinates of dustbins in terms of latitude and longitude and plots the coordinates on the map as markers.

The system determines the active nodes based on dustbin levels and marks them separately. A route is drawn after a certain count of active nodes is reached.
This route is displayed to the truck driver so that it can be followed for efficient garbage collection.

IX. SUMMARY

After analyzing the existing systems and their drawbacks, and researching various technical, journal and conference papers, we have finalized the hardware and software based on the shortcomings of the existing systems.

The main component used in smart dustbin is the Node MCU which is not only readily available and cheap, but also facilitates us with its built-in Wi-Fi module. Cloud technology is used to store the real-time monitored data of dustbins. Using the android application, the drivers will be provided with an optimized route for garbage collection. Also, real time monitoring of the dustbin's level will be done.

Agile methodology is used in the whole project which makes it more efficient, increases the development speed and is developer friendly as well. Moreover, the latest requirements or technologies can be easily incorporated as and when needed.

X. CONCLUSION

The increase in population, has led to tremendous degradation in the state of affairs of hygiene with respect to garbage collection system. The spill-over of waste in civic areas pollutes the neighboring areas. The proposed system has smart dustbins that constantly monitor and send the level of dustbins on the cloud server where each dustbin is uniquely identified. Ultrasonic sensors are utilized to compute the level of waste in the dustbin, which are transmitted by means of Node MCU. Upon transmission, only if the level of waste in the dustbin reaches some threshold limit, then that dustbin needs to be emptied and it becomes an active node. When a certain amount of nodes becomes active, a network will be formed.
An Android application is responsible for the overall controlling of the system and for providing the Graphical User Interface(GUI) for the users. The application retrieves data from NoSQL database in JSON format. Thus, providing lightweight data transfer. The location coordinates of dustbins will be displayed on the map and after the dustbins turn active, route will be determined and displayed to the truck drivers.
This route will be optimized considering the parameters like roads, traffic, fuel consumption, capacity of dustbins and trucks.

Abstract—**In engineering colleges, many students from all over India work on various topics throughout their engineering course. There are chances that some topics would be similar or some component or part of topic might be similar to another topic. If students are made aware of this, then can collaborate together and reduce the duplication of efforts done behind a project and hence can focus on the other innovative part of their project. Such projects could also be incorporated in University's curriculum for smooth functioning of project by faculties in college. In current systems, colleges have to manually keep record of projects being made year by year, this manual work leaves very less scope for domain based analysis. Hence with use of Project Club will reduce that tedious work. It will provide a space where college authorities could analyze and understand what kind of projects, in regards with domain, are being developed in their colleges. This project will make use of a recommendation system to suggest similar projects based on the description uploaded by the students, this kind of idea yet remains unimplemented. We have Platforms that allow code sharing, communication, discussion forum but Project Club provides all these functionalities under one roof. Students can also seek guidance from faculty members, which will also be included as one of the entities in the proposed solution. With Faculty, Industry Personnel will also be included with the aim of providing students a direct contact with what is trending in the industry. Along with that, the presence of Industry personnel on the platform will motivate students to work as there would be chances of them getting popular. There will be a special space allotted to teams after they have collaborated on a project, to work on the project, manage their project as well as act as an interface for communication between various entities present.**

Keywords:Project,management,students,Industry,Hiring, Analytics, recommendation, Engineering, Feedback, mentor, Collaboration

I. INTRODUCTION

across India, thousands of students in various engineering colleges develop projects in various domains. There are chances that the project developed by these students might be the same

or might have some similar key features. These projects are being developed on a small scale in these colleges and students spent a lot of time developing project and including features which have already been developed by some other team in some other part of our country. This leads to duplication of efforts and waste of time students in developing an already existing project.
Lack of guidance and motivation results in students leaving the project midway. Absence

of a platform where students can discuss projects and get guidance with already working and experienced personnel hinders the development of projects. We propose a solution which acts as a platform for students to upload the description of the project. Using a recommendation system, the students will get recommended of projects similar to theirs. Further, the students can collaborate with the teams recommended to them by our recommendation system.

On a college level, many projects are being developed each semester, each year by students. These projects belong to various different domains, colleges cannot keep track of them all manually. Overall analysis becomes tedious when there's a need to list down projects in presence of some external body or committee. To tackle such cases we propose the use of analytical dashboard which will be one stop for all of analysis to be down at a college or university level.

Students can also seek guidance from faculty members, which will also be included as one of the entities in the proposed solution. With Faculty, Industry Personnel will also be included with the aim of providing students a direct contact with what is trending in the industry. Along with that, the presence of Industry personnel on the platform will motivate students to work as there would be chances of them getting popular. There will be a special space allotted to teams after they have collaborated on a project, to work on the project.

II. IMPORTANCE OF PROJECT

The main objective of the project is to provide a platform where students can collaborate and club projects, faculties can mentor students and Industry Personnel can offer opportunities to students and colleges can perform analysis on projects being made in their college/ university.
Also, as students will be recommended about similar projects there will a reduction in the development of repetitive projects.
students will be able to upload projects, get recommended, communicate and get mentored all under

one roof.
Students will be motivated to upload projects as they will be watched by Industry Personnel and might be offered of certain opportunities if their projects are liked.
Chances of students being hired by the industry personnel is also increased as they will be uploading their actual work in form of projects.

III. OBJECTIVE AND SCOPE

The following lists different types of objectives that this project aims to achieve and its scope

1. To provide a platform for students, faculties and industry personnel coexist and work on projects
2. To help in finding out similar projects
3. To help in reducing duplication of efforts in making project
4. To provide colleges an analytical dashboard which can be used to analyzed type and the number of projects being developed in colleges.
5. To help faculties to track project progress
6. Help team members manage project

IV. PROBLEM DEFINITION

Currently there is no solution to manage such a large number of projects in Engineering Colleges and to store them digitally also Colleges do not have analytical system to get insights of students , faculties and projects. Students also face problems in finding guidance from peers or faculties related to their project.
Project Club aims to solve all the above problems.

V. MODULES

A. Student

1. Student will register on Project Club.
2. Student will add his profile details like internship, certification, projects, skills
3. Every Project can have Project Repository
4. He can view his rank among other colleges students or his college students
5. Share his profile to others
6. Form team with his group members and mentor

B. Faculty

1. Faculties will register on Project Club
2. Add all Profile and professional Details
3. Accept/Reject Team request
4. Dashboard to see all team's progress at one place
5. Individual dashboard for all teams to keep detailed update
6. Receive weekly update of each team on email

C. Teams

1. Well Designed Dashboard to manage project with team members
2. View all projects details
3. send/reject connection request
4. Chance of being noticed by our industry tie ups
5. Project Repository to show project details to others
6. Share profile of team
7. Separate dashboard to discuss with connected Teams
8. Give updates to faculty from anywhere anytime

D. Analytics

1. Provides various insights of students, faculties and projects in one click.
2. Data Table of students and projects
3. Faculty – Project Allocation

E. Industry

1. We have tie ups with various companies which may offer internships or jobs by seeing student's profile and project work.
2. Companies can also collaborate with students if they are working on similar project.
3. Companies will get periodic notification from Project Club about recommended students and projects along with their profile link.

F. Django Workers

Worker is used to execute process in application which may block or take time to execute and takes user's time. Workers runs in background independently of application processes. It makes use of database to store task which are to be executed in queue with various parameters like start time, task name, end time, arguments etc.
Workers used in this application for:

a. Send email notification for user action which are important. e.g.: team formation, task allocation, updates posted etc.
b. Periodically train machine learning models on data collected in application.
c. Send weekly updates in pdf format to faculties of projects they are mentoring.
d. Send push notification on important user actions

Using Django workers improved efficiency and speed of web application and also user experience improved.

G. Recommendation System

- The use of machine learning based recommendation systems can be seen on the rise in the industry today.
- Recommendation helps users to get what they want very quickly instead of searching from list.

-We have used Content based recommendation system in this project.

- Steps followed:

a. Collected all required data which was used for recommendation.
b. Performed Tokenization on data
c. Performed stemming on output received from above step
d. Performed lemmatization on output received from above step
e. Vectorized above data using TF-IDF
f. used cosine similarity to find similar objects and save matrix received in this step
g. query similar objects based on decided threshold from above metrics

We have used Recommendation System in this project for:

a. Recommend students and projects to industry based on summary and interest of industry.
b. Recommend similar projects to team based on their abstract, keywords and domain.

H: Component Based Architecture in Django

The Component-based architecture in Django framework treats Input field, button, checkbox etc. like components, which once generated, can be used in multiple pages. This introduces reusability in the code and one does not have to rewrite code again for declaring them. If the UI has to be altered then one does not need to change it on all pages specifically, just changing at the source would replicate it throughout the application. This reduces the developer's extra work in which they would have to rewrite the same lines of code for every new page.

VI. DEPLOYMENT

Current: Currently Application is hosted on monolithic VPS cloud server with 2 cores and 4 GB ram. Database, application server, workers, machine learning all these services are running on same server instance.

Future: Depending on requests and server load, we will scale server horizontally instead of vertical.
Instead of directly making distributed system, first we will separate database to different server which will scale app to considerable percent. Depending on further load on server it is always better to separate all services like database, application, workers, machine learning, cache to different instances to serve more concurrent users.

VII. FUTURE SCOPE

This platform currently caters to the basic needs of a student to form team, collaborate with other teams and get recommendations about teams working on similar projects like themselves. Following is a list of features that can be added or already exist and can be improved upon in the future:

Video chatting provision: Using this feature, team members of the connected teams can interact with each other on a video call or conference voice call. They can also share screens of their

devices in video calls to showcase specific project related slides or dashboards

Private version control system: A private version control system will enable the connected teams to use the repository with all the features of a git system like commit, push, pull. This will help teams to keep their work private by eliminating the need to use third party git sites to save their work

Improved Machine learning algorithms: Improving the machine learning algorithm will allow the platform to provide recommendations about the projects that other team are working on, with even more accuracy. The recommendation system can be improved by training it with more amount of data that will be generated on the site by its users. The recommendation system can also be improved by putting in place a better data cleaning system that will ensure only the right data gets fed to the algorithm in its training phase

Discussion Forum: Place where anyone can post their question and can get answer to their questions from other people along with like and comment.

VIII. SUMMARY

Project Club reduces the efforts taken by students and their mentors to communicate and synchronize the development of the project. By providing utilities like a chat section, code file uploading, screenshots uploading and more, Project Club eliminates the need to juggle between third party applications. Project Club offers students a platform to connect with industry personnel and be judged by their actual work i.e. the projects. Industry personnel can either advertise their brand or company among younger academic peers, hire them based on their works and field of work. Students get exposure to the corporate world. Project Club eradicates the need of manual bookkeeping involved in keeping tracks of projects being developed by students. Analytical dashboard provides insights to colleges by using graphical representations. Project Club also provides digital storage for projects of all the projects being developed in the institution over a long period of time

RESULTS

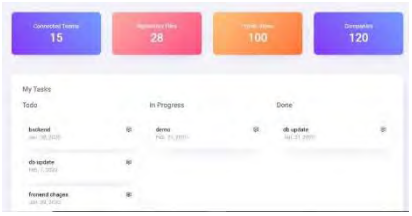

Fig1: Team Dashboard

Team Dashboard has features to manage project among team members and provide updates to faculty

Fig2: Project Management

Team Leader and Faculty can assign task to team members with deadline. Colors shows status of task. blue color: doing, red color: deadline passed, green color: done within deadline

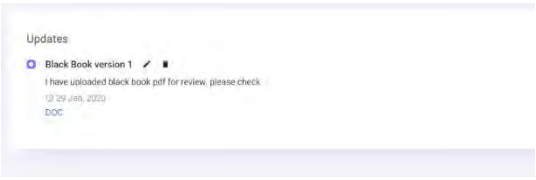

Fig3: Project Updates

Team members can post updates of project so that other members can see and comment their opinion.

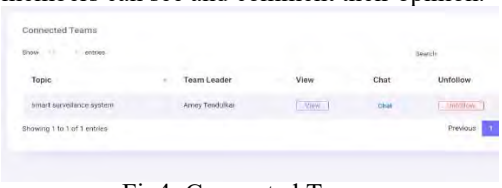

Fig4: Connected Teams

Team can discuss with other similar team to get their guidance or work related to project.

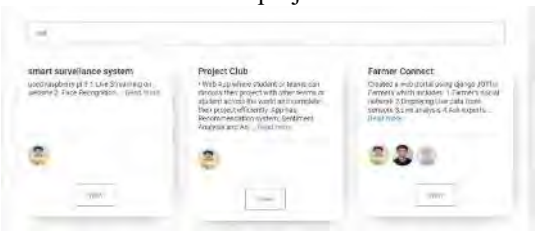

Fig5: View Projects

Team members can view projects using dynamic search and send connection request to team if they like their work

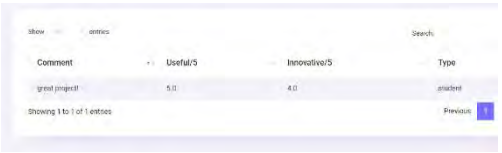

Fig6: Feedback

Receive Feedback on your project from others by sharing team profile and get to know who has given you feedback i.e.: student, faculty, industry or guest.

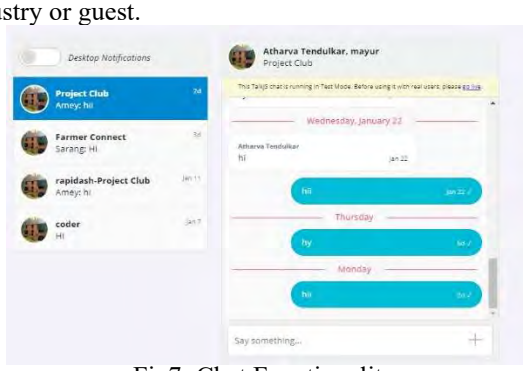

Fig7: Chat Functionality

In app chat functionality for team members to discuss project and also to discuss with connected teams.

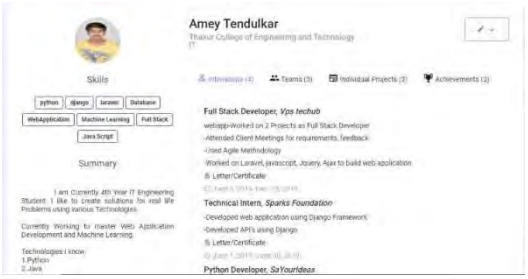

Fig8: Profile

Students can create their profile by adding their summary, skills, internships, projects and achievements and share profile with others.

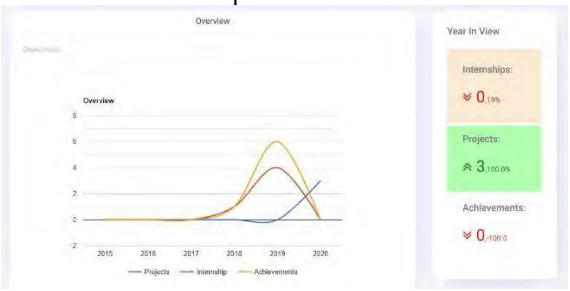

Fig9: Analytics

In depth analysis for college authorities which shows insights of projects and students of college.

Fig10: Keyword Count

This Graph shows keywords used in projects using frequency of keywords. Size of keyword proportional to frequency in projects

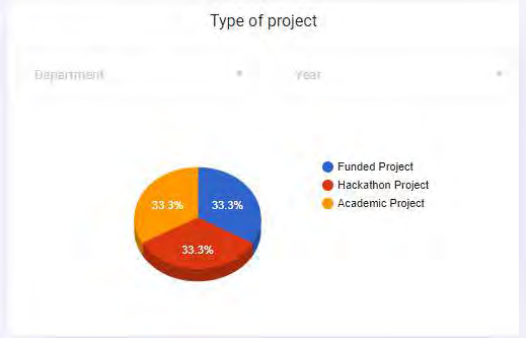

Fig11: Project Type

This Graph shows types of project going on in college Department and year wise.

IX. CONCLUSION

The use of machine learning based recommendation systems can be seen on the rise in the industry today. Recommendation systems are being used in applications for tasks ranging from suggesting which TV show to watch next to what dishes to be ordered and from which restaurant on food delivery apps.This project makes use of a similar recommendation system in helping students find other groups working on projects similar to them.

This platform will not only help students connect with other likeminded individuals, but also give them a space share codes file, communicate, get offers and mentoring all at one
place. Communication will be made easier as there will be a discussion forum present in the
project. Faculties and students can contact and discuss about a project in one place. In this way by taking advantage of all these features that the platform has to offer, students can reduce the duplication of effort build projects together, efficiently.

This platform also aims to ease the process of project management for faculties of colleges who guide students with their projects. With the student-teacher dashboard feature, students will be able to update progress they are making on projects with their respective guides seamlessly. Faculty will be able to track the progress of their groups in Realtime making the process of project management and mentoring students at college level projects hassle free.

The analytics module provides an overview of all the projects present on the platform. This helps higher authorities of colleges gain insights on the progress of projects done by the students on the platform, the domains of these projects and other trends identified by students activities on the platform. The data collection from the platform and knowledge generation done by this module will help students, faculty and industry entities to acquire a deeper understanding of the latest trends in the field of engineering by the analytical reports generated by this module.

Lastly, with the introduction of the industry entity, students will be motivated to upload more projects and increase their engagement with the platform as of this will increase their potential of getting noticed by industry personnel. This platform will benefit both the students and the industry in a mutual manner. Students will be able to showcase their talent just by being an active user the site whereas the recruiters can ease their hiring process by quickly skimming through potential employees based on skill, domains and area of interest of the individuals present on the platform.

X. ACKNOWLEDGEMENT

We sincerely thank our guide Mr. Sudhir Dhekane for his guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

We thank the HOD, Dr. Rajesh Bansode the Principal, Dr.B.K. Mishra and the college management for their support

Land Registry using Blockchain

Krati Paliwal, Siddhi Poojari, Mayur Singal, Sandip Bankar
Information Technology, Thakur College of Engineering and Technology, Mumbai, India
kratip11@gmail.com, siddhipoojari7@gmail.com, mayursingal9@gmail.com, sandipbankar1@gmail.com

Abstract - **A blockchain is a growing list of records, called blocks, that are linked using cryptography. Blockchain contains a comprehensive approach in industries which requires to be protected from corruption, human error or human intervention. Land Registry is one of the use cases that involve plenty of intermediaries to place trust within the system. The present solutions in place are out of date. Land registration generally describes systems by which matters concerning ownership, possession or other rights in land will be recorded (usually with a bureau or department) to produce evidence of title, facilitate transactions and to prevent unlawful disposal. The knowledge recorded and therefore the protection provided will vary by jurisdiction .The current land registry system is rife with corruption and inefficiencies. With blockchain, we've an opportunity to mend many of those problems.**

I. INTRODUCTION

Land registration is a process by which matters concerning ownership, possession or other rights pertaining to the respective land may be recorded (usually with a office or department) to supply proof of ownership, facilitate transactions and to avoid discrepancy. Keeping track of who owns which pieces of land or property is difficult once you have hundreds or maybe thousands of years of land records and therefore the current systems in situ are outdated.

It's common to encounter discrepancies within the paperwork, including forged documents, counterfeit titles and, in some cases**,** a whole loss of all documentation. Such situations result in expensive court battles between conflicted parties. The transparent nature of blockchain can make it possible to trace how property changes hands. Blockchain's immutable, auditable and traceable features are enticing governments around the world to implement the decentralized technology within the land registry process. Using the blockchain technology it's possible to make a land registry and a history of transactions which will be easily verified at any given point. [1]

II. OBJECTIVE AND SCOPE

The objectives our project aims to achieve and its scope are:

1. Develop an accessible database to store land titles and transactions
2. To provide high capacity and throughput for millions of records
3. Data immutability that brings trust and auditability to the records
4. Quick retrieval of transaction histories

III. PROBLEM DEFINITION

Currently no solution exists to the issues faced within the existing land registry system. Thus, our system aims at building a true time record maintenance system that captures various attributes of land by using blockchain because the key technology. The system will let users to shop for and sell land securely while maintaining authenticity of the ownership. We've divided the project into 2 stages.

Stage I - will focus on shaping a base for the project. With intensive arranging, examination and structure, we'll guarantee that the important usage is smoother. Planning aims at deciding the agile methodology for arranging our land registry project. Analysis focuses on preparing an analysis of our own project. founded an itemized investigation on present enlistment and approval forms and conquering its impediments and execution benchmarks. the planning phase focuses on designing of event system application.

Stage II will concentrate on building up the undertaking and guaranteeing that the planned highlights will function as we needed them to. This stage includes developing phase where,we will send a Blockchain in which the qualifications of purchasers and venders as hashes is put away likewise in this stage we will build up an interface for our users to list our their properties and get them approved. Testing includes doing the different test framework application. The last phase is deployment where beta testing for distinguishing any further mistakes, bugs and enhancements that can be performed.

IV. TOOLS & TECHNOLOGIES

Etherium: Ethereum is a distributed public blockchain network. Ethereum specializes in running the programming code of any decentralized software. In the Ethereum blockchain miners work to earn Ether, a kind of crypto token that fuels the community. Beyond a tradeable cryptocurrency, Ether is also used by application builders to pay for transaction expenses and offerings on the

Ethereum network. There is a 2nd type of token this is used to pay miners fees for which includes transactions in their block, it is known as gasoline, and each clever contract execution requires a certain quantity of gasoline to be despatched at the side of it to trap miners to position it inside the blockchain. [5]

Metamask: MetaMask is a bridge that allows you to connect the distributed web with a normal web browser. It allows you to run Ethereum based Dapps right in your browser without implementing a full Ethereum node. It is a web browser extension that injects the Ethereum web3 API into every website's javascript context, so that Dapps can read from the blockchain.

MetaMask also lets the user create and manage their own identities, so when a Dapp wants to perform a transaction and write to the blockchain, the user gets a secure interface to review the transaction, before approving or rejecting it. Since it adds functionality to the conventional browser context, MetaMask requires the permission to read and write to any webpage.

Solidity: Solidity is an object-orientated language particularly evolved for contract writing. It is a high-stage language, which inherits traits from C++, Python, and JavaScript. The Solidity compiler compiles your source code into bytecode that runs on Ethereum Virtual Machine.Solidity is a statically-typed programming language designed for developing smart contracts that run at the EVM. With Solidity, builders are able to write programs that put into effect self-enforcing commercial enterprise logic embodied in clever contracts, leaving a non-repudiable and authoritative record of transactions. [5]

Ganache: Ganache could be a personal blockchain for Ethereum development you'll use to deploy contracts, develop your applications, and run tests. It's available as both a desktop application in addition as a command-line tool (formerly referred to as the TestRPC).

Ganache Accounts shows the accounts generated and their balances. Blocks shows each block as mined on the blockchain, together with gas used and transactions. Transactions lists all transactions run against the blockchain. Contracts lists the contracts contained in your workspace's Truffle projects. Events lists all events that are triggered since this workspace's creation. Ganache will try and decode events triggered by contracts in your Truffle project. Logs shows the logs for the server, which is beneficial for debugging. [6]

Web3: Web3 is a extensive movement and an inclusive set of protocols aiming to make the web and the net extra decentralized, verifiable, and relaxed. WEB3 is the imaginative and prescient of the serverless internet, the decentralized web. An net in which users are in control in their very own statistics, identity and future.

Remix IDE: Remix is a Solidity IDE that's used to write, compile and debug Solidity code.
Solidity is a high-level, contract-oriented programming language for writing smart contracts. It was influenced by popular languages such as C++, Python and JavaScript.

V. METHODOLOGY

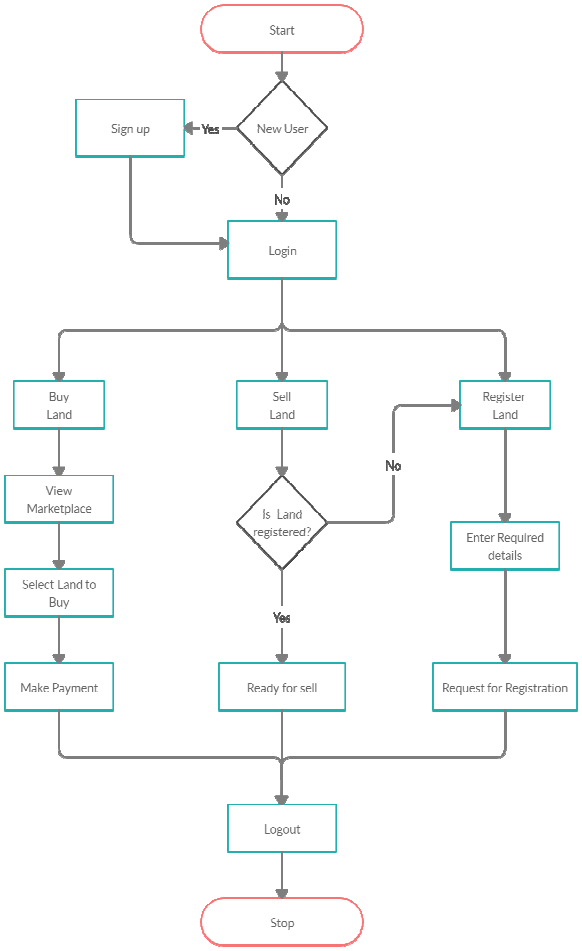

Fig 5.1: Flow chart: User [3]

User: For buying land

1. The user will register on the portal.
2. The user can view the marketplace and check the different properties listed.
3. As per his requirements the user can select the land to buy.
4. On selection of land, the payment can be made.
5. When user buys property, registration need not be requested as it will already be a part of blockchain from the seller's end.

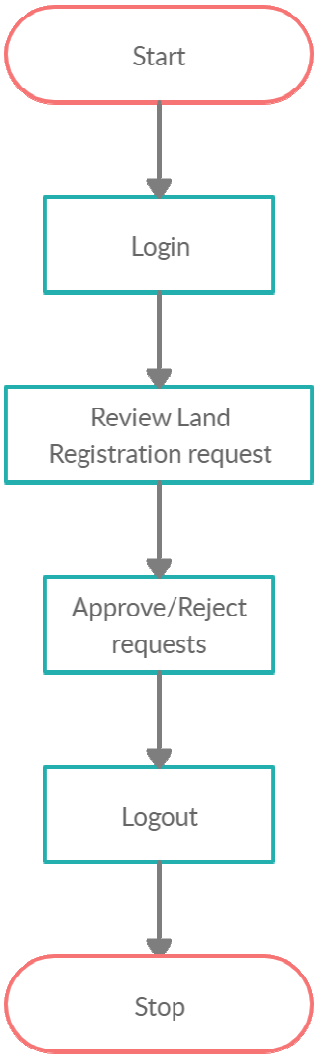

Fig 5.2: Flow chart: Registrar [3]

User: For selling land

1. The user will register on the portal.
2. For registered property, the user can list it out for sale.
3. If the property is not registered, the user will have to fill in the required details and documents and request for registration,
4. Upon completion of registration process, the property can then be listed for sale.

Registrar

1. The registrar will login into the portal.
2. He can view the registration requests on the dashboard.
3. The registrar can accept and reject requests based on the details uploaded by the requester.
4. The accepted requests will be stored as a block in the blockchain.

VI. FUTURE SCOPE

Currently the proposed system can be used to authenticate and validate property ownership and allow the user to put up properties for sale.as the verified user ownership information gets stored as a block in blockchain, it becomes secure due to security aspects of blockchain. The information will be available to different departments as per their usage. The resultant system will serve as an easy, quick and cost efficient record maintenance and retrieval system. The current project can be extended by increasing the area coverage. The proposed system can be extended to different states. The project can be further integrated with maps for better geographical identification and understanding. The system can be used as a secure and trustworthy resource to store, maintain and retrieve property information of various users over a given region.

VII. SUMMARY

The project aims at delivering a trustworthy and reliable system that will make land registration process hassle-free while maintaining security. Large amounts of records can be stored easily. The transparent nature of blockchain can make it possible to trace how property changes hands. Also, the challenges of time delays, involvement of middlemen and frauds can be overcome.

The capacities required for the venture are reasonably in the attainable range. A GUI is required, for the clients to make their records and rundown out their properties for selling or for enlisting another one. The enrollment office requires an interface for confirming the ownership. Verified data will be included to the blockchain. The GUI will be kept basic and moderate. This application will have numerous positive applications on society. It will improve the validity of the clients and give validness to proprietorship. The philosophy that we decided for our task is Agile. Light-footed enables us to be adaptable, oversee evolving necessities, deal with the regularly expanding extension just as get purchaser viewpoint.

VIII. RESULTS

Fig 8.1: Land Registry Smart Contract

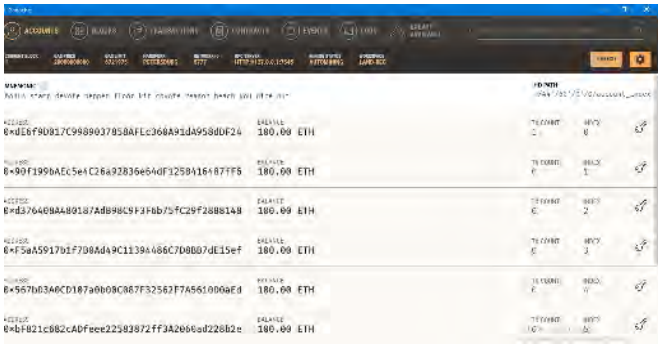

Fig 8.2: Land Registry Smart Contract [6]

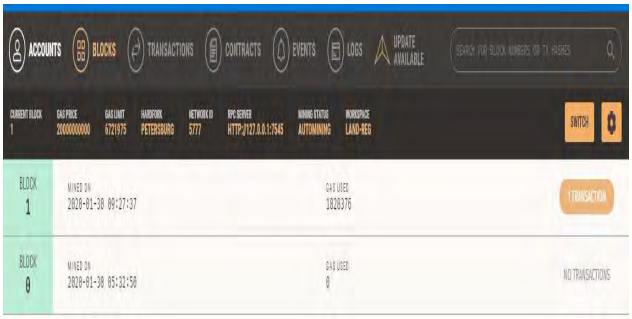

Fig 8.3: Mined Blocks

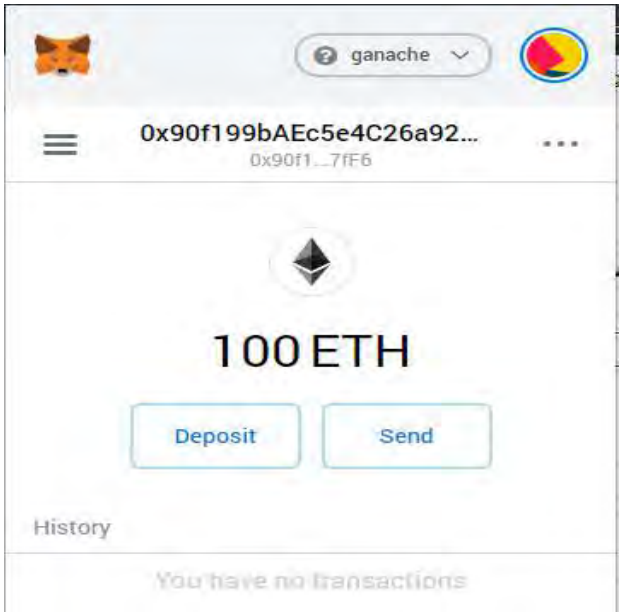

Fig 8.4: Metamask: Injected Web3 Provider

Fig 8.5: User Registration Page

IX. CONCLUSION

The Blockchain based Land registry system will facilitate integration and validation of land records over a given region. The system allows users to buy, sell and register new properties. It is easy to use and a secure way of buying and selling land. Blockchain provides the key feature of security which allows the registrar to validate the user's authenticity in a hassle freeway. As the verified user's record is entered in a block in blockchain its can surely be relied upon. The problem of discrepancies and false records is eliminated in our system. Thus, it can be guaranteed that the property listed by a user belongs to him only. This makes the system trustworthy.

Sports Analytics using Neural Networks

Samyak Tripathi, Kuldeep Trivedi, Chintan Agrawal

Abstract— **Sports Analytics includes the use of data related to sports such as players' statistics, weather conditions, information from expert scouts, etc. and build predictive models around it to make informed decisions. Analytics in the field of sports is quite necessary as historical and statistical data sets about performances of players on the field will help the managers and players evaluate their performance and make better strategies and decisions off field to improve their performance on a wholesome level. Data management tools, analytical models, information systems are all combined together for the decision-making process. Such information is primarily sought for improving the team performance. Sports analytics makes use of machine learning and neural networks to achieve its prescribed goals and working of the desired system.**

I.INTRODUCTION

The interest in sports analytics has surged, such that advances in digital technologies increases the capacity to produce data for enhancing market and leadership development in professional sports business organizations.

Sports analytics research demonstrates that creativity, framing, and robust technical analysis over intuition is behind the development of a successful sports business organization.

On the other hand, sports analytics has the potential to predict outcomes, inform management about alignment, performance improvement and business. Analytical leadership broadly refers to an analytically driven level of excellence and competitive advantage as a result of a better execution of existing analytical concepts.

Although analytics have been used widely to inform on-field performances such as player decisions, the adoption of analytics to assist other business activities in professional sports organization is often limited and anecdotal. For example, little work has been done to understand fans ' relationships to their favorite teams and athletes.

Sports analytics refers to specific use of data analytics in the industry of professional sports. Though regarded as one form of data analytics, the specific context of the sports industry refers to processes and operations involved in the sports analytics, which are different from generic business analytics or enterprise analytics.

Davenport identified three areas of activities sports analytics involve: team and player performance analytics, sports business analytics, and health and injury prevention analytics. In this sense, sports analytics entail a much more complicated and diversified process. It is for this reason that, to engage in sports analytics, professional sports teams often have to work within an ecosystem and collaborate with a range of data, software, content and services providers.

Sports Analytics is a term describing sporting operations in which a team endeavors to analyze and predict outcomes of games, analyze the market for players and buy what is undervalued and sell what is overvalued. It uses various factors for value estimation and some of them are age, performance, popularity, versatility, marketability, adaptability and a lot more.

II. PREVIOUS RESEARCH

Artificial neural networks have been studied for decades and have a significant body of literature. Even so, it has proven difficult to apply them to real world applications. The research by Purucker introduced the idea of using ANNs to predict the outcome of NFL games. This research offers an excellent introduction to using ANNs in foot- ball predictions. Purucker applied several types of supervised and unsupervised networks to predicting weeks 15 and 16 of the 1994 NFL season. Work by Kahn used 13 weeks of game data, including total yardage differential, rushing yardage differential, time of possession differential, turnover differential and home field advantage to predict weeks 14 and 15. He achieved 62.5% and 75% accuracy in these two weeks. Considering the ESPN experts in 2009 had between 61% and 67% accuracy predictions, this methodology shows promise. Loeffelholz et. Al. performed a more extensive study of neural network prediction of NBA games in. The work in this paper incorporated ideas of these past studies with several key additions including season- to-date statistics combined with previous seasons, a simple method for incorporating team statistics, a robust method of combining multiple ANNs and analysis of the performance of this methodology

III. BACKGROUND

Sports Analytics includes the use of data related to sports such as players' statistics, weather conditions,

information from expert scouts, etc. and build predictive models around it to make informed decisions. Data management tools, analytical models, information systems are all combined together for the decision-making process. Such information is primarily sought for improving the team performance.

IV. IMPORTANCE OF THE PROJECT

The sports industry uses sports analytics to increase revenue, predict outcomes, study strategies, improve player performance, calculate and evaluate player's value and a team's quality of play, prevent injury and for many more enhancements.
All this data is a great resource; however, it serves no use without people to interpret and analyses how it may be useful. Sports analysts are currently in high demand as many teams are developing entire departments just to analyses statistics. In other words, sports teams are using
Analytics for a competitive advantage.

Three specific advancements include integrating data sources to advance competition, communicate why the data is useful and create a different fan experience. The data is beneficial to many in the industry including coaches, managers, agents, scouts, marketing professionals, medical personnel and the analytics staff.
With the current available technology, sports analysts are able to take data and create insightful yet simple visualizations to communicate to other key decision makers of a team. Many teams use these models to predict the outcomes and also engage in deep analysis of oppositions performances while analysing their own as well.

V. OBJECTIVES & SCOPE

The main goal is to build a model for expected run statistics in order to better understand a team's performance and thus to generate better predictions for the future. In the process the system will test different Machine Learning techniques and algorithms in order to obtain the best possible performance.

It helps in evaluating player's value to the team and how a player may respond to various situations. It helps in analyzing player's strength and weaknesses. It will assess player's strengths and weaknesses. It will assess player's attributes such as attacking prowess, heading, defense, tackling, passing and more.

The scope of this project is:

- Predict Outcomes: Based on the historical and statistical data available, the system will be able to predict outcomes of the games based on the performances of the players and the teams.
- Coaching decisions: Coaches can use sports analytics to ascertain important and precise data sets that would help them regulate their tactics for better results on the field. Using this data, coaches and players can make more well-versed decisions that could decide wins and losses. They can also analyze the data from past matches or tournaments to frame a better game plan and remove the tactics that do not give favorable results.
- Live field data: At present, a huge amount of data is gathered manually during a game of sports matches.
- Player recruitment: Recruitment changes as young players who can be nurtured are bought or who will increase their market share with their popularity.

VI. STATISTICAL DATA

The statistics we gathered were mostly from English Premier League games throughout the course of the season. We collected a total of 46 statistics per game from this site for the EPL. We also gathered average stadium attendance, the previous season rating, and the opponent's win percentage for both home and away teams of each football game for a total of 46 statistics.

All of this was done with Perl scripts and then written to Excel files. Simple Perl modules were installed from (LWP and Spreadsheet) to work with online sources and to write to Excel files. After retrieving the raw data, we then calculated the season-to-date averages for each team. This was done using both Perl and MATLAB scripts. The results were separated by week and by the season.

The last step before using the data as input to the ANN was to average each of the expected offensive statistics with the expected defensive statistics of the opponent. So for example, if team A and team B are playing each other, instead of just using the number of goals team A is expected to score (their current season-to-date average for scoring) as in- put, we would average the number of goals team A is expected to score with the number of goals team B is expected to allow. This final number was the one that was used as input to our model. These calculations were all done with MATLAB scripts

VII. ARTIFICIAL NEURAL NETWORK

Inspired by the biological neural networks of the brain, an Artificial Neural Network (ANN) is ultimately a function, where the input is a vector of input data. This network is composed of "neurons" or processing units which are highly connected. The neurons the ANN can be taught

specific patterns by feeding the network input vectors, and targeted output vectors. Given enough data the ANN can be trained to approximate additional data vectors or find relationships between input and target vectors.
An artificial neuron can be understood as a mathematical function or object that takes input data and produces some output. Suppose that we have a n element vector as the input data, the neuron will scale each data element rj , by a weight wj . The scaled data is summed and offset by some bias b and then put through a differentiable transfer function f. The neuron output can be viewed analytically as

$$f(r1w1 + r2w2 + ... + rnwn + b). \quad (1)$$

The neuron is able to interpret the data differently depending on the weights and bias. A stronger weight for a given data point allows that data point to change the output more dramatically. The transfer function f can be linear f(x) = x, or something nonlinear. Nonlinear transfer functions can be useful for understanding nonlinear relationships. For the models used we implemented "Tan-Sigmoid" transfer functions

Now that we have introduced the basic building block of our network, we construct the feed forward three layer ANNs used in the more successful models. The first layer is constructed of 4 "hidden" neurons. In the hidden layer we implement the nonlinear transfer function "Tan Sigmoid". There exists a weight between every element of the input vector and every hidden neuron. The outputs of this layer is passed as the input vector into a hidden layer of 6 neurons with"Tan Sigmoid" transfer functions. The outputs of this layer are put through an output neuron with a linear transfer function and may be compared to the target vector and the squared error gives the error function. The error function is what we attempt to minimize with respect to the weight matrices. By optimizing the error function the ANN is being "trained".

Before we train the ANN we must first prepare both the network and the data for training. First the data is partitioned into 3 sets, the training set, the validation set, and the testing set. We use 70% for the training, 15% are used for the validation, and 15% for testing set. This is done randomly. The training data is used to create the error function. Each input and target vector creates an error function which is then averaged among all the other training data yielding the mean squared error. Iterative methods are used for optimization and the mean squared error of the validation set is plotted along with the training set. The ANN can fit the training data arbitrarily well but can easily over-fit the training data yielding higher error functions for the problem the ANN is trying to approximate. For this reason the training is stopped when the error function on the validation set is minimized. The testing data is used to test the ANN as it has not been involved in the training process. The weights and biases were updated to Levenberg-Marquardt optimization. Basic ANNs still had a good deal of variability in predictive ability. For example networks with the same structure trained on different data sets may make substantially different predictions in future seasons. This is because different ANNs partition the input data into the 3 data sets randomly. In order to create an algorithm that will give more consistent and robust results, we took an approach generally referred to as a committee of machines (CoM). In this approach many networks are trained against different random partitioning of the data set. Then based on the mean square error against the testing data, the top models are chosen to use predictively

To get the most robust approach to NFL game prediction, we used a committee of committee's approach where many committees' predictions are combined to form our final prediction. Using this approach with 500 ANNs in the training stage, the best 100 were used in each committee, then 50 such committees were used to achieve the results below. The mean was used to form each committee vote and to combine the committees' predictions.

VIII. DIFFERENT MODELS

To create an accurate model, we must either reduce the number of statistics to a manageable amount or create a large enough neural network that can find patterns in the large amount of data. We tried 5 different models for the prediction of football games. These models varied mainly in terms of the data reduction techniques implemented.

The first model we tested utilized only five different parameters. For simplicity we will refer to these statistics as on the field statistics. The statistics we got were a good starting point.

Principal component analysis (PCA) was another method we used to reduce the data being used in the model. PCA takes the 46 stats, normalizes them and creates a new lower dimensional data set made up of linear combinations of the old statistics. The new statistics are orthogonal to each other and ordered in such a way that the first principal component accounts for the maximum variability in the data. By computing this transformation, we are able to discard all but 14 principal components and keep 90% of the variance. This makes a simpler problem for the artificial neural network. This procedure also tells us that 46 independent statistics gives redundant data to differentiate games. The mathematics required was implemented using a software package in MATLAB.

Using a technique that we call linear regression combinatorial optimization we came up with a set of LRCO statistics. This method tests every possible set of statistics to identify the optimal com- bination. We started by getting the statistics from the previous season and used them to train linear regression models. The models were then tested on the following season. We repeated this procedure for every season and on every possible com- bination of statistics. The average error for each season was used to judge which statistics were best for the model. Since linear regression is many times faster than ANNs, the

computation time required to run every combination of statistics was manageable.
The results were not entirely expected. No previous research shows that 4th down conversions or attempts have a big impact on the outcome of a game. These may have been identified as useful by our models because of over-fitting or because they represent a new variable to the game. For example, scoring and time of possession both have a strong correlation of winning, but using both of them in a model might be redundant.

Another data set tested used every statistic gather. For this model we increased the size of the ANNs to 8 neurons in the first hidden layer and 4 neurons in the second hidden layer. This model was not found to be very successful.

IX. STATISTICAL ANALYSIS

One of the techniques we used in understanding our model was a derivative-based technique. In the case of ANNs, the derivatives tell us how much a change in each input will affect the output. Essentially, this will tell us which statistics are the most important. A similar methodology is used to analyze the most important factors of a deterministic model of HIV dynamics. It's a visual representation of how this technique works using ANNs.

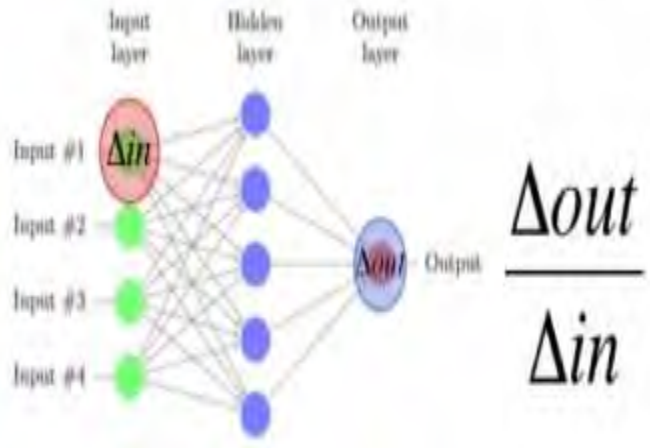

Figure 4: Visual representation of the derivative process.

Using this technique is common, however there are a few challenges using this approach on our model. Since ANNs are nonlinear functions, their derivatives will not be constant. For example, two different games will yield different derivatives. The second challenge is that our final model has 5000 ANNs. Each network will yield a different output and a different set of derivatives. To overcome this we looked at the average derivative of our model when all of the statistics are season averages. We then normalized the derivative by the input value, giving the partial derivatives the same units.

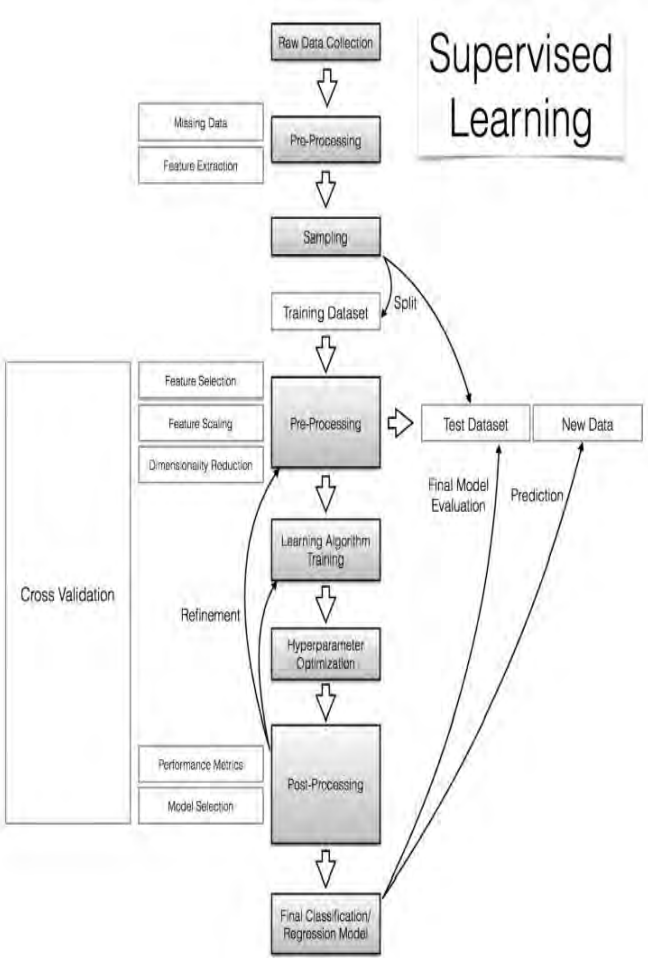
To calculate, the partial derivative was calculated for each ANN and then averaged. This was done for each statistic. Once the statistics were normalized we were able to see what percentage each statistic makes up the derivative information or the sum of the normalized derivatives.

X. PROPOSED METHODOLOGY

A. BLOCK DIAGRAM

In this paper, we propose a model to predict the outcomes of football matches in the English Premier League. We train the final dataset on various machine learning classifiers. We compare the performances of each classifier and choose the one that returns the best result. Then, we optimize the classifier that yields the best result to further enhance the model accuracy in making predictions. Our final output or target label is the Full time Match Result (FTR). This label will indicate a Home team win (H), an Away team win (A), or a Draw (D).

Architecture/Design



B. DATASET DESCRIPTION

We are going to be predicting match outcomes using data from past games for a few seasons. We obtained this data-set from football.co.uk. The data around 65 attributes per season regarding the home team, the away team, the venue, scores, to name a few. We filtered these attributes into a final list which proved to be the most influential for predicting the outcome.

C. PRE-PROCESSING

The data-set we obtained from football.co.uk consists of several attributes from each season. A lot of these features are pretty much unnecessary for making outcome predictions. Hence, our primary task is to clean the data to only retain the features or attributes that we require the most. We calculate the Scatter Matrix to observe how much one attribute affects another attribute in the dataset and their correlations. This will help us pick the most influential features that we want to use to build our new data-set.

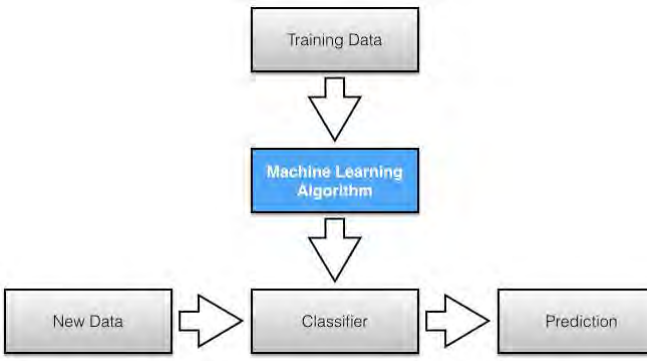
D. DATA SPLITTING:

Once we finish building our new set of crucial attributes, we split the data into training and testing data.

E. MODEL BUILDING

In this module, we apply the machine learning classifiers required for making our prediction.

F. FLOWCHART



XI. ACTUAL RESULTS

We were able to construct the required neural network using machine learning tools and successfully created a data set for 10 seasons of English Premier League using tools like rapid miner to construct accurate data sets to give us great prediction results of above 51%.

Additionally, from our findings, it was discovered that logistic regression techniques could only predict win or lost results. Further, the system could predict win, draw or loss results using DNN techniques.

The image below is our training log which shows an average of 52%-win prediction.

25	2500	0.511628	0.978204	1.541667
26	2600	0.511628	0.971994	0.978966
27	2700	0.505814	0.979173	1.541667

XII. FUTURE SCOPE

Currently the project focuses on gathering a structured authentic data. As sports data and prediction is a complicated process which enlists predicting win-losses based on historical data needs to have a comprehensive and accurate database for correct predictions.

Our proposed system will need work on in enhancing the prediction rate as the current prediction rate could be better, our team will be working on increasing the prediction rate using other models and choose the one that is the most accurate one. A match making rating will be added to further boost our prediction outcomes.

XIII. CONCLUSION

Our proposed system will help us greatly in predicting match outcomes long before they are played using logical regressions and deep neural network. The AI and machine learning techniques helped us in creating results from our vast data sets that were based on data mining tools. There is a possibility that the neural network classification could be improved no matter which prediction data is used with additional training data however this additional data may be met with diminishing returns. Due to the highly volatile nature of sports, outcomes maybe difficult to predict based solely on objective data. It is possible that the additional of a human element to the prediction model would further increase its accuracy. For example, incorporating factors like team morale or saving a coach from getting fired based on the team performance in the season may add to the team's motivation to perform better and win matches that our system predicted them to lose. Our proposed system is

in no way completely accurate in predicting victory, however it indicates that an objective, statistically based system can be implemented to predict the outcomes of football matches.

Abstract—**Rank misrepresentation in the portable Application advertise alludes to extortion/misleading exercises whose lone object is to have a reason for hitting up the Applications in the prominence list.**

It turns out to be more incessant for Application designers to utilize terrible means, for example, expanding their Application deals or posting false App evaluations, to confer positioning extortion. It is vital to avoid positioning frauds there is restricted comprehension and research in this field.

Ranking extortion in the portable App business sector alludes to fake or misleading exercises which have a motivation behind knocking up the Apps in the fame list. For sure, it turns out to be more successive for App designers to utilize shady means, for example, swelling their Apps' business or posting fake App appraisals, to submit positioning extortion. While the significance of averting positioning extortion has been broadly perceived, there is restricted comprehension and examination here. To this end, in this project, we give an all-encompassing perspective of positioning misrepresentation and propose a positioning extortion recognition framework for portable Apps. In particular, we first propose to precisely find the mining so as to position misrepresentation the dynamic periods, to be specific driving sessions, of versatile Apps. This project gives a whole perspective of positioning misrepresentation and describes a Ranking fraud identification framework for mobile Apps. This work is grouped into three categories. First is web ranking spam detection, second is online review spam detection and last one is mobile app recommendation. The Web ranking spam refers to any deliberate actions which bring to selected Web pages an unjustifiable favorable relevance or importance. Review spam is designed to give unfair view of some products so as to influence the consumers' perception of the products by directly or indirectly influating or damaging the product's reputation.

Keywords: Sentiment, User Review, Fuzzy Logic System, Fake Review, Genuine Review, Fraud Application.

I. INTRODUCTION

Most of us use android Mobile these days and also uses the play store capability normally. Play store provide great number of application but unluckily few of those applications are fraud. Such applications dose damage to phone and also may be data thefts. Hence such applications must be marked, so that they will be identifiable for play

store users. So, we are proposing a web application which will process the information, comments and thee reviews of the application with natural language processing to give results in the form of graph. So, it will be easier to decide which application is fraud or not. Multiple application can be processed at a time with the web application. Also, User cannot always get correct or true reviews about the product on internet. So, we can check for more than 2 sites, for reviews of same product. Hence, we can get higher probability of getting real reviews. The recent trend in market used by the dishonest App developers for App boosting is to use fraudulent means to consciously boost their apps. At last, they also distort the chart rankings on a App store. This is usually implemented by using so-called “internet bots” or “human water armies” to raise the App downloads, ratings and reviews in a very little time. For example, Venture Beat
[1] reported that, when an App was promoted using ranking manipulation, it could be precipitated from number 1,800to the upmost 25 in Apple’s top free leader board and more than 50,000100,000 new users could be acquired within a couple of days. In actuality, such ranking fraud promotes great concerns to the mobile App industry. For example, Apple has notified of cracking down on App developers who commit ranking fraud [2] in the App store. Leading events of mobile Apps forms different leading sessions. The mobile Apps not always ranked high in the leader boards, but it usually happens in the leading sessions. So, detecting ranking fraud of mob Apps is actually the process to detect it within the leading session of the mobile Apps. Especially, this paper proposes a simple and effective algorithm to recognize the leading sessions of each mobile App based on its historical ranking records. This is one of the fraud evidence. Also, two types of fraud evidences are proposed based on Apps’ rating and review history, which gives some anomaly patterns from Apps’ historical rating and review records. In addition, we propose an unsupervised evidence aggregation method to consolidate these three types of evidences for assessing the credibility of leading sessions from mobile Apps. The main objective of this project is to develop a disease prediction system that will help the patients with finding the disease they are suffering with. It isimplemented as an application in which user answers some predefined questions and based on these questions the disease would be predicted. Along with that we can also provide some additional symptoms as inputs. The disease would be predicted using some Machine Learning algorithms. Algorithms such as Naïve Bayes, Random Forest and decision trees would help to simply the complex task of finding the disease. The margin of errors would be reduced by using such complex algorithms. It analyses the symptoms and predicts the most probable disease to the user. This application will also provide online help to the patients to get more detail about the already diagnosed disease by suggesting remedies.

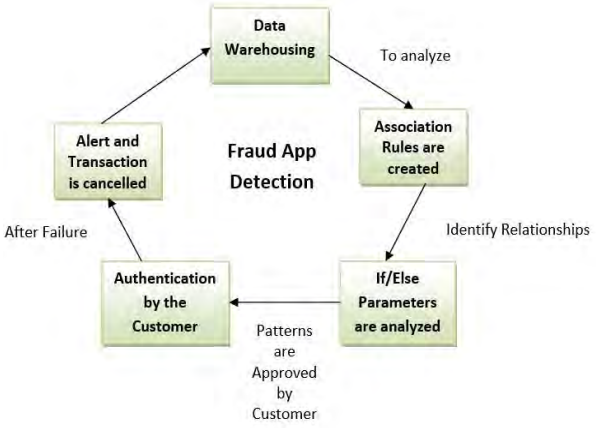

Fig 1: Fraud App Detection system

II. LITERATURE SURVEY

Liu M and others [3] Proposed that due to convenience of giant quantity of apps, apps retrieval and recommendation of apps is incredibly necessary, after that there is a need of top quality of app retrieval and recommendation there ought to be an explicit app relationship calculation for recommendation. He finished that various strategies supported app's context, which may solely find whether or not 2 apps square measure downloaded, put in meantime or offer similar functions or not.

Mohammad Aamir and others [4], explained a categorical assess of the sphere of recommender systems and Approaches for analysis of advice System to propose the
advice methodology that may any facilitate to reinforce opinion mining through recommendations.

G.Angulakshmi and others [5], discussed that the assorted tools and techniques of opinion mining, She explained that Opinion mining may be a style of tongue process that may track the mood of the folks concerning any specific product by review. Opinion mining is additionally referred to as sentiment analysis attributable to giant
volume of opinion that is made in internet resources obtainable on-line.

Vijay.B. Raut and others [6]. discussed the ways for opinion extraction, classification, and summarization. He additionally explained all approaches of summarization techniques, techniques utilized in method of opinion mining. He showed that approaches of machine learning and sentiment analysis of knowledge like motion-picture show, product, hotel etc., whereas lexicon based mostly approach is appropriate for brief text in micro-blogs, tweets, and comments knowledge on internet.

Kularbphettong. K and others [7] proposed a diamond recommendation system by mistreatment K-Means and cooperative Filtering techniques. He recommended the model system by that user mechanically so as to maximize users' satisfaction. The total system designed and developed in the form of automaton (android operative system). He divided the result by the analysis functions into a pair of parts: developing the Mobile application for diamond recommender users their evaluation and testing. The results showed that the specialists and users are happy with the system at a decent level.

Beel, J., LangerS and others [8], reviewed that of 176 publications and it showed that no agreement exists on a way to assess and compare analysis paper recommender approaches. He examined that ends up in the dissatisfactory state of affairs that despite the numerous evaluations, the individual strengths and weaknesses of the planned approaches stay
for the most part unknown.

Nikolaos Polatidis and others [9] explained the all mobile recommendation system technologies and gave the challenges long-faced the technologies. He additionally explained that mobile devices and for information retrieval various factors are crucial. He planned that development of recent Role-Based Access management (RBAC) model that improve privacy issues of permissions in apps and information accessed by user.

III. METHODOLOGY

In this section we present proposed methodology in detail. In this project, we use effective algorithm to spot the leading sessions of every App depend on its historical ranking records. Then, with the analysis of Apps' ranking behaviors, we discover that the fraud Apps usually have completely different ranking patterns in every leading session compared with normal Apps.

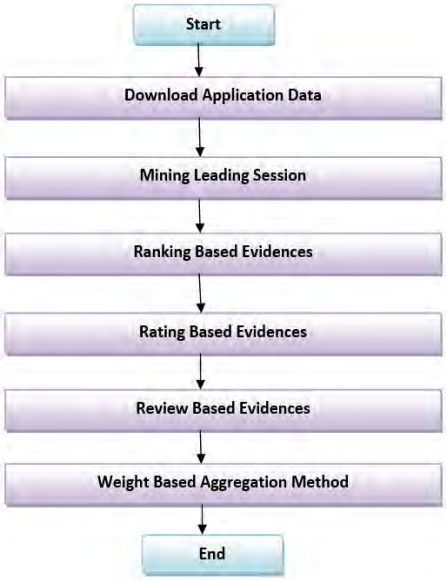

Fig 2: Fraud App Detection proposed system

1. Identifying Leading Sessions

We need to observe ranking fraud inside leading sessions of mobile Apps then propose an easy but effective algorithm to spot the leading sessions of every App depend on its historical ranking records.

After this we discover that the deceitful Apps usually have completely different ranking patterns in every leading session compared with traditional Apps.

2. Ranking based Evidences

We need to analyze the fundamental characteristics of leading events for extracting fraud evidences. By analyzing the Apps' historical ranking records, we observe that Apps' ranking behaviors in an exceedingly leading event continuously satisfy a particular ranking pattern, that consist of different ranking phases, namely, rising phase, maintaining phase and recession phase. Specifically, in every leading event, an App's ranking first will increase to a peak position within the leader board, then keeps such peak position for a time being, and finally decreases until the end of the event.

3. Rating Based Evidences

User rating is one among the utmost vital features of App promotion. An App that has higher rating could attract a lot of users to download and can even become higher on the leaderboard. Thus, rating manipulation is additionally a crucial perspective of ranking fraud.

4. Review Based Evidences

The App stores permit users to write some comments as reviews. Such reviews will project the personal perceptions and usage experiences of existing users for specific mobile Apps. Before downloading or buying a new mobile App, users read its historical reviews & based on lot of positive can download it. Thus, imposters usually post faux reviews within the leading sessions of a particular App so as to inflate the App downloads.

5. Evidence Aggregation

The study describes a ranking fraud detection process where there is some evidence considered and integrated to get an aggregated result which is most reliable in finding a fraudulent application in a mobile market [1]. Most generally the ranking fraud is happening in some particular phase of many leading events [1]. A leading event may occur due to an advertisement campaign or etc. This study can be extended to get a recommender system to enhance user experience.

IV. SENTIMENT ANALYSIS ALGORITHM

Sociologists have studied human sentiment for half a century. In the pattern of interaction between people, the meaning of vocabularies has the central role to show people's reaction to each other and also works and other actions meant to evoke a sentimental response from between vocabularies.

The increase of social media like blogs and social networks has fueled interest in sentiment analysis. So as to find the new opportunities and to manage the reputations, business folks typically read the reviews/ ratings/ recommendations and different types of online opinion. this enables to not solely realize the words that are indicative of sentiment however additionally to seek out the relationships between words in order that each word that modifies the sentiment and what the sentiment is regarding will be accurately identified.

Scaling system is employed to work out the sentiment for the words having a positive, negative and neutral sentiment. It also analyzes the following concepts to know the words and the way they relate to the conception.

There are many sentiment analysis algorithms available for developers. Implementing sentiment analysis in your apps is an easy job. There are not any servers to set up, or settings to configure. Sentiment Analysis analyzes the text of news articles, social media posts like Tweets, Facebook, and more. Social Sentiment Analysis is an algorithm that's tuned to research the sentiment of social media content, like tweets and status updates. The algorithm takes a string, and returns the sentiment rating for the "positive," "negative," and "neutral." Additionally, this algorithm provides a compound result that is an overall sentiment of the string.

For this purpose, we tend to use Classifiers is Sentiment Analysis is to see the subjective value of a text-document,

i.e. however positive or negative is that the content of a text document. Regrettably, for this purpose, these Classifiers fail to determine a similar accuracy. This can be because of the subtleties of human language, irony, context interpretation, use of slang, cultural variations and also the other ways during which opinion will be expressed. In this paper, we are using Naive Bayes classifiers.

Naive Bayes classifiers are studying the classification task from a Statistical point of view. The starting point is that the probability of a class C is given by the posterior probability P (C|D) given a training document D. Here D refers to all of the text in the entire training set. It is given by D= (d1, d2, . dn), where di is the attribute (word) of document D.

V. RESULTS

a. Outputs (Output of the project only)

Fig 3: Result

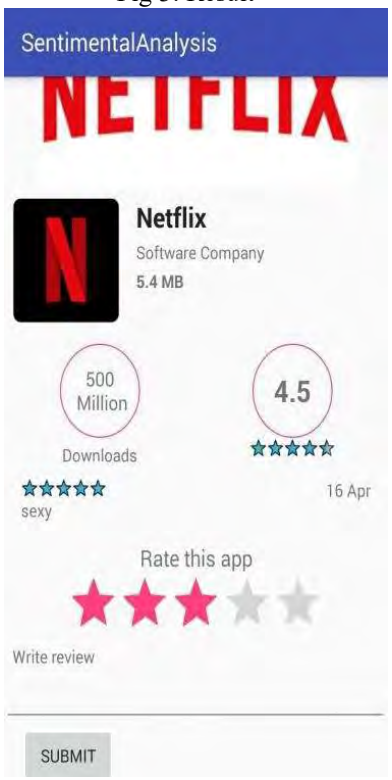

Fig 4: Result

Fig 5: Result

b. Outcomes:

The project intends to correctly analyze the input data on the basis of 14-16 parameters to correctly judge the presence of the disease. It uses complex algorithms like Naïve Bayes, Decision Tree, and Random Forest.

c. Discussion:

AI systems are now a part of a variety of specializations from stock trading to the setting of real estate prices; from fraud detection to translation of vernacular languages; from designing our daily shopping lists to forecasting which movies we might like and diagnosis of medical condition.

This is merely the beginning. Not long from today, AI will be used to advance our understanding of biological phenomenon through analysis of highly dense and huge datasets, help us invent new drugs and make treatments more thorough and personal. Self-driving vehicles can revolutionize transportation and allow new paradigms in planning of architecture. Machines will run our homes more efficiently, make businesses more productive and help predict risks to society.

Before AI systems can be deployed in healthcare applications, they need to be 'trained' through data that are generated from clinical activities, such as screening, diagnosis, treatment assignment and so on, so that they can learn similar groups of subjects, associations between subject

features and outcomes of interest. These clinical data often exist in but not limited to the form of demographics, medical notes, and electronic recordings from medical devices, physical examinations and clinical laboratory and images.

There are several techniques that can be used to correctly classify and predict when a new tuple is entered.

VI. CONCLUSION

A unique perspective of this approach is that each one the evidence is model by statistical hypothesis tests, therefore it's simple to be extended with alternative evidence from domain data to discover ranking fraud. The admin will notice the ranking fraud for mobile application. The Review or Rating or Ranking given by users is accurately calculated. Hence, a new user who needs to download an app for a few purposes will get a clear view of the present applications. Finally, we tend to validate the proposed system with in- depth experiments on real-world App information collected from the App Store. Our system will detect the ranking frauds based on three types of evidences, such as ranking based evidences, rating based evidences and review based evidences. Further, an optimization-based aggregation method combines all the three evidences to detect the fraud. This examination effectively built up an improved feeling characterization strategy for peculiarity location through web-based social networking investigation. The viability of the proposed technique is shown utilizing tweet information as a contextual investigation. The oddity estimation designs were effectively distinguished and translated through the use of the proposed technique. The contextual investigation exhibited the handiness and predominance of the technique. This exploration offers new thoughts for outlining a hearty opinion examination technique via web-based networking media information to distinguish inconsistency occasions or examples. The strategy will likewise be pertinent in cases including design changes after some

time. This ought to be considerably profitable for organizations to fortify their administration center, for political hopefuls and government pioneers to comprehend the premise of their continuous surveying comes about, and for other private associations to refine their incentives and brand guarantees to their clients.

VII. FUTURE SCOPE

In the future, we will decide to study more practical fraud evidence and analyze the latent relationship among rating, review, and rankings. Moreover, we can add more services in ranking fraud detection approach to enhance user experience. Currently the project focuses on gathering a structured authentic data. As medical data and analysis is a sensitive field, the project intends to find an assimilation of the results of various algorithms and compare the accuracy. Over the next 2 months, the team intends to build a model that best suits the input data. The model and the algorithms used are structured and developed using python as the main programming language and will use libraries like SciKit, NumPY, Django and Rasa forNLP.

The developments of the project in the future are aimed at careful consideration of the disease. This can make a prediction of the diseases by looking at a medical history of a number of patients.

Thereafter, the team intends to build a web framework to create a rich user interface.

***Abstract*—The design cycle for a web site starts with creating mock-ups for individual web pages either by hand or using graphic design and specialized mock-up creation tools. The mockup is then converted into structured HTML or similar markup code by software engineers. This process is usually repeated many more times until the desired template is created. In this study, our aim is to automate the code generation process from hand-drawn mock-ups. Hand drawn mock-ups are processed using neural networks and subsequently some deep learning methods are used to implement the proposed system.**

Keywords—convolutional neural network, deep learning, automatic code generation, HTML

I. INTRODUCTION

The importance of the Internet web sites has increased considerably due to the progress made in today's technology. Nowadays web sites reflect the face of the states, institutions, communities, people, etc. Web sites are available in almost every field, from knowledge to social work, from games to training and many more. Web sites created by companies come to the fore for financial reasons for product marketing or advertising purposes. On the other hand, official institutions aim to provide more efficient services.

At the front-end of every web site is a "web page" which is the part of the web site that interacts with the user. It is very important to serve a page that attracts the attention of the end-user, is easy to use and has enough functional features. However, developing web pages that respond efficiently to these needs involves a very burdensome process. In the preparation of web pages, graphic designers, software specialists, end-users, corporate authorities and people employed in many different areas are required to work together. Usually, the process starts with the mock-up design of the user interface by the graphic designers or mock-up artists, either on paper or a graphic editing software, in line with the needs of the institution. Software experts write code for the web pages based on these drafts. The resulting web pages may change based on feedback received by the end users. There process involves a lot of repetitive tasks. Rewriting the code for components with similar functions and page structures changing over time makes the process tedious. This reveals the need to explore more efficient solutions in web page design.

The idea of designing a web page by generating automatic code is gaining importance as a research subject. Automatic production of web pages reduces programming time, process cost and resource consumption. Thanks to the faster progressive design stages, the final web-site is produced in a shorter time.

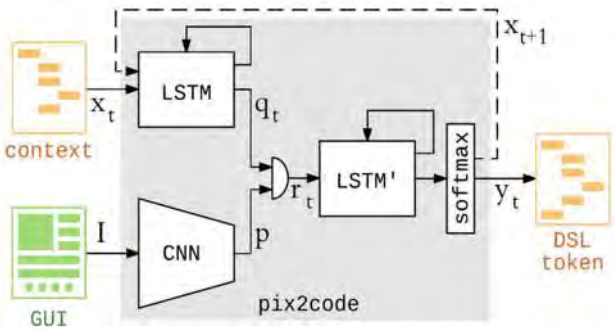
In this study, an algorithm has been developed to automatically generate the HTML code for hand-drawn mock-up of a web page. It is aimed to recognize the components created in the mock-up drawing and to encode them according to the web page hierarchy. A public dataset of hand-drawn images of web sites obtained from Microsoft AI Labs' GitHub page [13] is used to train and verify the proposed scheme. The images on the dataset are processed using a deep neural network model involving convolutional neural networks is used to train the data. Afterwards a structured HTML code is obtained. Our model achieves 96% method accuracy and 73% validation accuracy.

II. RELATED WORK

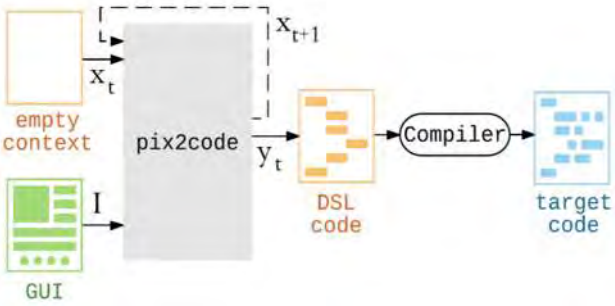
The automatic generation of programs using machine learning techniques is a relatively new field of research and program synthesis in a human-readable format have only been addressed very recently.

Pix2code is the essential work, this paper is dependent on. It is a Keras-based usage, which at its discharge likewise incorporated the dataset utilized right now. The principle distinction among pix2code and our methodology is that it is utilizing a solitary start to finish model without a pre-prepared CNN. This methodology, at its face, appears as though it would improve at the undertaking since it utilizes its own CNN prepared on interface pictures. Be that as it may, its normal exactness of 77% is lower than our methodology and Emil Wallner's. Another related work is an undertaking created by Emil Wallner, which is another Keras execution of pix2code, utilizing the equivalent dataset. It separates itself from pix2code by parting the model into an encoder and decoder, and utilizing a pre-prepared CNN as the base of the encoder model.

(a) Training



(b) Sampling



In [5], the algorithm named ReDraw takes mock-ups of mobile application screens and creates a structured XML code for it. In the first stage of their implementation computer vision techniques are used to detect individual GUI components. The second stage involve classification of the detected components according to their function, e.g. toggle-button, text-area, etc. In this stage deep convolutional neural networks are used. In the last stage, the XML code is generated by combining with the kNN

algorithm according to web programming hierarchy.

Microsoft has recently developed a system that takes hand drawn mock-ups of simple web pages and creates the structure HTML code [13]. There are no literature that explains their work, however they have published their code and dataset online. In this project we use some of the images from this dataset.

III. Dataset and Features

Our approaches require a dataset which contains a wireframe sketch and associated website code. Sourcing a quality dataset is often a challenge in many machine learning projects.

We were not aware of any dataset which contained wireframes sketches and associated website code, and therefore created our own. We considered three options to create such a dataset: (i) Finding websites and manually sketching them. (ii) Manually sketching websites and building the matching website. (iii) Finding websites and automatically sketching them. Deep learning methods require a sufficiently large dataset with hundreds of samples. Even with data augmentation techniques (augment smaller dataset into larger by modifying current samples) (i) and (ii) would require significant resources to complete.

In addition, human error and different human opinions on how exactly to create the sketches could undermine the quality of the dataset. As result we use method (iii). Our aim is to work generally on any website wireframe and therefore we required a dataset which represented a wide variety of wireframes. As such, we used real websites rather than a synthetic approach like that used by pix2code [1]. Our process involved collecting pairs of a sketched version of the website as well as the structural code of the website.

Web pages contain structure from HTML and style from CSS. We show a sample of elements with various styles. This highlights the need for a processing step to normalize web page style. We identified a number of challenges to collecting the structure from websites: (a) Wireframes have a small element set, HTML has a much larger element set, a simplified representation is required e.g. HTML has both an and tag but both represent a graphical element. (b) Wireframes are style invariant, and therefore we require only the structure. Websites have many different styles for elements. (c) Wireframes are static however; website structure can be manipulated JavaScript. (d) Wireframes only represent structure with no content. Websites contain structure and content. Content can alter the structure i.e. two web pages may have a (paragraph) element but if they had different length text the size of the paragraph would be different. As such, the structure would change. (e) HTML is sometimes invalid or poorly formatted, this would decrease our dataset quality. (f) HTML has multiple representations of the same structure. This dilutes the quality of the dataset. These issues highlight the need for careful data processing.

A. Design Mockup Features

Since we need to insert one screenshot for each word, this becomes a bottleneck when training the network. Instead of using the images, we extract the information we need to generate the markup.

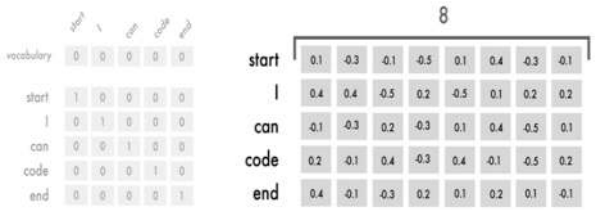
The information is encoded into image features. This is done by using an already pre-trained convolutional neural network (CNN). The model is pre-trained on ImageNet. We extract the features from the layer before the final classification.

We end up with 1536 eight by eight pixel images known as features. Although they are hard to understand by us,

a neural network can extract the objects and positions of these elements from the features.

B. Markup Features

In this version, we'll use a word embedding for the input and keep the one-hot encoding for the output.The way we structure each sentence stays the same, but how we map each token is changed. One-hot encoding treats each word as an isolated unit. Instead, we convert each word in the input data to lists of digits. These represent the relationship between the markup tags.



The dimension of this word embedding is eight but often vary between 50 - 500 depending on the size of the vocabulary.

The eight digits for each word are weights similar to a vanilla neural network. They are tuned to map how the words relate to each other. This is how we start developing markup features. Features are what the neural network develop to link the input data with the output data. For now, don't worry about what they are, we'll dig deeper into this in the next section.

IV. Proposed Method

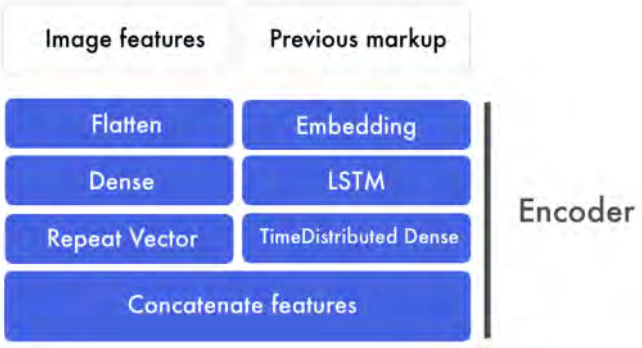
The task of generating computer code written in a given programming language from a GUI screenshot can be compared to the task of generating English textual descriptions from a scene photography. In both scenarios, we want to produce a variable-length strings of tokens from pixel values. There are two major sections. First, the encoder. This is where we create image features and previous markup features. Features are the building blocks that the network creates to connect the design mockups with the markup. At the end of the encoder, we glue the image features to each word in the previous markup. The decoder then takes the combined design and markup feature and creates a next tag feature. This feature is run through a fully connected neural network to predict the next tag.

A. The Encoder

CNNs are currently the method of choice to solve a wide range of vision problems thanks to their topology allowing them to learn rich latent representations from the images they are trained on [8, 11]. We used a CNN to perform unsupervised feature learning by mapping an input image to a learned fixed-length vector thus, acting as an encoder. We'll take the word embeddings and run them through an LSTM and return a sequence of markup features. These are run through a Time distributed dense layer - think of it as a dense layer with multiple inputs and outputs. In parallel, the image features are first flattened. Regardless of how the digits where structured they are transformed into one large list of numbers. Then we apply a dense layer on this layer to form a high-level features. These image features are then concatenated to the markup features. The input images are initially re-sized to 256 × 256 pixels (the aspect ratio is not preserved) and the pixel values are normalized before to be fed in the CNN. No further pre-processing is performed. To encode each input image to a fixed-size output vector, we exclusively used small 3 × 3 receptive fields which are convolved with stride 1 as used by Simonyan and Zisserman for VGGNet [4]. These operations are applied twice before to down-sample with max-pooling. The width of the first convolutional layer is 32, followed by a layer of width 64, and finally width 128. Two fully connected layers of size 1024 applying the rectified linear unit activation complete the vision model.

a) Markup features

Here we run the word embeddings through the LSTM



layer.

In this graphic, all the sentences are padded to reach the maximum size of three tokens.

To mix signals and find higher-level patterns we apply a TimeDistributed dense layer to the markup features. TimeDistributed dense is the same as a dense layer but with multiple inputs and outputs.

b) Image features

In parallel, we prepare the images. We take all the mini image features and transform them into one long list. The information is not changed, just reorganized.

Again, to mix signals and extract higher level notions, we apply a dense layer. Since we are only dealing with one input value, we can use a normal dense layer. To connect the image features to the markup features, we copy the image features. In this case, we have three markup features. Thus, we end up with an equal amount of image features and markup features.

c) Concatenating the image and markup features

All the sentences are padded to create three markup features. Since we have prepared the image features, we can now add one image feature for each markup feature.

After sticking one image feature to each markup feature, we end up with three image-markup features. This is the input we feed into the decoder.

B. The Decoder

Our model is trained in a supervised learning manner by feeding an image I and a contextual sequence X of T tokens xt, t ∈ {0 . . . T − 1} as inputs; and the token xT as the target label. As shown on Figure 1, a CNN-based vision model encodes the input image I into a vectorial representation p. The input token xt is encoded by an LSTM-based language model into an intermediary representation qt allowing the model to focus more on certain tokens and less on others [8]. This first language model is implemented as a stack of two LSTM layers with 128 cells each. The vision-encoded vector p and the language-encoded vector qt are concatenated into a single feature vector rt which is then fed into a second LSTM-based model decoding the representations learned by both the vision model and the language model. The decoder thus learns to model the relationship between objects present in the input GUI image and the associated tokens present in the DSL code. Our decoder is implemented as a stack of two LSTM layers with 512 cells each. This architecture can be expressed mathematically as follows:

[1] p = CNN(I)
[2] qt = LSTM(xt)
[3] rt = (q, pt)
[4] yt = sof tmax(LSTM0 (rt))
[5] xt+1 = yt

Here we use the combined image-markup features to predict the next tag.

In the below example, we use three image-markup feature pairs and output one next tag feature.

Note that the LSTM layer has the sequence set to false. Instead of returning the length of the input sequence it only predicts one feature. In our case, it's a feature for the next tag. It contains the information for the final prediction.

V. RESULTS

In this study, the purpose of generating automatic HTML code from mock-up images was successfully reached. The neural network however was trained using limited datasets and so this version will not be able to predict HTML from random websites, but it's still a great setup to explore the dynamics of the problem.
The dense layer works like a traditional feedforward neural network. It connects the 512 digits in the next tag feature with the 4 final predictions. Say we have 4 words in our vocabulary: start, hello, world, and end.

The vocabulary prediction could be [0.1, 0.1, 0.1, 0.7]. The softmax activation in the dense layer distributes a probability from 0 - 1, with the sum of all predictions equal to 1. In this case, it predicts that the 4th word is the next tag. Then you translate the one-hot encoding [0, 0, 0, 1] into the mapped value, say "end".

Example output on training the model with 'n' epochs:

10 epochs: start start start end

100 epochs: start

<HTML> <H1>Hello

World!</H1> </HTML>

<HTML> <H1>Hello

World!</H1> </HTML>

end

300 epochs: start

<HTML> <H1>Hello World!</H1> </HTML>

end

A. Output

250 epochs

450 epochs

350 epochs

VI. Conclusion

This dissertation has built upon existing research and extended this research to a novel domain of wireframe to code translation. We have presented an end to end framework which translates wireframes into websites and produces results in real time. While our work demonstrates the potential of such a system to automate the process of implementing GUIs, we only scratched the surface of what is possible.

Our model consists of relatively few parameters and was trained on a relatively small dataset. The quality of the generated code could be drastically improved by training a bigger model on significantly more data for an extended number of epochs. Implementing a now-standard attention mechanism [1, 7] could further improve the quality of the generated code. Using one-hot encoding does not provide any useful information about the relationships between the tokens since the method simply assigns an arbitrary vectorial representation to each token.

Therefore, pre-training the language model to learn vectorial representations would allow the relationships between tokens in the DSL to be inferred (i.e. learning word embeddings such as word2vec [6]) and as a result alleviate semantical error in the generated code. Furthermore, one-hot encoding does not scale to very big vocabulary and thus restrict the number of symbols that the DSL can support.

Our approaches focus on single page websites. However, they could be modified to input multi page websites. This would require our framework to be modified to accept multiple images along with information on how to link the pages together. This would allow full websites to be designed using our approaches. Finally, we focus on websites but we assert that it would primarily be an engineering challenge to use our approach described in other domains such as mobile apps or desktop applications.

Abstract-**Our aim is to assess the techniques of data processing in the fields of clinical and health care to develop correct choices. It conjointly offers a detailed exchange of healthful info handling ways which can improve numerous components of Clinical Predictions. It's a latest powerful technology that is of high interest in the computer world. It uses already existing info in many databases to transform it into new researches and results. From huge data sets, to extract new patterns and the knowledge related to these patterns data mining and database management. Particularly the task is to get data by the means of automatic or semi-automatic. The various parameters confined in processing of body agglomeration, forecasting, path analysis and predictive analysis. To beat the drawback of existing framework we've created good health prediction System. We have designed up a specialist framework known as good Health Prediction framework, which is utilized for improving the task of specialists. A framework checks a patient at initial level and proposes the doable diseases.**

Health monitoring systems have rapidly evolved during the past two decades and have the potential to change the way health care is currently delivered. Although smart health monitoring systems automate patient monitoring tasks and, thereby improve the patient workflow management, their efficiency in clinical settings is still debatable. This paper presents a review of smart health monitoring systems and an overview of their design and modeling. Furthermore, a critical analysis of the efficiency, clinical acceptability, strategies and recommendations on improving current health monitoring systems will be presented. The main aim is to review current state of the art monitoring systems and to perform extensive and an in-depth analysis of the findings in the area of smart health monitoring systems. In order to achieve this, over fifty different monitoring systems have been selected, categorized, classified and compared. Finally, major advances in the system design level have been discussed, current issues facing health care providers, as well as the potential challenges to health monitoring field will be identified and compared to other similar systems.

It begins with getting some information about manifestations to the patient, in the event that the framework can distinguish the fitting sickness, at that point it proposes a specialist accessible to the patient in the closest conceivable territory. In light-weight of accessible total knowledge, the framework can demonstrate the result.

I. INTRODUCTION

Sometimes we need the help of doctors immediately, but due to some reasons they are unavailable. In our project we propose a system that is user favorable to get guidance on health issues instantly through online health care system. In recent years, with reference to the various algorithms and posterior distribution the puzzles of huge data are solved highly. Meanwhile, such extracting algorithms apply to economic, social science and a few different fields.

With no additional info, classification rules are generated by the samples trained by them.

The project makes the prediction to the disease's and with the help of data mining we analysis the problem and the future solution is that we are going to provide the medicine for the disease's and the recommendation of the same.

Such associate degree outsized quantity of data cannot be processed build to form to create health predictions within the early stage and make treatment schedules to diagnose.

Our aim is to assess the techniques of data processing in the fields of clinical and health care to develop correct choices.

Data Mining is one of the most motivating area of research that is become increasingly popular in health organization. Data Mining plays an important role for uncovering new trends in healthcare organization which in turn helpful for all the parties associated with this field. This survey explores the utility of various Data Mining techniques such as classification, clustering, association, regression in health domain. In this paper, we present a brief introduction of these techniques and their advantages and disadvantages. This survey also highlights applications, challenges and future issues of Data Mining in healthcare. Recommendation regarding the suitable choice of available Data Mining technique is also discussed in this paper.

This framework improves undertaking of the specialists as well as helps the patients by giving vital help at a soonest organize conceivable. With the overall development of the web portal area the understanding of disease with the help of the user (doctor) input is the crucial aspect of till date development with the login input within the system

II. LITERATURE SURVEY

It additionally offers an in-depth exchange of healthful info handling methods which can improve varied components of Clinical Predictions.
It's a latest powerful technology that is of high interest in the computer world.
It uses already existing info in many databases to transform it into new researches and results. From huge data sets, to extract new patterns and the knowledge related to these patterns data mining uses machine learning and database management. Particularly the task is to get data by the means of automatic or semi-automatic.

1. This tells how this algorithm is used to find frequent data items and compares them with the existing algorithms.
2. Data mining techniques is used to apply on medical data which has abundant scope for improving health solutions.
3. Electronic health records and other historical medical data can prove miracles if used for a right purpose.
4. Huge amounts of complex data generated by health care sector include details about diseases, patients, diagnosis methods, electronic patient's details hospitals resources.

Our framework involves fundamental parts, for example, quiet login, enter side effects in the System, and recommend medications, proposes an adjacent specialist. The application takes the contribution of different manifestations from the patient, does the examination of the entered side effects, and gives fitting sickness expectation. Our framework enables the clients to get an examination of the indications they give for anticipating the malady they are experiencing. Some of the time the circumstance happens when you need the specialist's assistance quickly, yet they are not accessible because of some reason. Along these lines, it enables the clients to get an examination of the side effects they give for anticipating the infection they are experiencing.

III. OBJECTIVE AND SCOPE OF THE PROJECT

There square measure varied application of information mining like telecommunication business, commercial industry, biological data analysis and many more.

With the advance changes happening in the technology, especially in the field of health organization a lot of data is produced day by day. Since there is need of analysis of data and the amount of data analyzed is in large amount, so there is need of excessive knowledge regarding the technology of data mining.

For health identification E-healthcare applies data processing and telecommunication techniques. E-health was primarily used for patient knowledge analysis and wellness identification at varied levels.

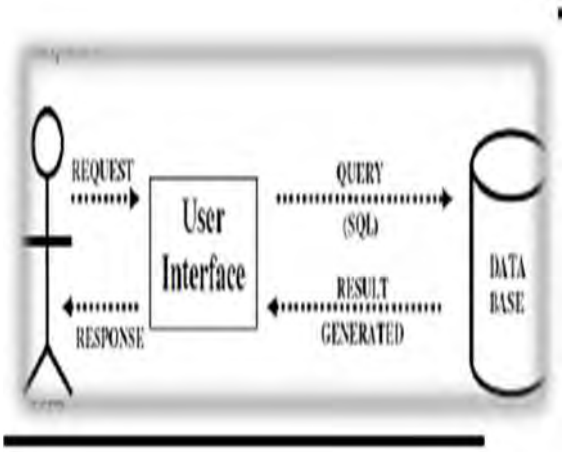
There square measure some patients World Health Organization need continuous scrutiny and would possibly would like doctor facilitate right away.

In the proposed system, hidden knowledge will be extracted from the historical data by preparing datasets by algorithm.
Predicting good health may be done solely is system responds that means.

These datasets will be compared with the incoming queries and the final report will be generated
.
Since this projected methodology can work on real historical knowledge, it will provide accurate and efficient results, which will help patients, get diagnosis instantly.
The further enhancements that can be done would be integrating this web application in an Android app.

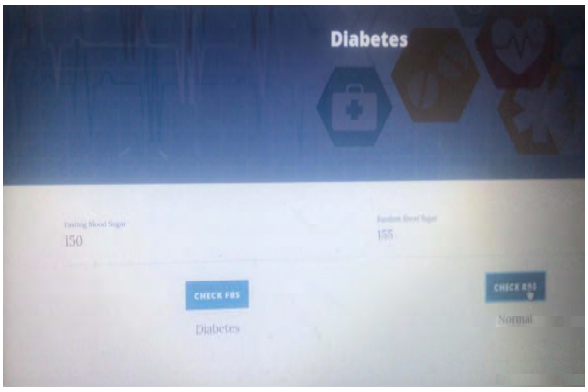
This will be obtainable to users on mobile basis and its use may be additional multiplied. Also feature like obtaining the doctor on-line on chat in order that patients will directly check with the involved doctors.
For eg the modules doing blood pressure analysis can be integrated to find how close the person associated with health issue is. This will make this web application predictable in true sense.

The further enhancements that can be done would be integrating this web application in an Android app. This will be available to users on mobile basis and its use can be further increased. Also feature like getting the doctor online on chat so that patients can directly talk to the concerned doctors. The modules doing different disease analysis can be integrated to find how close the person associated with disease is. This will make this web application predictable in true sense

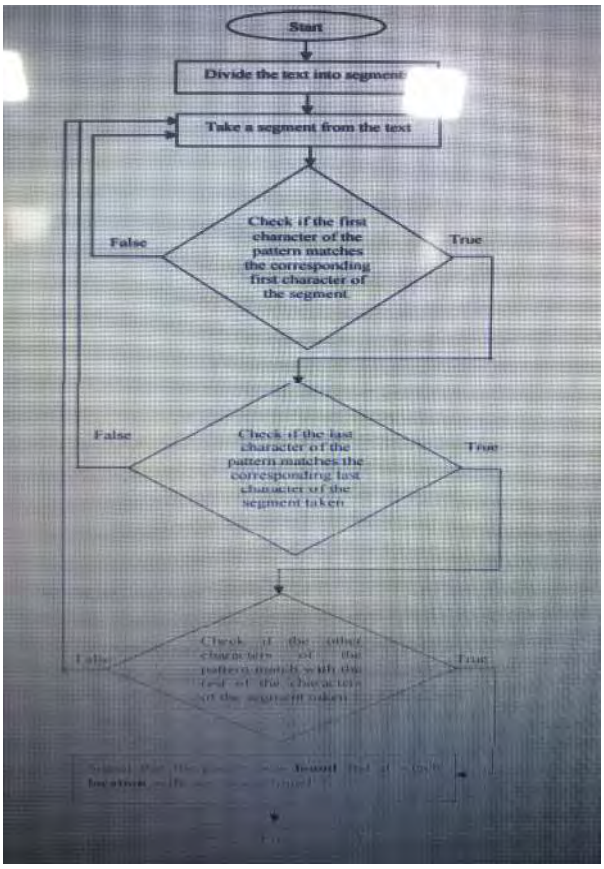


IV. PROPOSED METHODOLOGY

A. Block Diagram:



We have created an online consultation project which will help end user to get instant guidance for their health. In this system, we have imposed various symptoms and diseases which are related to them.
In the above figure the project represent as the details of patients is manually added to the dataset and with the
help



of data mining we analyses the problem and the amount of symptoms.

Here, there will be doctor's panel, Admin panel and Patient panel.
Admin can access all the information and will let patient know their requirements.

Patient will login into the system it will register and then can search various medicines and provide symptoms. Then all the disease's related to those symptoms will appear, this will be the guidance for healthcare. Doctors can view who searched for them and what they searched about.
Doctors can add various doctors and they can recommend various medicines. There will be online quesnaire andit will help the patient to understand and choose between the best.

For accuracy we are using the intelligent data mining techniques. This will help us in the accurate data sets and most accurate probability.

Health is one of the most important assets of our life which directly reflects in any form of progress or development. In today's hustle and bustle of life, most of the people neglect this asset which may be due to lack of time and complexity in the vast data available over the Internet. Data mining has introduced various techniques which would overcome this problem and assist us to emphasize on both health and work simultaneously. In present era, Data Mining is

becoming popular in healthcare field because there is a need of efficient analytical methodology for detecting unknown and valuable information in health data.

V. ACTUAL RESULTS

A. Outputs (Output of the project only)

Successfully implemented the consultation project and helped the patients to consult the doctors online and get the proper guidance.
In our project we propose a system that is user favorable to get guidance on health issues instantly through online health care system. In recent years, with reference to the various algorithms and posterior distribution the puzzles of huge data are solved highly. Meanwhile, such extracting algorithms apply to economic, social science and a few different fields.
With no additional info, classification rules are generated by them.

B. Outcomes:

Such associate degree outsized quantity of data cannot be processed build to form to create health predictions within the early stage and make treatment schedules to diagnose.
Our aim is to assess the techniques of data processing in the fields of clinical and health care to develop correct choices.
It additionally offers an in-depth exchange of healthful info handling methods which can improve varied components of Clinical Predictions.
It's a latest powerful technology that is of high interest in the computer world.
It uses already existing info in many databases to transform it into new researches and results. From huge data sets, to extract new patterns and the knowledge related to these patterns data mining uses machine learning and database management. Particularly the task is to get data by the means of automatic or semi-automatic.

C. Discussion of the results

In the proposed system, hidden knowledge will be extracted from the historical data by preparing datasets by applying algorithm.
Predicting sensible health is done solely is system responds that method.
These datasets will be compared with the incoming queries and the final report will be generated using Mining.
Since this projected methodology can work on real historical information, it'll offer correct and economical results, which can facilitate patients get identification instantly.
The application takes the contribution of different manifestations from the patient, does the examination of the entered side effects, and gives fitting sickness expectation. Our framework enables the clients to get an examination of the indications they give for anticipating the malady they are experiencing. Some of the time the circumstance happens when you need the specialist's assistance quickly, yet they are not accessible because of some reason. Along these lines, it enables the clients to get an examination of the side effects they give for anticipating the infection they are experiencing.

VI. FUTURE SCOPE

In the future, with the advent of remote monitoring devices and wireless communication systems, information/communications systems have the potential to support continuous monitoring of a patient's health status at home, rapid diagnosis by clinicians, and timely, effective therapeutic interventions in the home by the patient or a family member, with guidance by health professionals. Furthermore, by capturing process and system performance data for systems analysis, control and design, information/communications technologies can facilitate the use of systems-engineering tools by patient care teams, provider organizations, and environmental actors at all levels of the health care delivery system. Will add various chat systems and mapping will provide diet plans and locate various conference chatting.

Data mining can be helpful in the field of restorative space. Anyway protection, security and unfit to sign into the record are the huge issues on the off chance that they are not tended to and settled appropriately. It portrays the proposition of a crossover information mining model to separate arrangement learning for the guide of different maladies in the clinical choice framework and presents a structure of the apparatus different devices utilized for investigation. Now and again the circumstance happens when you need the specialist's assistance promptly, however they are not accessible because of some reason.

One of the most significant challenges of the data mining in healthcare is to obtain the quality and relevant medical data. It is difficult to acquire the precise and complete healthcare data. Health data is complex and heterogeneous in nature because it is collected from various sources such as from the medical reports of laboratory, from the discussion with patient or from the review of physician. For healthcare provider, it is essential to maintain the quality of data because this data is useful to provide cost effective healthcare treatments to the patients. Health Care Financing Administration maintains the minimum data set (MDS) which is recorded by all hospitals

For effective utilization of data mining in health organizations there is a need of enhance and secure health data sharing among different parties. Some propriety limitations such as contractual relationships among researcher and health care organization are mandatory to overcome the security issues. There is also a need of standardized approach for constructing the data warehouse. In recent years due to enhancement

of internet facility a huge dataset (text and non-text form) are also available on website. So, there is also an essential need of effective data mining techniques for analyzing this data to uncover hidden information.

VII. CONCLUSION

The system would drastically reduce the human effort, reduce the cost and time constraint in terms of human resources and expertise, and increase the diagnostic accuracy. The prediction of diseases using Data Mining applications is a challenging and risky task as the data found are noisy, irrelevant and massive too.

In this situation, data mining tools come in handy in exploring of knowledge of the medical data and it is quite interesting.

This system will also guide the users of how to remain healthy and fit using tips provided here. The further enhancements that can be done would be integrating this web application in an Android app.

This will be out there to users on mobile basis and its use may be more inflated.

Also feature like obtaining the doctor on-line on chat in order that patients will directly sit down with the involved doctors

we can also conclude that there are no single data mining techniques which give consistent results for all types of healthcare data. The performance of data mining techniques depends on the type of dataset that we have taken for doing experiment. So, we can use hybrid or integrated Data Mining technique such as fusion of different classifiers, fusion of clustering with classification or association with clustering or classification etc. for achieving better performance.

It is difficult to acquire the precise and complete healthcare data. Health data is complex and heterogeneous in nature because it is collected from various sources such as from the medical reports of laboratory, from the discussion with patient or from the review of physician. For healthcare provider, it is essential to maintain the quality of data because this data is useful to provide cost effective healthcare treatments to the patients. Health Care Financing Administration maintains the minimum data set (MDS) which is recorded by all hospitals

The modules doing different disease analysis can be integrated to find how close the person associated with disease is. This will make this web application predictable in true sense.

***Abstract*- — The goal of this project is to use variety of algorithms on a comprehensive dataset of cricket match results to predict the team agnostic match outcomes. The target competition was The Indian Premier League (IPL) which is a twenty over format cricket league. We have extracted the results of every IPL match from the years 2008 to 2018. This data allowed us to calculate arbitrary batsman and bowler statistics before every game. The models were optimized with individual player features and then both team and player features. The models were trained based on the data of 11 IPL seasons from 2008 to 2018. The optimal model was a simple prediction method which can predict the outcome of a match based on the opponents and the players in particular team. Although it is difficult to take into account all features that influence the results of the matches, an attempt to find the most significant features is made and various classifiers are tested to solve the problem.**

Overview:

I. Introduction:

As a sport cricket is played globally across 106 member states of the International Cricket Council (ICC), with an estimated 1.5 billion fans worldwide (ICC, 2012-2013).However, much of the global finance and interest is focused upon the 10 full ICC member nations and more specifically upon 'the big three' of England, Australia and India .Cricket is the India's most popular sport. It is played, watched, and enjoyed by billions of people country wide. And in India particularly, the sport has more in common with religion than entertainment.

The IPL is the most-attended cricket league in the world and ranks sixth among all sports leagues. In 2010, the IPL became the first sporting event in the world to be broadcast live on YouTube. The brand value of IPL in 2017 was US$5.3 billion, according to Duff & Phelps. According to BCCI, the 2015 IPL season contributed ₹11.5 billion (US$182 million) to the GDP of the Indian Economy. So, one can easily understand that Cricket is a multi-billion-dollar market. Although Cricket is a game of uncertainties there is a strong incentive for models that can predict the outcomes of matches and beat the odds provided by bookers. The aim of this study is to investigate to what degree it is possible to predict the outcome of cricket matches.

II. Background

The main objective of this project is to develop an IPL win-loss and score predictor that will help the Management to find the best combination of player. The goal of this project is to use variety of algorithms on a comprehensive dataset of cricket match results to predict the team agnostic match outcomes. The target competition is The Indian Premier League (IPL) which is a twenty over format cricket league. We will be extracting the results of every IPL match from the years 2008 to 2018. This data will allow us to calculate arbitrary batsman and bowler statistics before every game. The models will be optimized with individual player features and then both team and player features. The models will be trained based on the data of 11 IPL seasons from 2008 to 2018. The optimal model was a simple prediction method which can predict the outcome of a match based on the opponents and the players in particular team. Although it is difficult to take into account all features that influence the results of the matches, an attempt to find the most significant features is made and various classifiers are tested to solve the problem.

III. Importance of the project

Project will able to predict the probability of a particular team winning a certain T-20 match of IPL based on the input by the user. The project will help to decide how much a given team has the chance of winning at a particular venue considering the given conditions. It will help to form a better team which is most suited to face the opponent team and increase the overall chances of winning. Using neural networks and machine learning our project aims to deliver an application to predict the success of a team in an IPL match.

Objectives and Scope of the project:

The aim of the project is to predict the probability of a particular team winning a certain T-20 match of IPL based on the input by the user. The input will take consideration of the following factors: teams playing the match, toss winning team, toss decision and the venue where the match is being played.

The input will go through several algorithms in order to predict the outcome of the match i.e. team winning the match. It will also try to predict the probable score

range for the winning team using neural networks based on the attributes passed to it. The project will help to decide how much a given team has the chance of winning at a particular venue considering the given conditions. It will help to form a better team which is most suited to face the opponent team and increase the overall chances of winning.

Other scopes of this project are:

Using neural networks and machine learning our project aims to deliver an application to predict the success of a team in an IPL match.
To predict the success of the team we are taking the statistics of every innings of batsman as well as the bowler through every IPL season from 2008-2018. Also, the team statistics at a particular venue are considered.
The prediction will be based on the outcomes to all the IPL matches in the past 11 years.
Since neural networks work on experience, we will be providing more than 600 different matches to our network, each with complete ball by ball data. This will help to gain accurate results. The number of matches won with a particular team combination, the average score of the team as well as the progress of the team through the season will be the deciding parameters.

Summary:

The project is to develop a "IPL win-loss and score predictor" this will help the Management to find the best combination of player. This project will use variety of algorithms on a comprehensive dataset of cricket match results to predict the team agnostic match outcomes. The target competition is The Indian Premier League (IPL) which is a twenty over format cricket league. We will be extracting the results of every IPL match from the years 2008 to 2018. This data will allow us to calculate arbitrary batsman and bowler statistics before every game. The input will go through several algorithms in order to predict the outcome of the match i.e. Team winning the match. It will also try to predict the probable score range for the winning team using neural networks based on the attributes passed to it.
The project will help to decide how much a given team has the chance of winning at a particular venue considering the given conditions. It will help to form a better team which is most suited to face the opponent team and increase the overall chances of winning.
Using neural networks and machine learning our project aims to deliver an application to predict the success of a team in an IPL match. To predict the success of the team we are taking the statistics of every innings of batsman as well as the bowler through every IPL season from 2008-2018. Also, the team statistics at a particular venue are considered.
The prediction will be based on the outcomes to all the IPL matches in the past 11 years. Since neural networks work on experience, we will be providing them various different matches to our network, each with complete ball by ball data. This will help to gain accurate results.

IV. Design and Implementation:

Figure No 1: Proposed Methodology

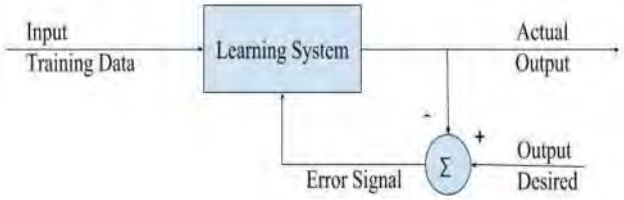

Figure No 2: Block diagram of Supervised Learning

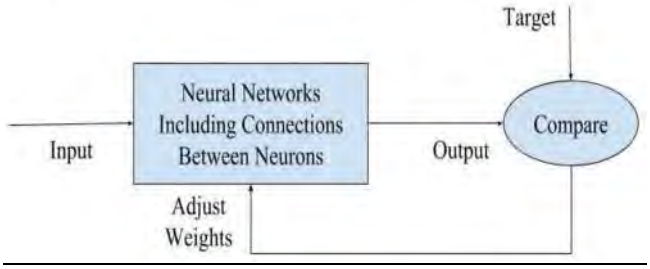

Figure No 3: Block diagram of Unsupervised Learning

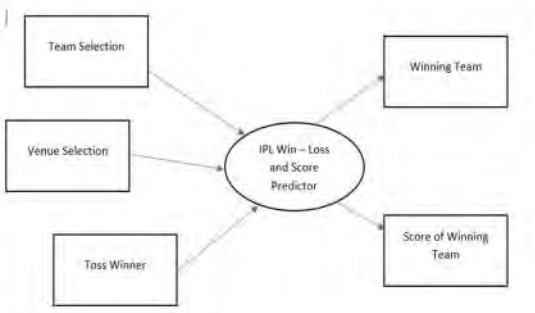

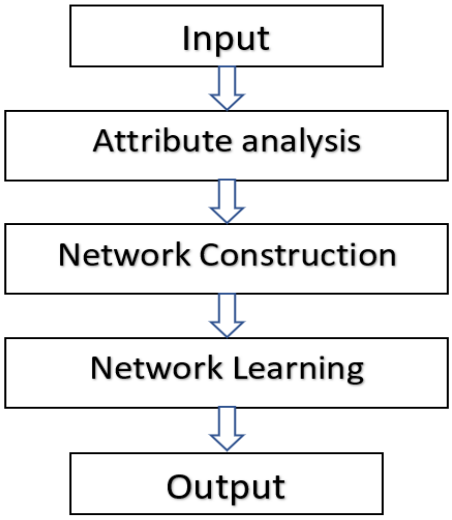

Figure No 4: DFD

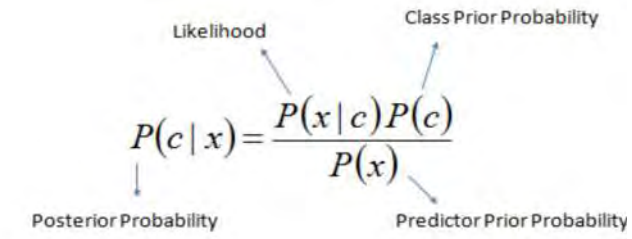
V. Algorithms

It is a classification technique based on Bayes Theorem with an assumption of independence among predictors. In simple terms, a Naive Bayes classifier assumes that the presence of a particular feature in a class is unrelated to the presence of any other feature.



$$P(c \mid X) = P(x_1 \mid c) \times P(x_2 \mid c) \times \cdots \times P(x_n \mid c) \times P(c$$

Figure No. 5: Naïve Bayes Algorithm

Random Forests grows many classification trees. To classify a new object from an input vector, put the input vector down each of the trees in the forest. Each tree gives a classification, and we say the tree "votes" for that class.

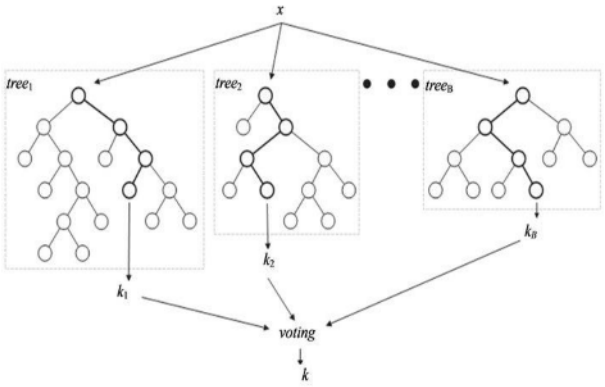


Figure No. 6: Random Forest Tree

A Support Vector Machine (SVM) is a supervised machine learning algorithm that can be employed for both classification and regression purposes. SVMs are more commonly used in classification problems and as such, this is what we will focus on in this post. SVMs are based on the idea of finding a hyperplane that best divides a dataset into two classes, as shown in the image below.

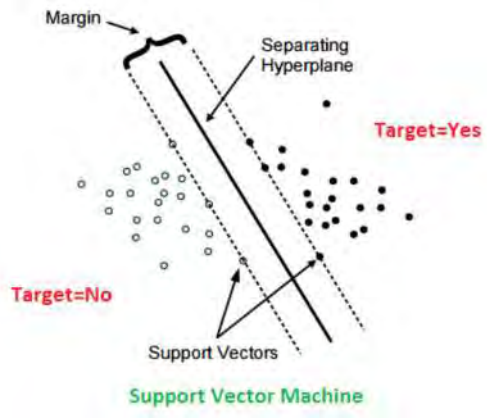

Figure No. 7: Support Vector Machine

VI. Results and Discussion

Actual Results:

Implementation Details

The implementation plan for an IPL match win-loss prediction using neural networks is as follows:

1. A database of all the IPL matches containing various match statistics is stored in MS Excel.

2. The user will be given a form that will be generated using a suitable programming language. This form will contain various attributes that will be used as testing data.

3. All the coding will be done in Python.

4. The Excel files are imported to Python, where the initial Excel database is taken as Input and later as target.

5. Training is performed on 70% of the data and testing on the remaining 30% of the data.

6. Initially, random weights are assigned all the entries in the database.

7. The weighted sum of all input nodes is then calculated and the activation for the node is calculated.

8. Necessary adjustments will be done according to error difference obtained between target output and achieved output.

Figure No. 8: Team Selection

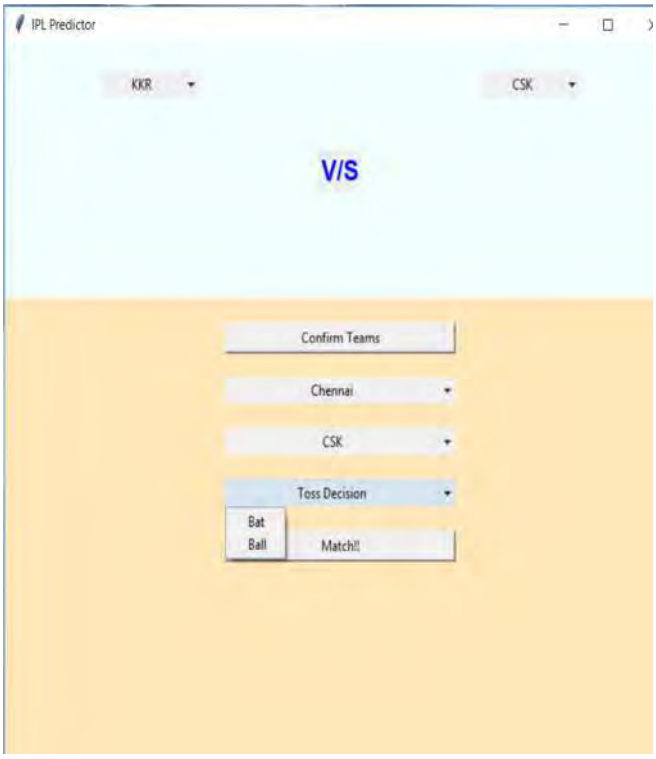

Figure No. 9: Toss Decision

Figure No. 10: Match Winner and Winning Team Score Prediction

Outputs:
We have used accuracy as a metric to evaluate correctness for all the algorithms.
Win-Loss prediction:

We obtained following accuracy for –

1) Support Vector Machines: 69.08%
2) Naïve Bayes Classifier: 64.70%
3) Random Forest Classifier: 51.55%

The algorithm with the maximum accuracy was used to predict the winning team for an IPL match.

Score Prediction:

Accuracy of neural network: 62.02%
Using the above model with given accuracy, the score for the winning team was predicted.

Outcomes:

The project intends to correctly analyse the input data on the basis of 14-16 parameters to correctly judge the winning team and its score. It uses complex algorithms like Naïve Bayes, Decision Tree, and Random Forest.

Discussion:

AI systems are now a part of a variety of specializations from stock trading to the setting of real estate prices;

from fraud detection to translation of vernacular languages; from designing our daily shopping lists to forecasting which movies we might like and diagnosis of medical condition.
This is merely the beginning. Not long from today, AI will be used to advance our understanding of biological phenomenon through analysis of highly dense and huge datasets, help us invent new drugs and make treatments more thorough and personal. Self-driving vehicles can revolutionize transportation and allow new paradigms in planning of architecture. Machines will automate our homes more efficiently, make businesses more productive and help predict risks to society.
There are several techniques that can be used to correctly classify and predict when a new tuple is entered.

VII. Future Scope:

Using neural networks and machine learning our project aims to deliver an application to predict the success of a team in an IPL match. By using neural networks and machine learning our project can be extended to develop a world cup-based application or for any other international sports tournaments.
To predict the success of the team we are taking the statistics of every innings of batsman as well as the bowler through every IPL season from 2008-2018. Also, the team statistics at a particular venue are considered. The prediction will be based on the outcomes to all the IPL matches in the past 11 years.
Since neural networks work on experience, we will be providing more than 600 different matches to our network, each with complete ball by ball data. This will help to gain accurate results. The number of matches won with a particular team combination, the average score of the team as well as the progress of the team through the season will be the deciding parameters.
Future research in this project can be predicting the bowl by bowl outcome of a match while the match is being played. This will require real time data collection as well as statistical measures for successful prediction.

VIII. Deployment:

Deployment can be a major challenge in software which involves machine learning. Huge amounts of processing is required just to get it up and running. Data generated in the process is humongous as well.
The ML model will be deployed using Google firebase or spring. The cloud platform will provide a base for future developments where flexibility, portability and reliability are required.
The GUI by itself is not very difficult to deploy. We have multiple ways of offering interfaces, such as web interfaces and command line interfaces. It will expand to a desktop GUI in the future as well.
The web interface will be deployed using Heroku or AWS, depending on the relative cost of hosting.
The command line can be used as a windows executable file. Users can simply download it and run it natively on their windows PCs.

IX. Conclusion:

By observing recent trends and strategies, the scope of machine learning is growing day by day. The project based on machine learning will evaluate and improve the understanding by using this project as a path. By using the technologies like ml, python, neural networks. Using our derived set of features, we will be able to predict the outcome of a match with approximately 65% accuracy, and the score with 60% accuracy. Predicting the outcome as well as the score of a cricket match has multiple factors involved, some of which we have tried to incorporate, others being difficult to correctly specify and represent in this project. Greater prediction accuracies can be achieved through more define data that better correlates to features significant for an IPL Match.

A GAN based Autoregressive approach to Music Generation

Aniket Ladukar, Advait Maduskar, Shubhankar Gore, Neha Patwari
Thakur College of Engineering and Technology, Mumbai, India
aniket.ladukar@gmail.com, advaitmaduskar.1@gmail.com, shubhankar27gore@gmail.com, neha.patwari@thakureducation.org

Abstract – **Music Generation is a challenging task from the perspective of machines. Even as humans, composing musical sequences is demanding to those that lack the knowledge of the nuances of music. Autoregressive models are effective for generation of locally coherent audio, but break down when it comes to generating globally coherent structures. In such cases, Generative Adversarial Networks, or GANs, prove to be substantially efficient if provided with sufficient data. The only drawback of GANs is the computational power required for the generation of musical structures. In this paper, we explore the applications of autoencoders as well as GAN networks for the generation of medium-to-long musical sequences** [1]**.**

Keywords – Generative Adversarial Networks, Autoregressive, music generation, deep learning, music

I. INTRODUCTION

Audio synthesis is very instrumental process in vast gamut of applications like music generation systems, audio synthesis algorithms used in text to speech conversions also known as synthesizers in music.

Synthesizers have a long history of being handmade devices taking a range of inputs. The inputs can be categorized as either control parameters (‘pitch’, ‘velocity’, etc..) or filter parameters (‘tone’, ‘timbre’, etc.). These inputs are then used to generate fine-tuned audio signals which we perceive as music.

Despite their drawbacks, or maybe due to them, synthesizers have had a deep impact on the advancement of music and culture in the past half century (Punk, 2014).

Music, like other diverse forms of information, has an elemental pattern indistinct to human eyes. Humans create new pieces music based on years of experience and instinct, rather than following some predefined mathematical formulae.

The objective of this project is to imitate a human like “thinking” in a computer. To achieve such a goal, the approach of using deep learning can be effective.

We aim to train an autoregressive model using a GAN based approach on current musical data to discern fundamental pattern in order to generate new audio sequences of medium to long duration.

II. BACKGROUND

One of the major issues with music generation is the lack of consistency at global and local level. Primitive papers written by Chen et al discuss about model that can create a melody but lacks harmony.

This proposes the following avenues to advance upon -

1. Music should be generated with proper tempo, variety of notes and various musical structures.
2. Create a model capable of producing music with long- and short-term coherent structures.

Liu et al tackle the same problem but are unable to overcome either challenge. They mention that their representation of music cannot accurately interpolate between the melody and the other parts of the piece, while also failing to note the complexity of musical pieces.

Two LSTM networks are used by Eck - one to process chord structure and local note structure and the other to learn long term dependencies in order to try to learn a tune and while maintaining coherence. However, this architecture is trained on set chords and thus cannot create a more diverse sequence of notes [2].

III. SIGNIFICANCE

Music can be considered as a complicated yet exceptionally structured continuous set of data. These structures can be found at timescales spanning from milliseconds all the way to the entire composition lasting several minutes. Creating such sequences consisting of temporal correlations arising from these structures is a demanding task because they span many different orders of magnitude.

The scope of this project is confined to conquer the challenge of music generation. It serves as a tool for taking individual skill a step ahead and speeds up composition of music. Moreover, the project will work as a tool to identify cases of plagiarism and settle cases of copyright infringement in the music industry. Ultimately the project highlights the cultural shift that is a result of incorporating deep learning with one of the bedrocks of human culture – music.

IV. OBJECTIVES

Like any other form of information, musical sequences have underlying patterns that are indiscernible to human eyes. Humans compose new music based on experience and intuition and not mathematical patterns. Our objective is to replicate this kind of "thinking" in a computer and to that purpose, the deep learning approach can prove fruitful. We aim to train a generative network on existing musical data and learn patterns in the data in order to generate new sequences of medium to long length.

We are working towards hypothesizing a new model for music generation that combines the properties of models we previously studied while omitting the shortcomings and integrating the positive aspects. We aim to conceptualize a model that amalgamates the properties of Autoencoders and GANs in a recurrent feedback loop.

V. METHODOLOGY

Classical music is being considered for the training of models for the following reasons:

1. MIDI files for classical music are available in abundance.
2. Classical music is more graded and regulated when compared to other genres.
3. It contains complex yet well-defined structures as opposed to the abstract nature that one might encounter in other styles of composition.

The files will be processed using the music21 library available in python. Each piece of music is decomposed into a sequence of chords with each chord having a predefined time period.

A chord is created for every corresponding new note. Each chord is represented as an encoded vector for processing. Almost 390,000 notes will be generated from a total of 700 A 70-15-15 split will be used for training, validation and testing respectively [3].

Both Generator and Discriminator are implemented as CNNs. The Generator develops along the time axis followed by the pitch axis. The Discriminator wraps in the opposite direction. The Generator is retrained for every five training iterations of the Discriminator [4].

VI. PROPOSED SYSTEM

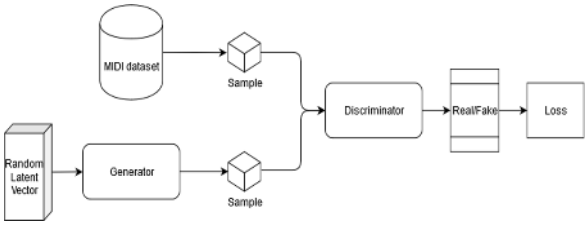

Fig 6. 1 GAN Architecture

The concept of GAN is fundamentally unambiguous and simple. The discriminator and the generator operate in an adversarial manner. The aim of Generator is to generate data which appears to be like the real data. The discriminator serves to distinguished the synthesized data from the genuine data. Here we plan to train the Generator once for every five training iteration of the discriminator. It is essential to realize that GAN is basically an approach taken to make two networks work together. Both Generator and Discriminator have their individual architecture [3] [4] [5].

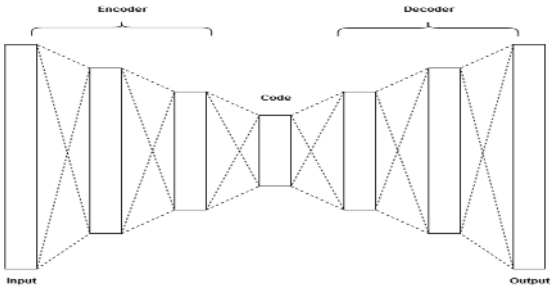

Fig 6. 2 Autoencoder architecture

Autoencoders are a distinct type of feed forward neural networks. Their basic goal is to reduce the dimensionality of the input. Here, the input and output remain the same. Autoencoders consist of mainly an encoder, a dimensional code and a decoder [6].

The encoder compresses the input into a dimensional code. This code is like a concise representation of the input and is also referred as the latent-space representation. The job of the decoder is to recreate the input from the dimensional code.

Autoencoders are very data-specific, i.e. they can only compress data similar to what they are trained on. The output generated by the autoencoder is not identical to the input. There is a certain amount of loss due to compression [6].

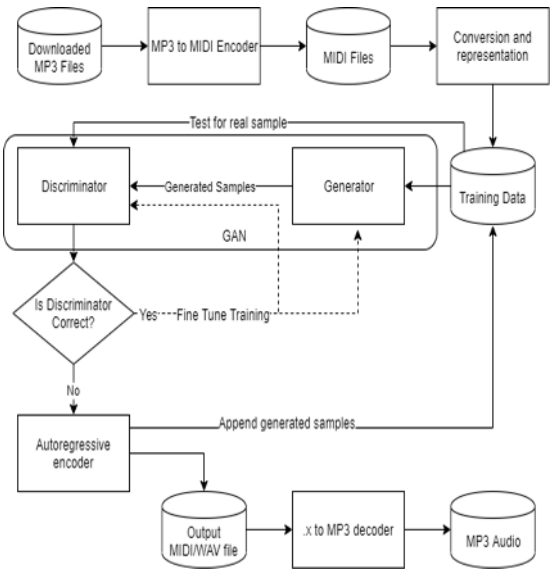

Fig 6. 3 Proposed System Architecture

Finally, we propose a system which combines both GAN and Autoencoder to generate using. By doing so, we can we aim to improve on the shortcomings of the existing models. Current models face one of the following issues –

- Training models which can generate quality results is a computationally heavy task.
- The models that train in a short span of time generally suffer in the quality of output that is produced.

The GAN based Autoregressive approach can prove to be fruitful because GANs being very effective in modelling an underlying pattern will produce quality results. Meanwhile, Autoencoders can be used to compress the data without losing important features will aid in speeding up the training process. This will eventually result in a faster and better generation of music.

VII. RESULTS ACHIEVED

A GAN based model was used to achieve the following results. The model was trained on a MIDI file of Al Adagi's composition. The pitch of the notes was the characteristic that was used to train the model. The generator learns to generate new audio sequences of varying timbre to represent different instruments.

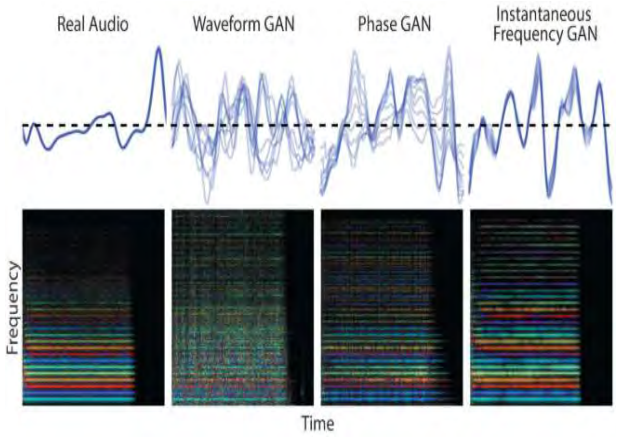

Fig 6. 4 Representation of musical waveform of musical waveforms

Here, we have used random interpolation to generate music on a scaled GAN architecture. After combining the MIDI files and parsing them, they can be represented as follows –

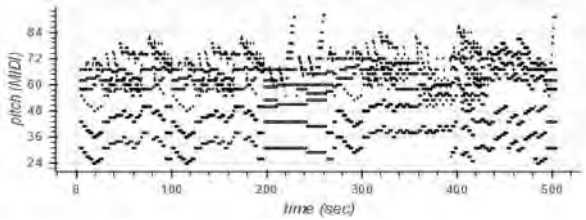

Fig 6. 5 Pitch vs Time representation of dataset used for random interpolation

Following the training of the model using this data, the time interval for random interpolation between instruments was set as 5 (sec/instrument) and constant Q-spectrogram of the generated music was obtained.

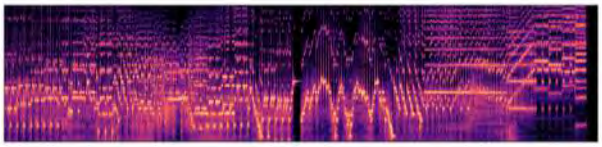

Fig 6. 6 Constant-Q spectrogram of generated music

Thus, from our dataset, we were able to randomly subsample, interpolate and generate 656 samples.

We observed that the interpolation between latent vectors was coarse and could be improved by increasing the time period between interpolations. Thus, to produce music that sounds smoother, we can set this time period to higher values and compare with currently produced music. Furthermore, more training data will help refine the model and help towards smoother conformation between instruments.

Few important observations include:

1. The tracks play at a analogous scales.
2. Some samples exhibit chord like playtime.
3. The bass plays at a lower pitch and is consistent in nature.
4. The drums tend to follow a balanced and musical pattern of 8 or 16 beats.
5. The pitch of instruments like piano and guitars tends to overlay each other with suggests the existence of symphonic affiliation.

VIII. FUTURE SCOPE

In the near future, we are focusing on improving established baselines by manipulating training data and interpolation times. We also plan on conducting a comparative analysis with other methods for music generation with various permutation of functional parameters.

We aim to improve the musical and aesthetic appeal of the music generated by the model as it lacks certain qualities and falls behind the music generated by consummate artists.

Future scope includes development of an autoregressive GAN model in a recurrent feedback loop that can be used not just for music generation, but also for detection of plagiarism in music by introducing original work as a sample data point and the dubious work as the fake samples in the discriminator function of the GAN.

Abstract – **Software development methodologies are needed so that the software development life cycle can become systematic to complete application development within the right time frame. This paper focuses on architecture that redefines the DevOps pipeline by turning the Version Control System (VCS) and the Integration Server (IS) into a decentralized system as a separate and independent fabric channel. The advantage of having such a system is that it prevents the problems occurring in the pipeline due to centralized architecture. This also allows the system to generate reports at each stage hence improving the compliance and transparency of the architecture. The report consists of well-formed data that is derived from transactions up until that point thus providing the ability to monitor concurrently the progress at any stage and at any time.**

Keywords: Hyperledger Fabric, SDLC, Blockchain, version control, decentralization, DevOps, Continuous Monitoring, Continuous Integration.

I. INTRODUCTION

One of the most fundamental notions of the software development process is SDLC models which stand for Software Development Life Cycle models. SDLC–is a continuous process that begins at the moment when a decision is made to launch the project and ends at the moment when it is permanently removed from exploitation [1]. No single model exists with an SDLC. It is divided into major groups, each having its own features and weaknesses. They originated from the first and oldest SDLC "waterfall" method, and their range grew significantly. The scope of SDLC models is dictated by the wide range of product types-starting with the development of web applications to complex medical devices. The problem with 'Agile methodology' came into picture when things started to get difficult for the organizations who took up client services. Development teams tended to deploy their work on a large scale onto the operations team. There was very less coordination between the teams from all levels, specifically teams that were responsible for developing the service (development team) and the teams that were responsible for bringing the service into delivery phase / production phase onto the customer's hand (operations team). The operations team was not on the same pace as the development team. So for some organization work standards, agile methodology was not enough. DevOps is an IT Culture [2]. It consist of various practises and the approaches that influence organizations in organizing teams, build systems and influence even the structure of the systems that you create. Hyperledger Fabric is a Blockchain development framework and one of Hyperledger's collaborators in the Linux Foundation. Intended as a platform for software development or modular architecture implementation, Hyperledger Fabric enables plug-and play applications, such as consensus and membership services. Hyperledger Fabric leverages container technology to host "Chaincode" smart contracts that exemplify the application logic of the system. Originally,

II. MOTIVATION

Multiple entities are involved in the overall software development life cycle (SDLC) throughout the traditional approach to application development and maintenance [1]. This approach is often granulated in terms of features, cost, schedule, quality, performance, and other administrative overheads such as vendor integration by techniques, frameworks, processes, people, and tools that impact the final product. The SDLC operations and production engineers work together throughout the project lifecycle from design through to the development process to assist in the whole production.

It is therefore important to bridge the gap between engineering and operations team by establishing a meeting point for two of Blockchain and SDLC's most promising technologies. Blockchain's strength lies in its decentralized nature [4], which means that each member of its peer-to-peer network can depend on the other. If some Blockchain businesses have systems that are optimally incorporated with the

system and can produce high-quality software, but others cannot, the trust in the system begins to break down, and those within it. Implementing Blockchain with a DevOps approach is an IT philosophy that can prevent this issue. This consists of different practices and strategies tha

t affect organisations in coordinating teams, building systems and affecting even the program structure y ou are building [2].

III. EXISTING SYSTEM

Recent work is moving from traditional software development models to DevOps approaches. DevOps came into existence because of certain problems in the traditional way of managing development and operations. DevOps is mode of work, by using a series of tools to increase the communication and collaboration between development teams and operations teams to reduce the conflicts between the two teams and improve

the development efficiency and quality. This section will give an overview of the main challenges [6, 7] that sparked the evolution of proposed method.

- Lack of trust between Development and Operations
- Communication, Collaboration gap between development and operations
- When problem occurs, people may blame between teams
- Geographical distribution can create challenges
- Lack of management structure between the developers and the operations
- DevOps has not been systematically organized and managed in large-scale projects
- The working pressure on the operations team is growing
- Lack of senior management involvement, stubbornness mindset.
- People is a challenge when using DevOps, as people have to work together in the ways they never saw before
- Developer and Operations lack of interest in the "other side"
- Change in mindset to achieve successful DevOps is a challenge
- DevOps artifacts are usually bound to certain tools, which make it difficult to reuse
- Different software versions and dependencies
- Smoothly deliver code from development to production is a challenge

The reality of Software Development Life Cycle is very complex and untrusted in enterprise with multiple lines of business. In an environment of rapid software development and deployment it is necessary to strengthen the DevOps by providing decentralized data storage of documents on Blockchain to increase trust, auditability and traceability.

3.1 Continuous Monitoring and its drawbacks

Today organizations are required to deliver greater levels of customer satisfaction through their online services. Many, however, are forced to support these initiatives with an interrupt-driven approach as they react to repair things after they break. However, for a more proactive approach and to manage expected high levels of SLAs, organizations can prefer to reduce their amount of unscheduled downtime by implementing Continuous Delivery (CD) model to their development strategy and add to their efforts. What's critical within the CD model is that the ability to watch and manage systems using a structured way, getting early detection of problems so organizations can make changes before the system is impacted. While unexpected failures make interrupt-driven work unavoidable sometimes, organizations can become more proactive by examining their current approach and toolset against business has to help create a path to continuous service delivery optimization.

DevOps involves a lot of tools and processes that go within an organization's pipeline. Monitoring of these tools play a major role in management of these tools [2]. When an organization automates their pipeline, namely implementing a Continuous Integration / Continuous Deployment (CI/CD) model for their software engineering process, they need to be also ready for the different problems that can occur at each stage of the pipeline. Generally, companies tend to use tools like Nagios or rely upon Cloud services for their deployment procedures but using a tool also requires you to itself manage that tool itself since they are licensed and versioned preciously. Companies cannot afford to spend time looking after the tools when they got their own product deployment to worry about.

Most software organizations lack the idea of monitoring their pipeline from start to finish in an environment of multiple somewhere in the pipeline. Monitoring solutions that companies are trying to adopt can become quite complex when they have numerous microservices to look after [2]. A Continuous Monitoring solution is presented as a better solution to solve this issue of having to track numerous microservices from previous stages. On a second note, Kubernetes which is a popular Orchestration service becomes complex enough that it requires a separate set of operations microservices, where their product is ready or stuck engineers to manage the tool and again, this tool comes with its own set of licensing because the company chose to use an external tool and does not have anything they can use within their infrastructure.

IV. Proposed Solution

In the traditional SDLC models usually, there are separate environments and teams at every stage of the delivery process, each separated from the other by physical and logical controls, which slows down the delivery of the final product. So, there is a need for a solution to speed up the overall DevOps lifecycle as well as control the separation of duties in an agile environment. Blockchain has been one such technology that has proven its advantages such as recording legitimate transactions, traceability of origin of an entity, enhanced security model, transparency. Software industries expect newer technologies to overcome the hurdles they face after implementing legacy technologies in an out-of-the- box manner. Therefore, Blockchain technology can be leveraged to build more open and secure software distribution chains. By using Blockchain technology, specifically its traceability feature, we can not only develop better software delivery chains but also eliminate the usage of

third-party tools such as continuous integration servers and automated test suite to trace the successful movement of code through the pipeline. With the help of Blockchain's various advantages, monitoring different stages in a DevOps pipeline becomes natural. Companies do not have to look out for better tools now that a technology provides a solution for Continuous Monitoring. The architecture focuses on relying on the Blockchain data structure to provide more of a timeline oriented architecture for monitoring each stage in any DevOps pipeline irrespective of what technology is used to perform the tasks during any stage.

4.1 Features of Hyperledger Fabric framework

1. Permissioned membership - The Hyperledger Fabric is a Blockchain system for permitted networks. For each network member this structure identifies a certain identity. Access control policies are enforced which require authorized access to network participants.
2. Performance, scalability and levels of trust - Hyperledger Fabric is a modular architecture that divides the transaction processing into threephases: distributed logic processing and agreement (chain code), ordering of transactions, and validating and committing transactions. This separation or modularity improves the scalability of the network and requires fewer verification procedures across the nodes leading to optimized performance.
3. Modular architecture supporting plug-in components - Hyperledger Fabric's modular architecture lends developers leverage to use their preferred components. Many multi- company networks, for example, have their own identity management systems which can be used as a plug-in to rebuild.
4. Rich Queries - By default, Hyperledger fabric uses LevelDB database for the state management. This database provides only simple query support but Hyperledger Fabric can be integrated with CouchDB, a database that provides rich query support. Thus, complex business logic and queries can be implemented for the advanced systems.

4.2 Utilizing critical features of the framework

The proposed architecture is currently focused on utilizing few specific advantages namely, Permissioned membership and Channels. Permissioned Membership allows us to audit each transaction and members associated with the transaction and Channels help in isolating and implementing a separate audit for a few important parts of the pipeline by having a separate copy of ledger. This framework helps our product to perform parallel monitoring throughout the lifecycle of a product. The transactions [1] that are present in our Chaincode / Smart Contract in This work are based on all the inputs and outputs of various tools and participant's documents.

V. Proposed Architecture

5.1 Architecture Overview

This work consist of a decentralized architecture. The proposed solution redefines the DevOps pipeline by making Version Control System (VCS), Integration Server (IS) as separate, isolated Hyperledger Fabric channels feature. Isolation also allows us to make our pipeline have a pluggable environment.

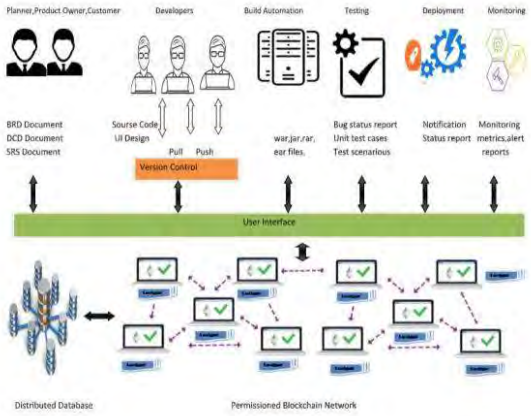

Fig. 5.1: Project Architecture

Figure 5.1 shows the overall architecture which covers the different participants, inclusion of the Distributed Database (IPFS) and Permissioned Blockchain Network (Hyperledger Fabric).

5.2 Role of DevOps

This proposed system consists of a deployment pipeline that permits parallel monitoring service and storage in a distributed database. This work focuses on preventing the problems of having a centralized architecture in the pipeline. Furthermore, keeping the two channels locally available will not disrupt the development team from committing their code and checking whether it fits with all the other modules coming from other teams built into one executable application.

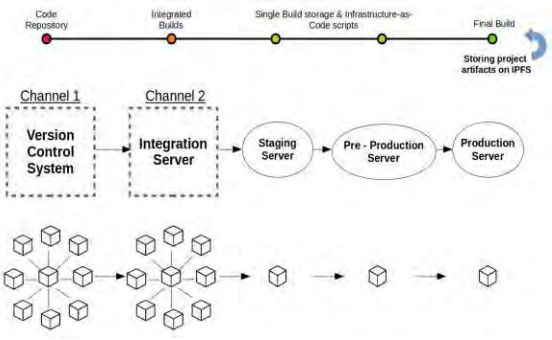

Fig. 5.2: Proposed DevOps pipeline

Figure 5.2 shows the proposed DevOps pipeline which is flexible as it does not depend upon any certain tool that

an organization would like to use or using in their current development or operations stages.

The architecture currently plan on allowing Operations side to be hosted on the internet since it involves provisioning real-time Virtual Machines (VMs) and that has to be done physically. However, the scripts they write for provisioning as seen in case of tools like Chef or Puppet configuration management, will be going under our VCS channel.

Compliance and transparency throughout each stage of DevOps pipeline.

The ability to perform Continuous Monitoring and able to generate reports at each stage of the pipeline is not only important to the people working on building and maintaining the product but also to the people who proposed the work on this product. They have the right to see the status of their product and decide the compliance value of an organization. This will also add to the key point that organization is being as transparent as it can to satisfy their customer's needs and making sure they are regularly keeping their clients updated about the status of the product they proposed.

5.3 Role of Blockchain

This work enables transparency throughout the pipeline. Compliance specialists are able to fetch a summarized report of all the relevant data that can be flexibly added.

Continuous Monitoring is also enabled throughout the pipeline as the underlying Blockchain is storing all the transactions such as data entering / passed to a tool at each stage in pipeline and similarly recording the output from each tool. Thereby ensuring that each transaction that occurred can be traced back to know relevant details about a certain stage of the pipeline.

5.4 Role of Interplanetary File System (IPFS)

The backend file store, namely, IPFS file store allows us to store files on IPFS nodes set in a network or in a cluster of nodes on the network and provides a way to access these files rapidly without huge latency that was caused due to dependency on a far-away server that hosts the file. So even when a node or peer who is situated physically next to us has the file you desire, the network fetches the file contents from that node and does not rely on the central server. Nodes communicate with each other and they are able to store the files of each other. They only store the files that are requested by the nodes themselves.

IPFS allows accessing files by their metadata's hash. It is termed as a "multihash". The purpose is to remove the dependency from referring to a physical location (via IP addresses) and referring by content- based addressing mechanism to allow looking up on any peer that is in the network and fetch the desired file or folder faster as compared to a server's response timeRelying on the hash of file / folder (collection of files) is that one is able to preserve the integrity of the file uploaded. Any change to the file will result in a new hash of the file and would require re-uploading the file and thus a new reference is generated to be able to access this modified file.

All the artifacts that are uploaded to or produced after a version control, build or testing tool's operations will be stored on IPFS. IPFS utilizes content based addressing and allows us to fetch files with the help of file hash, from a nearby IPFS node. This removes the unwanted overhead of relying on the URL based addressing mechanisms if an organization were to go for cloud based DevOps pipeline solutions.

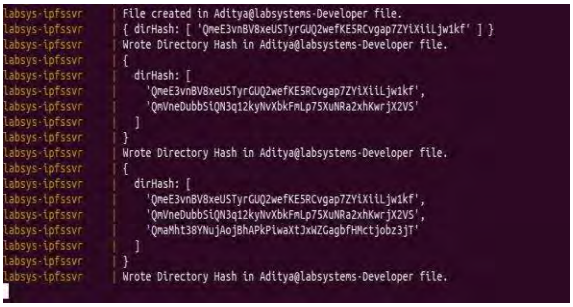

Fig. 5.4: IPFS content-based addressing.

Figure 5.4 shows the way this work stores hashes of different directories in a JSON file. It allows us to keep track of the different versions irrespective of whether it's a single file or a batch of files since any uploaded file is stored in a directory named 'DocumentsDir'. The 'dirHash' JSON array stores different versions of the directory hash as and when the files within the directory are modified or new files are added.

The files or artifacts are stored in the form of chunks of 256kb. After which it utilizes a Linked List based referencing mechanism to link chunks of a relatively larger file. This means that users need not worry about confidentiality of their project artifacts.

VI. IMPORTANCE OF THE ARCHITECTURE

Version control is essential to documents that undergo a lot of revision and redrafting, and as a result of this is particularly important for electronic documents, they can simply be updated by a number of users. These changes might not be directly apparent. Knowing what version of a document you're starting at is vital, for instance, if you're making an attempt to search out that version of a policy is presently good, or that version of the policy was in use at a selected time. Version management is additionally vital if you're engaged in a cooperative document with a variety of contributors and/or with frequent revisions. As you build and implement documents such as standardized rules or project documents version

tracking, you can find the document occurrence over a prolonged duration, e.g. multiple versions of a draft and final regulation. This allows traceability-retention of drafts and details of changes created, typically as a result of contributions from multiple collaborators within the development of documents, order of changes, and recording of those versions of documents considered final and/or approved by relevant teams or individuals.

It has the potential to link documents to choices, contributions, contributors, and time. All documents are associated by metadata such as computer filename, author, and date. Multiple versions of documents are also to be differentiated, so the latest version is known. Also, continuous integration is the practice of combining feature branches into the main branch of code to be designed and tested mechanically. Since this is often an automatic flow, this could be done anyplace from many times daily to many times per week.

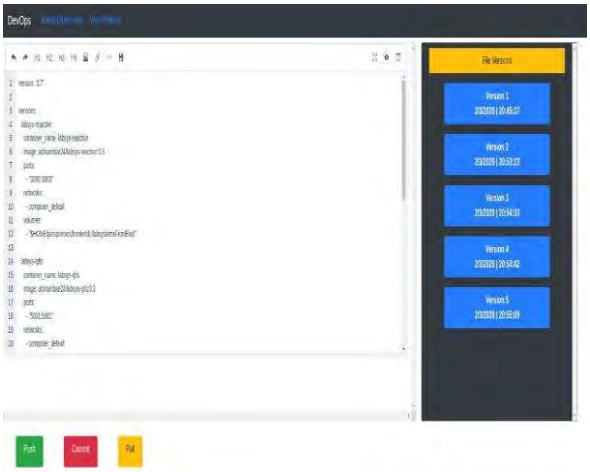

Fig. 6: File versions

Figure 6 shows the different versions of files that a developer handles. These versions are generated whenever a 'Commit' operation is executed by clicking on the Red 'Commit' button on the User Interface. Also user has to push their changes before commit since the idea is to only create versions of the file where you will be having significant changes in each version you view for the file.

The utilization of a git repository acts as a trigger for the build server to compile, execute and, take a look at the code changes. If code changes cause the automatic take a look at cases to fail, associate alarm are raised to tell the developers that their amendment was a failure. The developers can then either rollback their changes to the antecedent productive version of the code or roll forward to bring in a fix to the code thatcaused the failure. Continuous Integration / Continuous Deployment (CI / CD) is the agile development lifecycle which is beneficial to large organizations compared to the normal waterfall where the delivery part would last weeks to months after integration and testing phases.

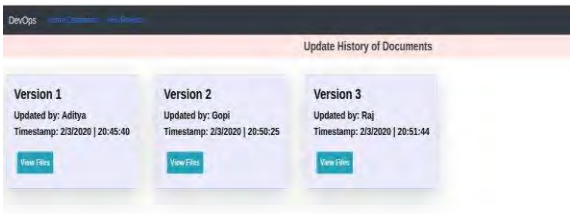

Fig. 6.2: Users' project timeline

Figure 6.2 shows the different versions of the batch of files, we named it as 'Documents'. The Figure depicts the usage of the auditability and traceability of the batch of files a participant uploads. The architecture allows another participant (peer) to update a document of other peer since the fundamental feature of Blockchain is a distributed ledger which allows all participants to have access to it and perform transactions and record on it.

VII. Future Scope

Machine learning is a technology that now everyone is aware of as it has changed the entire IT industry because of the capabilities it possesses and the ability to give more productive output. Going on the similar lines we look forward to integrate the power of Blockchain with machine learning alongside DevOps. The proposed solution will use reinforcement learning to predict the possible interruptions in the development pipeline and most importantly we will train the model in such a way that it automatically detects any problem arising in the pipeline. Furthermore, the model will learn over the period of time through its experience and prepare its own knowledge base so that in future it can figure out any problem in the pipeline more efficiently.

VIII. Conclusion

The purpose of using Hyperledger Fabric in the architecture was clearly to do justice to the corporate standards. This includes the organizational disciplinary behaviors which is incorporated by the Hyperledger Fabric framework quite well. Its features enable one to utilize it as a base for development in the corporate environment. This also makes sure that the organization tends to cope up with the trending and upcoming technologies while not leaving behind its traditional principles. The practice of SDLC in an organization tends to help in deploying the outcome of a project faster by including the Operations team with the development team which is quite different than what is done traditionally in the real world. This also ensures the product quality and also withstands most of the flaws and potential rectifications that must be made once the product passes various tests and eventually the customer acceptance test. The purpose of this architecture was to merely build the SDLC practices

onto the Hyperledger Fabric platform such that organizations find it easier, better and still maintain the same quality of the product as they would without any additional functionalities.

IX. 9. ACKNOWLEDGEMENT

The quality and ultimate outcome of this paper involved a great deal of support and expertise from many people and we are incredibly privileged to have successfully completed the paper. We take this opportunity to thank everybody for their support.

We sincerely thank our principal Dr. B. K. Mishra, vice Principal, Dr. Deven Shah, Mentor Dean Dr. Kamal Shah and HOD Dr. Rajesh Bansode for always guiding us to paths that were right for us. We are grateful to our guide Mr. Sandip Bankar who supported and constantly monitored this work and helped us in not only completing this project but also providing us with basic knowledge with their practical aspect that really proved beneficial to us. We are forever thankful and fortunate enough to receive constant encouragement, support and guidance from all IT department faculties that helped us finalize our paper work successfully. We would also like to extend our sincere gratitude to all the laboratory support staff for their timely support. We would like to convey our heartfelt thanks to our parents for their kind cooperation and encouragement without which none of this was possible.

Abstract- **Sarcasm is an advanced type of assumption articulation where speaker express their feelings inverse of what they mean. Sarcasm location and Emotion identification from long range informal communication destinations has been an extraordinary field of study. With the development of e-administrations, for example, web-based business, e-the travel industry and e-business, the organizations are excited about misusing feeling and sarcasm examination for their promoting methodologies so as to assess the open demeanors towards their image. Consequently, productive feeling and sarcasm demonstrating framework can be a decent answer for the above issue. This work targets building up a framework that gatherings post dependent on feelings, assessment and find mocking posts, if present. The proposed framework is to build up a model that help to go to an induction about the feelings of the posts specifically outrage, shock, cheerful, dread, distress, trust, expectation and disturb with three sentic levels in each. This aides in better comprehension of the presents when looked at on the methodologies which detects the extremity of the posts and gives only their suppositions i.e., positive, negative or nonpartisan. The posts dealing with these feelings may be snide as well. The Sentiment and feeling recognizable proof module distinguish the notion or feeling of the post by assessing score of each word in the remark which is utilized by sarcasm recognition techniques to identify sarcasm. The feeling recognizable proof module utilizes the lexical databases Word Net, SentiWordNet to locate the correct opinion scores for the words as for every feeling. It likewise utilizes Sarcasm discovery calculations like Emoticon sarcasm recognition, Hybrid sarcasm location, Hashtag Processing, Interjection Word Start (IWT).**

Keywords- SentiWordNet, Emoticon sarcasm detection, Hashtag Processing

I. INTRODUCTION

There are various patterns opening in the period of slant examination, which dissect 'mentality and assessment individuals in web-based life, which including social destinations like Facebook, Twitter, web journals, and so on. [1] The primary point of opinion investigation is to distinguish the extremity (positive, negative or impartial) in a given text. Sarcasm is a unique kind of assessment which can flip the extremity of the given content. [3] Sarcasm is characterized as 'the utilization of incongruity to taunt or pass on hatred'. Sarcasm is a complex type of conclusion articulation where speaker express their assessments inverse of what they mean. Sarcasm is a complexity between positive opinion word and a negative circumstance. What makes undertaking of recognizing sarcasm hard is that even people think that it's difficult to comprehend them now and again without earlier information on the point. Model: "Goodness! He out on a duck, what a legendary batsman". Right now, use to communicate the positive feeling (significance) however by and large tweet reflect negative conclusion toward the batsman. In contrast to a basic invalidation, a wry book, normally passes on a negative sentiment utilizing just positive word

II. BACKGROUND

Scarcely any innovation patterns of the previous decade have been more conspicuous than the ascent of Big Data. Driven by the accessibility of modest attractive stockpiling on a formerly remarkable scale, this bounty of information speaks to a tremendously important asset if significant data can be precisely removed. Information mining has gotten extensive consideration especially in the field of assumption examination which looks to extricate and characterize emotional substance. The use of ground-breaking factual procedures to customary normal language preparing strategies has yielded fascinating outcomes with regards to numerous zones. Notwithstanding, the acknowledgment and order of silliness, and specifically sarcasm, stays a difficult issue and to be sure it is one that structures the ideal test stage for a propelled degree of comprehension by a PC. Sarcasm has for some time been viewed as a fascinating issue with regards to phonetics, however right ID of its quality additionally speaks to a chance to accomplish exactness gains in the field of notion investigation. Since 2001, assumption investigation, a field of Natural Language Processing that worries about deciding the extremity of emotional substance, has seen significant research premium. This intrigue has been fundamentally roused by its conceivably important business applications. As exhibited by, the effect of online surveys on item buy is generous. Directed slant examination permits an organization.

Association to amplify their responsiveness to such audits by encouraging an evaluation of their online notoriety dependent on the proof of social cooperation's. Additionally, exact opinion examination permits a company to measure the adequacy of a promoting effort or to test the capability of a market opportunity, both significant vital capacities. From a

logical point of view, it has empowered people to look at human reactions to social wonder on a worldwide scale. Given these potential advantages, Twitter and other advanced stages has normally pulled in both corporate and scholarly consideration for leading notion examination as one of the biggest and most assorted internet-based life stages.

III. PROBLEM DEFINITION

Sarcasm sentences can be utilized nearly in all points. They can take variable linguistic structures. Likewise, to get sarcasm, one needs to know the setting of the sentence. For example, the sentence "I love being rich" isn't sarcastic without anyone else. In any case, on the off chance that you realize that the speaker is poor, you will conclude this is a sarcastic sentence. In this manner, to identify sarcasm, you must have earlier information about the subject or sarcasm, which may not generally be accessible.[5]

Sarcasm is defined as a cutting, often ironic remark intended to express contempt or ridicule. Sarcasm detection is the task of correctly labelling the text as “sarcastic” and “non-sarcastic”. It is a challenging task owing to the lack of intonation and facial expression in text. Nonetheless humans can still spot a sarcastic sentiment in the text and reason about what makes it.So, recognizing sarcasm in text is an important task for Natural Language Processing to avoid misinterpretation of sarcastic statements as literal statements.

IV. PROPOSED METHODOLOGY

We shall exploit a deep neural network for sarcasm detection, we shall build a neural model, with two sub neural networks to capture tweet content and contextual information, respectively. The two-component structure closely corresponds to the two feature sources of the baseline discrete model. We will model the tweet content with a gated recurrent neural network (GRNN) OR Long-Short-Term-Memory.

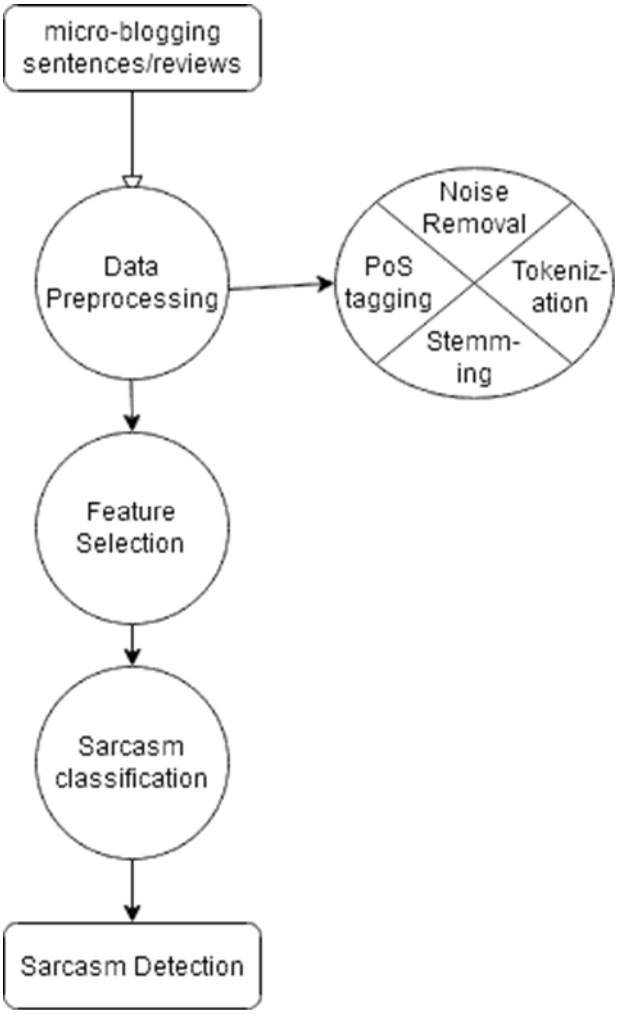

Fig.4.1 Methodology

Micro-blogging Sentences/Review: Micro –blogging sentences are extracting from various Social media like Reddit, twitter, Facebook etc.[11]

Data Preprocessing: In the data preprocessing stage at first, the info data is taken and hashtags are distinguished. These hashtags are expelled from the information data. This module incorporates Tokenization, Stemming, Noise Removal, and PoS Tagging.

Noise Removal: Noise Removal from the info information is the way toward evacuating the stop words, URLs, accentuation and so on. These are expelled from information with the goal that the purified information can be effectively prepared for the following stage.

Tokenization: Tokenization is the way toward parting the information into little units called tokens. The information is isolated into tokens in order to handily process the information.

POS Tagging: It is the way toward coordinating a word to its linguistic class, which assists with understanding its job inside the sentence. Basic grammatical features considered in Pos Tagging are Noun, Verb, Adverbs, and Conjunctions, and so on. Grammatical feature taggers for the most part accept a grouping of words as information and give a rundown of tuples as yield, where each word is related with the related tag.

Stemming: Stemming is the way toward shortening a word to its root structure. By utilizing the stemming method, the quantity of words can be diminished in the information. Porter Stemming algorithm is used for the stemming process.

Feature Selection: Feature Selection is the way toward separating the necessary features from the accessible info dataset. The necessary features resemble tweet id, tweet, date of the tweet and so forth.

Classification of a sarcasm: In the classification stage, the item surveys/remarks/tweets are gathered and are characterized utilizing classification calculations so as to distinguish the sarcasm in the tweets. For tweets, the classification is sure extremity or negative extremity. For the item surveys the classification procedure used to distinguish audit thinking about a size of 5.

Sarcasm Detection: It is the way toward distinguishing whether a tweet is sure, negative. Sentiment Analysis is useful for the advertisers to perceive the popular conclusion about their organization and items, and furthermore to think about consumer loyalty.

V. RELATED WORK

Semantic demonstrating of sentence significance is an all-around inquired about point in NLP.[3] Because of 'terrible language' in Twitter and a recognizable drop of precision for start of-the-workmanship electorate parsers on tweets, the semantic displaying of tweets has caught the consideration of analysts. To manufacture a semantic portrayal of a sentence in different NLP undertakings, for example, notion examination, analysts have utilized syntactic structure to form an all-out portrayal as a capacity of the word-vector portrayal of a sentence's parts. (Nakagawa et al., 2010) depicts a

Tree-CRF classifier which utilize an information driven reliance parser, maltparser2, to acquire a parse tree for a sentence, and whose arrangement work utilizes the head-modifier relations of the parse tree. (Mitchelland Lapata, 2010) and (Mitchell and Lapata, 2008) defined the sythesis capacity of a sentence by mathematical tasks over word meaning vectors to obtain sentence meaning vectors. (Guevara, 2010) and (Malakasiotis, 2011) defined their structure work utilizing a lot of explicit syntactic relations or explicit word classifications (Baroni and Zamparelli, 2010). (Socher et al., 2011) proposed an organized recursive neural system dependent on the convolution activity, while (Kalch brenner et al., 2014) proposed a convolution neural system (CNN) with dynamic k-max pooling, considering max pooling as an element of the info length. For sarcasm identification, because of the unpredictability of the undertaking and the to some degree more unfortunate exactness of beginning of-the-craftsmanship body electorate parsers on tweets, specialists have considered surface-level lexical and syntactic signs as genuine highlights. Kreuz and Caucci (Kreuz and Caucci,2007) investigated the job of lexical pointers, for example, additions (e.g., "hmm" or "gosh"), punctuation symbols (e.g., '?'), intensifiers, and different linguistic markers for example non-veridicality and metaphor, in recognizing sarcasm in stories. (Tsur et al.,2010) noticed the event of "whoopee!" or "incredible!" As a common part of snide examples in Amazon product surveys. (Davidov et al., 2010) analyzed the viability of online networking markers, for example, hashtags to distinguish sarcasm. Lukin (Lukinand Walker, 2013) proposed a potential bootstrapping technique for sarcasm grouping in social discourse extend lexical N-gram prompts identified with sarcasm (for example "gracious extremely", "no chance", and so on.) just as lexico-syntactic examples. (Riloff et al.,2013) and (Liebrecht et al., 2013) applied N-grams highlights to a classifier for English and Dutch tweets and saw that a few themes repeat regularly in mocking tweets, for example, schools, dental specialists, church life, open vehicle, the climate, etc

VI. NEURAL NETWORK

Semantic displaying of sentence importance utilizing neural systems has been an objective of consideration in the internet-based life network. Neural system structures, for example, CNN, DNN, RNN, and Recursive Neural Systems (RecNN) have indicated phenomenal capacities for demonstrating complex word piece in a sentence. A snide book can be considered essentially as a grouping of content signals or word blends. RNN is an ideal fit for displaying fleeting content signals as it incorporates a worldly memory part, which permits the model to store the transient logical data straightforwardly in the model. It can total the whole arrangement into a worldly setting that is liberated from express size limitations. Among the numerous usages of RNNs[3]

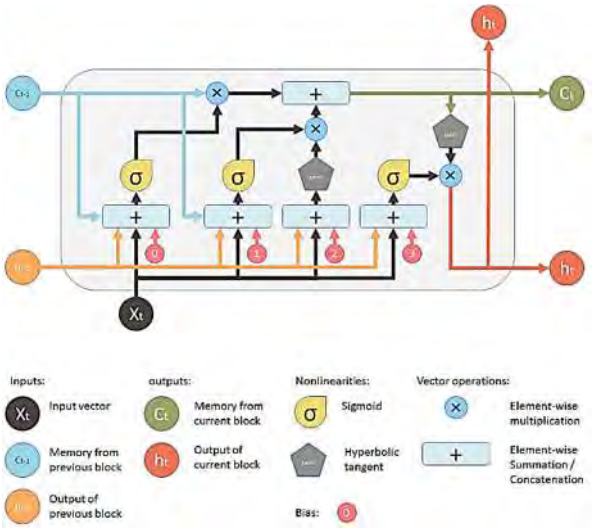

Fig 6.1Structural LSTM[9]

LSTMs are anything but difficult to prepare and don't experience the ill effects of evaporating or detonating slopes while per shaping back proliferation through time. LSTM has the ability to recall long separation fleeting conditions. In addition, as they perform transient content displaying over info highlights, more elevated level demonstrating can recognize elements of phonetic variety inside the information.

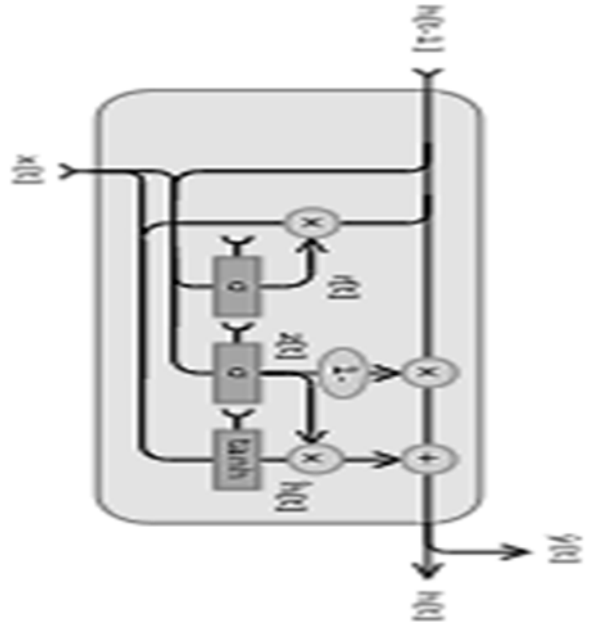

Fig6.2 Structural Gated recurrent unit[10]

RNN has shown the intensity of semantic displaying productively by joining criticism cycles in the system engineering. RNN systems incorporate a fleeting memory part, which permits the model to store the fleeting relevant data straightforwardly in the model. At each time step, it thinks about the present info xt and concealed state ht−1.[1] Thus the RNN can't plot long haul conditions if the hole between double cross advances turns out to be excessively huge. LSTM, which can plot long haul conditions by characterizing every memory cell with a set of doors <d, where d is the memory measurement of the shrouded territory of LSTM, and it doesn't experience the ill effects of disappearing or detonating angle while performing back spread through time.[3] LSTM contains three entryways, which are elements of xt and ht−1: input door it, overlook entryway ft, and yield entryway ot. The gates together settle on the memory update component. Condition (3) and (2) indicate the measure of data to be disposed of or to be put away from and to store in memory. Condition (5) signifies the yield of the cell ct.

$$it = \sigma (Wi[ht-1, xt] + bi) \quad (2)$$

$$ft = \sigma (Wf [ht-1, xt] + bf) \quad (3)$$

$$qt = \tanh (Wq[ht-1, xt] + bq) \quad (4)$$

$$ot = \sigma (Wo[ht-1, xt] + bo) \quad (5)$$

VII. STRUCTURAL DESIGN (DFD)

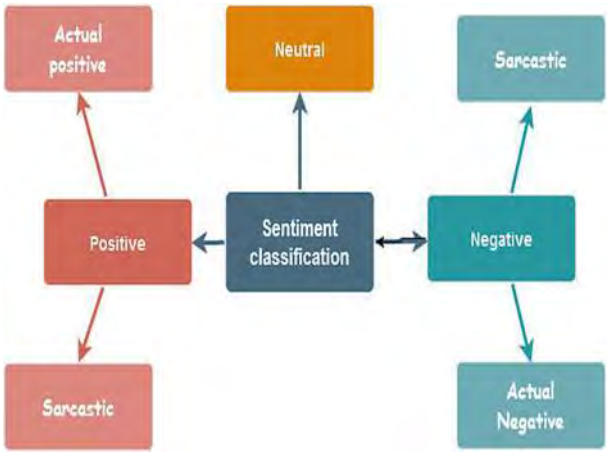

Fig7.1 Structural Design

As from the figure 7.1 as sarcasm location is a subset of sentiment examination. From the outset sentiment examination is ordered into three segments. Each area has its different kind, the three areas are in particular positive, negative, and impartial. In positive the objective information might be genuine positive or sarcastic in negative the objective information might be really negative or it might be sarcastic. Similarly, as with the assistance of sentiment examination the extremity of the objective information is resolved yet because of sarcastic in nature of target information the genuine is turned around extremity.

VIII. EXPECTED OUTCOME:

The yield characterizes the sarcastic and non-sarcastic tweets from the given rundown of tweets. Sentiment Analysis arrange the tweets into positive tweet or negative tweet. The neural models show altogether better exactness contrasted with the comparing discrete baselines. Utilizing likewise setting tweet includes, the exactness of the neural model will be improved, demonstrating the quality of the history data. As in Deep learning the machine naturally extricates the highlights with the assistance of loads of the hubs, inclination, initiation capacity and its ability of forward and in reverse proliferation which encourages it to lessen the cost/mistake. Likewise, with assistance because of our discoveries from different research papers it has been seen that Long-Short-Term-Memory and Gated Recurrent-Neural-Network are promising than Recurrent Neural Network. Profound learning approaches are preferable as far as exactness over regulated learning draws near.

IX. FUTURE SCOPE

Sarcasm Detection in future will be useful to explore and recognize wrongdoing against singular character through advanced methods and stage like twitter and so forth will be useful to forestall against digital bulling .As sentiment analysis is the subset of sarcasm Detection along these lines it will be useful for the online business proprietor and shopper by separating the key terms from the utilization audits which are get posted by client. In future this framework may get computerize and it will be useful to naturally expel mocking tweet without manual intercession.

X. CONCLUSION

Sarcasm is a mind-boggling wonder and it is phonetically and semantically rich. Sarcasm discovery is a captivating State-of-the-craftsmanship. It assesses differing highlight types for sentiment extraction including sentiments, words, examples and n-grams, affirming that each element type adds to the sentiment arrangement structure. Right now, will utilize a Gated Recurrent Neural Network and Long-Short-Term-Memory which gives a superior precision and are intended for the most part message type information. As in Deep Learning dissimilar to Machine Learning, machine removes includes naturally with the assistance of different parameters, for example, loads of the hubs, actuation capacity, and predisposition, forward and in backward propagation to limit the cost/blunder. As identifying sarcasm from content information is a difficult work as it requires to recognize the right feelings of the creator, his history remarks/tweets and furthermore what was nature when such movement happen.

Abstract – **The digital transformation of the world is at its peak currently. The internet has had more users in three years than it had ever. This digital transformation has given rise to many online frauds, theft and hacks because of the low security of web applications. As the number of users online has rapidly increased over the years, their privacy and security are a major concern. The loopholes in the security is mostly because of old versions of the software being used and poor coding style. These concerns can be minimized if there is an online tool which constantly monitors the application to find vulnerability using the known threats. There are many precautions that are available in the market but prove to be inefficient because of poor coding of the application. Our aim is to provide an advance penetration testing using the built-in Kali Linux tools through a simple easy-to-use web interface where in the user puts in the URL of the website from the front-end and the rest of the hassle of parsing the URL is handled by Kali Linux server which will be remotely hosted on the internet. The report will be generated and will be stored as a file on the server which can be sent to the user.**

I. INTRODUCTION

The world is experiencing a digital age. Almost everything we do today is digitalized and we are going paperless. Everything is online therefore there is an urgent need to protect those content from hackers. The web application is prone to several attacks which might lead to data loss, data theft, data integrity loss etc. In the current scenario, according to DOS arrest, more than 90 per cent of the websites that are existing on the internet are subjected to various flaws and vulnerabilities. Most of the vulnerabilities are because of the outdated version of the software used for the web application stack. OWASP (Open Web Application Security Project) focuses on the top 10 vulnerabilities that are existing on the web. The project is to detect top 10 OWASP vulnerability in a Web Application. Firstly, the user inputs the URL/IP address of the website. User will be shown several options for the scan that it can perform. The active (attack mode testing) and passive(safe mode) testing can be selected by the user. The front-end dashboard will show and store the result in the database, and the user also receives an email for it. The log reports will be generated and command to test the desired application will be triggered. The actions of the tools are triggered, and the targeted website is scanned for any known vulnerabilities standardized by CVE. We test the application for more than 200+ vulnerabilities that also includes top 10 OWASP vulnerabilities. The various vulnerabilities will be listed down with their potential threat along with their remedy solutions to the user. An email will also be generated in the meantime, which will be sent to the user.

The top 10 vulnerabilities are:

a. Injection
b. Broken Authentication and Session Management
c. Sensitive Data Exposure
d. XML External Entry
e. Broken Access Control
f. Security Misconfiguration
g. Cross-site Scripting
h. Insecure De-serialization
i. Using Components with Known Vulnerabilities
j. Insufficient Logging and Monitoring

We in our project "Vulnerability Assessment Scanner" are

trying to cover all these OWASP vulnerabilities through a simple web interface where in the user simple puts in the target URL in the input box provided. The input box then shoots the POST request on the Linux server which will be intercepted by our NODE JS server running in the backend. The NODE JS server will parse the URL and execute a shell script which will have the commands for running the tests. The Shell Script will accept the URL as a parameter to the function that we write.

II. BACKGROUND

The main objective of this project is to develop a vulnerability assessment scanner that will detect the vulnerabilities present in the web application and generate a report of the same and send it to the user via mail.It is implemented as a system in which a user inserts the URL of the web site, he/she wants to check. The system scans the URL and detects the vulnerabilities present in the system.The system will perform active and passive attacks and based on that; the result will be generated. The system will combine various algorithms that will be required to detect different types of vulnerabilities.

III. RELATED WORK

1. Development

The application will use the following stack for the development.

a. Kali Linux x64 AWS instance hosted remotely
b. React.js front end for user dashboard and login
c. Node.js for handling the backend of the application
d. Php for the Shell Script Calls
e. External JS Libraries

The final deployed application will be a KALI Linux instance running on a cloud server (preferably AWS) that has the frontend and the backend logic written. The front-end of the website will provide the user with a simple interface that allows the user to enter the URL of the website that is to be scanned.

The POST request from the front-end will be proxied and sent to the NODE.js backend which will parse the URL of the user. After parsing the URL, a function will be triggered through the backend of the application. The function will contain all the necessary commands that are required to run the test which are written in a shell script. The tests are for the vulnerabilities which could be found on target URL. On triggering the tests, an asynchronous call would be made to the URL and all the shell script files will start running. The process will be asynchronous, the user on the front end will be shown a loading screen. The user will also be notified by an email once the tests are completed.

The shell script will contain the commands in KALI Linux. After the execution of those commands, an output.txt will be generated which is stored on the server and in NODE JS directory. The results will be generated in a few minutes. The backend NODE on receiving the file will parse it and send the content to the front-end. It also sends an email to the user with the generated report. The user will log in to his dashboard and see the vulnerabilities that are listed.

2. Importance of the project

The project aims at creating a system that scans the vulnerability present in the website or web applications.

In an era where nothing is completely secured, it is unfair to discard the importance of the security. This project aims to make a website free of all the vulnerabilities by performing various active and passive attacks and by checking which attacks are being accepted by the system.

One often faces problems checking various kinds of vulnerabilities together using a single software. Therefore, this project will be built in such a way that it will combine all the codes used to check different types of vulnerabilities in a single system.

3. Economic feasibility

The project relies on open source software, such as OpenVAS, Nexpose Community, Niko, Wireshark, Nessus Professional. The functionality provided by these software's is enough to construct a system that will scan all kind of vulnerabilities. This project is very low cost and thus feasible from an economic standpoint. As such, we do not need any outside funding. The project will be expected to make minimal sales, due to the presence of a variety of other similar tools and the slow adoption of software's in a professional Industry.

4. Ethical Backgrounds

While the software is meant to help users to check their system vulnerabilities, there still is potential for improper usage leading to damage. If the user's system is suffering from various attacks, it might be difficult to detect those attacks. This system is very ethical and legal. It follows all the ethical norms and follows the 3 main aspects of security, I.e. Confidentiality, Integrity and Availability.

First, we will collect all the open source tools onto one virtual machine which will be hosted on AWS. The machine will work as a daemon which will wait for the request to initiate. On receiving the target URL, it will distribute it to all the scripting inputs which are installed on the machine. The process will take around 10-40 mins depending upon the size of the website. The scans will be active or passive depending upon the user. If the user chooses an active scan on the internet, then there will be bombardment of http requests on his server. A passive scan is a quite scan with minimum payload to ensure the website is scanned and the performance should not be affected during testing of the application.

Project planning is essential to managing the scope, schedule and budget of the project. For this, we used tools such as MS Excel, MS PowerPoint, online MS project as well as various modelling tools.

Stakeholder perspective is crucial to the success of this project. Part of the reason is that this system is a highly sensitive field, and even the slightest of errors, which are evidently unavoidable in even the most sophisticated software, can lead to cause error in the result report.

IV. METHODOLOGY

Vulnerability Gathering

Vulnerability gathering is the second process of the advanced penetration testing which consist to

collect the vulnerability of the technology used by the web application. Enumerate the vulnerability from client side to server side. The vulnerability also is done purely manually by using some international common database for vulnerability such as CVE database, CWE database, and NIST database. This vulnerability will show to the penetration tester what the latest vulnerability of the technology are and will be able to locate and exploit them if some exploit framework is available or exploit them manually. Vulnerability gathering is crucial process for the advanced penetration testing because, the vulnerabilities collected in this phase must be specific to the technology that the web application is using. As the database for vulnerability is huge a considerable time have to be consumed on each and every vulnerabilities database. As in the gathering information we get to know the technology used in the web application as an example JavaScript. The advanced penetration establishes some gap analysis between the current version used and the latest version. The advanced penetration testing then identify the vulnerability for the current version either cross-site scripting, security misconfiguration, some flaws in the technology used, DDOS attack possible because of certain aspect of the web.

V. RESULT

Implementation of top 10 OWASP Vulnerability

a. SQL INJECTION

Sql injection attack implies injection of malicious SQL queries to web applications. This attack majorly targets the database of the web application. SQL Injection is performed to test whether any vulnerability is present in the application or not. This is done by adding " ' "or leveraging the URL parameter of the web application. . This will confuse the database and the web application will throw an error because the database doesn't know how to handle the query.

b. BROKEN AUTHENTICATION

Broken Authentication is used to bypass the web application authentication procedure. Here, the attacker mainly uses Brute force attack or dictionary attack. Dictionary attacks use a predefined list of username and password whereas brute force uses all the possible combinations to find the correct username and password.

c. SECURITY MISCONFIGURATION

Security misconfiguration is another threat for web application. Security misconfiguration implies that some parts of the application is not in order which results in the emergence of flaws in the application. Unpatched component, non-used page, default configuration, default location and many more form security misconfiguration. Security misconfiguration may reside either at the client side or the server side of the web application. Some examples of security misconfiguration at client can be improper input sanitization, X-frame options not enable, security protocol not implemented such as HTTPS, SSL or TLS or weak https which have a vulnerability in key exchange (DHE).

d. CROSS-SITE SCRIPTING (XSS)

The cross-site scripting happen with a written script in the input field and reflected on the web application and the second was uploading an exe file (virus) into the web application. Cross-site scripting is an attack against a web application which exploit some vulnerability of it. There are many types of cross-site scripting such as reflected cross-site scripting, DOM cross-site scripting. The result of the cross-site scripting is showing below and demonstrate how cross-site scripting is effective.

e. SENSITIVE DATA EXPOSURE

Sensitive data can be any confidential data such as credit or debit card, business confidential information and many more. If the web application doesn't use secure network protocols, sniffing tools can be used to retrieve the data.

f. XML EXTERNAL ENTITIES

The utilization of the xml processor can cause damage to the web application because xml file can contain malicious code and if the file is uploaded, the attacker can exploit the code in the xml file or exploit some dependency. Modifying the URL from the browser directly allows the attacker to edit any content on the website.

g. BROKEN ACCESS CONTROL

Access control implies security mechanism which is either implemented physically or logically to prevent unauthorized access to network, services, databases and many more. Broken access control is contradictory. It is a major negative impact for the web application. Advanced penetration testing uses sqlmap to bypass the login page of a web application as following:

h. INSECURE DESERIALIZATION

Insecure deserialization is the most recent attack that has been included IN OWASP. It allows the attacker to access directory which is not supposed to be index. Insecure deserialization attack enables discovery of source code and file of html pages that

are not index. Insecure deserialization an attack in which web application de serializes untrusted user input.

i. USING COMPONENT WITH KNOW VULNERABILITY

Web application consists of various components. Some of those components might include serious vulnerabilities which can be easily exploited by the attackers. Examples are WordPress module, windows server and many other components. Vulnerabilities can be exploited by developing some frameworks. Metasploit is an already existing framework which can be used by any attacker or unauthorized user.

j. INSUFFICIENT LOGGING AND MONITORING

Insufficient logging and monitoring is the last attack defined by OWASP. To perform an attack, attackers get into the system and search for as many vulnerabilities as present in the application. By doing this if the attacker is not being detected by the web application or web application firewall or SIEM, then it implies poor or insufficient logging and monitoring of web application.

VI. CONCLUSION

To provide assurance of appropriate level of confidentiality, integrity and availability of information, vulnerability assessments are important mechanisms through which organizations can identify potential security exposures. Routine self-assessments in combination with penetration tests helps us identify security critical areas and provide a good picture of how security is managed and improved. Our tool analyzes and assesses different aspects of any known vulnerability and will generate a detailed report and summary of the vulnerability. The exposure will be fixed through an expert, not through this tool. This tool will be a perfect solution for small scaled web application assessment for vulnerability. A system and method for a vulnerability assessment mechanism that serves to actively scan for vulnerabilities on a continuous basis and interpret the resulting traffic in context of policy is provided. Vulnerability information is presented within an enterprise manager system enabling the user to access vulnerability information, recommended remediation procedures, and associated network traffic. A studio mechanism is used to add scanners to the appropriate policies and control the scope and distribution of scans within the target network.

The network security policy information is merged with the output of the vulnerability scanner. Using the network security policy's information, the output of the scanner is filtered, so that redundant information is removed about applications that are sanctioned by policy. This reduction of information reduces the information overload associated with vulnerability scanning technology, especially when continuous scanning is undertaken.

In addition, the policy monitoring system is provided, through said network security policy, with a description of the intended action of the vulnerability scanner. This permits the monitoring system to report the scanner's operation as a normal usage pattern of the network, eliminating the confusion that can result when a vulnerability scan is monitored.

These enhancements make it possible to run the vulnerability scanner in a continuous scanning mode, with both acceptable monitoring and vulnerability scanner results.

The vulnerability assessment system presents current vulnerability state of the infrastructure. When continuous scanning is used, the vulnerability assessment system provides changes to this state based on new vulnerabilities found or existing vulnerabilities removed. Throughout the process the policy adds context in terms specific to the customer applications allowing prioritized action to be taken to remediate problems. The policy further allows fine grain control of which network hosts are scanned, thus adapting easily to customer operating procedures for how scans may be carried out.

VII. ACKNOWLEDGMENT

We would like to express our special thanks to Dr. Sangeeta Vhatkar to give us this golden opportunity and guide us throughout in completing this project. She has helped us to overcome the obstacles related to the implementation of the project.

Abstract—**Speech recognition systems have been extensively improved over the years. However, accent classification remains a highly challenging task. Accent classification technology can be a great benefit to automatic speech recognition applications, telephony- based service centres, immigration offices and in military operations. The application of convolutional neural networks has been an efficient and effective way to solve the accent recognition problem. The English language is spoken by many around the world, with different accents originating from various geographical locations. Accent identification is an important problem in technology today. Unfortunately, accent identification is suboptimal for certain accents.**

Keywords- ASR- Automatic Speech Recognition
CNN- Convolutional Neural Network
MFCC- Mel Frequency Cepstral Coefficients

I. INTRODUCTION

Speech is one of the most important media of communication between humans. Humans use it to express their opinions as well as their feelings and moods. The adaptation, usage, processing and understanding of human speech by computers can be considered a significant challenge in modern societies. Although many achievements and improvements have been made in the automatic speech recognition (ASR) application area, and more specific with its application in Apple's Siri, Google's Assistant and Amazon's Alexa, the issue of accent recognition seems to be a problem for these programs as they can only understand the American English accent. The above applications can recognize speakers of American English with high accuracy but may fail in recognizing speakers of English with Scottish or Irish accent. The problem seems to be more apparent when the speakers are not native English. We at that point normally resort to a constrained emphasize so as to get the ASR to perceive the discourse accurately, which is unnatural and verification that ASR frameworks can in any case be improved. Since highlight is such a pivotal viewpoint in ASR, we were propelled to assemble a complement grouping AI model which could be utilized as a starter step in the ASR pipeline, permitting it to receive a progressively appropriate discourse acknowledgment model adjusted to the recognized emphasize for better execution. Right now, objective is to build up a profound learning model that can distinguish and group a speaker by their anticipated local language. The contribution to our calculation is an articulation of a word by a speaker. [1]

II. LITERATURE SURVEY

Accent Identification by Combining Deep Neural Networks and Recurrent Neural Networks Trained on Long and Short Term Features, paper by Jiao, Yishan & Tu, Ming & Berisha, Visar & Liss, Julie has the key findings presented an accent identification system by combining DNNs and RNNs trained on long-term and short-term features respectively [4]. Deep Learning Approach to Accent Classification written by Leon MakAn Sheng, Mok Wei Xiong Edmund found out the capabilities of the Deep Neural Networks to classify both native and non-native features [10]. Accent Classification Using Deep Belief Networks written by Rishabh G. Upadhyay had the key findings that Origin of country can be classified [11]. Furthermore MFCC feature acts as human ears.. Deep Voice: Real-time Neural Text-to-Speech written by Sercan Arik, Adam Coate, Andrew Gibiansky, & Jonathan Raiman had the major key findings of the 2-layer CNN struck the best balance between accuracy and model complexity, the Italian accent performed around 5% better on average than what we found in our literature review, the improvements in the Arabic and Japanese accents were less significant, and may have been due to our choice of dataset, the Korean accent still performed poorly, consistent with current findings. [7]

III. PROPOSED SYSTEM DESCRIPTION

The system architecture consists of the processes of collecting the voice signals, preprocessing, feature extraction, classification and output in order to identify the accent of the voice signal. The process of pre-processing was necessary because it could affect the results of the experiments. In every machine learning project the need of using clean data is crucial in order to acquire a good result and output from the system. The pre-processing procedure is divided into two stages. The first stage is to convert each mp3 audio file downloaded from the website to a WAV file of 16 kHz, mono channel and 16-bit. The second stage is to normalise the maximum amplitude of each WAV file to -1.0 dB. The aim of the second stage is to ensure as much possible a universal volume level of each audio file. Figure 16 depicts the diagram of the proposed system

A .Data Set

It consists of speakers who read an elicitation paragraph written in English, which contains common English words and difficult English sounds and sound sequences. The elicitation paragraph consists of English words that cover almost all the sounds of English language and contains as many as possible consonants, vowels and clusters of the standard American English. It is worth to note that each speaker was allowed to read the paragraph for some time and after the recoding was applied.

B. Need of Preprocessing Audio Data

The importance of using clean data in the neural network is high. If clean input data is used, then it is most likely that a clean output can be achieved, in this case meaning a good approximation and accuracy of the model of the convolutional neural network. Usually a satisfactory sampling rate for human voice is at 16 kHz and mono. But the fact of existing unnormalised audio signals is dangerous and it is an alert for the engineer to apply normalisation for the maximum amplitude of the signal. The value of -1.0 dB is the default in Audacity and often it is so in order to leave some headroom for a possible final editing of the audio signal. Fourier analysis is fundamentally a method for expressing a function as a sum of periodic components, and for recovering the function from those components. When both the function and its Fourier transform are replaced with discretized counterparts, it is called the discrete Fourier transform (DFT). [2]

IV. METHODOLOGY USED

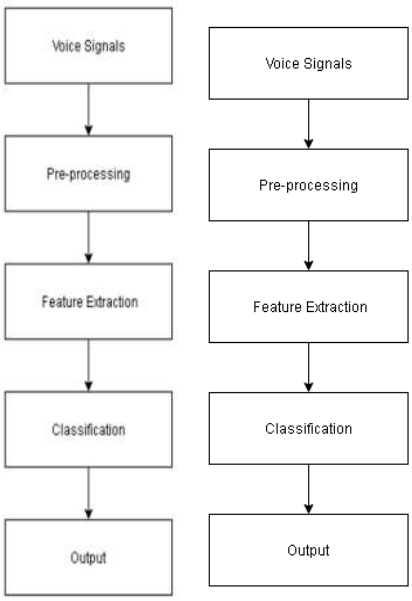

FIG 4.1 ASR FLOWCHART

The pre-processing procedure was a significant process although the dataset from the website was of a good quality. First of all, the downloaded dataset from "The speech accent archive" (Weinberger 2015) was in mp3 format. The proposed system uses audio file of the form of WAV files, sampled at 16 kHz, mono and 16-bit. Winamp was used in order to change the dataset in mp3 format to the desired format. The process is easy as one can load all the audio files in the playlist of the program and set its audio output to Nullsoft Disk Writer and its conversion to PCM 16.000 kHz; 16 Bit: Mono. The second step of the pre-processing was to normalize the maximum amplitude of each WAV files of the speakers. Most of the audio files were quite good concerning their normalization but some of them had low amplitude, which may result in incompetent usage of inputs for the neural network. The program used for the normalization of the audio files was Audacity 2.1.1. And the normalization was also not difficult to implement as one can load all the audio files and apply normalization of the maximum amplitude to -1.0 dB using the batch programming mode of the software.

The importance of using clean data in the neural network is high. If clean input data is used, then it is most likely that a clean output can be achieved, in this case meaning a good approximation and accuracy of the model of the convolutional neural network. Usually a satisfactory sampling rate for human voice is at 16 kHz and mono. But the fact of existing unnormalised audio signals is dangerous and it is an alert for the engineer to apply normalization for the maximum amplitude of the signal. The value of -1.0 dB is the default in Audacity and often it is so in order to leave some headroom for a probable final editing of the audio signal

A. MFCC FEATURES

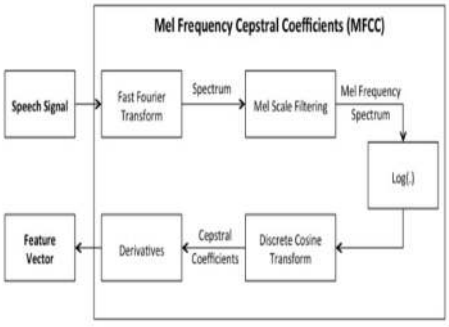

FIG 4.A MFCC ARCHITECTURE

The Mel-Frequency Cepstral Coefficients (MFCCs) of a signal are a small set of features (usually about 10-20) which concisely describe the overall shape of a spectral envelope. In MIR, it is often used to describe timbre. Applications. MFCCs are commonly used as features in speech recognition systems, such as the systems which can automatically recognize numbers spoken into a telephone. MFCCs are also increasingly finding uses in music information retrieval applications such as genre

classification, audio similarity measures, etc. In sound processing, the Mel-Frequency Cepstral (MFC) is a representation of the short-term power spectrum of a sound, based on a linear cosine transform of a log power spectrum on a nonlinear Mel scale of frequency. Mel-Frequency Cepstral Coefficients (MFCCs) are coefficients that collectively make up an MFC. They are derived from a type of cepstral representation of the audio clip. Mel-Frequency Cepstral Coefficients (MFCC of the real cepstral of a windowed short-time signal derived from the Fast Fourier Transform (FFT) of that signal. The difference from the real cepstral is that a nonlinear frequency scale is used, which approximates the behavior of the auditory system. Additionally, these coefficients are robust and reliable to variations according to speakers and recording conditions. MFCC is an audio feature extraction technique which extracts parameters from the speech similar to ones that are used by humans for hearing speech, while at the same time, deemphasizes all other information. The speech signal is first divided into time frames consisting of an arbitrary number of samples. In most systems overlapping of the frames is used to smooth transition from frame to frame. After the windowing, Fast Fourier Transformation (FFT) is calculated for each frame to extract frequency components of a signal in the time-domain. FFT is used to speed up the processing. The logarithmic Mel-Scaled filter bank is applied to the Fourier transformed frame. This scale is approximately linear up to 1 kHz, and logarithmic at greater frequencies. The relation between frequencies of speech a Mel scale can be established as:

Mel (f) = 1125 ú log (1 + f/700) 2

MFCCs use Mel-scale filter bank where the higher FIG frequency filters have greater bandwidth than the lower frequency filters, but their temporal resolutions are the same. The last step is to calculate Discrete Cosine Transformation (DCT) of the outputs from the filter bank. DCT ranges coefficients according to significance, whereby the 0th coefficient is excluded since it is unreliable. [6]

B. CONVOLUTIONAL NEURAL NETWORK

A CNN architecture is formed by a stack of distinct layers that transform the input volume into an output volume (e.g. holding the class scores) through a differentiable function. A few distinct types of layers are commonly used.

The accent classification problem presented in this thesis was solved by the implementation of two convolutional neural networks. The difference between them is found in the activation functions of their layers.

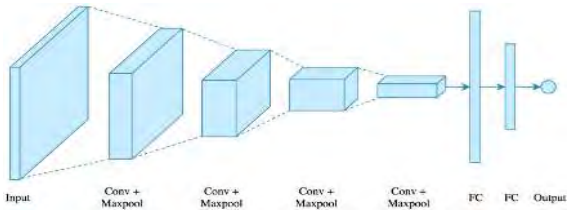

FIG 4.B CNN ARCHITECTURE

Specifically, the first CNN consists of a 2D convolution layer with an output filter of dimension 32 in the convolution, an input shape of 13x30x1 and a ReLU activation function. The data format is set to channels last which means that the ordering of the dimensions in the inputs has the form of (batch, height, width, channels). This includes the number of segmented audio files in batch, the shape of audio files after applying the MFCC with 13 coefficients and the number of channels, which is 1 in the current case. In the domain of image processing this could be seen as an image of dimension 13x30. Next a max pooling operation with a pool size of 2x2 is applied in order to down scale the spatial dimension. The pool size refers to the vertical and horizontal factors of the process of downscaling.

Next a second 2D convolutional layer is applied with the output filter of dimension 64 and the same input shape and activation function as the first convolutional layer. The following step is to apply the same max pooling operation and a dropout operation with a rate of 0.25 in order to avoid overfitting of the network. Next an operation of flattening takes place and the input is flattened into 1 dimension without affecting the batch size. Next a regularly densely-connected layer is added with 128 units and the activation function of ReLU. Another dropout operation is applied next with a 0.5 factor in order to avoid the cases of overfitting. The last layer is a fully connected layer with the number of accent classes used for the model and a softmax activation function.

The second CNN is almost the same as the first with the difference that on the third layer (fully connected) with 128 units instead of ReLU the sigmoid activation function was used. In addition, several other configurations have been tested. These configurations did not result in a better accuracy. However, the two proposed models gave good approximations. [8]

V. RESULTS

If sound frequencies could be turned into images in some manner and sent to eyes to differentiate we might be able to understand a larger range of frequencies. Plotting the audio signal amplitude. The first conversion that can be applied on any sound signal is to plot its samples'

amplitudes over time. Since the dataset contains digits from 0 to 9 we have:

FIG 5.1 PLOTTING A SPECTROGRAM

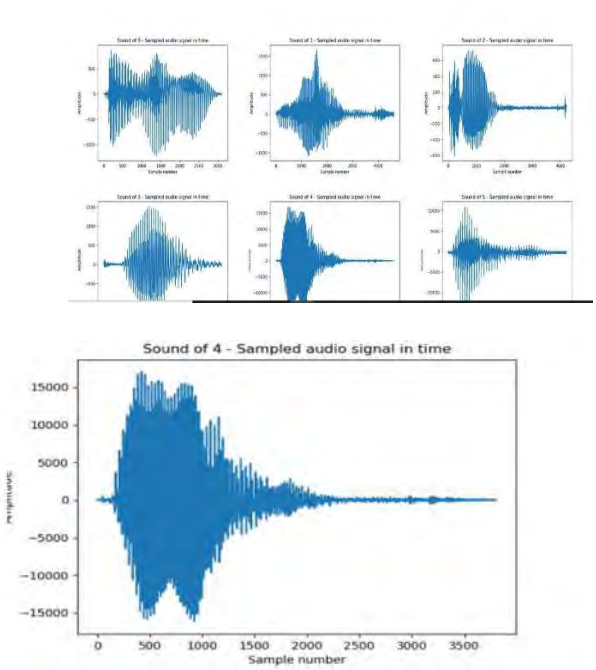

FIG 5.2 AMPLIFIED IMAGE

To plot the spectrogram we break the audio signal into millisecond chunks and compute Short- Time Fourier Transform (STFT) for each chunk. We then plot this time chunk as a colored vertical line in the spectrogram.

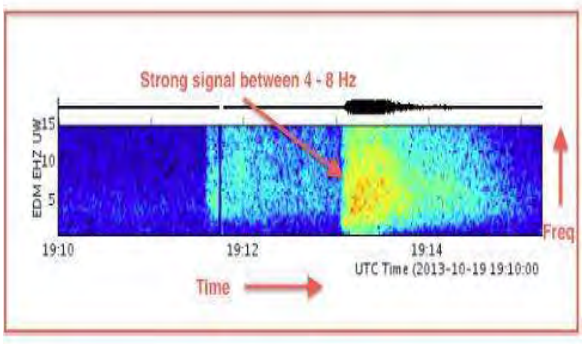

FIG 5.3 TIME CHUNK

Logically both of them can be used to train our CNN. We tried doing that and observed that pure audio signal yields a test-accuracy of 94% as compared to the spectrograms that yield a test- accuracy of 97%.The CNN we use has the following layers

1. Convolution layer with kernel size : 3x3
2. Convolution layer with kernel size : 3x3
3. Max Pooling layer with pool size : 2x2
4. Dropout layer
5. Flattening layer
6. 2 Dense layered Neural Network at the end

VI. CONCLUSION

Speech recognition is the interdisciplinary subfield of computational linguistics that develops methodologies and technologies that enables the recognition and translation of spoken language into text by computers. It is also known as automatic speech recognition, computer speech recognition or speech to text. It incorporates knowledge and research in the linguistics, computer science, and electrical engineering fields. This paper describes an automatic accent identification system.

Our research confirms, this by showing that a DNN system outperforms the GMM system even after an accent- dependent acoustic model was selected using Accent Identification (AID), followed by speaker adaptation. The average performance of the DNN system over all accent groups is maximized when either accent diversity is highest, or data from “difficult” accent-groups is included in the training set.

VII. FUTURE SCOPE

In order to carry out future research, experiments will be performed on the proposed data sets using Deep Belief networks. MFCC features will be employed. Discussion and comparison to these findings would be carried out in order to determine good feature set in combination with new techniques. Features selection will be used to get good results. The results will be compared with various classifiers such as DNN, KNN and ANN. As this classifiers have shown good results in the field of accent classification. Performance will be evaluated on the basis of accuracy of the classifiers. [9]

Sentiment Analysis On Twitter Data In R

Shubham Maheshwari, Nevil Kaspale, Darshan Faldu mentored by Dr. Anand Khandare
Thakur College of Engineering and Technology, Mumbai, India

Abstract – **Social media has seen a rapid rise since the past decade. The microblogging sector has evolved massively and have emerged out as a vital source of information on one too many occasions. The reason being that these enable people to express their opinions about something or someone in a short manner of expression. Here, in this paper we look into Sentiment Analysis on Twitter Data using text mining and natural language processing with the help of R Programming Language libraries.**

In this paper, we first have a look at what sentiment analysis is, the rise of social media and what are the challenges for researchers. We then write about the related work int his field and discuss about data in Twitter. We then have articulated and visualized our experimentation on performing sentiment analysis on data from twitter. We have used two kinds of datasets

: one is directly extracting real-time current tweets(about a person in our case) and the other is through an external dataset consisting of tweets.

Keywords: Microblogging, Sentiment Analysis, Twitter

I. INTRODUCTION

A. Background

Sentiment Analysis , also referred to as Opinion Mining or Emotion AI, basically means to identify, extract and quantify and study of subjective opinions collected from various sources about a particular subject(s). We know that every person across the planet has some kind of an attitude or 'view' about the things he/she experiences; and since many people experience similar or different kinds of these 'things', there will be dozens of opinions from these billions of people. When all these are viewed collectively, an overall viewpoint about a particular things or product can be ascertained. That was Sentiment Analysis described in general terms.

Rise in interconnectivity through WAN has been of a massive boon to the people. And nowadays, social media platforms like Facebook, Instagram, WhatsApp, Snapchat, YouTube are unignorable[1]. Now, as aforementioned, microblogging websites have seen an exponential rise since the past decade. And it is showing no signs of stopping down as the companies keep optimizing and finding new methods to keep people engaged towards them. Implying more in less amount of words is what is attracting people towards microblogging, where they discuss about, practically anything, be it a public issue, a cricket match, launch of a new kind of technology or an electronic device, and express their view or "sentiment" over it, which can be positive or a complaint (negatory) or maybe neutral[2].

B. Problem Definition

Companies manufacturing these platforms have begun conducting polls in these microblogs to get an idea about user opinions about their product. One challenge for the researchers is to create a technology which gets the company the entire user sentiment data for them and there have been so many successful approaches towards achieving it[2]. We, as well, have taken the most popular microblog, Twitter for our analysis. We have experimented on two kinds of datasets : one being about a person for which we accessed current real time tweets and the second one being an external data set consisting of old tweets and then analysing it. Our results have been visualized for a clearer understanding. We have done all this using R Programming language, as it consists of the necessary libraries with corresponding functions which enable us to extract and analyse Twitter data without much complexity as such.

II. LITERATURE SURVEY

It is vividly evident that the rise of real time information networking sites such as Twitter have led to an assemblage of an unparalleled and a public group of user opinions about every global entity of interest. However, it still poses a challenge as without a tool which analyses these opinions, the user consumption of the product will not expedite. The challenges are mainly attributed to its characteristic of microblogging.

Pak and Paroubek[3] rationale the use of Twitter as a corpus for sentiment analysis. They cited :

People use microblogging platforms to express their opinion and about different topics, thus it is a valuable source of public opinion.

Twitter consists of huge heaps of text and its only growing further. The corpus collected is huge.

Twitter is represented by its users from multiple countries.

Go et. Al[4] proposed distant supervision technique in order to acquire sentiment data. This was initially proposed by Read[10]. They built models using Naïve-Bayes, MaxEnt and Support Vector Machines(SVM) and their training data consisted of tweets with emoticons which served as noisy labels. They report that SVM outperforms other classifiers.

Pak and Paroubek[3] did similar work and classified the tweets as positive, negative
and objective. In order to procure objective data, they retrieved text from Twitter accounts of popular newspapers like "New York Times" and "Washington Post". Their classifier was based on Naïve-Bayes' classifier that uses POS-tags as approach and was based on the N-gram model. Barbosa and Feng[5] were also significant in contributing to sentiment classification. They also classified tweets as objective and subjective and then subjective was further classified into positive and negative tweets. However, they proposed the use of features such as hashtags, retweet, link, punctuation and exclamation marks in conjunction with features such as prior polarity and POS of words.

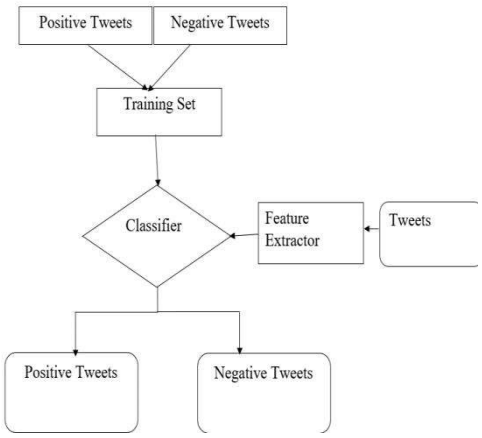
Parikh and Movasatte[6] implemented two Naïve-Bayes unigram models, a Naïve- Bayes bigram model and a Maximum Entropy model to classify tweets. It was found out that the Naïve-Bayes classifier worked better than the Maximum Entropy Model could.

Sentiment Analysis can be done at several levels of granularity, namely, at sentence, phrase, or word level. As twitter permits users to share information in a limited number of characters(280), so it is suited for word level granularity[1].
Further, different approaches have been applied towards automating sentiment analysis in order to predict the sentiments of words, expressions or documents. These include Natural Language Processing (NLP) and Machine Learning (ML) algorithms[2]. In our attempt to mine the sentiment from twitter data here we introduce a hybrid approach which combines the advantages of both dictionary
& corpus based methods along with the combination of NLP & ML based techniques[1].

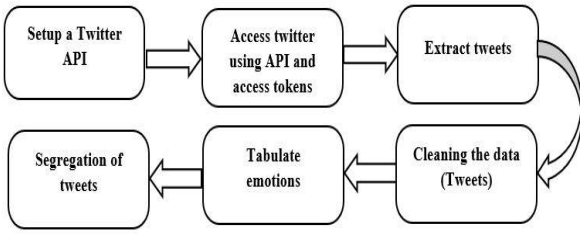
III. DATA DESCRIPTION

Twitter is a social networking and a microblogging platform that allows users topost real time messages, called as 'tweets'. The tweets are now restricted to 280 characters in length. Because of this, people often resort to make spelling mistakes, use acronyms, slangs, emoticons and other characters to express special meaning. Following is a brief terminology with respect to Twitter :
Hashtags: People use "#" to mark topics in order to increase their tweet visibility to a larger audience.
Emoticons: These are representations of facial expressions using punctuations and letters, used to express the mood of the user.
Target : Users use the "@" symbol whenever they are referring to some other user. Using this symbol automatically notifies them.
RT : It is used to indicate that it a user has repeated another user's tweet.

Model Architecture and Data Analysis Opinion words are those which are used by people to express their opinion(positive, negative or neutral). Since our approach is very basic and we have made use of R libraries, our proposed architecture is as :



Our analysis on both datasets works based on the above mentioned architecture. Here, the training set and the classifier(Naïve- Bayes) are all provided by the R library called "syuzhet"[8], developed by Nebraska Literary Lab. It Extracts sentiment and sentiment-derived plot arcs from text using a variety of sentiment dictionaries conveniently packaged for consumption. The text mining is done by the package called "tm".[9]
So our first analysis is on the tweets about our former cricketer Sanjay Manjrekar, who has been gathering a lot of negative limelight lately due to his controversial comments. The flowchart for our process is as follows :



Implementation : Firstly we setup a Twitter API in order to retrieve real-time tweets and then through access tokens we authenticated to the API in R (ROAuth and base64enc packages have their roles here).We went for 50 tweets only under "#SanjayManjrekar". After retrieval, the cleaning of tweets was done so as to remove the unnecessary elements(punctuation, digits, very common words, links etc.). Data cleaning is a very important, although tedious, step towards acquiring sentiments. We then used a function called "get_nrc_sentiments"[8](of syuzhet package) to classify the tweets using string matching into positive, negative and neutral. Then we displayed the tweets that are negative and tweets are positive. Finally, we got the number of positive, negative and neutral tweets, then we visualise them through bar and pie plots. The results are as follows :This is the sample data of the project with keyword "#SanjayManjarekar with 50 most recent tweets. From 50 first six are shown below:
The fetched tweets are classified into three categories: Positive, Negative & Neutral.

```

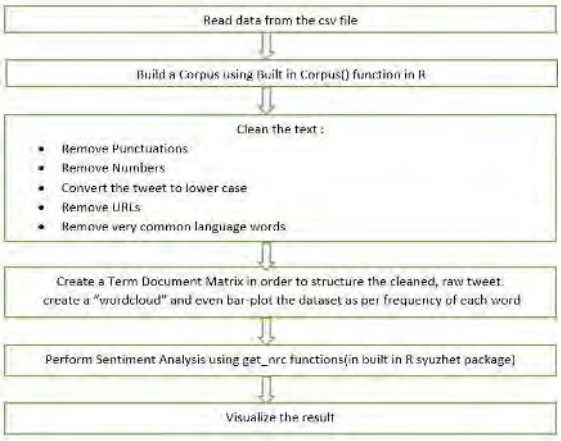
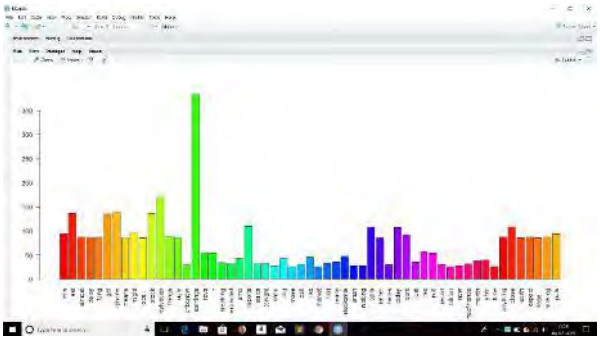
In our second experiment, we took an external dataset of Apple Inc. consisting of
1002 tweets. The data is in the form of csv file. This is a corpus based approach with the use of Natural Language Processing. The Workflow for this is as follows :



Implementation : Firstly, the entire dataset is read from the csv file in R. Then, a corpus (it is just a way to store documents in R readable format). Then text cleaning is done, as explained in the previous example
as well, all unnecessary elements are removed from the tweet. After that, the (cleaned) data which we have is

plain and unstructured, in order to structure it, we need to create a Term Document Matrix. It is a table that contains the frequency of the words. Row names are documents and column are words and. The function *TermDocumentMatrix()* from the text mining(tm) package is used. Bar plot for term document matrix is as :



Then a word cloud[7] is created which helps a lot in text mining as it gets us to know the most relevant words. Wordcloud can be a very handy tool whenever you want to highlight the most commonly cited words. Wordcloud can be of any shape depending on us. Our wordcloud came as :

After changing shape of cloud:

It is evident that 'earnings' is the most relevant word here.Then finally, we get the sentiment scores of the Term Document Matrix (all of the tweets) using the get_nrc_sentiment() function provided by the R library syuzhet. It categorises sentiments into ten categories.
The entire Source Code of R is :

```
#READ DATA
apple <- read.csv(file.choose(), header = T)
str(apple)
#CORPUS
library(tm)
corpus <- iconv(apple$text, to='UTF-8', sub
= "byte")
corpus <- Corpus(VectorSource(corpus))
inspect(corpus[1:5])
#DATA CLEAN
corpus <- tm_map(corpus, tolower)
inspect(corpus[1:5])

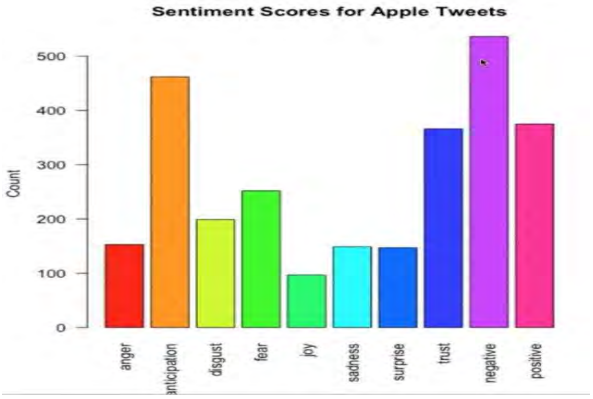
head(s) tweets[4] get_nrc_sentiment('delay')

# Bar plot barplot(colSums(s),
```

las = 2,
col = rainbow(10),
ylab = 'Count',
main = 'Sentiment Scores for Apple Tweets')
The sentiment scores looks as:

```
> head(s)
  anger anticipation disgust fear joy sadness surprise
1     0            0       0    0   0       0        0
2     0            0       0    0   0       0        0
3     0            0       0    0   0       0        1
4     1            0       2    2   0       1        0
5     0            0       0    0   0       0        0
6     0            0       0    0   0       0        0
  trust negative positive
1     0        0        1
2     0        0        1
3     0        0        0
4     0        3        0
5     0        0        0
6     0        0        0
```

And the above result, when visualised as a bar plot looked as :



IV. CONCLUSION

Sentiment Analysis is a valuable advancement in technology that allows us to get realistic feedback from users in a less- biased manner. The work presented in this paper specifies the results for sentiment analysis on Twitter data using the libraries provided by R. The exponential growth in microblogs like this provides the best opportunity to mine sentiments using new technical models and postulates. We investigated two kinds of datasets: first about a person where real time tweets were extracted through API and second was an external csv file consisting of tweets. The corpus-based method was used(in the latter case) to find semantic orientation of adjectives. Then the overall tweet sentiment was calculated and then the result was visualized as well. The domain is exploratory in nature and for future approach, we will do feature analysis and explore on even richer linguistic analysis, as in, parsing, topic modelling and sentiment analysis.

Abstract – **The Internet of things (IoT) is the extension of Internet connectivity into physical devices and everyday objects. IoT is a rapidly expanding field in the world of technology. It helps ease life for a person by means of internetworking physical devices, automotive, home appliances and other items embedded with electronics, software, sensors and actuators.In normal garages it is very tedious and challenging task for people to use the pulley or to open the shutter. It not only consumes time but require a lot of human effort. So to overcome with this type of issues we came up with an idea where we can simplify the process and make it feasible for the people. This improvised ideaof accessing your garage will not just save your time but also human effort.Smart garage is one such device that helps ease the access of the garage doors in domestic use. Unlike most solutions, smart garage helps you to access your doors with the help of a computable device which is as simple as a RFID tag to authorize the access. We designed one such garage using Node MCU and a RFID sensor. Which we compared with existing methods. We have illustrated the construction process of the prototype of our garage and the various components required for the same.**

I. INTRODUCTION:

The Internet of things (IoT) is the extension of Internet connectivity into physical devices and everyday objects. IoT is a rapidly expanding field in the world of technology. It helps ease life for a person by means of internetworking physical devices, automotive, home appliances and other items embedded with electronics, software, sensors and actuators. In normal garages it is very tedious and challenging task for people to use the pulley or to open the shutter. It not only consumes time but require a lot of human effort. So to overcome with this type of issues we came up with an idea where we can simplify the process and make it feasible for the people. This improvised idea of accessing your garage will not just save your time but also human effort. Smart garage is

one such device that helps ease the access of the garage doors in domestic use. Unlike most solutions, smart garage helps you to access your doors with the help of a computable device which is as simple as a RFID tag to authorize the access. We designed one such garage using Node MCU and a RFID sensor. Which we compared with existing methods. We have illustrated the construction process of the prototype of our garage and the various components required for the same.

II. BACKGROUND:

A garage door opener is a motorized device that opens and closes garage doors controlled by switches on the garage wall. Most also include a handheld radio remote control carried by the owner, which can be used to open and close the door from a short distance.

The first garage door opener remote controls were simple and consisted of a simple transmitter (the remote) and receiver which controlled the opener mechanism. The transmitter would transmit on a designated frequency; the receiver would listenfor the radio signal, then open or close the garage, depending on the door position. The basic concept of this can be traced back to World War II. This type of system was used to detonate remote bombs. While novel at the time, the technology ran its course when garage door openers became popular. While the garage door remote control transmitter is low power and has limited range, its signal can be received by other, nearby, garage door openers. When two neighbors had garage door openers, then opening one garage door might open the neighbor's garage door as well.

In normal garages it is very tedious and challenging task for people to use the pulley or to open the shutter. It not only consumes time but require a lot of human effort. So to overcome with this type of issues we came up with an idea where we can simplify the process and make it feasible for the people. This improvised idea of accessing your garage will not just save your time but also human effort.

III. IMPORTANCE OF THE PROJECT:

The requirement of the Smart Garage System is because every time it is not feasible to get out of the car to manually open the garage door and close it when the car is parked. Hence there is a great importance of the project in day-to-day life. Importance of Smart Garage System are as below:

- Convenience

One of the main benefits is you can stay in your car until you're in (or out of) your garage, so you don't have to get out of your car to open or close your garage.

- Automatic closing

Automatic closing means that you won't need to get out of your car to close the door or remember to press the button on your remote; your garage door opener can close itself too.

- Low energy use

IV. SUMMARY:

Smart Garage System is boon which helps to overcome the problem of manually opening and closing of garage door while parking the car or removing it from the garage. . IoT is a rapidly expanding field in the world of technology. It helps ease life for a person by means of internetworking physical devices, automotive, home appliances and other items embedded with electronics,

software, sensors and actuators.

The project focus on building an IoT based Smart Garage System using Arduino as platform. Before the project starts there is the first chapter which speaks about the background of the project, why it is required, and it adds about the need for the project which is the removal of manually opening of garage doors. Thus, the project was a great success with all the use cases and fulfilling all the phases of a project development and deployment.

V. LITERATURE SURVEY:

In this paper, Sanjay, B. S. et. al., have expressed the process that the consumer can access the garage just by passing the RFID tag across the sensor. This helps overcome the manual labor of the consumer to access the door. In case of multiple user, a unique tag can be given to any number of authorized person, rather than sharing a selected number keys to the lock or eases to the possibility of losing the key. Replacing PC with low-cost single chip processor can make the cost effectively

Although automatic garage door openers can be highly advanced and technical, they do not need a lot of power to work. This makes them highly cost effective to run, and less damaging to the environment.

VI. OBJECTIVES AND SCOPE OF THE PROJECT:

This project aims to automate the garage door because many times it is not feasible for car owner to get out of the car and open the door manually and close it manually whereas this project helps it to overcome this problem of opening the door manually by making it connect through smart devices.

It can also be used in parking lots where daily tons cars are parked and removed and with help of this project problem of manually opening the door , parking the car and manually closing the door is overcome because with this project the garage door will be automatically gets opened when an authenticated car enters the passage of the garage.

less. Moreover, the Smart garage is accessible to the authorized person, as it is authenticated with a unique RFID tag. This method is more secure than the standard biometric identification method, which can be implemented to the system and hence overcome the problem of security. The Smart Garage also has an IR sensor which detects the presence of the car inside the garage and accordingly notifies the user.[1]

The simplification of the system aims to provide a security access to the restricted and most protected parts of the industry through a system that manages the security of the arena. Margulies, Jonathan mentioned in their paper [2] that several automation models and smart door management systems were considered in modeling the system with the required inclusion relevant for the industrial arena.

Several automation systems for secured access have been introduced in this era of smart phones. Initially several door lock mechanisms were introduced. Further adding to these words Prarthana, R. Jenifer, et al in their paper [3] expresses it is a combo of RFID for maintaining the authentication data, LCD and motor part for maintaining door motions, sensors for inquiring the environment, an inter communiqué module, and control module for establishing overall control

.In this paper, Sunny, R. Jenifer, expresses that garage door is the largest moving object in the home. These doors are often operated by electric door openers. Proper installation, operation, maintenance and testing of the garage door and automatic opener are necessary to provide safe, trouble free operation.[4]

VII. PROBLEM DEFINITION:

The history of the garage door could date back to 450 BC when chariots were stored in gatehouse. The manual method of accessing doors of a garage uses a pulley and a lever or a switch which trigger a motor. The doors are secured with a lock, this arise the difficulty of manually controlling. A fingerprint recognition system is also installed for security purposes preventing unauthorized users

VIII. PHASES OF PROJECT:

Phase 1: Planning, Analysis, Designing and Implementation.

- Analysis: Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation.

- Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and getting a rough picture about what would be our problem definition for the project.

- Designing: Then we will construct the design of the project and according to that, will list down all the requirements needed for the construction for

1. Features of the project:

The Project consists of the following features:

High sensitivity and fast response:

The RFID Tag and module are highly sensitive when the RFID tag comes near the contact with the RFID module and if the Tag is authenticated then the garage door will be opened and if it is not authenticated then the door won't get open.

Simple drive circuit:

The connections and the circuit design of this system is simple hence it is much more convenient to develop.

Long life and stable:

The components are short lived because of the from gaining entry. People may have difficulty accessing the

entry door to their house because it is difficult for them to turn a key or they cannot maneuver a wheelchair into a position to either open the door or grasp the doorknob or scan their finger.

We will use various components such as RFID sensor and the reader for detecting the valid user, Node MCU as a processor which turns out to be the best and most suitable option, Servo Motor for opening and shutting the doors, IR Sensor to detect the presence and absence of the car and used for the internet connectivity. Overall the system provides a complete solution for the problem.

the prototype of our project.

• Implementation: After acquiring the requirements we first developed the connections of the hardware components and then added the coding part later with help of USB cable to the Node MCU.

Phase 2: Testing and Deployment

• Testing: After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again.

• Deployment: After, complete integration and testing of project real time running and operation of the system will be done. User need to check the value.

components used are of low grade here in this the sensor and the alert system gives alert if the car enters the garage or exit's the garage.

IX. METHODOLOGY:

The proposed method takes input from the RFID Tag and Reader authenticates the tag whether the tag is valid or not. If the tag is valid the door of garage will automatically get opened. Once the car is parked the owner of the car gets the message in mobile. The presence of the car is detected using Infrared Sensor (IR Sensor) . If the car enters the garage then IR has detection for the car hence the owner of the car gets message that the car has entered in the garage and if the car exits the garage then IR has no detection for the presence of the car hence the owner of the car gets message that the car exited the garage.

Fig 4: RFID sensor authenticates RFID tag and garage door opens

XII. RESULTS:

Outputs:

- When the car enters the garage it gives notification in application that "CAR ENTERED"
- When the car exits the garage it gives notification in application that "CAR EXITED

Fig 6: Notification in the Blynk application when car enters and exits the garage

XIII. OUTCOMES:

Phase 1:

- Analysis:

Creating the synopsis, literature survey and feasibility study for proposed solution which will act as an input to the design phase.

- Planning:

Proposing Statement of work, scope definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done.

- Designing:

Proposing the design architecture for the prototype.

- Implementation:

Implementation of Node MCU model with the help of code running in the Arduino IDE environment.

Phase 2:

- Testing:

Testing was done with the cases when car wasn't present the garage and what happens when the car enters the pathway of the garage. The testing of the model was a success which is shown in above figures.

- Deployment:

Real time observation was noted when the car entered the pathway of the garage and with the help of RFID reader and tag the car is authenticated and if the car is authenticated the door of garage will be opened automatically.

XIV. IMPROVEMENTS IN RESEARCH GAPS (FINDINGS):

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

As this system is currently used for automatic opening of door this this project can be further extended to provide features like setting up an alarm which will ring if the garage door is broke openedThe lights inside the garage can also be automated so that whenever the car enters the lights will go on and whenever the car is not present the lights will remain off. Increase the security level of the garage by implementing image processing to read the number plate of the car and process it to check whether the car is authorized to enter inside or not.

XV. FUTURE SCOPE:

The functionality of this project can be further extended to provide features like setting up an alarm which will ring if the garage door is broke opened. The lights inside the garage can also be automated so that whenever the car enters the lights will go on and whenever the car is not present the lights will remain off. Moreover, we can further increase the security level of the garage by implementing image processing to read the number plate of the car and process it to check whether the car is authorized to enter inside or not. This concept of smart garage can be extended to convert many traditional garages to highly secure smart garages.

XVI. CONCLUSION:

We presented Smart garage, an application of loT,

which is used to access the shutter of a domestic garage, with the help of a simple RFID tag, without compromising on the security. As we compare it with the existing solution we can say that, smart garage is effective in terms of mitigating the process and securing. But with more advancement in terms of design and security, we can ensure the ease in consumer's utilization.

Smart Floor Cleaner Robot Using Android-App

Mukesh Sahani, Affan Shaikh, Harshal Goyal
TCET, MUMBAI
mukeshsahani92.ms@gmail.com, affanshaikh85.s@gmail.com, harshalgoyal155@gmail.com

Abstract— **In this project we've tried to implement an RC robot using Bluetooth Module HC-05, Arduino and Motor Driver L298N.It's a wireless Bluetooth control floor cleaning machine and can be amazed at the simplicity and effectiveness of the concept. It's basically DC motors wired on a wheeled wooden container with a cleaning solution placed on top and a scrub attached within the bottom through one among the motors. the comb cleans the ground . Anybody can operate this machine easily. Hence it's very useful in hospitals, houses, etc. Bluetooth module is employed for controlling the complete system with help of remote or mobile. there's an application in mobile for Bluetooth connection between the system and mobile. By using Bluetooth module we are able to direct and switch the system because the user needs. It works great and controlled manually supported the user convenience. Categorically makes cleaning easier and merrier while enabling anyone to make something instead of buy. In modern days interior decorations are getting a very important role in our life. Onslaught of floor may be a important one for our health and reduces the person power constraint. Hence our project is incredibly useful in our day to day life.**

Keywords –, – Arduino UNO;Bluetooth Module, Motor Drivers

I. INTRODUCTION

In recent years, robotic cleaners have taken major attention in robotics research because of their effectiveness in assisting humans in floor cleaning applications at homes, hotels, restaurants, offices, hospitals, workshops, warehouses and universities etc This paper deals with the designing and fabrication of Floor cleaning Machine. The aim of this work is to develop and modernized process for cleaning the ground with wet and dry. it's very useful for cleaning the floors. Floor cleaning system is extremely much useful in cleaning floors in hospitals, houses, auditorium, shops, computer centers etc; it's very simple in construction and simple to control. Anybody can operate this machine easily. It incorporates moisture cotton brush, the comb cleans the ground. Hence it's very useful in hospitals, houses, etc. The time taken for cleaning is extremely less and also the cost is additionally very less. Maintenance cost is a smaller amount. Much sort of machines is widely used for this purpose. But they're working under different principles and the cost is also very high. In this paper a very simple drive mechanism and simple to control any persons. the scale of the machine is additionally portable, so we will transfer from one place to other place very easily. the ground cleaning machine is straightforward, modern house holding device; even children can even operate it easily with safety. it's vital one for every and each houses and hospitals etc. Households of today have become smarter and more automated. Home automation delivers convenience and creates longer for people. Domestic robots are entering the homes and people's daily lives, but it's yet a comparatively new and immature market. However, a growth is predicted and also the adoption of domestic robots is evolving. Several robotic cleaners are available on the market but only few ones implement wet cleaning of floors. the aim of this project is to style and implement a Robot Autonomous and Manual via Phone Application. Cleaner Robot is meant to create cleaning process become easier instead of by using manual cleaners. the most objective of this project is to style and implement a cleaning robot prototype by using Arduino uno, ,motordriver,Bluetooth hc-05 and to attain the goal of this project.

II. PROBLEM DEFINITION

As the task of cleaning floors is done manually, but in the age of growing technology things are getting automated and easier. A number of work has been
done to automate the task of cleaning but it has been implemented on a larger scale requiring more equipment's which in turn require more cost.So to automate to work of cleaning on household level this project has been implemented. This floor cleaning robot requires less component and works on a usual power supply which makes it effective and budget friendly.

III. BACKGROUND

This system is designed with the intention to simplify the process of cleaning by providing remote control to floor cleaning robot. The robot will work as

directed by the user by taking inputs from the provided control.

IV. IMPORTANCE

People desire to use things that are efficient and helpful for reducing their tasks. For keeping this in mind there was the main challenge that robot should clean the floor efficiently and accurately. For this purpose we used water and brushes for pure cleaning.Apart from cleaning another important objective is to develop the robot and it must be of low cost and user friendly. So we designed a robot that is not only cost effective but also easy to operate.

V. OBJECTIVES AND SCOPE

Apart from the small technicalities and conceptual challenges faced in this project, there is one above all, which is meant to serve as a breaking point in the world of common user robotics, amateurs, and engineers, and this is enabling a certain robot that operate automatically in all situations and decide that it can do on its own.

The scrubber design should be modified in future because the current design has few problems. Few of those are the motor is not detachable and the high rpm leads to vibration of the whole system. If these features will be modified, this will work well. The development can be made in the field of sensing and to detect as well as move in the direction of dust and thus resulting in better cleaning of floors. Monitoring, self-charging, lighter body weight and to set alarm on/off time manually are the future scope of this paper.

VI. PHASES

Phase 1: Planning, Analysis, Designing and Implementation.
Analysis: Perform literature survey and find all the research gaps Prepare a report or synopsis to set a path that is to be followed.

After understanding the requirements and making the synopsis the development is to be started.

Designing: In development the first step is to plan on how the project is to be done.

The second step is to set the Arduino and make the connection using connecting wires.

After both the steps are completed properly, the actual development is to be started taking help of the plans and designs created.
We have created a code and the code is applied when the USB is connected to the LCD.
Phase 2: Testing and Deployment.
Testing and Deployment: Various test have being carried by trial and error.

The code has been rechecked and the needed corrections have been made. After Testing and approval, apply the proposed system.

VII. METHODOLOGY

A number of software and hardware implementation techniques were accustomed design and develop the system. Fig. 1 shows the diagram of system. We used a 12VDC motor, Bluetooth HC-05,Motor Driver and Arduino to develop our system. The operation of the robotic cleaner goes to be supported retrieving data from an array of inputs that may tell the condition of the ground space round the scrubber.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

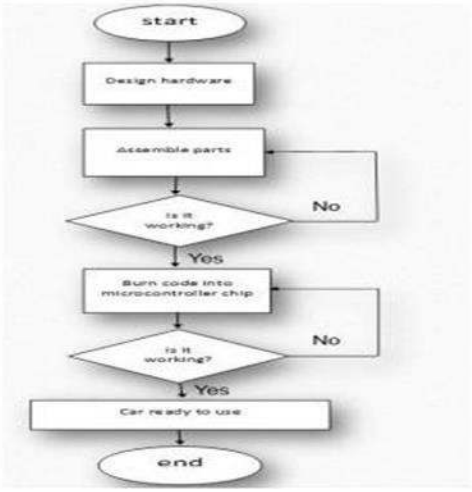
Hardware o Arduino UNO x 1
o Motor Driver L298 Module x 1 o Bluetooth HC-05 Module x 1
o Connecting Wires
o DC Motors x 5

Software

ARDUINO IDE

IX. BLOCK DIAGRAM

Fig1. Block Diagram



The above block diagram represents the actual working of our project. Here the voice input is given to the mic which is processed using the raspberry pi and the reply is given through the speaker in human language.

X. CIRCUIT DIAGRAM

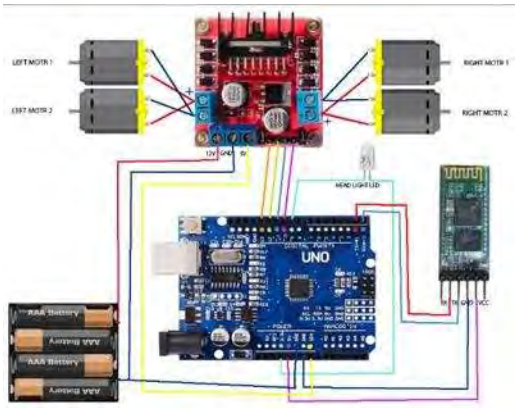


Fig2. Circuit Diagram

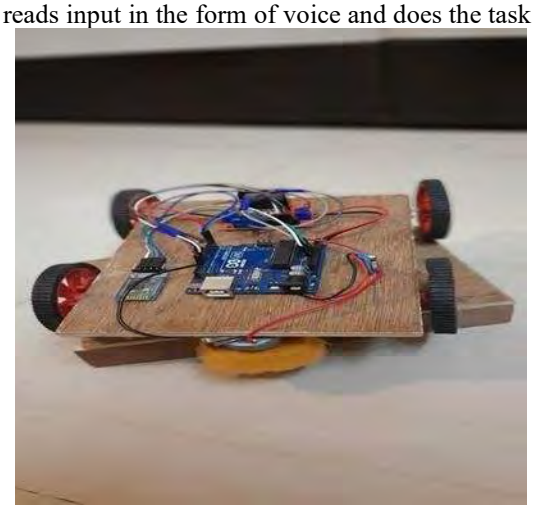
This circuit diagram shows us the connection of different components used in the project. We used Jumper Wires for connecting the components. First we connected the Motor driver with the Arduino
through 10,11,12,13 of Arduino. Then we connected bluettoth module with Arduino. To connect the motors with Motor Driver we did cross connection of
4 motors and connected them .

XI. OUTPUT

When we say OK Google! The assistant starts running and reads input in the form of voice and does the task according to the input received.

XII. RESULT

When we say OK Google! The assistant starts running and reads input in the form of voice and does the task



XIII. OUTCOMES

Creating the outline, works survey and achievability study for proposed solution which will act as an input to the design phase.

Suggesting Statement of work, scope description and scope border for planning the model from the problem definition to decide what needs to be done and what not to be done.

XIV. SUMMARY

Smart floor cleaning system offers a variety of advantages over the traditional cleaning system.The user may sit at a place, start a bot and clean wherever needed. The system consists of a transmitter app. This app is run in an android mobile phone that allows user to transmit command based on user input. Based on these commands the transmitter sends movement commands to the robot. The transmitter is
an android mobile phone that allows user to transmit commands to the robot. On receiving the movement commands from the android. On receiving the movement commands from the android device through Bluetooth receiver. The microcontroller on receiving the commands, decodes them and thus operates the motors in order to achieve the desired motion.This makes floor cleaning a very easy, fast and an effortless process.

XV. CONCLUSION

The project proposed here is an automated android based floor cleaning machine. The system is capable of cleaning the floor cleans using a cleaning mop. The system can work without much loss of human physical energy. The system is provided with an android control which uses Bluetooth communication. The android application can be used to control the robot forward, left, right or back.

This presents that floor cleaning process can be done in an easier manner and more efficiently by robot utilizing wireless robotic system. This proposed robot reduces the time and cost of labor floor.

An Introduction of Heartbeat Monitoring System

Mr. Bhavneet Sankhala, Mr. aakash Paliwal, Mr. Rohit Pal,
Information Technology, Thakur College Of Engineering and Technology, Mumbai
sankhalabhavneet1@gmail.com, heyaakashpaliwal08@gmail.com, palrohit03@gmail.com

Abstract— **Technological innovations in the field of disease prevention and maintenance of patient health have enabled the evolution of fields such as monitoring systems. Heart rate may be a very vital health parameter that's directly associated with the soundness of the human circulatory system. Heart rate is that the number of times the guts beats per minute, reflects different physiological conditions like biological workload, stress at work and concentration on tasks, drowsiness and the active state of the autonomic nervous system. It are often measured either by the ECG waveform or by sensing the heart beat - the rhythmic expansion and contraction of an artery as blood is forced through it by the regular contractions of the heart. The pulse are often felt from those areas where the artery is on the brink of the skin. This paper describes a way of measuring the guts rate through a fingertip and Arduino. It is supported the principal of photophelthysmography (PPG) which is non-invasive method of measuring the variation in blood volume in tissue employing a light and detector. While the guts is thrashing, it's actually pumping blood throughout the body, which makes the blood volume inside the finger artery to vary too. This fluctuation of blood are often detected through an optical sensing mechanism placed round the fingertip. The signal are often amplified and is shipped to Arduino with the assistance of interface communication. With the assistance of processing software pulse monitoring and counting is performed.**

Keywords –Arduino; Pulse Sensor; Pulse max; photoelectric plethysmography (PPG)

I. INTRODUCTION

A pulse monitor may be a personal monitor that permits a topic to live their pulse in real time or record their pulse for later study. Early models consisted of a monitoring box with a group of electrode leads that attached to the chest. The heart rate of a healthy adult at rest is around 72 beats per minute (bpm) & Babies at around 120 bpm, while older children have heart rates at around 90 bpm. The heart rate rises gradually during exercises and returns slowly to the remainder value after exercise. The rate when the heart beat returns to normal is a sign of the fitness of the person. Lower than normal heart rates are usually a sign of a condition referred to as bradycardia, while higher is understood as tachycardia. Heart rate is just measured by placing the thumb over the subject's arterial pulsation, and feeling, timing and counting the pulses usually during a 30 playing period . Heart rate (bpm) of the topic is then found by multiplying the obtained number by 2. This method although simple, isn't
accurate and may give errors when the speed is high. More sophisticated methods to live the guts rate utilize electronic techniques. Electro-cardiogram (ECG) is one among frequently used method for measuring the guts rate. But it is an expensive device. Low-cost devices within the sort of wrist watches also are available for the instantaneous measurement of the guts rate. Such devices can give accurate measurements but their cost is typically in more than several hundred dollars, making them uneconomical[1]. So this pulse monitor with a temperature sensor is certainly a useful instrument in knowing the heart beat and therefore the temperature of the topic or the patient.

II. OBJECTIVES:

The goal of this thesis is design low-cost device which measures the guts rate of the topic by clipping sensors on one among the fingers then displaying the result on a android application interface. Miniaturized heart rates monitor system supported a microcontroller. It offers the advantage of portability over tape-based recording systems. The thesis explains how a single-chip microcontroller are often wont to analyze heart beat rate signals in real time. The Hardware and software design are oriented towards a single-chip microcontroller-based system, hence minimizing the dimensions .

III. SCOPE OF THE PROJECT:

The scopes during this project include the hardware and software parts. For the hardware part, ECG circuits are designed so as to interpret data from ECG simulator, which act as a patient. Then, a temperature sensor was developed to live the temperature of person . Both systems are controlled by Arduino Nano board, which connected to the Bluetooth module and wish some programming works. For the software part As and Arduino IDE software are used.

IV. LITERATURE SURVEY

Heart Rate:

The heart is that the organ that liable for pumping blood throughout the body. it's located within the middle of the thorax, slightly offset to the left and surrounded by thelungs basically; the human heart consists of 4 chambers which are two atriums and two ventricles. the proper atrium receives blood returning to the guts from the entire body. That blood passes through the proper ventricle and is pumped to the lungs where it's oxygenated and goes back to the guts through the left atrium of the heart , then the blood passes through the ventricle and is pumped again to be distributed to the whole body through the arteries.[1]

Figure 1.1 heart behavior and part of the generated signal

V. MEASURING THE HEART RATE:

By detecting the R peaks and measuring their frequency, the guts rate are often calculated and then displayed. someone's pulse before, during and after exercise is that the main indicator of their fitness. Measuring this manually requires an individual to prevent the activity they're doing so as to count the amount of heart beats over a period of your time . Measuring the guts rate using an circuit are often done much quicker and more accurately. pulse measurement is one among the vital parameters of the human circulatory system . the guts rate of a healthy adult at rest is around 72 beats per minute (bpm). Athletes normally have lower heart rates than less active people. Babies have a way higher pulse at around 120 bpm, while older children have heart rates at around 90 bpm. the guts rate rises gradually during exercises and returns slowly to the remainder value after exercise. the speed when the heart beat returns to normal is a sign of the fitness of the person. less than normal heart rates are usually a sign of a condition referred to as bradycardia, while above normal heart rates are referred to as tachycardia.[1] Endure athletes often have very low resting heart rates. pulse are often measured by measuring one's pulse. Pulse measurement are often achieved by using specialized medical devices, or by merely pressing one's fingers against an artery (typically on the wrist or the neck). it's generally accepted that taking note of heartbeats employing a stethoscope, a process referred to as auscultation, may be a more accurate method to live the guts rate. There are many other methods to live heart rates like Phonocardiogram1 (PCG), ECG, vital sign wave form and pulse meters but these methods are clinical and expensive.[2] ,[5]

VI. MAXIMUM HEART RATE:

The maximum pulse (Max HR) is that the fastest of heart can beat for one minute. A generalized rule anchors Max HR employing a mathematical formula. Inside each zone, there are different exercise changes which occur because the results of spending training time within the zone. Heart zones is expressed as a percentage of the utmost pulse , reflect exercise intensity and therefore the result benefit.

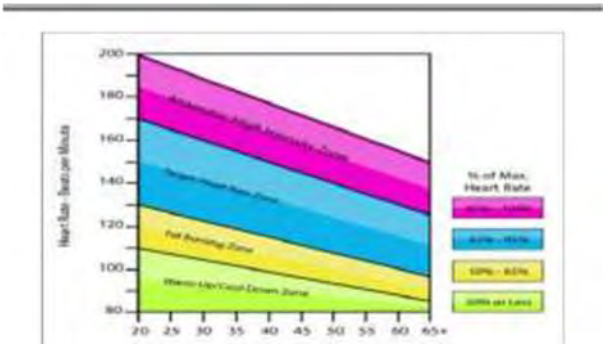

Figure 1.2 Exercise target zone chart

Calculate the utmost rate of the guts is that the subject of ongoing research for an extended time due to the inaccuracy of the calculation. So there are many methods of calculating such

1) The easiest and best known method to calculate your maximum heart rate (MHR) is to use the formula MAXHR = 220 – Age
2) Dr. Martha Gulati et al For Male, MAXHR = 220-Age. For women, MHR= 206 - (0.88 x age).
3) Londeree and Moeschberger • For male and female, MHR = 206.3 - (0.711 × Age) Studies have shown that MHR on a treadmill is consistently 5 to six beats above on a bicycle ergo meter and a couple of to three beats higher on a rowing ergometer. Heart rates while swimming are significantly lower, around 14 bpm, than for treadmill running. Elite endurance athletes and moderately trained individuals will have a MHR 3 or 4 beats slower than a sedentary individual. It was also found that well trained over 50s are likely to have a higher MHR than that which is average for their age.[3],[4]
4) Miller et al For male and female, MHR = 217 - (0.85 x Age)
5) USA Researchers MHR = 206.9 - (0.67 x age)
6) UK Researchers For Male, MHR = 202 - (0.55 x age) For Female, MHR = 216 - (1.09 x age)
7) Miller, Londeree and Moeschberger

To determine your maximum pulse you'll use the subsequent , which mixes the Miller formula with the research from Londeree and Moeschberger.

- Use the Miller formula of MHR=217 - (0.85 × age) to calculate MHR.
- Subtract 3 beats for elite athletes under 30.
- Add 2 beats for 50 year old elite athletes.
- Add 4 beats for 55+ year old elite athletes.
- Use this MHR value for running training.
- Subtract 3 beats for rowing training.
- Subtract 5 beats for bicycle training.

Fingertip sensor:

Use of sunshine to live pulse may be a field of study where abundant research has been wiped out the past few decades. Fingertip sensor relies on measurement of a physiological signal called Photoplethysmogrpahy (PPG) [1,4.], which is an optical measurement of the change in blood volume within the arteries. Fingertip sensor acquires PPG signals by irradiating wavelength of light through the tissue, and compares the light absorption characteristics of blood under these wavelengths.[5]

Photoelectric Photoplethysmogrpahy:

The hardware and software for the MEDAC photoelectric plethysmography (PPG) represent an integrated system for real time monitoring of relative changes in peripheral blood

flow and for recording pulse using a simple to connect sensor. Under appropriate conditions, the software can derive the subsequent measures from the PPG signal: relative blood volume pulse height, pulse wave rise time, pulse wave fall time, the inter-beat- interval (IBI)2, and pulse .

Plethysmography may be a generic term pertaining to a spread of techniques for monitoring volume changes during a limb or tissue segment. Volume changes occur during a pulsatile manner with each beat of the guts as blood flows in and out of some of the body. The study of vascular activity by fluid displacement methods dates back to a minimum of 1890. Photoelectric plethysmography (PPG) was developed in both Germany and therefore the us within the 1930's.

Recent advances in photoelectronics make it possible to utilize photoelectric plethysmography as a sensitive physiological monitoring technique which will be practically applied during a clinical setting.[3]

VII. PROBLEM DEFINITION:

The heart rate monitoring system being developed for the following reasons:

• The goal of this thesis is design low-cost device which measures the guts rate of the topic by clipping sensors on one among the fingers then displaying the result on a android application interface.

• Providing immediate notification of abnormalities in cardiac activity on a monitored patient or user.
• Providing low cost and low power consumption devices provides an inexpensive and reliable method for monitoring patients in developing countries. Providing microcontroller based QRS analysis.
• Providing easily accessible, user friendly and portable device.

VIII. FEASIBILITY:

This project was developed to supply low-cost device which measures the guts rate of the topic by clipping sensors on one among the fingers then displaying the result on a android application interface. This project, as far as feasibility cares , didn't cost an enormous amount because we used Arduino Uno and it's a less price and most of people use for his or her projects. This project are often implemented around a price of 1000 Rs for every setup.

Analysis and Planning

Hardware Requirement:

- **Arduino Uno:**

Fig 1.3 Arduino UNO

Arduino Uno may be a microcontroller board developed by Arduino.cc which is an open-source electronics platform mainly supported AVR microcontroller Atmega328.

The current version of Arduino Uno comes with USB interface, 6 analog input pins, 14 I/O digital ports that are wont to connect with external electronic circuits. Out of 14 I/O ports, 6 pins are often used for PWM output.

It allows the designers to regulate and sense the external electronic devices within the world .

This board comes with all the features required to run the controller and may be directly connected to the pc through USB cable that's wont to transfer the code to the controller using IDE (Integrated Development Environment) software, mainly developed to program Arduino. IDE is equally compatible with Windows, MAC or Linux Systems, however, Windows is preferable to use. Programming languages like C and C++ are utilized in IDE.

Apart from USB, battery or AC to DC adopter also can be wont to power the board.

- **Pulse Sensor:**

Pulse Sensor may be a well-designed plug-and-play heart-rate sensor for Arduino. It are often used by students, artists, athletes, makers, and game & mobile developers who want to simply incorporate live heartrate
data into their projects. The sensor clips onto a fingertip or earlobe and plugs right into Arduino with some jumper cables. It also includes an open-source monitoring app that graphs your pulse in real time.

Fig 1.4 Pulse Sensor

1) A 24-inch Color-Coded Cable, with (male) header connectors. you will find this makes it easy to embed the sensor into your project, and hook up with an Arduino. No soldering is required.
2) An Ear Clip, perfectly sized to the sensor. We searched many places to seek out just the proper clip. It are often hot glued to the rear of the sensor and simply worn on the earlobe.
3) 2 Velcro Dots. These are 'hook' side and also are perfectly sized to the sensor. you will find these Velcro dots very useful if you would like to form a Velcro (or fabric) strap to wrap around a fingertip.
4) Velcro strap to wrap the heart beat Sensor around your finger.
5) 3 Transparent Stickers. These are used on the front of the heart beat Sensor to guard it from oily fingers and sweaty earlobes.
7) The Pulse Sensor has 3 holes round the outside edge which make it easy to stitch it into almost anything.

IX. BREADBOARD:

A breadboard may be a solderless device for temporary prototype with electronics and test circuit designs. Most electronic components in electronic circuits are often interconnected by inserting their leads or terminals into the holes then making connections through wires

where appropriate. The breadboard has strips of metal underneath the board and connect the holes on the highest of the board. The metal strips are laid out as shown below. Note that the highest and bottom rows of holes are connected horizontally and split within the middle while the remaining holes are connected vertically.

Software Requirements:
● Database using MySQL

MySQL is that the hottest Open Source Relational SQL management System. MySQL is one among the simplest RDBMS getting used for developing various web-based software applications. MySQL is developed, marketed and supported by MySQL AB, which may be a Swedish company.

MySQL fully satisfies the ACID requirements for a transaction-safe RDBMS, as follows:

Server-side semaphore variables and locking mechanisms act as traffic managers to assist programs manage their own isolation mechanisms. for instance , MySQL's InnoDB engine uses fine-grained row-level locking for this purpose

Design and Implementation

Circuit Diagram:

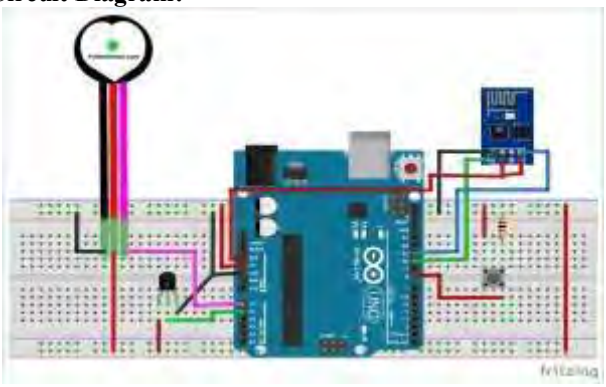

Fig 1.5 Circuit Diagram

X. EXPLANATION:

Circuit of heartbeat monitor is shown below, which contains arduino uno, heart beat sensor module, push button and LCD. Arduino controls whole the method of system like reading pulses form Heart beat sensor module, calculating pulse and sending this data to LCD. we will set the sensitivity of this sensor module by inbuilt potentiometer placed on this module.

Heart beat sensor module's output pin is directly connected to pin 8 of arduino. Vcc and GND are connected to Vcc and GND. A 16x2 LCD is connected with arduino in 4-bit mode.

Flowchart:

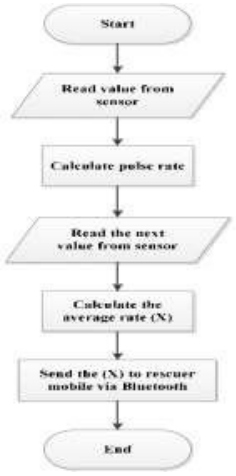

Fig 1.6 Flowchart

The sensor is placed on the hand and measures the heart beat rate when the sensor is activated by the availability voltage. Then, the info is shipped to the controller to look at the heart beat rate through multiple readings. The sensor then transmits the heart beat rate to the swimmer's unit via Bluetooth after half a moment , as displayed in Fig. 1.8

XI. RESULT &DISCUSSION

Result:

The Arduino board is related to the guts beat sensor, presently after finishing the microcontroller and sensor setup the board must be related to an influence source. Since here we utilize sequential correspondence for showing the result or the recognized heart beat we are interfacing the microcontroller with the PC through the USB port. Presently the program is aggregated and transferred into the Arduino board utilizing Arduino compiler and therefore the outcome is accordingly acquired within the sequential screen of the alleged compiler and furthermore the BPM is decided . Presently, the detected information are often put away into an exceed expectations sheet with the help of PLX-DAQ device and that we will change over the straightforward.

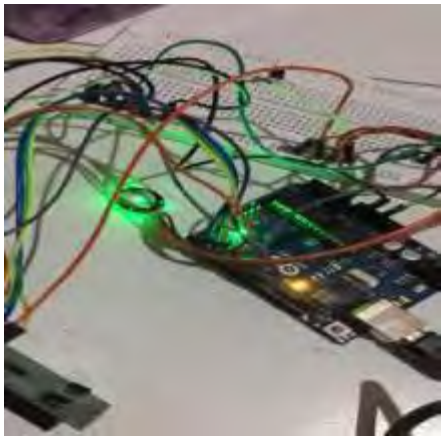

Fig 1.7 working of pulse sensor

Working of Pulse Sensor:

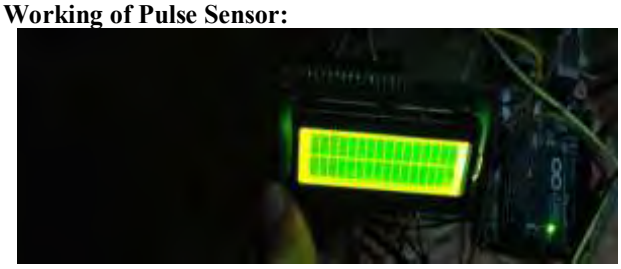

Fig 1.8 LCD displaying BPM

First, we'd like to connect the heart beat Sensor to any organ of body where it can detect the heart beat easily like finger, ears etc. Then the heart beat Sensor will measure the change in volume of blood, which occurs when whenever heart pumps blood within the body. this alteration in volume of blood causes a change within the candlepower through that organ. The Arduino will then convert this alteration into the guts beat per minute (BPM). The LED connected at pin 13 also will blink consistent with the guts Beat.

Conclusion & Future scope

This chapter discusses the suggestion of future work for the project and conclusion are going to be made consistent with the project development. This thesis has discussed the event of the fingertip sensor and interfacing with microcontroller and other peripherals units.

XII. CONCLUSION:

Biomedical engineering (BME) combines the look and problem solving skill of engineering with medical and biological sciences to reinforce patient's health care and so the standard of lifetime of people. disorder is one in all the most causes of untimely deaths in world, heart beat readings are far and away the only real viable diagnostic tool that may promote early detection of cardiac events. By using this we'll measure ones pulse through fingertip.
This paper focuses on the center rate monitoring and alert which is during a position to observe the center beat rate condition of patient. The system determines the center beat rate per minute then sends short message service (SMS) conscious of the mobile . . it's portable and price effective. it is a really efficient system and very easy to handle and thus provides great flexibility and is a superb improvement over other conventional monitoring and alert systems.

XIII. FUTURE WORK:

To ensure the accuracy of pulse rate monitor device, more testing may be performed to larger number of individuals with different ages and weights.

In terms of creating the device more portable, the device would be miniaturized onto a computer circuit board making it light weight and more stable.

We can develop GUI program to point out the center drill PCB. Another alternative we will use free scale microcontroller which use widely in biomedical application to point out the heartbeat because they need GUI program that showing the signals at ADC channels.

the info acquisition system can to become decentralized which suggests localized data acquisition systems that are a part of the PCB of this device can be built that wirelessly transmit the signals collected to the decentralized data acquisition system or on to the processing centre.

Dynamic Traffic Management System

M.Abhishek Soni, Ms. Aarushi Singh
Department of Information Technology,
TCET,Mumbai.
abhisheksoni1998@gmail.com, aarushisingh.lm10@gmail.com

***Abstract*—Internet of Things (IoT), is one of the current trends in the Branch of Information Communication Technology. In today's world, urban mobility is one of the unprecedented challenges to be dealt in the administration of a big city. This documentation analyses the ever growing urban population around the globe and discusses about the traffic systems in densely populated cities like Mumbai and Delhi. Further, a traffic management system is proposed and implemented using IoT. The old classical traffic management systems are static i.e just based on predefined structure they operate over a loop. In our Traffic Management System we try to implement a dynamic system that based on current iteration values modify the system over these inputs for next iteration. The main objectives include creation of a Dynamic Traffic management system that will operate according to the number of cars and also detect the presence of vehicles over a range in consideration that the traffic is not steady. After studying the literature survey it was planned to overcome the research gaps and the system was tested using the test cases and then the outputs were generated which justifies that effective time allotment was observed for more congested lanes, preceding over the static system that wasn't capable for the same.**

Keywords – IoT, Dynamic Traffic Management System , Piezo/IR Sensors,Traffic Congestion,Smart City.

I. INTRODUCTION

Traffic signal management is one of the major problematic issues in today's world. In today's scenario, every lane gets a timing of about 1 minute on the road at a regular interval, even when traffic on that particular lane is dense. In our proposed model, we will be optimizing the timing interval of the traffic signal that depends on the number of incoming vehicles on that lane. The major advantage of this system is that it is able to decrease waiting time for the drivers to cross road signal.

One of the important things in the Internet of things in smart cities is the Intelligent Transportation System (ITS).This is possible because of ITS, it utilizes advanced information and communication, and this communication will be helpful for decreasing traffic congestion and to reduce the accidents on the road, which is dangerous in the urban areas.

Managing traffic signal timing is an important thing in urban cities. Managing the time on the road will decrease the waiting time of the drivers on the road, and that will help to reduce the fuel consumption.

A. Importance of the Project

The requirement of the project was to design a dynamic system because in major cities traffic is one of the major problem and our system acts as an alternative to the old classical static system. Also by modifying the green time we would be solving traffic as well as waiting time problems.

Upgrading all the signals in the city will:

- Reduce everyday congestion, by providing time for the lanes that are more congested based on the prior system inputs collected by sensors.
- Reduce pollution throughout the vicinity.
- Developing a dynamic Traffic Management system that fulfills our needs to solve congestion problems and provide smooth journey with less waiting time for the passengers.
- It will provide opportunities to install equipment's/sensors to collect much more detailed traffic information.

You need to carefully consider the benefits that you can achieve by reducing the number of Traffic situations.

B. Motivation

The various issues related to traffic congestion that happened in the previous years. Some of them are as follows:

1. Reaching the office late on the day of an important meeting or discussion, or worse the day of a presentation.

2. Missing a flight due to a traffic jam. This situation has caused people to be hopelessly stuck for many hours, without being able to do anything about it and having to make peace with the fact that they are helpless and can do nothing but sit and wait as the time passes in front of their eyes.

3. Sadly, a traffic jam also causes emergency vehicles like Ambulances or Police Vans to get stuck for a long period of time, which may result in major losses.

4. All these incidents prove that the road infrastructure isn't up to the desired expectations and thus something must be done to deal with these situations.

II. LITERATURE SURVEY

.

A. Literature Survey Table

Paper Title	**Project**	**Author**
Smart Traffic Management System	Article in International Journal of Computer Applications (IJCA) DOI:10.5120/13123-	Ninad Lanke

	0473	
Real Time-Smart Traffic Management System using IoT	Article in International Conference of Emerging Technological Trends(ICETT) DOI: 10.11.09/icett.2016.78736603	Patan Rizwan Kumar Govind Suresh Rajshehara Babu

Few More findings and papers related to the same topic were.

1. Osman et al. recommended a system in which surveillance cameras were used to measure traffic density using MATLAB, a traffic controller and a wireless transmitter used to send images to the server after the server had measured traffic density using those images in each segment. An algorithm was used to set the time span of red light for a specific intersection path, which is calculated by the traffic density on the road and forwarded to the microcontroller and then to the server [1].

2. Jadhav et al. used surveillance cameras, MATLAB and KEIL (Microcontroller coding) to monitor traffic congestion, this paper also addresses priority traffic clearance and red signal broker (Number plate detection). Sensors were used to monitor traffic where vehicle-to-vehicle and vehicle-to-infrastructure contact was conducted using wireless communication systems, controllers positioned at the center of the intersection collected vehicle and pedestrian information and requests and processes using the first-come first-serve method [2].

3. Swathi et al. suggested a smart traffic routing scheme that would choose the shortest route with the least congestion. Sensors are used to collect traffic density data, these sensors use solar energy and batteries, sensors keep transmitting infrared light, and when the object is close, they detect traffic density by tracking the vehicle's reflected light [3].

III. PROPOSED WORK

A. Problem Definition

Traffic congestion leading to more waiting time has been one of the major issues observed by current urban areas since the wide use of vehicles. Only a typical couple of moment's excursion to a store may take up to thirty minutes because of automobile overload or stoppage. As indicated by the police, blockages are really the reasons for certain issues like street rage, street menaces and significant mishaps. The little street limit is additionally one of the contributing components. As the quantity of private vehicles increments incredibly throughout the years, traffic blockage happens when the required street limit isn't satisfied. Improvements of the road can easily solve this problem. Since congestion occurs frequently in the cities, local government municipal can consider passing laws on limiting the quantity of vehicle claimed in a family.

B. Objectives and scope of the project

This project aims for a smarter city with a smarter and better Traffic Management system that will reduce traffic and thus, contribute in the smooth functioning of day to day activities of people living in that city. Our project is a mini replica of the same. The real specimen, however must be tested thoroughly before using it on a large scale in order to test its compatibility. Thus, our project can be expanded on a large scale using better sensors and other advanced forms of technology.

- The project can be further extended by increasing the number of Piezo strips, number of IR sensors at multiple distances to attain more accuracy.
- Also we can determine whether a vehicle has crossed the lane on red light and alert the traffic police with a message for the same.

C. Features of Project

The Project consists of the following features:

1. Dynamicity: Based on input values for different lanes the timings for next iteration are varied accordingly depending on which constraints these values fall.

2. High sensitivity and fast response: The IR sensor and ultrasonic sensor used are highly sensitive to a distant obstacle, along with piezo sensor that takes input on the basis of pressure generated. Output is obtained each point of time in the region as soon as it senses the vehicles nearby.

3. Long life and stable: The system is long lived and much more efficient as compared to the standard traffic management system.

D. Methodology

Our project is divided into two lanes each having different approach to produce the required output by collecting values in two different methods and evaluation for the same using different functions and useful parameters.

For the current iteration, we count the number of vehicles present in Lane 1. For Lane 2, we have IR

readings obtained using the IR sensor, Previous +New-> Ultrasonic Readings. Here, we have used an Ultrasonic

sensor as a rectifier. Based on these values, we decide what amount of green time must be given for the next iteration. At the end of the loop we reconsider all the inputs transform them to useful values and then set all the factors necessary for the change in the system. Now over the next iteration the same is repeated again and again and if the values tend to be minimal no modifications are made in the system.

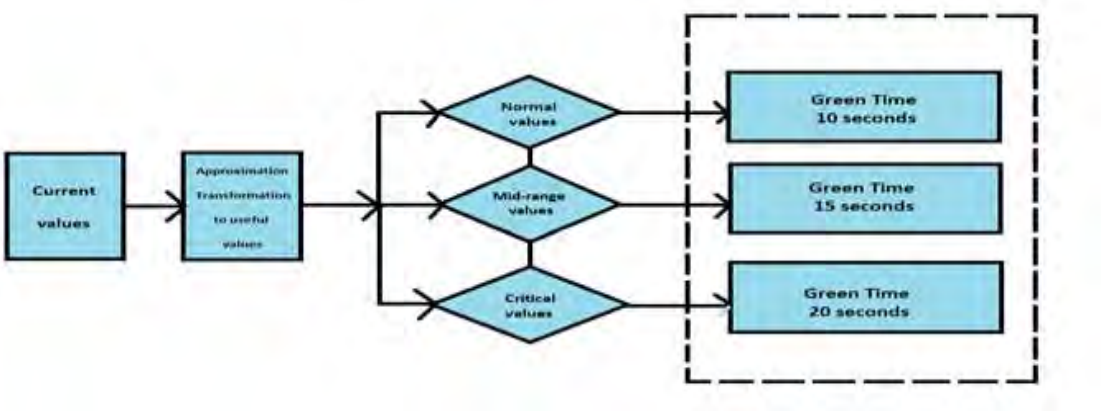

Figure 1: Block Diagram

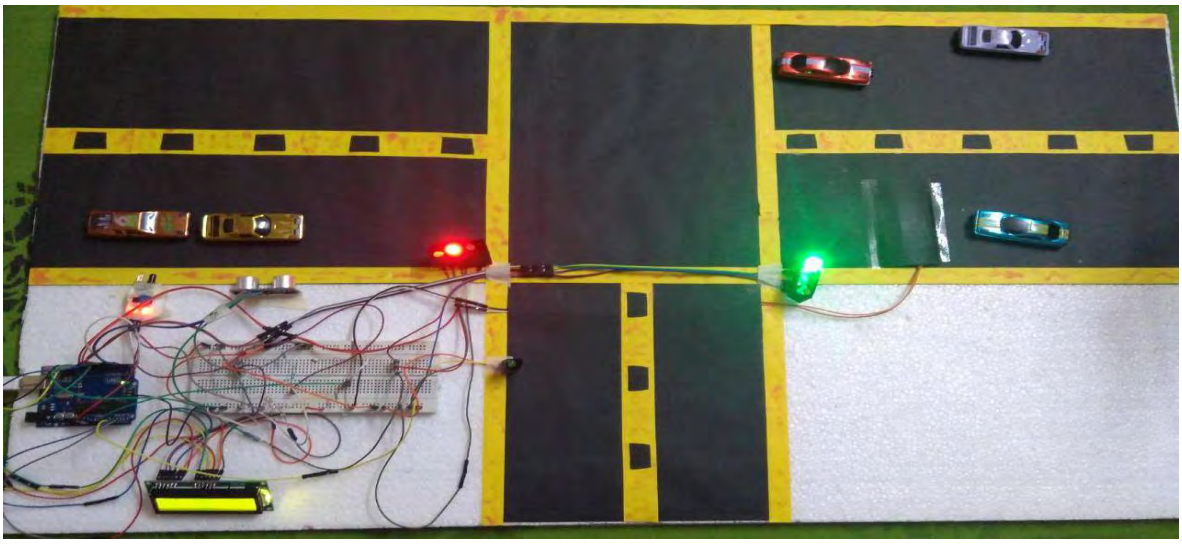

Figure 3: Working Model (Small Scale Prototype)

E. Project Resources(Tools/Components used.)

Hardware Tools

Quantity	Hardware Components
1	Arduino Uno
1	Ultrasonic Sensor
1	IR Obstacle Sensor
2	Piezo Sensor
1	Breadboard, Jumper wires
1	LCD Display (16X2)

Software Tools

1. Arduino IDE 2.Tableau

Along with these additional requirements were soldering of LCD Display, Piezo strip soldering making switches for the traffic signals, etc.

IV. RESULTS AND DISCUSSIONS.

In this project we implemented an Arduino based traffic management model with the help code running on its microprocessor programmed using the Arduino IDE. Testing was done with smaller specimens of vehicles that were passed over piezo sensor or near IR/ Ultrasonic sensor from which outputs were obtained and over those readings Data analysis was done.

Real time sensing was done when the smaller vehicles were passed and the sensor identified the number of iterations correctly and changed the timing of the traffic signal accordingly. Thus the model works efficiently.

Important observations made and results obtained include.

1. This system optimizes the traffic signals over the next iteration based on current inputs to the system.

2. The approximate vehicle count was used to determine green time for the first lane.

3. Simultaneously, a track of the traffic zone in the second lane is kept in consideration that traffic moves over green time and based on that lane 2 timings are optimized.

Figure 4.1: Lane1 Statistical Plot

Figure 4.2: IR Readings and Zone Prediction

V. CONCLUSION

Traffic is one of the major problems faced by the most developed countries. Despite the enormous problem being faced worldwide, almost all the Traffic Management systems are static, i.e. they do not optimize the traffic signals based on current inputs. Our system on the other hand acts as an alternative to this old classical system. This is because on the basis of the current situation of vehicles and traffic zones we have optimized green time, which will be very effective to significantly reduce traffic/ wait time.

This project aims for a smarter city with a smarter and better Traffic Management system that will reduce traffic and thus, contribute in the smooth functioning of day to day activities of people living in that city. Our project is a mini replica of the same. The real specimen, however must be tested thoroughly before using it on a large scale in order to test its compatibility. Thus, our project can be expanded on a large scale using better sensors and other advanced forms of technology.

VI. ACKNOWLEDGEMENT

The author would like to thank his teachers, guides, IT department and everyone who helped him with their guidance, wisdom and support resulting in successful

completion of his project. Also, would like to extend our sincere thanks to all staff in the laboratory for their timely support.

We would like to express our gratitude towards our parents for their kind cooperation and encouragement which helped us in completion of this project.

Smart Wardrobe

Khushi Dave, Ami Desai & Radhika Fichadia
Thakur College of Engineering and Technology
khushidave36@gmail.com, desaiami54@gmail.com, fichadiaradhika2@gmail.com

Abstract — **IoT, i.e. Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology. Smart wardrobe is one of its kind implemented with components generally used in automation to enhance functionality of wardrobe. Although similar systems exist for some inventories resembling wardrobe, various features included in this project are original and aren't present in other systems. These features when comes together results in great user experience when it comes to wardrobes which is never seen before. This project is comprised of either freely available software and IDEs for development of required firmware and apps. Hardware installed is widely available and mostly available at a very cheap price. People nowadays like to shopping and buy clothes. However most of the clothes will be storing inside wardrobe for long time even up to several years. Especially in those countries with high humidity, clothes can easily get molded while putting it aside for long time. Smart wardrobe will help them to manage their clothes inside wardrobe. Besides an attached screen, it can also push all data into cloud and further sync up data with mobile application. User can get suggestion on what to wear today from their phone app base on what event are there in their calendar and also the weather. The application will provide a dashboard to show that which cloth having the highest frequency of wearing and which is never touch for long time.**

Keywords – RFID- Radio Frequency Identification

1. INTRODUCTION

Today, individuals have access to an array of smart applications like smartphones, laptops, smart televisions, refrigerators, microwave ovens, etc. However, there aren't many smart devices for the bedroom department of the house. One prominent and important feature that exists in the bedroom is a wardrobe or closet. In fact, over 80% of the respondents we surveyed agreed to have access to a wardrobe. Smart wardrobe helps users manage their clothes inside their wardrobe. Besides having an attached screen to show the status of each cloth, it can also push all data into a cloud and further sync up data with a mobile application. User can get suggestions on what to wear today from their phone app based on the events in their calendar and the weather. In this thesis project, our goal is to put together a set of technologies into a system that could be used to aid the user in the planning of their clothes. In order to achieve this goal, we need to be able to identify which clothes are worn very often and those which are seldom used. We need to categorize our clothes like Casual, Formal, Dinner Party, Business Party, and Social Function and so on. The application will provide statistics to show the clothes that are being worn frequently and those that haven't been touched for a long time. Application can further suggest the user to sell the unwanted clothes or donate them to charity.

2. PROPOSED SYSTEM

To design a microcontroller (IoT) based Smart Wardrobe that will detect the area of clothing present and thereby, will help us locate the clothing materials easily and hassle-free.

A. BACKGROUND

Girls will tend to buy more clothes than their need and ended keep inside wardrobe for years but never wear it. While buying clothes, girls will be controlled by emotion rather than rational. They will likely buy without thinking and this ended up as a result paying more money and occupied more spaces.

Besides, living in the high humidity and warm weather country such as Singapore, new clothes can easily become moldy and smelly.

The idea integrated IoT units together with mobile app. It is not only an inventory tracking system but an established mobile personal inventory management system. With a better management of clothes, user have a better view on which clothes they wear the most frequent at the same time which is least frequent. This may help them to further decide for those least frequent clothes to either give to friend or make a donation for charity. Nowadays RFID technology is becoming more mature and common. The usage of RFID tag has become very common and even printable using a printer. Also, the RFID reader module become cheaper and cheaper at the same time better performance. This can greatly reduce the set up cost of an inventory tracking system. The system only require one time set up and one time registration of cloth, the rest of the process will be automated. Whenever user taking or putting in a cloth, it will be tracked automatically. Once the data is collected, it can be processed further and analyzed to give user suggestion on what to wear today, which cloth has been ignored etc. This concept simply help user understand what their need and help them to save money for buying clothes or suggest them to make a better arrangement for their unused clothes (donate, exchange or sell).

IMPORTANCE

Nowadays RFID technology is becoming more mature and common. The usage of RFID tag has become very common and even printable using a printer. Also, the RFID reader module become cheaper and cheaper at the same time better performance. This can greatly reduce the set up cost of an inventory tracking system.

The system only require one time set up and one time registration of cloth, the rest of the process will be automated. Whenever user taking or putting in a cloth, it will be tracked automatically. Once the data is collected, it can be processed further and analyzed to give user suggestion on what to wear today, which cloth has been ignored etc.

This concept simply help user understand what their need and help them to save money for buying clothes or suggest them to make a better arrangement for their unused clothes (donate, exchange or sell). As a result, small investment bring user great saving.

B. OBJECTIVES AND SCOPE OF THE PROJECT:

Automatic cloth detection:

Using UHF RFID reader instead of LF RFID reader to completely remove the task of user scanning each item manually one by one. This will prevent many fail cases to occur in smart wardrobe which can occur due to causes like scanning multiple items at once.

1. Can fit perfectly in every house and in daily life of people

2. Automatically manage and perform tasks

3. Providing free time for rest of their chores

4. Liberty from repetitive wardrobe management activities

5. Relieving mental stress Affordable.

C. FEATURES OF THE PROJECT

The Project consists of the following features:

1. Simple drive circuit: The connections and the circuit design of this system is simple hence it is much more convenient to develop.

2. Time saving: the project helps us to save time by doing all the search work with the help of RFID tags.

3. Hassle-free: no mess and untidiness to find the clothes which was In the case of traditional method of finding clothes.

3. DESIGN

PHASES OF PROJECT

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation.

Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and also get a rough picture about what would be our problem definition for the particular project.

Designing: Then we will construct the design of the project and according to that, will list down all the requirements needed for the construction for the prototype of our project.

Implementation: After acquiring the requirements we first developed the connections of the hardware components (Arduino, LEDs etc) and then added the coding part later with help of Arduino data cable to the Arduino.

Phase 2: Testing and Deployment

Testing: After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again. Deployment: After, complete integration and testing of project real time running and operation of the system will be done. User need to check the value.*Subject Learning Outcomes and Contents*

4. ANALYSIS AND PLANNING

A. Feasibility Study

Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation. After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project.

Technical Feasibility: Here one has to test, whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the solution is technically feasible.

Economic Feasibility: As part of this, the costs and benefits associated with the proposed system compared and the project is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So the proposed system is economically feasible.

B. Cost estimation:

Components	Cost
Arduino uno, jumpers, resistors, led,bread board	Rs. 720
RFID-RC522 & RFID tags	Rs. 250
Total	Rs. 970

C. Project planning (Resources, Tools used, etc.)

Hardware Tools:

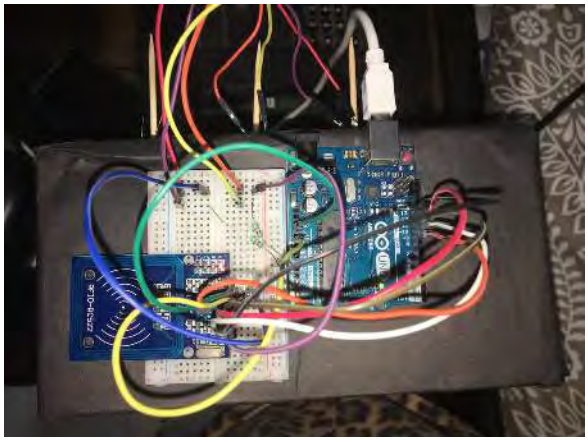
Hardware Components

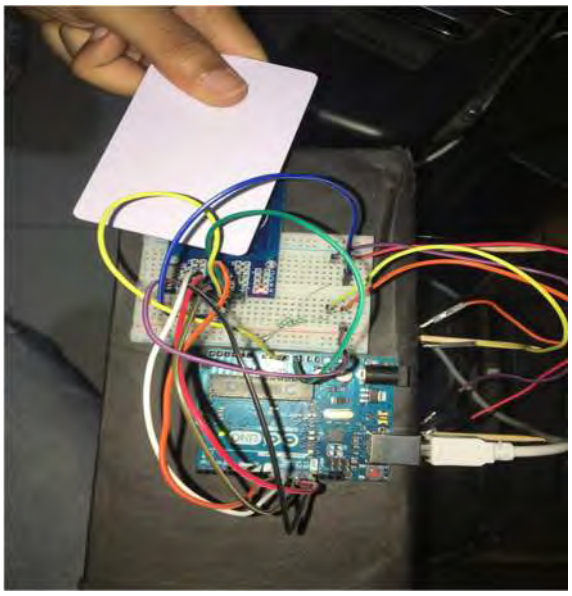
1. Arduino Uno
2. Breadboard
3. Led bulbs
4. Jumpers
5. RFID Reader
6. RIFD Tags
7. Connecting wires

D. Software Tools:

1. Arduino uno
2. RFID Reader

E Result(Expected Ourtcome):





5. CONCLUSION

Thus by this we conclude that the proposed system for smart wardrobe can be used effectively by fashion bloggers, organization etc. Not only an organizer but a normal person can use the system as it is simple to understand. As is, the system may require quite some changes to realize a user experience that would be acceptable but at least we have provided a basis for future research. We have identified challenges and future enhancement.

6. ACKNOWLEDGMENT

We would like to thank subject lecturers (current and previous), education designers and other staff members from the Thakur College of Engineering and Technology who previously designed, developed and taught this subject at various times. The success and final outcome of this project required a lot of guidance and assistance from many people and we am extremely privileged to have completed the project successfully. We would like to thank everyone for their guidance.

Predicting Customer Purchase Behavior on Black Friday

Devesh Varma, Harsh Ramani, Angela Roy, Abhishek Yadav
Third Year, Department of Computer Engineering, Thakur College of Engineering and Technology, India

Abstract- **It is no surprise that businesses spend millions of dollars in carrying out market research before coming up with a new service or product. Despite that, it is important to recognize that the final product doesn't sell itself and actually requires the right marketing tools or personalized marketing to make itself visible to the potential consumers. With millions of buying options at our disposal, the behavior of this era's consumers keeps flickering, and it is important to advertise the right product to the right customer at the proper time.**

The project is built with to accurately predict how much will a user spend on a Black Friday sale given his details. The data for our model is a sample of the transactions made in a retail store. We intend to know better the customer purchase behaviour against different products. Specifically, here the problem is a regression problem where we are trying to predict the dependent variable (the amount of purchase) with the help of the information contained in the other variables.

The features of customer like age, marital status, occupation, Current city, will help us accurately predict the amount he/she will spend on a Black Friday Sale. Root mean square Error (RMSE) is used for performance measure. RMSE is commonly used general purpose error metric.

Key Terms- Black Friday, Shopping, Prediction, Multivariate Linear Regression

I. INTRODUCTION

A. Background

The term Black Friday is known to shoppers and retail- ers in the USA as both the day after the Thanksgiving holiday and one of the busiest shopping days of the year the day is characterized by high demand for retail goods. This makes stores to reduce the price on most of its products in order to attract customers due to increased competition. As a result, many stores offer highly pro- moted sales on Black Friday and open very early, such as at midnight, or may even start their sales at some time
on Thanksgiving. Black Friday is not an official holiday, but some states observe "The Day after Thanksgiving" as a holiday for state government employees, some- times in lieu of another federal holiday, such as Colum- bus Day [1].

Black Friday has routinely been the busiest shopping day of the year in the United States since more than a decade [2].
With the use of recent development in Data Science and Machine Learning we can use the details of a person to find his purchase habits, predict his future purchases and use this to give personalized offers to them. This was not possible a few decades ago where the technology was not as advanced as it was today.

B. Problem Definition

Given a data of users such as Gender, Age, City location, Marital Status, Money spent and products bought, build a model to predict the amount of money he will be spending on a Black Friday sale. The main goal is to accurately predict the amount a person spends and the secondary goal is to predict the major factors influenc- ing his spending habits from the given data.

II. LITERATURE SURVEY

A. Machine Learning for Prediction

Machine learning is a subset of artificial intelligence (AI) which learns from experience with respect to some class of tasks, thereby improving its performace with experience. that provides system the ability to automat- ically learn and improve from experience without hav- ing someone programming it. The main goal of machine learning is to focus on the development of computer programs that can access data and use it learn for them- selves. The process of learning begins with observa- tions, facts, information or data, such as examples, di- rect experience, or instruction, in order to look for pat- terns in data and make better decisions in the future based on the examples that are given by the user. The main goal is to allow the computers learn automati- cally without human intervention, help or assistance and adjust actions accordingly. Machine learning with the help of suitable algorithm enables analysis of large quantities of data. Although it generally gives faster and accurate results, it also requires addition resources such as CPU time and memory time to do the necessary pro- cessing and get accurate results [3].

Predictive analytics is a part of Machine Learning which is mainly driven by predictive modelling. It's more of an approach than a process. Predictive analytics and ma- chine learning go hand-in-hand; as predictive models typically include a machine learning algorithm. These models can be trained over

time to respond to new data or values, delivering the results the business needs. Pre- dictive modelling largely overlaps with the field of ma- chine learning.

There are two types of predictive models. They are Classification models, that predict class membership, and Regression models that predict a number. These models are then made up of algorithms. The algorithms perform the statistical analysis, determining trends and patterns in data and predicting the values based upon them. Predictive analytics software solutions have built in algorithms that is used to make predictive models which help in predicting the most accurate value. The algorithms are defined as 'classifiers', identifying which set of categories data belongs to [4].

B. Multivariate Linear Regression Model

The goal of data analysis is to extract meaningful data or information from raw data with accurate estimation. One of the most important and common question con- cerning if there is statistical relationship between a re- sponse variable (Y) and explanatory variables (Xi). An option to answer this question is to employ regression analysis in order to *model* its relationship. Further it can be used to *predict* the response variable for any arbitrary set of explanatory variables.

Multivariate Regression is one of the simplest Machine Learning Algorithm. It comes under the class of Super- vised Learning Algorithms i.e, when we are provided with training dataset [5].

Multiple/Multivariate linear regression models the rela- tionship between two or more known variables and a re- sponse variable by fitting a linear equation to observed data. Every value of the independent variable/varia- bles *x* is associated with a value of the dependent varia- ble *y*.

Fig. 1 Structure of Input Dataset

The analysis of the Black Friday data set used in this paper includes 12 variables: Product_ID, Gen- der, Age, City_Category, Stay_In_Cur- rent_City_Years, Marital_Status, Product_Cate- gory_1 and Purchase.

This data set is cleaned from the original data set which contained 3 additional variables - Product_Cate- gory_2 and Product_Category_3 Product_Cate- gory_2 and Product_Category_3 contain missing obser- vations which are imputed as zero.

The Black Friday data set is further cleaned by stating the format of each variable. This included chang- ing Product_ID, Gender, Age, City_Category, Mari- tal_Status and Product_Category from character varia- bles to integers. These variables are nominal since they do not have order or a distance metric. 'Age' is ordinal because the age groups are increasing with actual age, but are not equally spaced.

# Marital status versus Average purchase amount ggplot(new_data, aes(Marital_Status, Avg_Purchase_Amount, fill = Marital_Status)) + geom_col() + labs(title = "Marital Status Vs Avg_Purchase_Amount")
```

V. RESULTS AND DISCUSSION

	Actual	Predicted
7	6187	5959.1365
16	15854	15854.9660
32	5293	4370.1015
34	6914	8411.8718
38	7381	7683.1275
47	19614	14659.7044
48	9872	10107.2901
49	19203	18826.6010
54	11877	14204.1258
56	16662	16446.5617
60	10946	12680.8579
64	12642	15482.4698
66	19681	16202.0383
67	8718	8614.0623

Fig. 2 Actual value v/s Predicted values

The Root Mean Squared Error (RMSE) is:

```
> rmse
[1] 1711.175
```

Gender played a major role in the Amount of Money spent. Men spent three times more when compared to Women.

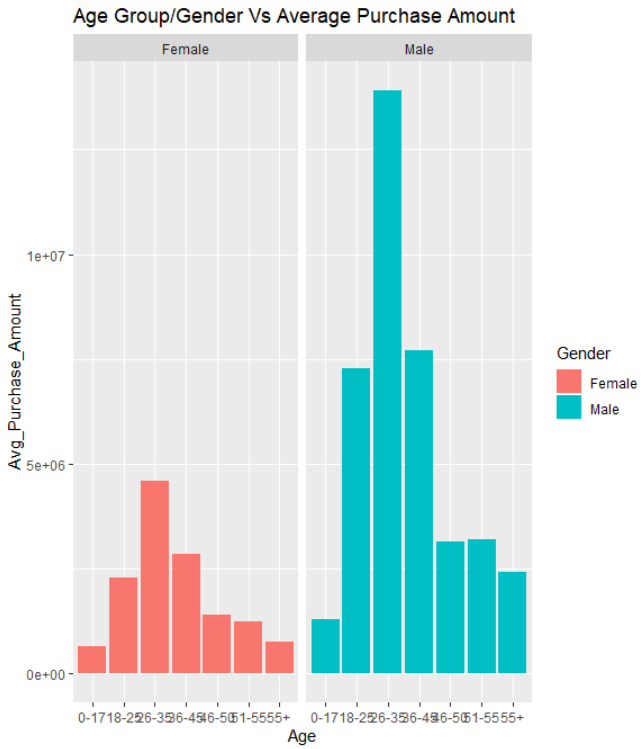

Fig. 3 Graph of Age v/s Purchase Amount

Comparion of which city spent the most money:

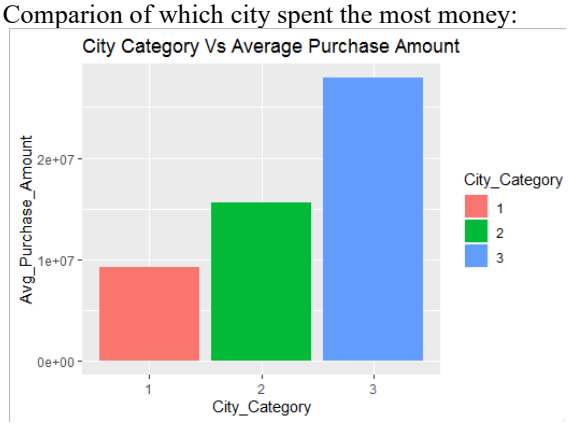

Fig. 4 Graph of City Category v/s Average Purchase Amount

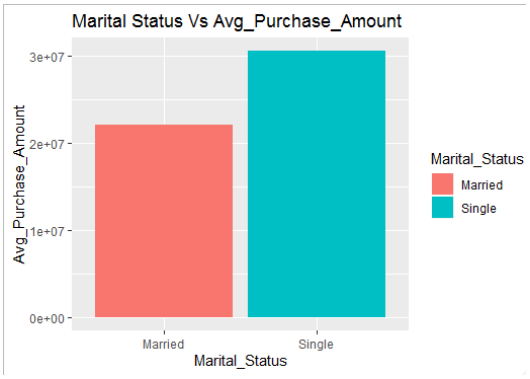

Fig. 5 Relation between Marital Status and Purchase Amount

Thus from our results we have proved some features of a person demographic to decide on how much he spends whereas some features had neglible outcome on the Purchase amount.

Abstract— **In recent years numerous product development and innovations have been used. From the very beginning, waterfall and V-models have been utilized for programming advancement. But currently there is a noticeable paradigm shift in the way in which software is developed. Hence, we need a product development framework which is rapid and developer friendly. This paper provides a systematic description of Rapid Remote Development.**

Keywords—rapid, remote, development, framework, optimize.

I. INTRODUCTION

Emerging startups are getting progressively mindful of the benefit of offering remote work chances to their employees. Contingent upon the kind of work their employees perform, permitting more remote days or time when employees can work remotely from anywhere other than the place of work, for example, at home or from a local café can profit organizations by expanding efficiency and boosting worker maintenance and productivity. The framework centers around the idea of approved learning and the build-measure-learn feedback loop along with the key idea of remote development. It also attempts to acquire a methodical way to deal with estimating the advancement at a startup. Remote employees are in good company, and as the remote workforce grows, so does the data on its efficacy and the potential benefits for business owners

II. WHY REMOTE DEVELOPMENT

A- Increase in productivity

Several employees say that they are more productive when they work remotely, which could be due, in part, to the fact that many remote workers (58 percent) are able to work from home. All things considered, not every person feels incredible after they work off-site. Albeit over a third of representatives studied appear to feel remote situations are additionally unwinding, 30 percent state they experience expanded pressure while working remotely.

Still, 71 percent say the amount of distraction either stays identical or decreases.

B- Positive impact on workers.

When asked if remote work has a positive or negative impact on various areas in a remote employee's life, answers varied. In general, the capacity to work remotely appears to positively affect most significant regions of a worker's life, including life objectives, family, psychological wellness, and accounts.

Figure 1. Effect of remote development on team members

III. ADVANTAGES

As we mentioned, avoiding the commute to work place is the biggest benefit noted by remote workers (46 percent say this can be the most good thing about remote work).

Having control over their schedules, not having to induce ready for work, and therefore the ability to sleep longer are also benefits. Meanwhile, 28 percent of respondents say having the flexibility to look after their kids could be a good thing about working from home, while just over 25 percent say watching their pets is an important benefit. When received some information about remote work, most of the telecommuters gave it either four or five stars.

1- You're more likely to stay long term

Probably the greatest bit of leeway of remote work is that you're ready to deal with the majority of what life tosses at you—including the moments that might have previously put your position in danger. Going back and forth between work and home feels like a major stressor. Not so with remote work. A laptop means you can work from home and even on the road. Remote occupations additionally imply that in case you're thinking about maternity leave or your partner finds a new line of work in an alternate city, you don't need to forfeit the activity you love for the individual (or future little individual) you love.

2- You'll have more time for deep work

A study came out that proved that work interruptions cost you up to six hours a day. Working from home or a place where you don't have the foggiest idea about the individuals around you implies more clarity of mind. Another reward: remote work is based on the conviction

that you'll complete your work, not that you have to sit for precisely 40 hours every week. The result is that you'll concentrate on quality not amount, which is useful for everybody including the organization.

3- You'll learn some seriously impressive communication skills

One could contend that it's a lot harder to communicate when you work remotely, yet we would really oppose this idea. Working remotely implies that correspondence is everything. It's promptly clear when the manner in which you're communicating isn't working, and you'll be compelled to fix issues much more rapidly. You're going to significantly improve each technique from how you present plans to how you voice disappointments about a collaborator.

4- You'll feel healthier

A recent report from the University of Minnesota found that work environment flexibility brought down pressure and the danger of burnout. So that's better emotional wellness. Individuals driving to workplaces announced that they were less inclined to exercise and healthy eating, telecommuters don't have those hindrances.

IV. CHALLENGES OF REMOTE WORK.

Among some of the contrary difficulties looked by the working from home workforce is the affinity to work more hours during a day. A little more than 29 percent state this is their top test. About a similar level of respondents state individuals accepting they aren't really working while they work remotely could be a significant test, and more than 26 percent refer to inspiration as their greatest test. Other big challenges for remote workers include disconnecting from work, loneliness, and bad internet connections. On the other side, some employees stated one issue with remote work was having the ability to trace employees time worked. While some people struggle with eliminating distractions and specializing in completing their work tasks, others have a tough time unplugging at the end of the work day. When you work from an office, the end of your day is when everyone goes home. Once you work remotely, it can be difficult to disconnect and step away from work when you know there are pending tasks, and although occasionally it's going to be important to relinquish the additional mile at work, making a habit of it can be detrimental to your health and cause you to burn out. If you're someone who likes indulging in gossip around the water cooler, occurring lunch dates, and meeting new people around the office, working remotely might not be for you. While you'll still meet with and interact with clients, many of those conversations take place over phone calls or video chats—not a conference room or coffee shop. To be sure, those living the cubicle life often complain of distractions within the form of regular interruptions, but sometimes distractions are preferable to isolation! If you're working remotely for yourself, you'll be tasked with finding leads, pitching, and shutting prospects, then doing the particular work, taking care of finances, and managing your time—all without the oversight of a boss or the help of another department.

V. TIPS FOR SUCCESSFUL REMOTE DEVELOPMENT

1- Hire trustworthy people to work remotely

In case you're addressing whether you can confide in your group to work remotely, you should be addressing whether you made the correct decision by employing them. The primary question to pose when hiring people is 'do I trust you to work remotely' and if the response is 'no' the meeting stops there. Regardless of whether your group is office based or not, just recruit individuals you trust to work remotely, independently and still reach the goal.

2- Make uncompromising collaboration and communication Every single effective group needs consistent correspondence and joint effort and remote teams are no exemption. You have to double-check that everybody in your group comprehends why they have to impart and work together with their associates and watch out for any individual who's especially calm. Make discussion as open as possible, stick to open channels of communication to give that buzz of work and progress you'd get if your group were in an open office.

3- Provide the means to make it happen

In the event that you need a remote group continually imparting and teaming up, you need to give them the tools to get it going. At Hired By Startups, we utilize an assortment of interior and outside apparatuses however the primary ones are Slack (for all inner correspondence),

Google Meet (Hangouts – for video calls), Google Docs and Sheets and Trello.

4- Daily Updates

Perhaps the greatest danger of building a remote group is that everybody is engaged in their own work with zero ability to see into what others are really going after. To battle this, we have a day by day standup (on Google Meet) where everybody examines their earlier day's accomplishments and focuses for the day. It's quick and reminds everybody that they are a team. After the standup, the group is urged to catch up

straightforwardly with one another on explicit questions to guarantee there's a steady progression of data and everybody is completely updated on what they are taking a shot at as an organization.

developer can remotely work from. It employs a technique that has a business model, a product road map, and a view of partners, competitors, and customers. The product is the result of the strategy. Products constantly change (improve). Strategy changes occasionally (evaluate). Vision rarely changes. Normally management, failure to deliver results is caused by failure to plan or failure to execute. Both are frowned upon. But within the modern economy, both are useful tools for testing new ideas. It carries with it 3 major stages namely: Build, Launch, Improve. We will have a look at each of these steps thoroughly.

5- Create ways to meet in person

Getting time together and getting to know other employees is indispensable. You can have the best remote group on the planet yet nothing beats some time in person. You can organize a few days a month where you come together and collaborate in person. For groups that are more geologically disseminated , you should attempt to meet for at least one week of the year, regardless of whether that is in one go or maybe two collective ends of the week.

1.Build:

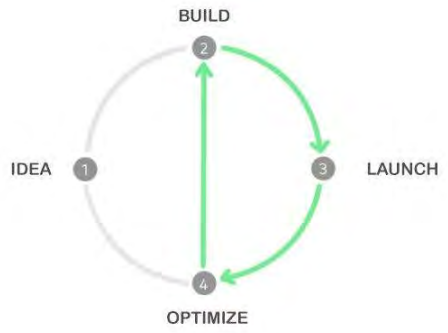

Figure 2: Development cycle of R2D

6- Get to know each other personally

Your remote group will be more productive when they truly know each other personally – passion, leisure activities and non-professional life. As far as we can tell, the best two mechanisms for personal conversation are food and drink. There can be days where the entire team sit together for some essential "team-building". If gathering week after week is beyond the realm of imagination, you could take a stab at doing this over video chat (Google Meet) – it'll likely work similarly!

7- Smart work strategy and management

The most important thing gained from driving a remote group, it's that the indispensable elements for progress (trust, correspondence, coordinated effort) don't simply occur – they're the result of a well-executed remote working technique and management. You need to show others how its done and put forth a cognizant attempt to support remote working if it will work for your startup.

VI. WORKING:

R2D method proposes incremental and iterative approach to software design which is broken into individual models that

- Understand Requirements:

Realizing an approach to assemble prerequisites might be an aptitude that each investigator, and venture director, – ought to have. Nonetheless, it is by all accounts an expertise that is commonly ailing in numerous associations. Poor prerequisites social occasion might be a significant clarification for venture issues in numerous associations. Social event necessities are over simply posing a few inquiries and afterward continuing to the accompanying advance inside the lifecycle. The essential piece of the fast remote advancement requires welcoming the correct individuals to share business objectives, innovation capacity, and client need. The objective of this stage is to extend the comprehension of the item or undertaking. This is the place the prerequisites are first accumulated. To inspire precise prerequisites, the investigator must pose the correct sort of inquiries and afterward listen cautiously to the appropriate responses. There are various strategies for inspiring prerequisites and your task may need to utilize different methods relying upon the conditions. This incorporates interviews, encouraged sessions, models, polls and that's only the tip of the iceberg.

- Distribution:

It is counterintuitive, but smaller batches are far better for progressing through a project quickly and efficiently while working remotely. They seem inefficient but allow faster turnaround for the product resulting in a more rapid iterative cycle. It helps in earlier detection of a controversy additionally as quick feedback from the customers. Toyota utilized the little bunch way to deal with contend with its somewhat more promoted American partners whose cluster sizes were generally greater.

- Evaluation:

This framework is focused on rapid software development while working with remote employees, so the progress evaluation of teams is done on outcome basis. THere is no track of how many hours an employee has worked. Only the outcomes achieved are used to measure the progress of remote teams, it develops an outcome based state of

mind which is useful for developers for long run by keeping the milestones in mind which is self-motivating. Weekly code review and progress evaluation is conducted by using various tools like Chat and collaboration tool (Google Hangouts, Slack, etc.), Video calling, Screen sharing, Project management system (Asana, Wrike, etc.), Automated onboarding software, HR software with employee self-service, Recognition and reward system. Putting processes in place and managing projects in a way that you can involve remote employees easily is an easy way to manage teams remotely.It's extremely hard to feel like you are passing up a great opportunity since you're not in the workplace. What causes the separation between colleagues to feel like separation is the absence of correspondence. On the off chance that you message someone who lives hours away and they don't react for a few hours, I'm going to wish we worked in a similar room so we didn't need to manage that. Be that as it may, on the off chance that each time I message them, they react quickly, at that point it's simply equivalent to in the event that we were both in the workplace together.

2.La
unch
:

Every business plan begins with a collection of assumptions. It spreads out a procedure that acknowledges those assumptions as ensured and keeps on pointing out a way to deal with achieving the association's vision. Since the doubts haven't been wind up being substantial (they are assumptions, taking everything into account) and in truth are often erroneous, the target of a startup's underlying undertakings should be to check them as quick as could be normal the situation being what it is.

- Minimal prototype:

A minimal prototype helps developers start the method of improving as quickly as possible.It isn't really the littlest item possible, however; it is basically the quickest method to get past the remote fast improvement cycle with the base measure of exertion. In spite of conventional advancement, which ordinarily includes an extended , attentive timeframe and takes a stab at item flawlessness, the objective of the negligible model is to begin the strategy for improving, not end it. A negligible model is implied not simply to answer item plan or specialized inquiries. Its will probably test central business theories.

- Prototype complexity:

Least model range in unpredictability from incredibly straightforward smoke tests (minimal in excess of a commercial) to real early models total with issues and missing highlights. Deciding exactly how complex a minimal prototype needs to be cannot be done formulaically. It can be done by judging different factors like urgency of deployment, lack of technical requirements from customers or simply faster optimization.

3.Opti
mize:

Before development, a project is little more than a model on a piece of paper. The financials in the marketable strategy incorporate projections of what number of clients the organization hopes to pull in, the amount it will spend, and how much income and prot that will prompt. It’s an ideal that’s usually far from where the product is in its early days. In optimization, we thoroughly measure where it is at this moment, standing up to the hard facts that appraisal uncovers, and afterward devise trials to figure out how to draw the genuine numbers nearer to the perfect reflected in the undertaking plan.

- Baseline metric:

Once the minimal product has been established, the developing teams can work toward the second learning milestone: optimization. Each advancement, advertising, or other activity that a startup attempts ought to be focused at improving one in everything about drivers of its development model. For instance, an undertaking group or organization may invest energy improving the vibe of its item to make it simpler for new clients to utilize. This assumes the enactment pace of late clients could be a driver of development and that its pattern is less lower than the organization would truly like. To exhibit approved learning, the plan changes must improve the actuation pace of new clients. In the event that they don't, the new structure ought to be passed judgment on a disappointment. This can be a

crucial principle: a great structure is one that improves client conduct. It sets out with an unmistakable benchmark metric, a speculation about what will improve that measurement, and a lot of analyses intended to test that theory. Over time, a team that’s learning its way toward a more robust working product will see the numbers in its model rise from the horrible baseline established by the minimal prototype and converge to something just like the ideal one established within the software project design plan.A startup that neglects to do so will see that perfect retreat ever more remote into the separation. At the point when this should be possible right, even the preeminent ground-breaking reality mutilation field

won't have the option to conceal this basic certainty: in case we're not moving the drivers of our plan of action, we're not gaining ground. That turns into a definite sign that it's time to pivot.

- Optimization siliency:

Engineers, designers, and marketers are all skilled at optimization. As an example, direct marketers are experienced at split testing value propositions by sending a distinct offer to two similar groups of consumers so that they can measure differences in the response rates of the two groups. Engineers, of course, are skilled at improving a product's performance, even as designers are talented at making products easier to use. Notwithstanding, these apparatuses for item improvement don't work the indistinguishable route for new companies. In the event that you are building an inappropriate thing, improving the item or its advertising won't yield noteworthy outcomes. An undertaking group needs to quantify progress against a high bar: proof that a manageable business can be worked around its items or administrations. That is a standard that can be surveyed just if a startup has clarified, substantial forecasts early. Without those forecasts, item and system choices are undeniably progressively troublesome and tedious.

- Pivot or Preserve:

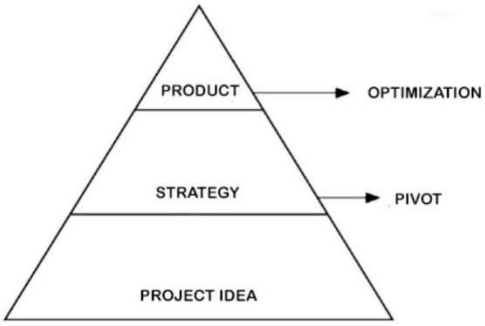

Figure 3: Pivot & Optimize

Each project team in the long run faces a superseding challenge in building up a fruitful item: choosing when to rotate and when to continue on. Everything that has been talked about so far is a preface to an apparently basic inquiry: would we say we are gaining sufficient ground to accept that our unique key speculation is right, or do we have to roll out a significant improvement? That change is known as a turn: an organized course rectification intended to test another basic speculation about the item, procedure, and motor of development. The choice to turn requires a reasonable look at and target mentality. We've examined the indications of the need to turn: the diminishing adequacy of item explores and the general inclination that item improvement ought to be increasingly profitable. At whatever point you see those side effects, think about a rotate. There are many ways to pivot based on observation and customer feedback. A popular feature can become a new product, or a less popular product may become only one of the features of the new product. Adding new features based on customer needs, Or changing product from a single-user product to a multi-user platform. New customers come from the actions of past customers. They inform others, end up showing the product to others, or end up purchasing the product again.

VII. CONCLUSION

Remote development environments, such as those provided by code-server and therefore the Google Cloud and Microsoft Azure Cloud Shell code editors, provide users with multiple benefits over local development environments. They can be connected to from anywhere, standardized across your team, and scaled to satisfy your performance needs. All of this can be accomplished with little to no changes to your existing development flow. To summarize, working remotely as a developer can be an incredible journey. Years full of professional learning, travel, connections, and new experiences. This reflection is solely based on the developer's own experience, so it can differ from someone else working remotely. People like the lifestyle and freedom they have, but it could change in the future. Their eventual goal is to become financially independent so they can spend their mental energy on things that they deeply care about. It has become the North Star that guides them forward and gives motivation. Developers see the path that can take to achieve that goal.

Home Automation

Raj Jaiswa, Rajesh Gupta, Shubham Gupta
raj.jaiswal053@gmail.com, rajeshgupta828230@gmail.com, shubhamssg19@gmail.com

Abstract— **IoT, i.e. The main objective of this project is to develop a home automation system using an Arduino board with Bluetooth being remotely controlled by any Android OS smart phone. As technology is advancing so houses are also getting smarter. Modern houses are gradually shifting from conventional switches to centralized control system, involving remote controlled switches. Presently, conventional wall switches located in different parts of the house makes it difficult for the user to go near them to operate. Even more it becomes more difficult for the elderly or physically handicapped people to do so. Remote controlled home automation system provides a most modern solution with smart phones. In order to achieve this, a Bluetooth module is Interfaced to the Arduino board at the receiver end while on the transmitter end, a GUI application on the cell phone sends ON/OFF commands to the receiver where loads are connected. By touching the specified location on the GUI, the loads can be turned ON/OFF remotely through this technology. The loads are operated by Arduino board through opto- isolators and thyristors using triacs.**

Keywords – Home Automation; Internet of things(IoT); Smart home; Arduino; Microcontroller

I. INTRODUCTION

or automatic control of a few lights, or it can be a complete system that controls all major parts of your home, custom set to your own personal preference. Home automation is anything that gives you remote or automatic control of things around the home.

The concept of home automation has been around for a long time, especially in sciencefiction that imagined future homes being completely automated and robots helping us with household chores. The technology hasn't been available to make these fantasies into reality - until now! Before you can have smart appliances, you have to invent the appliances themselves! Between 1901 and 1920 there was a rapid development in domestic apparatus, kicked off by the invention of the engine-powered vacuum cleaner. After this, came the advent of refrigerators, washing machines, irons and toasters to revolutionise the lives of domestic maids - but these were still too expensive for most households to afford. As technology becomes more and more affordable, and with the majority of western populations having home internet and a smart phone, smart technologies are slowly integrating into our homes. Today, the focus is on convenience, security and energy efficiency through connectivity and interactivity.

II. LITERATURESURVEY

This project is one of the important Arduinos Projects. Arduino based home automation using Bluetooth project helps the user to control any electronic device using Device Control app on their Android Smartphone. The android app sends commands to the controller - Arduino, through wireless communication,namely, Bluetooth. The Arduino is connected to the main bluetooth and relay which has five 8 channel as shown in the block diagram. These relays can be connected to different electronic devices. Home automation is anything that enables you to use your home's lighting, heating and appliances more conveniently and efficiently. It can be as simple as remote or automatic control of a few lights, or it can be a complete system that controls all major parts of your home, custom set to your own personal preference. Home automation is anything that enables you to use your home’s lighting, heating and appliances more conveniently and efficiently. It can be as simple as remote A literature review collects scholarly publications, books, dissertations, conference proceedings, and other tools related to a particular issue, study area, or theory, and provides context for a dissertation through the analysis of past research. Research tells a story, and existing literature helps us figure out where we are in the story at the moment.

A literature review surveys scholarly articles, books, dissertations, conference proceedings and other resources which are relevant to a particular issue, area of research, or theory and provides context for a dissertation by identifying past research. Research tells a story and the existing literature helps us identify where we are in the story currently. It is up to those writing a dissertation to continue that story with new research and new perspectives but they must first be familiar with the story before they can move forward.

Analysis: Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation. Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project. Designing: Then we will construct the design of the project and according to that, will list down all the requirements needed for the construction for the prototype of our project. Implementation:

After acquiring the requirements we first developed the connections of the hardware components (Arduino, MQ2 sensor, DHT11 sensoretc) and then added the coding part later with help of Arduino data cable to the Arduino.

Phase 2: Testing andDeployment.

Testing: After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again. Deployment: After, complete integration and testing of

project real time running and operation of the system will be done. User need to check the value.

Arduino uno

The Arduino Uno is an open-source microcontroller board based on the Microchip ATmega328P microcontroller developed by Arduino.cc. The board is fitted with digital and analog input / output (I / O) pin sets that can be interfaced with different boards of expansion (shields) and other circuits.The board has 14 Digital pins, 6 Analog pins, and can be programmed with the Arduino IDE (Integrated Development Environment) via a Type B USB cable. It can be powered by a USB cable or an external 9-volt battery, although it supports voltages from 7 to 20 volts.

III. Hardware Tools PROJECT PLANNING (RESOURCES, TOOLSUSED, ETC)

Quantity	Hardware Components
1	Arduino uno
1	8 channel relay module, 5v power supply
1	hc-05 bluetooth module, Any smartphone
12	Jumper wires

Software Tools:

Fig 3.1:Arduino Uno

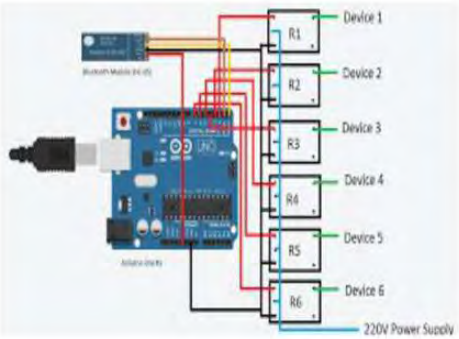
Relay circuit(8 channel):

Relays are switches that open and close circuits electromechanically orelectronically. Relays control one electrical circuit by opening and closing contacts in another circuit.. When a relay contact is Normally Closed (NC), there is a closed contact when the relay is not energized.

Bluetooth module (hc 05):

(Serial Protocol) module, designed for transparent wireless serial connection setup. HC-05 Bluetooth module provides switching mode between master and slave mode which means it able to use neither receiving nor transmitting data.

Circuit Diagram:



IV. DESIGN AND IMPLEMENTATION

- Connecte jumper wires and assemble adruino using circuit diagram.
- Connect Bluetooth module.
- Connect smart phone with bluetooth module and install application.
- Connect electrical appliance to the Relay module.
- Once done above steps, you can operate various appliances.

V. RESULTS

The adruino is given a code to operate on commands recieved via bluetooth module. This bluetooth module is connected with a smart phone. The smart phone has

installed an application to control 8 equipments. Using the application user can send commands which will be received by HC-05 bluetooth module which will execute instruction on adruino and gives us desired results.

A low cost and efficient smart home system is presented in our design. This system has two main modules: the hardware interface module and the software communication module. At the heart of this system is the Arduino Mega 2560 microcontroller which is also capable of functioning as a micro web server and the interface for all the hardware modules. All communication and controls in this system pass through the microcontroller

VII. IMPROVEMENT SINRE SEARCH G APS (FINDINGS)

- Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows: Proposals are made to design and build intelligent home meeting the modern requirements satisfying most living standards of consumers. Home security activities supported by real time audio visual system which

  permits only the entry of authorised visitors into the flat are incorporated in the system. Easy handling of selected home appliances in the flat by switching ON or OFF from any room is provided in the system. Moreover, remote control of these selected appliances are performed through telephone dialling or with Internet are accommodated in the system. A Home Assistant system software installed in the PC brings the daily activities to the monitor screen as obtained from the activities programmed in tables of data bases.

- The electrical energy requirements of the flats are partially supported by a unit extracting solar energy and wind energy. Saving of electrical energy by this unit is maximised by automatically changing the angles of the solar panel and wind mill fixed on the terrace. Furthermore, intruder detection unit included in the system dials automatically a pre-programmed sequence of digits to give message to a remote location while triggering a local alarm.

VIII. FUTURESCOPE

Home of the future is a space for the digital natives. With the invention of lots of automation technologies featuring IOT and AI, home automation has become a reality. One can implement several of their tasks with just a single command of verbal instructions. These technologies can used to build fully functional home automation system and control smart home devices including smart lights, connected thermostats, and appliances.

• Smart spaces outside homes: Smart parking through sensors will help to recognize whether the parking is available or not. Camera monitoring can be done and with the help of artificial intelligence and computer vision, both parking facilities and security can be provided. It would be a faster and smoother process and act as a reference for other smart systems to be build accordingly. Streetlights can also be automated through sensors and build for effective use for the people nearby.

Personal home delivery: Drones will be used to deliver the packages at the right time. They will replace the normal salesman job. They might also be used for several other tasks like monitoring the weather outside the home, returning something back to a relative's home nearby and so on. They can also be used for monitoring the traffic in our locality

The home automation system has been experimentally proven to work satisfactorily by connecting sample appliances to it and the appliances were successfully controlled from a wireless mobile device. We learned many skills such as soldering wiring the circuit and other tools that we use for this project and was able to work together as a team during this project. The Bluetooth client was successfully tested on a multitude of different mobile phones from different manufacturers, thus proving its portability and wide compatibility. Thus a low-cost home automation system was successfully designed, implemented and tested.

Automatic Medicine Reminder Machine

Akash Jangid, Asmit Juneja, Bhaarat Kotak

Thakur College of Engineering & Technology

jangidakash286@gmail.com, asmitjuneja333@gmail.com, kotakbhaarat@gmail.com

Abstract— **IOT, i.e. Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology Recent years have seen a rising in wearable sensors and today several devices are commercially available for personal health care and activity awareness. A recent health care system should give better health care services to people at any time anywhere in an affordable and patient friendly way. Currently, the health care system going to change from a traditional approach to a modernized patients centred approach. In the traditional way the doctors play the major role. For necessary diagnosis and advising they need to visit the doctor. There are two basic problems related to this approach. Firstly, the health care professionals must be in place of the patient all the time, the patient remains admitted in the hospital, wired to bedside biomedical instruments, for a long period. In order to solve these two problems the patient oriented approach has been received. Recent information from United Nations predicted that there will be 2 billion older people by 2050. In addition, research indicates that above 89% of the aged people are likely to live independently. However, medical research found that above 80% of the aged people older than 65% suffers from at least one chronic disease making them to have difficulty in taking care of themselves. Accordingly, providing a decent quality of life for aged people as become a serious social issue at that moment. The rapid proliferation of information and communication technologies is enabling innovative healthcare solutions and tools that promise in addressing the above challenges. Now, Internet Of Things (IOT) has become one of the most powerful communication paradigms of the 21st century. In the IOT environment, all objects in our daily life become part of the internet due to their communication and computing capabilities. Heart rate is one of the fundamental physiological limits, essential for monitoring and diagnosis of patients. To keep people effective and healthy, a readily accessible modern health care system is proving to be effective in saving costs, reducing illness and prolonging life. In this paper, an enhanced healthcare monitoring system is described, that is smart phone based and designed to offer wireless approach and social support to participants. After studying the literature survey it was planned to overcome the research gaps and the system was tested using the test cases and then the outputs were generated. The output of the gas detectors were been shown according to different test cases and thus the gas detection and sms alert system become more responsive then those currently in use**.

Keywords – Internet of things.

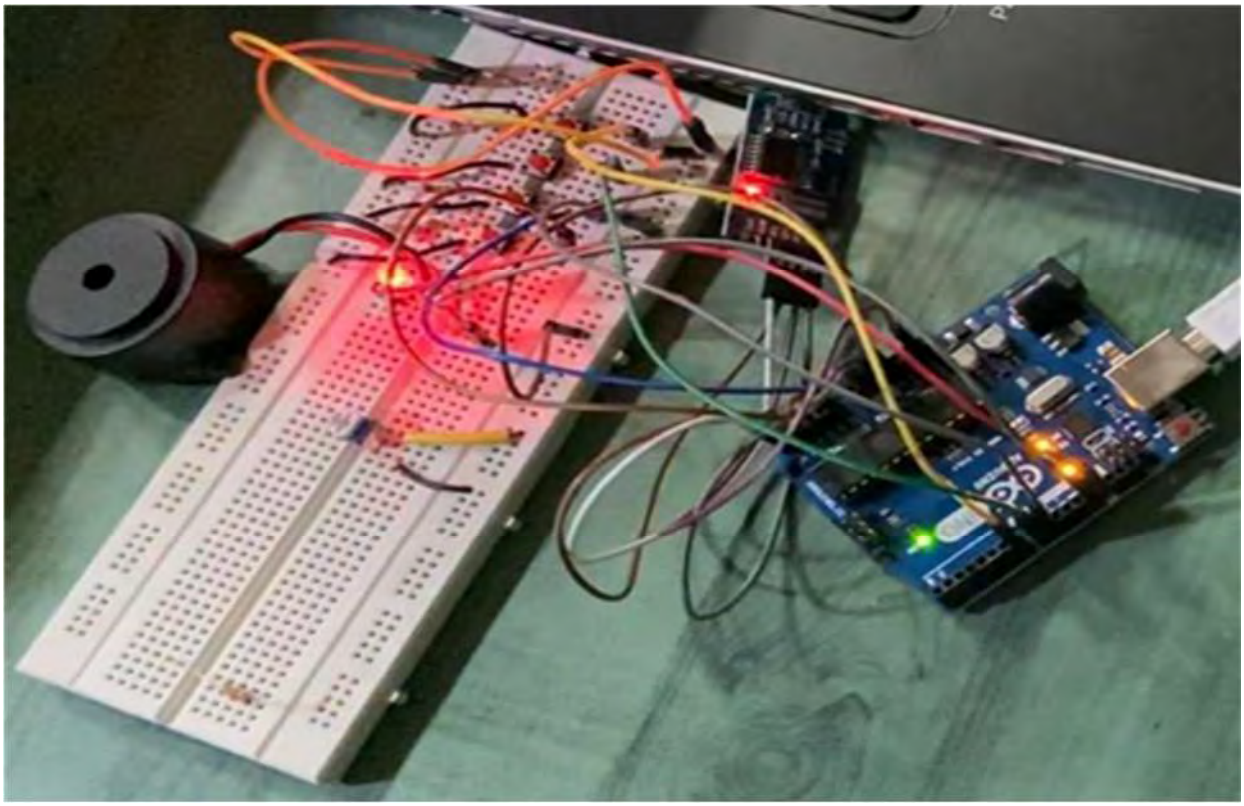
I. INTRODUCTION

Many medical errors are due to the fact that people in charge of patient or elders medication have to deal with sorting huge amounts of medicine each day. There are a lot of people who actually need help on daily basis – may it be our elderly people, family members, relatives, the ones who have special needs. Elders are more affected by the timing of taking a certain medicine as compared to others, in order to prevent any dysfunction or illness timing is a must. Automatic Pill Reminder Bottles Invented and patented in 2004 by innovator and inventor Joseph Lai the pill reminder bottle. This device is compatible and can be retrofitted inside a regular conventional pill bottle cap hence making it easily portable. This reminder device is installed inside the conventional pill bottle between the bottle cap and the bottle container. When the user closes the pill bottle cap on the bottle container, the electronic timer, with factory predetermined time interval, is automatically activated. That activated timer will generate alert signals not only remind user last pill has taken but also to remind the user to take his/hers next medicine on timely baisis. David P. Wagner invented the first pill organizer.Wagner was prompted to invent the device when he and his wife had trouble remembering if she had taken her daily pill. The application of Smart Medicine Reminder machine can be used worldwide at any time irrespective of the climatic conditions. When it comes to our loved ones, we always want to them to stay fit and healthy. But what will happen if they get ill and forget to take medicine on time. We become worried when people who are close to us forget to take medicine on time. At hospitals, there are many patients and it is difficult to remind every patient to take medicine on time. The traditional ways require human efforts to remind to take medicines on time. The digital generation doesn't follow that and we can use smart devices/machines to do that. The application of Automatic Medicine Reminder is a smart, very wide and can be used by patients at home, doctors at hospitals and at many other places. When it comes to reminding it is accurate and fast. Being light in weight it is easily portable.

II. SUBJECT DESIGN AND CURRICULUM

Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation. After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project. Here one has to test, whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the

solution is technically feasible. As part of this, the costs and benefits associated with the proposed system compared and theproject is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So the proposed system is economically feasible.

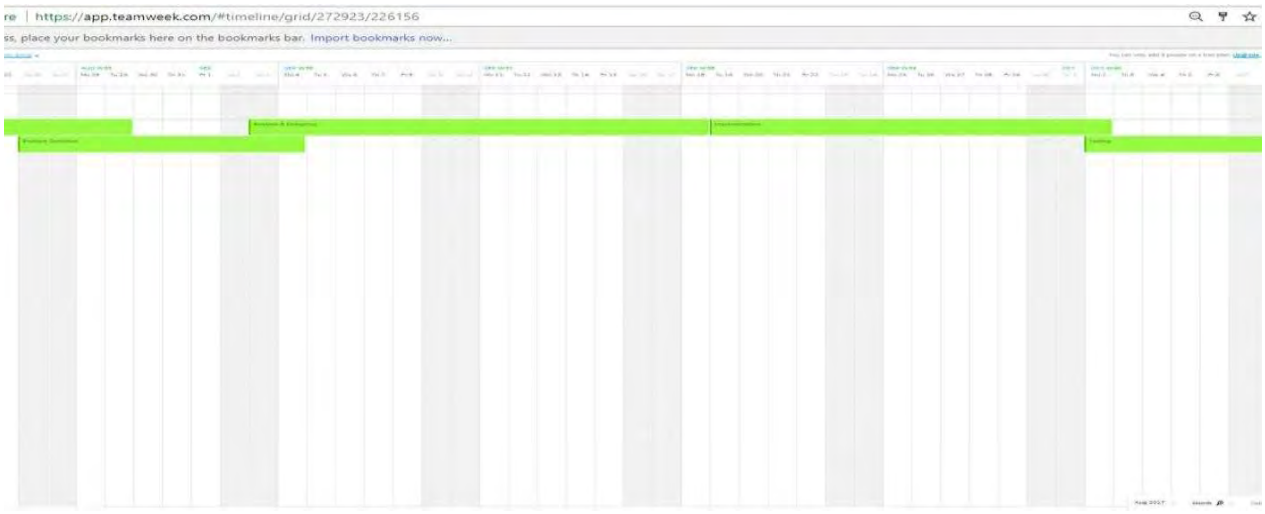


A. Subject Learning Outcomes and Contents

There are many systems which are helping for the same purpose. But these systems are problematic to use, non-mobile, expensive and complex process. The proposed system overcomes these problems. The 8051 Based Medicine Reminder is simple to use, affordable, better accuracy. This system is co-operative for every age group and can also be used in hospital for a group of people. This system will definitely reduce the bad effect caused due to wrong intake of medicine. This project in future may be more desirable via integrating it with GSM technology, in order that the affected person gets a reminder approximately the medication he has to take via SMS on his/her mobile phone. Also a provision to change the name of the drugs can be included by means of interfacing the device with a PC or EEPROM (non-volatile memory).

B.Subject Delivery

Table 1-Gantt Chart



The proposed method takes an automatic control action upon detection of time intervals of medicine. Initially if a delay is detected then the electronic sensor i.e. the buzzer that obeys the principle of sensor senses the delay, if any delay in timing is sensed then the output of this sensor goes high. This high signal is monitored by the microcontroller and it will identify the amount of delay occurred in taking the medicine . If there is a delay , the consumer is informed about it through the LED light and Sound of the buzzer.A Gantt chart is shown in Figure 1.

C. Components required

The Arduino UNO is an open-source microcontroller board based on the Microchip ATmega328P microcontroller and developed by Arduino.cc.[2][3] The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits.[1] The board has 14 Digital pins, 6 Analog pins, and programmable with the Arduino IDE (Integrated Development Environment) via a type B USB cable.

The **DS3231** is a low-cost, extremely accurate I2C real-time clock (**RTC**) with an integrated temperature-compensated crystal oscillator (TCXO) and crystal. The device incorporates a battery input, and maintains accurate time keeping when main power to the device is interrupted.

GSM/GPRS module is used to establish communication between a computer and a GSM-GPRS system. It requires aSIM (Subscriber Identity Module) card just like mobile phones to activate communication with the network. Also they have IMEI (International Mobile Equipment Identity) number similar to mobile phones for their identification.

LCD modules are vey commonly used in most embedded projects, the reason being its cheap price, availability and programmer friendly. Most of us would have come across these displays in our day to day life, either at PCO's or calculators. The appearance and the pinouts have already been visualized above now let us get a bit technical. **16×2 LCD** is named so because; it has 16 Columns and 2 Rows. There are a lot of combinations available like, 8×1, 8×2, 10×2, 16×1, etc. but the most used one is the 16×2 LCD. So, it will have (16×2=32) 32 characters in total and each character will be made of 5×8 Pixel Dots.

III. SCOPE OF THE PROJECT , UNDERSTANDING ,RESULT AND DISCUSSION

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too.As this system is currently not Wi-Fi based also there is no message to doctor via sms or email. This system only rings when there is time to take the medicine ,basically it rings after particular intervals of time but cannot show the exact time as shown in a clock. Also, the Potentiometer The major disadvantage is that it requires a large force to move their sliding contactsFurher we can use Lcd screen and also In Built voice Command which will make the system more accurate and attractive.

There are many systems which are helping for the same purpose. But these systems are problematic to use, non-mobile, expensive and complex process. The proposed system overcomes these problems. The 8051 Based Medicine Reminder is simple to use, affordable, better accuracy. This system is co-operative for every age group and can also be used in hospital for a group of people. This system will definitely reduce the bad effect caused due to wrong intake of medicine. This project in

future may be more desirable by making use of LCD and also by inserting In Built Voice Commands . These changes will make the machine more advanced as well as attractive.

A. UNDERSTANDING

In this after understanding the topic the project feasibility was analyzed by performing different types of feasibility studies and by also planning the project tools, their project schedule, timeline charts, etc. Feasibility study will help in better understanding the various feasibilities associated with the project and helping to make the correct decisions and completing the project within the schedule, budget, etc.

The tools were specifically identified in this chapter stating which technology can be feasible and how conveniently the project can be completed. This helps to understand the technology and tools that can be used for the project. The Gantt chart helps us to track the project and see the schedule of the project and to see if the project is on the right track and on schedule and not behind the deadline

B. RESULT AND DISCUSSION

Creating the synopsis, literature survey and feasibility study for proposed solution which will act as an input to the design phase.

Proposing Statement of work, scope definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done.

Proposing design and architecture for the prototype.

Implementation of the Arduino model with the help code running it in the Arduino IDE environment.

Testing was done with cases like medicine taken to test the buzzer, taking the medicine on time and the testing was done in a clinic under doctors guidance.

Real time sensing was done when in the doctor's clinic when a patient had to take the medicine and it was already time for him to take it and the buzzer reacted

IV. CONCLUSION

We have successfully shown the Medicine Reminder Machine by IOT based project is possible that patients can take medicine on time and the alarm so loud such that even the sound of it can be heard in areas where huge amount of noise is produced. It helps doctors, nurses and the caretakers for speedy recovery of the people .Being cost effective and light in weight it can be useful to everyone in the society.

ACKNOWLEDGMENT

The success and final outcome of this project required a lot of guidance and assistance from many people and I am extremely privileged to have completed the project successfully. I would like to thank everyone for their guidance.

We sincerely thank our principal, Dr.B.K.Mishra and HOD, Dr.Rajesh Bansode for always encouraging us to do our best. We highly indebted to our guide Dr. Sangeeta Vhatkar, who supported and constantly supervised us throughout the project and helped us in not only completing this project but also provided us with ample amount of knowledge that was really beneficial to us.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staffs of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their timely support.

We would like to express our gratitude towards our parents for their kind co-operation and encouragement which helped us in completion of this project.

Student Grievance Support System

Bimalesh Seth, Darsh Shetty, Vidhi Rana, Vikas Tiwari, Hardik Sodhani, Kavin Parikh
Department of Information Technology, Thakur College of Engineering and Technology, Mumbai
sethbimalesh@gmail.com, hettydarsh002@gmail.com, vidhidrana20@gmail.com, v8kgsm@gmail.com, hardik.sodhani@gmail.com, kpk1611@gmail.com

Abstract – **The goal is to design an online system which fetches the grievances from the users, categorizes it in a proper headings/tags and shows it to the admin. The complaints are safe/secure and the identity of the complaint is not revealed to any other user. The Online Grievance management system also shows the status of the complaint and the kind of action taken on the same. Administrator can generate a report of this system in between selected dates of his own choice. The data given by the users is secured and safe as the application and the database is protected by a 64 bit encryption, preventing the identity of the user to be revealed. This helps the user to prevent getting into further trouble. Only the authorized access to the reports will be available which just shows the time and date of entry by the user**

Keywords - Validity, student's grievance, process, student/ user.

I. INTRODUCTION

A grievance is an emotion that a person has about a current existing system. Most people don't come open with the problems they have and just keep it in their mind. Thus our objective was to create a way so as to make the people to come open about the problems they have with the system and we came up with a solution of an online Student Grievance management system which can be used to submit complaints regarding their problem online enabling the user to upload or post his complaint from anywhere by using an application on his mobile phone, computer or any other device that has access to an internet connection. This application will act as a safe platform for the people to tell their grievances without the fear of getting judged or being pushed into deeper trouble. This system also saves a lot of time when compared to the traditional manual system, saving the efforts and time of both the sides i.e. the administrator and the users.

II. HARDWARE REQUIREMENTS

A system which is compatible to support internet

III. SOFTWARE REQUIREMENT

Browser - Mozilla, Chrome, Express.js, MongoDB

IV. SCOPE

SGSS will be helpful to receive problems which are reported by the students for any institute. This platform will be extremely helpful for the Institute's management to understand what kind of problems are faced by the students. This system will help us to give quick responses to grievance and help to save time which is a very crucial requirement to any institute.

V. LITERATURE SURVEY

Initially, we have studied the current system available for grievance collection in college and also met administrative staff and the principal of college for collecting their requirements. After collecting different requirements of staff, we have met various students of different branches and took their suggestion and asked them what kind of system they want for hassle free resolution of their queries. We have also gathered data about challenges that are faced by students before submitting their grievances and after submitting their grievances. There can be two types of systems in which grievances are submitted either with a person's identity or anonymously. For submission of Anonymous grievances, the system must have high security so that none but the admin is able to see the student's identity. Security of this system ensures the student for their privacy and fearless submission of grievances. College authority can easily and quickly resolve student grievance through this online platform. Our team found out that the most appropriate to the research topic handling customer grievance using Android Architecture was tried to improve relation between students and faculties by presenting a new model based on Service Oriented Architecture (SOA). it will involve user in decision making and at the same time it will help the authority in reducing the people problems and dissatisfaction. E-Complaint, regarding this each organization has its own definition for grievance. Some define grievance as something related to the services they provide for users. The value of complaints, both as a bridge that connects the customer and administrator and as a means of giving them a chance to turn a dissatisfied customer into a satisfied and loyal customer. Customer complaining behaviour can be defined as a result of customer dissatisfaction. On the other hand, customer satisfaction is not an absolute scenario, but very much depends on interactions, feedback, understanding, and reviews. Grievance Redressal System is a system in which we accept the user grievance and it will make sure that the user grievances are properly solved and managed by the particular department to which grievance belongs. Based on this is the basic idea on which the grievance and report system of multinational brands like Amazon, Flipkart, Walmart function.

According to study in [1], unhappiness leads customers to both migration behaviour and negative referrals to other potential buyers, adversely hitting retention rates, profitability and organizational goodwill. Therefore, customers who make grievances provide the company with additional chances to identify internal shortcoming and to establish a suitable recovery strategy. This should focus on

gravely encouraging complaining actions and establishing influential procedures to solve grievances, remove the causes of dissatisfaction, and provide result in answers to affected customers. Accordingly, by designing an integrated complaint management system, organizations have the opportunity to learn from customer feedback and to use this information in order to reduce weaknesses, enhance business performance, avoid future opposing experiences, and necessarily re-establish customer satisfaction, faithfulness and relationship commitment.

Students are the most vulnerable parts at educational institutions often unable to express and sometimes fail to attempt proper support for the issues they face appearing at numerous levels. A prototype of grievance redressal had been worked out which could meet well with the solution delivery for the occurring conflicts for students. In this paper, The focus is on the evolution and the implementation of the above-mentioned prototype which could be integrated to be fixed to the grievance redressal for students. That paper puts deep perception into incorporating all those problem aspects which were noticed on the basis of the analysis phase plus some additional needed areas. [2]

In [3], Online students' complaint is an information system which is able to help study program in accepting censure and suggestions by the students to help it enhance the services. This creation will reduce paper usage, time and energy. This research implemented prototype model as development system model to structure, plan and design the system. The Complaint Management System [4] gives the service to the Users to see their previous grievances and also, they can see the remark provided on every stage of their grievance. As per the security reason this system needs an email validation which means only one email can be used by one user to use. For Admin the extra resources provided are that he can smartly track the User and it also displays the attempts taken by user to login into system and it gives the Email notification to the Admin on his Email about every new grievance.

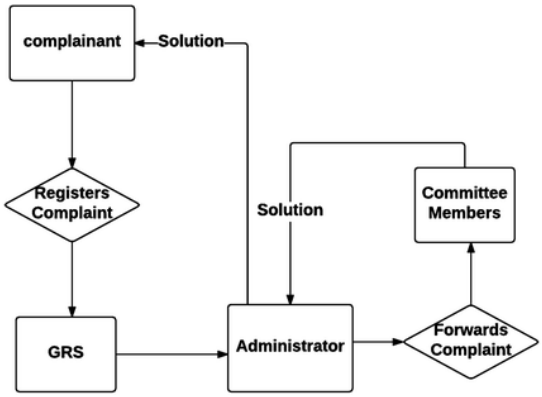

Fig. 1. System process

This website can be easily used by people even by those who are not from IT background. It is much easier and secure way of submitting a complaint.

This project includes two modules.

User to Admin: User can create their accounts and can complain about their problems and also can see action taken on their complaint. Users can check the status of current and as well as previous complaints. Users can submit their complaint easily after a quick registration. Existing users can lodge a complaint by using their registered username and password.

Admin can check the complaints also can take action on it. Admin also has the authority to remove the user. Admin can check the monthly report generated by the system. New features can be added as per requirements.

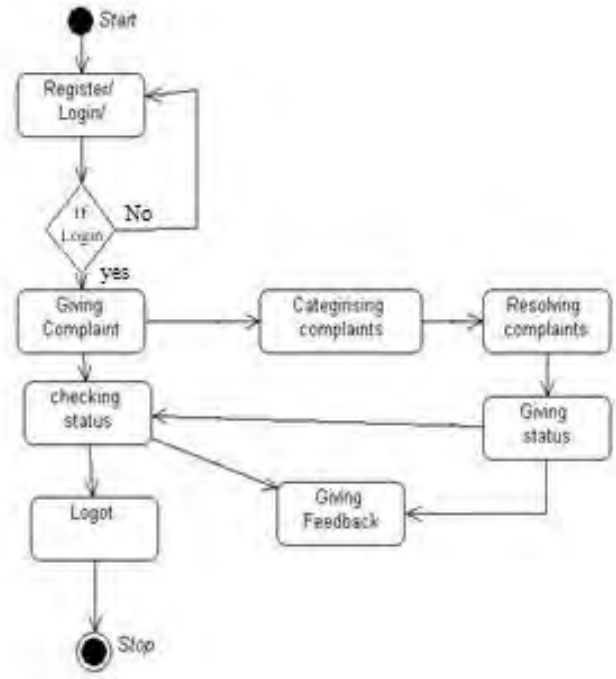

Fig. 2 Flowchart of model processing

VI. PROPOSED SYSTEM

The system which we have proposed that contains user interface through which a user can convey a grievance which is supposed to reach out to authorities hierarchically such that an action in accordance with the grievance can be taken as soon as the grievance is submitted by the user. Our system works in such a way that the user can easily access it in a user-friendly manner so that the grievance come into action. There are two types of grievance submission sections through which a user can submit the grievance with or without his/her personal details. It can be used widely within college campus, offices, industries, etc and not restricted with any particular area. For reference of system flow See Fig. 2.

VII. PROS AND CONS

The pros and cons of the proposed GRS system primarily includes human negligence since the system, though an automatic prototype to redress the complaints of the students/victims, will be controlled by humans who could be negligent at times in forwarding complaints to the respective committee member or while providing solutions to the respective administrator. Another shortcoming includes a poor network which could persist at times; as a result, the system of forwarding and resolving the complaints in the form of sending back the replies to the respective administrators and then to the concerned student could get delayed, the proposed GRS system being based on simple mail transfer mechanism.

VIII. FUTURE ENHANCEMENTS

The GRS working on the pretext of the grievance redressal for all students currently works as a Web application among the various members and the targeted audience. To extend this further in order to fulfill various requirements, following enhancements are suggested: Though several future enhancements of the system worked upon are possible, the prime focus also consists of development of a mobile application in order to increase the mobility of the application since the future limits the usage of mobile applications and as seen portable devices are found everywhere which will facilitate the receiving of all the notifications in the cell phone by the members. A Prototype for Grievance Redressal System and students associated with the application further increasing the reliability of the system and the rate of problem-solving at the same time. The mobile application and web application is targeted to improve the user experience by providing them with additional features for uploading the pictures the proof in the form of audio or video files, which might improve the case solving capability especially in such cases with a high rate of severity or even fatality. A toll-free helpline could be made available on a 24by7 basis for the victims in order to register a complaint at emergency hours or to seek counsel in case of catastrophes.

IX. RESULT AND DISCUSSION

This technical paper is an attempt to enlighten the fact that there are hardly such systems prevailing curtailing to the complaint redressed for students enrolled in numerous organizations. This article has demonstrated a GRS system for the grievance redressed of students covering various domains of complaints which could be lodged and solved easily as compared to the traditional system which involves paper and writing. The technologies used comprise of HTML and CSS to design a user-friendly graphical interface. PHP and SQL to keep track of the records at the back end. This system would be enhancer for any organization for the resolution of complaints of students and thus lead to a qualitative and quantitative development of the organization.

X. CONCLUSION

The Student Grievance Management System acts as a time saviour for the organization and helps them solve the issues faced by the students keeping the details of the student safe and secure. This helps save paper which was used in the traditional system making management of the report simpler and easy to access and solve for the admins. It was revealed in this study that organizational issues are inevitable. A grievance management system for the Institute that receives various complaints from students. Complaints lodged in the sectors like Academic, Administrative, social and other issues relating to the student. This platform allows for complaints to be lodged remotely by students with issues relating to their registration, examination, examination result, computation of their grades and hall of residence complaints and thereby improves the response time for the appropriate unit to resolve the complaints. This System is a boom for the organization as it can focus on development in all aspects.

Abstract— **Due to reasons like Portability, free availability and being a great stress buster, mobile games have always been part of the reason why smartphones have never gone out of trend. Games have a great quality of affecting your conscience without you even noticing about it. A lot of popular mobile games in today's day and age like PUBG, Call of Duty etc. don't send a good message to the youth. In this paper we want to present a game GIRL UP! Which is a positive psychology game which would help in women & child development in India. The situation of women & children in India has improved significantly but it is still not very respectable Positive Psychology games can influence a person's conscience by nurturing positive emotions, promoting engagement, as well as enhancing social integration and connectedness. We hope that our game can help in successfully improving the mentality of people and make our country a better place to live for women and children.**

Keywords – Positive Psychology, games, women & child development, mentality.

I. INTRODUCTION

.The development of positive psychology is to give us a new perspective. With the further study of video games, more and more researchers have begun to shift the focus to the positive field of video games and how bringing positivity into a very highly utilized commodity like video games can help in the overall development of the society.

The game will start with the Prime Minister addressing to the ministry that there is a need to implement a few reforms so that people especially in the rural areas are educated about the well-being of women & children. We plan to have a township game where initially a small town will be assigned to the player. The player will have to initially undertake a quiz according to which he/she will get some coins which they need to invest in the town to build hospitals, schools etc. A mentality meter will be allocated to every town which would check the mentality of the town with respect to women. As the mentality meter crosses 50% the player will be allowed to expand to different towns. Also, there will be an additional feature of a quiz which can be used by the user to get quick coins. Taking these quizzes will also affect the mentality meter.

.

Our game mainly focuses on innovative and intuitive ways in which we can subtly influence a person's thinking to develop a positive attitude with respect to women & children. Traditional psychology paid more attention on the negative effect of the mobile games. Exposure to violent video games will increase aggressive behavior in both the short term and the long term.

II. PROBLEM DEFINITION

Positive psychology games (Mobile/Computer) which help develop a. Respect for right and dignity of women and child b. which help promote objective of Beti Bachao Beti Padhao (BBBP).

III. BACKGROUND

According to SALEN & ZIMMERMAN (2004). RULES OF PLAY: GAME DESIGN FUNDAMENTALS **"A game is a system in which players engage in an artificial conflict defined by rules, that results in a quantifiable outcome".** It also implies that players create an artificial world in their mind when it comes to playing games. A lot of times they end up doing something in real life which has been inspired by a previous gaming experience. Hence these games manage to affect the conscience and thinking of an individual.

The researches of positive emotions in positive psychology focus on subjective well-being. Playing video games is conducive to arouse the emotion experience. Gamers had significantly better emotional experience, higher levels of well-being, and to some extent, less depression compared to non-gamers

Most of the popular games in today's day and age do not focus on building any sort of positive psychology. Either they are brainless games which serve a purpose of entertainment only or games that instill a violent or negative psychology among young people.

There are quite a few positive psychology games but none of them serve the purpose of women & child development.

IV. IMPORTANCE

As mentioned above most of the popular mobile games nowadays spread a negative psychology among the youth. One such example of a game is the very famous online multiplayer game PUBG (Player Unknowns Battle Ground). The negative effects of such games are that Children who play more violent video games are more likely to have increased aggressive thoughts, emotions,

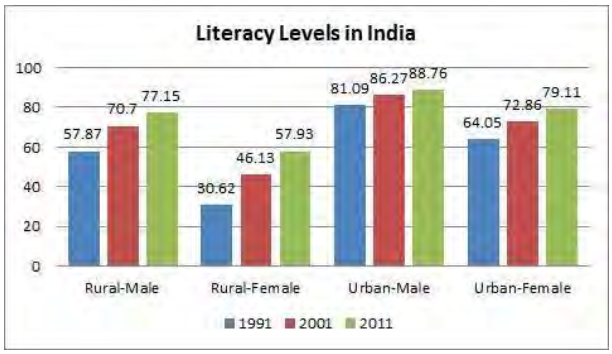
and behaviors, and decreased helping others.

On the other hand, games like Uncharted Waters collects many ports and islands in Asia, Europe, America and other places in 16th century, players in the game can find different parts of the historical sites and cultural landscapes, it widens the geographical knowledge of players. Meanwhile, to some extent, video games can improve individual's critical learning abilities and creativity. Since players need to learn the rules and the special symbolic meaning in the game, players can think critically the game as a system and a well-designed space, rather than a simple game environment.

Critical and creative thinking in the context of the game holds an important position in human psychological development and in the formation of thinking. Besides, video games have an important affect on people's behavior, moral behavior education which based on the emotion can make use of the positive effect of video games. Positive video games can promote virtue and strength of players, which is the core of positive qualities of individuals.

V. OBJECTIVES AND SCOPE

The main objective of developing this game is to improve the current situation of women & children in India There is a wide gender disparity in the literacy rate in India: effective literacy rates (age 7 and above) in 2011 were **80.9%** for men and **64.60%** for women. The low female literacy rate has a dramatically negative impact on family planning and population stabilization efforts in India.



Our game through its subtle ways wants to instill an ideology into the society that Women and Men are equally important. Due to the patriarchal approach especially in the rural areas, this game becomes that much more important as an effective way to feed a good ideology into the minds of the illiterate.

VI. PHASES

Phase1: Planning, Analysis, Designing and Implementation.

Analysis: Getting strong knowledge of the project title and doing exploration on it, we will get our description.

Preparation: After finalizing the problem statement from the SIH website we researched on existing similar games and found out the pros and cons.

Designing: Then we will build the design of the project and agreeing to that, will list down all the necessities needed for the creation for the prototype of our project.

Implementation: After gaining the requirements, we first learnt about game building software like UNITY and required back end database like SQLite.

Phase 2: Testing and Deployment.

Testing: After the model is ready, we will first associate the hardware with the allotted code and then we will check if it supports the machine or not. If not, we will resolve the issues relating to it and will crosscheck again.

Deployment: After completion of integration and testing of project, real time testing and operation of the system will be done.

VII. METHODOLOGY

The basic 2-D UI will be designed using UNITY. User details and game progress and quiz questions will be stored using SQLite database. More emphasis will be given on making the game user friendly and attractive so that it entertains as well as educates.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

Hardware

- Any Computer system with the required software installed

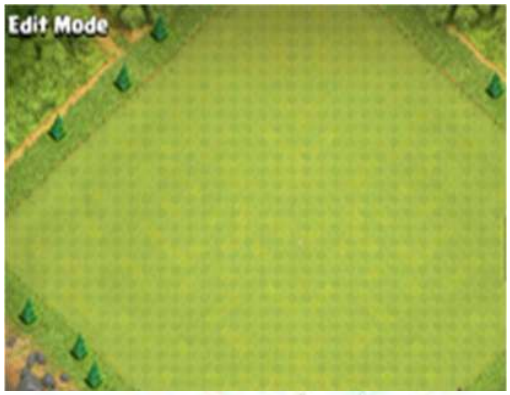
Software

- UNITY: Sandbox environment for developing the game
- C#: Used for writing the code
- SQLite: For designing of the database

For designing the game, it was planned that Unity would be used as it provides great Platform Support, very good features to add some enthralling graphics, helpful documentation for beginners to understand the dynamics that go behind making the game and also the support for easy debugging.

SQLite was chosen to design the back-end of the game as it is lightweight, reliable, portable and provides better performance as compared to other database systems when It come to dealing with comparatively smaller datasets.

IX. PROSPOSED UI SCREENSHOTS.



The above diagrams represent the proposed UI of the game. The game will start with empty land given to the player. Then the player with the help of coins has to build on that land and look to improve the mentality meter.

X. OUTPUT

The game will start with the Prime Minister addressing to the ministry that there is a need to implement a few reforms so that people especially in the rural areas are educated about the well-being of women & children. We plan to have a township game where initially a small town will be assigned to the player. The player will have to initially undertake a quiz according to which he/she will get some coins which they need to invest in the town to build hospitals, schools etc. A mentality meter will be allocated to every town which would check the mentality of the town with respect to women. As the mentality meter crosses 50% the player will be allowed to expand to different towns. Also, there will be an additional feature of a quiz which can be used by the user to get quick coins. Taking these quizzes will also affect the mentality meter.

XI. OUTCOMES

Creating the outline, works survey and achievability study for proposed solution which will act as an input to the design phase.

Suggesting Statement of work, scope description and scope border for planning the model from the problem definition to decide what needs to be done and what not to be done.

Phase 1 Implementation:

Implementation of the game with proper connectivity and no failures.

Phase 2 Testing:

Testing was done by making sure that the UI elements in the game are working smoothly and the game is not hanging or stopping due to errors in the code.

Phase 3 Deployments:

Real time working was done when we played the game until a certain level and it showed no faults. Thus, the model works efficiently.

I. RESEARCH GAPS

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

- The game might take more time to load on Android phones whose version is outdated.
- The game might fail in its purpose of educating people if it becomes too predictable and the players answer quiz questions based on the amount of coins that they will receive rather than their own opinion

XII. SUMMARY

Our game GIRL-UP focuses on improving the mentality of people in our country with regard to women & children. Games have become a very important part of smartphones and they subtly manage to influence our conscience. Most of the famous games nowadays are negative psychology games which affect the youth of the country in a negative manner. Hence a positive psychology game like GIRL-UP is the need of the hour.

XIII. CONCLUSION

We have successfully shown the implementation of our game. We will be using UNITY and C# to design the front-end and UI of the game. SQLite will be used to design the back-end part because it is a lightweight and portable database system which is efficient for such a kind of a game.

Abstract— **Malnutrition is not a direct cause of death but contributes to mortality and morbidity by reducing resistance to infections. There are a number of causes of death of children such as prematurity, low birth weight, pneumonia, diarrhoeal diseases, non-communicable diseases, birth asphyxia & birth trauma, injuries, congenital anomalies, acute bacterial sepsis and severe infections, etc. Our website focuses on how to improve nutritional outcomes in the country. The programme through the targets will strive to reduce the level of stunting, under-nutrition, anaemia and low birth weight babies. This website will bring clarity amongst the people, about the problems related to malnutrition and many diseases which cause death. Its benefits are amazing and this will help to reduce the negative impact of malnutrition on socio-economic development of India. We hope that our research will spread awareness amongst the people about the POSHAN ABHIYAAN. Our main aim is to promote holistic nutrition among women and children with the help of IT.**

Keywords–Malnutrition, diseases, holistic nutrition, women and child development, Poshan Abhiyaan.

I. INTRODUCTION

Our website has been specially designed to strengthen the Service Delivery System as well as the mechanism for Real-Time Monitoring (RTM) for nutritional outcomes. POSHAN ABHIYAAN was launched by Prime Minister Shri Narendra Modi in Jhunjhunu, Rajasthan in March 2018. Women from different villages and slums would be able to manage their work easily and awareness would be spread with the help of the website for efficient working. There will be different sections in which they will be provided with information such as how to feed their child, information on regular checkups and when to consult the doctor. Our website will be mainly concerned with how to stop malnutrition and also for pregnant women on what to be consumed or what not to consume during their pregnancy. The aim of this website is that till the end of the year 2020 there will be awareness spread amongst the people in every corner of India.The website will consist of honourable Prime Minister, Narendra Modi informing about the importance of Poshan Abhiyan and the need of the website to spread awareness for a disease-free and malnutrition free country till the end of the year 2022. Implementation strategy would be based on intense monitoring and Convergence Action Plan right up to the grass-root level. Our website will also concern with how to reduce stunting growth, anaemia among women and children.

II. PROBLEM DEFINITION

India is home to one of the largest populations of malnourished children in the world. Today's children are the future of tomorrow, and so it's important they have access to nutritious food right from birth through adolescence. So, the POSHAN Abhiyaan (also Known as The National Nutrition Mission (NNM)) was launched by Prime Minister Narendra Modi on March 8, 2018 in Jhunjhunu district in Rajasthan. The POSHAN stands for 'PM's Overarching Scheme for Holistic Nourishment'. The scheme aims to ensure holistic development and adequate nutrition for pregnant women, mothers and children. A key idea of the initiative is to incentivise Anganwadi Workers (AWs) for using ICT-based tools, making it easier to implement and monitor the programme. pregnant women to plan a proper meal for themselves and how to stay disease-free. The POSHAN ABHIYAN launched by the Prime Minister is an initiative to help women and children of our country.

III. IV. IMPORTANCE

Information Communication Technology enabled Real-Time Monitoring (ICT-RTM) is one of the key objectives in POSHAN ABHIYAN. Our website has a 'Dashboard System' for monitoring, supervision and overall user management. The website will be very user-friendly and easy to use for women. There will be different sections for women they will be allowed to borrow a loan at least interest and also they will be trained online via videos lectures on how to nurture their child and take care of them. Vitamin A tablets, food grains and rice, and fortified food packages are available for children and mothers who are showing signs of malnourishment. Weight-for-age growth cards should be maintained for all children under six years of age - children below the age of 3 should be weighed once a month and children aged 3-6 should be weighed quarterly. The women in need of any can contact directly through our website and immediate help would be provided. There will be awareness on how children should be given full vaccinations against six preventable diseases: poliomyelitis, diphtheria, pertussis, tetanus, tuberculosis and measles. Pregnant women should receive a vaccination against tetanus that reduces maternal and neonatal mortality.

IV. BACKGROUND

Malnutrition is the major problem that our country India is facing for many years. In 2018, Our Prime Minister started a scheme called POSHAN ABHIYAAN. The aim of the scheme is to protect children and women of our country with malnutrition, anaemia and stunted growth. Due to an increase in poor people, the number of people malnourished is increasing. So there is a need to promote how we can

help children and

V. OBJECTIVES AND SCOPE

The main objective for developing this project is not only to achieve the targets and objectives set up by the POSHAN ABHIYAAN but also to create the awareness of this programme among the public. The prime focus would be to increase the efficiency of this programme to a very large extent and ensure that it benefits the maximum number of people. The prime objective is to boost the execution of POSHAN ABHIYAAN. The Feb 2020 report shows there are still many states with below-average participation in this programme. Preparation: Based on those results, we will conclude which domains of nutrition need more emphasis and will try to prepare the website on that real.

Designing: We will build the design of our project by pondering over our analysis and accounting to that, we will specify all the necessities required for the creation of the prototype of our project.

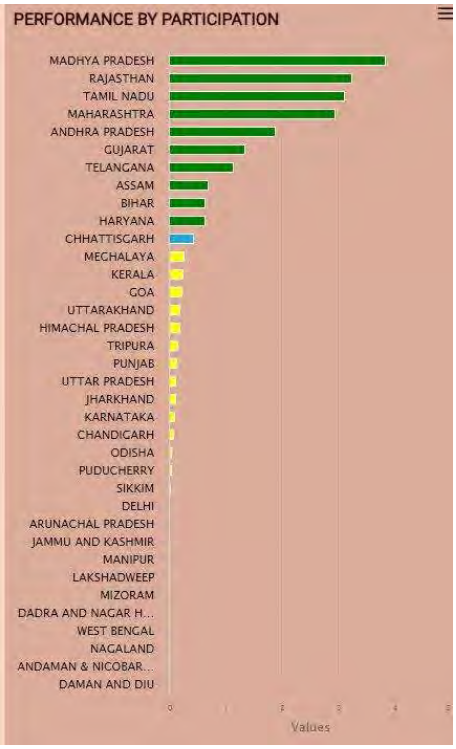
Implementation: The design can now be implemented through web application frameworks like AngularJS and the required databases can be handled through software like SQLite Many states including Uttar Pradesh are still below average in their participation in this programme. We aim to increase participation from these states and maximize the engagement from all parts of our country.

VI. PHASES

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: We will collect the data about the current status of nutrition among women & children from repositories of government. Based on those we will derive our statistics.

Planning: We will now analyse those statistics to stumble onto some result and will plan accordingly.



Phase 2: Testing and Deployment.

Testing: After the prototype is ready, we will test the UI/UX of our website and will try to ensure that it is feasible with our targeted audience and creates the impact as expected.

Deployment: After completion of integration and testing of the project, the project will be deployed with real-time databases and real-time & operation of the system will be done.

VII. METHODOLOGY

This proposed project will work as an interface between people and government. Users will get to interact with the various programmes of POSHAN ABHIYAAN, the user will also be able to update the information about ongoing programmes in their locality. Users can get the latest updates on POSHAN ABHIYAAN. Users can share their feedback with the government.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

Hardware: Any Computer System or Smartphone.

Software:IDE:

Intellij IDEA Ultimate 2019.3.1

Front-End:

HTML

CSS

Javascript

Java

Back-End:

MYSQL Database

PHP

IX. PROPOSED UI SCREENSHOT

The above screenshots represent the proposed UI of our website. The Homepage of

the website will contain registration to our website. The user will have to enter his/her

details, and after logging in the user can directly enter his/her problems and they can know more about holistic nutrition. There will be online teaching by professional doctors on how to take care of a child and how to have a proper diet.

IX. OUTPUT

As focus lies on the mother and children as per the National Nutrition Mission (aka NNM or Poshan Abhiyan) by providing guidance and appropriate aid,

the help of website based technology such as these, makes the work efficient. Several families could contact appropriate officials via the website and convey their problems. Since sharing of information has become quicker a better reach to rural areas can be expected. Such technology can be benefitted by the most as The Republic of India has successfully maintained its record of the low-cost Internet, which can be afforded by the middle or lower-middle class, consistently.

X. OUTCOMES

Creating the outline works survey and achievability

study for a proposed solution which will act as an input to the design phase.

Suggesting Statement of work, scope description and scope border for planning the model from the problem definition to decide what needs to be done and what not to be done.

Phase 1 Implementation:

Implementation of the website with a proper database and no failures.

Phase 2 Testing:

Testing was done considering the feasibility of UI of the website among the users and the portability of the website on different devices.

Phase 3 Deployment:

Real-time working was done with different kinds of users from different areas and people were comfortable with our website, they shared good user experience. Thus, the project works efficiently.

XI. RESEARCH GAPS

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows: Due to Internet issues in rural areas this website may take time to load on Computers/Mobile Phones. There is a need to provide training to the people in rural areas on how to access/use this website.

XII. SUMMARY

Our website is a platform between the government scheme i.e POSHAN ABHIYAAN and women from various parts of the country. The main focus will be promoting holistic nutrition. It will also contain data from various villages and that data will be submitted to POSHAN ABHIYAAN centre.There will be direct online teaching and camps to spread awareness about the importance of a proper diet and proper food a small child should be given. The website will be made with pure intentions of helping the women and children from various villages and cities through POSHAN ABHIYAAN.

XIII. CONCLUSION

We have successfully shown the implementation of our website. Technologies used to design this poshan abhiyaan website are mentioned. Thus effective execution of the project is done. The data of the people will be reported to the POSHAN ABHIYAAN and it will also be concerned that all people should get the benefits of POSHAN ABHIYAAN.

Mobile Applications for Police and Citizens Of Crime Records

Ganesh Verma, Yash Pancholi, Rahul Tandel, Ashish Suthar
Thakur college of Engineering and Technology, Mumbai, India
ganeshnv0@gmail.com, yashgreenlawns@gmail.com, rahulkv395@gmail.com, ashishsuthar1000@gmail.com

Abstract: **- In 21st century where mobile and information technology have become an integral part of our lives. A new area where mobile integrated with technology is beneficial for crime reportng since readily accessible information isn't available at any point in investigation this is often a key drawback for communication in police department. Thus, using cloud, we'll attempt to make all the knowledge associated with the criminals available on the Android Application to the police during their investigation which might speed-up the entre process of tracking down the criminals. A mobile application is made available to the common people in order to track down the safest path to reach their destination by giving motivation's Incident was true. This caused chaos among the overall public [1, 2]. The appliance will provide the overall users with the facilities like reportng any incidents which might cause holdup. Moreover, it'll also provide an alternate safe path on user's demand before entering the crime area. The database is going to be stored on cloud to achieve remote access. For avoiding any false incidence to be noted to other user, the data provided are going to be first verified by the police official. These is the intro of our problem statement named is mobile applications for police and citizens for maintaining of crime records.**
The project titled as crime applications for police and citizens is a web-based application. From the app when chosen a crime affected area and also providing an We provide a facility such as reporting online crimes, alternate route.
Keywords -- Authenticated criminal android application

INTRODUCTION

In today's era mobile technology may be employed in many other fields and application like Gaming, Maps, E - mail, Messaging, Photography and then on. One such area is crime area detection and storing criminal data record. A recent mobile application named Mobile Vic PD was released by the Victoria police in Canada for fighting crime. The mobile application may be accustomed report minor crimes, offer anonymous tips to police, stay updated on crimes current, receive missing child reports or check on transferred possession. Because the criminal data isn't available remotely there's a communication gap between the police officials investigating any case. The disadvantage of this application was that it had been liable to fake reportng of crime and there was no other thanks to verify that the Repots and status of any investigations.

PROBLEM DEFINATIONS

In the present scenario fling a FIR/complaint could be a hectic task since one must undergo a awfully huge process for justice. It matters how small or big the crime is. In general, to file a FIR/complaint one must look for a close- by station and must wait until a cop takes upon the request and either we've to recite or must provide it as a written statement. Certainly, this takes nearly every day of an individual's time. During this busy world, it's quite tough to relinquish au courant our routine works. The prevailing system of fling complaints/FIR affects our daily routine, makes us spend plenty of our precious time in it. Fling a FIR, meanwhile we could have done three. Mainly could provide a lot of chances and time for verdicts to simply get away cases making their pre bails ready or perhaps for absconding. To avoid such miserable situations, we've designed an app that creates everything happen in just jiffy.

BACKGROUND

The purpose of this technical is to develop an android app for crime area detection and store criminal records. It provides an application for the user that may provide an alternate path for the users passing by crime area. It allows user to report incidents and procure it verified by the police officials. it'll contains an application for police officials which can perform database operations on record and allows efficient retrieval of required information from the centralized database present on Cloud. The applying targets general public and police officials for managing the incidents and crime without consuming much time. This proposed system is going to be divided into three major modules. This application is going to be useful for the remote access of criminal data which is able to be helpful for the investigations carried by local department. Also, it'll provide the overall users with the facilities like reportng any incidents which might cause tie up. Moreover, it'll also provide an alternate safe path on user's demand before entering the crime area. The database for this project is going to be stored on cloud to achieve remote access. For avoiding any false incidence to be notified to other user, the knowledge provided are going to be first verified by the police officials. After approval of the knowledge it'll be broadcasted to other users using the applying.

Police Application

This module is resulting in the event of police android application which might work as follows. First and foremost, the police have to login with the username and also the password provided to him, as this application isn't publicly available for the final users. After logging into the applying, police are given the features like reporting incidents (crimes and incidents causing traffic jam), view user reported incidents. After the verification of the incident, the database is updated and also the notification is broadcasted to any or all the users who are using this application. Police are given privilege to try to to the criminal database manipulations.

General User Application

This module is resulting in the event of the overall user application which might work as follows. First and foremost, the users will must do one-time registration before using the applying. After registration, user is supplied with the facilities like report incidents, view the notifications and popups which will contain the data like signal and address of the nearby station house, hospital, free station. Moreover, option to view the alternate path are provided by the police officials. User won't run any privilege to form changes within the criminal database. Physical location of the user is tracked with the assistance of GPS which is inbuilt within the mobile phone. To avoid crime affected area, user can request a safest alternate which will be provided by police through the applying.

CloudDatabase

In cloud application, in this paper, cloud is used for storing the database to supply the ability of remote access. As mentioned within the police user application, the username and thus the password employed by the police are visiting be cross-verified with those stored within the database. The complexity of the crime is visiting be selected the first come first serve basis. So as to produce the security to the database SHA-1 algorithm are visiting be used.

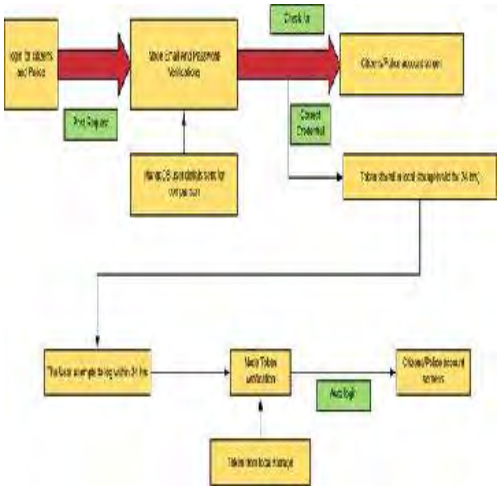
IV.IMPORTANCE

The proposed system consists of three different phases: Installation and configuration of the system, Data Specification of the system, Request/complaint Dispensation, Encryption & Decryption of request using cloud computing. the applying needs to be installed and configured to process the user's request/complaints against crime which is encrypted by the client and thus this information is further decrypted by the respective department of local government. The investigation of the complaint/FIR starts supported the data received from the sender whose details are already per the applying. The method of application allows users to register their complaints against social crimes using their mobile phones. All the complaints registered by public are through their own login credentials which follows by downloading app from their application stores/repositories and signing up into application using phone numbers/email id which generates an OTP to the registered phone number/email id. A brand-new account is created under the registered username in cloud once the OTP accepted by respective cloud.

OBJECTIVES

CREATION OF a mobile application for citizens as well as police to create a sustainable community platform in a society and provide a necessary prevention of crime. The basic idea is to promote safer and better society through crime detection, preventions and control program which include in the program. Through these applications the society will be educated in both ways as an individual and as a group. Crime prevention through mass media is a goal to be achieved in future. This software is made to efficiently and effectively. It results in regular and timely action against crime reported.it can be observed that the information's can be obtained easily and accurately. Assist senior police officer for better management of police force. Reduce manual and redundant records keeping interactions and sharing of information's among police Departments, District, State/headquarters and other police agencies can be made easier and more effective.

METHODOLOGY



TOOLS

Google map (Locations)
Mango DB (secured storage)
Block chain (Securely storing FIR data)
Nodejs-MySQL (Backend)
Lucid chart (Flowchart)
Rest API (fetching data)

RESEARCH GAP

Application pitched by us will help the citizens know about crimes happening around them and lodge a complaint/Fir immediately when they notice a crime happening around us. Verified police accounts will be able to access them and report to the scene as soon as possible. Our app will provide statistics about crime taking place and there solves rate the fir process is very slow and the criminal can get away if action is not taken soon.

EXPECTED OUTCOMES

We can update this system as online application.
The advantage of online application is that, a person can report the crime anytime from anywhere.
Users can view the progress of their complaint online.
The sensitive information can only be viewed by police officers.
The app reduces the time to report crime or for police officers to be able to reach on crime on crime scene on time.
Login for user and admin.

SCOPES

A generic platform for keeping human records from birth till death. Deploying this so platform will serve as a source of information on persons from various states within the country and even those outside. The crime record managements system can then be linked to the present system and thus provide comprehensive data on persons.

The crime record management system should be merged with the criminal justice system to form a mega system that spans over all facets of the justice system. This will enhance synchronization and transfer of data between the court of law and NPF.

CONCLUSION

In this paper we've overcome the matter of communication gap between the police during their investigation. We also provide solution to bridge the communication gap between police and general user. Also, the criminal information will be readily accessible to the police official's as it is stored on the cloud. The problem of reportng fake crimes will be overcome as this application will need the verification of police to report incidents reported by user to broadcast it to other users using the same application. In future, another security algorithm is often wont to provide better security measures for the criminal database. The only challenge of this proposed system is that GPS and the Internet connections has to be activated 24x7. Future research can be dedicated for these challenges.

Thakur College of Engineering and Technology, Mumbai, India

Abstract- **As technology is spreading its hands in every corner let it be hospitality, infrastructure, communication, education then why travel is returning void output in aspect of technology we know there are many apps, websites available for road, train travel but airplanes and airports are left behind which are the most reliable option for long distance travelling in aspect of comfort.**
Keywords: Arrival Delays, Departure Delays, Visualization, Security, Weather Delays

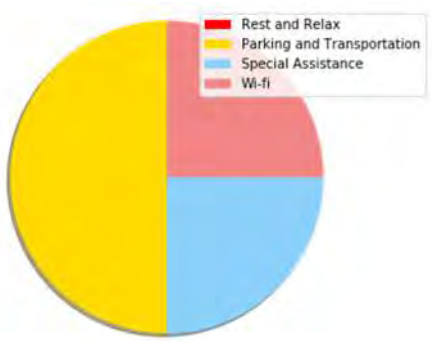
I. INTRODUCTION

"The representation & presentation of data that exploits our visual perception abilities in order to amplify cognition"
– Andy Kirk

Our group has concentrated on this area and is aiming to make a website which will solve general problems related to travelling by air like arrival- delays, departure-delays. It will show which particular airlines are prone to them by default and it is not only limited to delays but also the facilities provided by different airports so that the passengers can get a clear picture what they are going to get through individual airports through visualization which even an illiterate can understand.

II. PROBLEM DEFINITION

A web application is tried to made that is capable of projecting analyzed data through visual tools like bar graphs, pie-charts, packed-bubble on a web dashboard. Airport facilities include rest & relax, special assistance, parking & transportation and wi-fi . the application should have a separate category to visualize delays with respect to airlines and months.



III. C. OBJECTIVES & SCOPES

Classification of dataset based on nature of facility used by a passenger and available facilities provided
Data visualization at pan India level
A centralized dashboard containing visual data representation of facilities, delay of airlines, then delay of months

IV. LITERATURE REVIEW

Modern tourism is impossible without air transportation. The development of airports and tourism are dependent on each other. There are around 80 domestic airports and 12 international airports in India.
During February 2018-Feb 2019, air passenger traffic stood at 316.51 million. By 2020, passenger traffic at Indian airports is expected to increase to 421 million from 308.75 million in 2017-18. Also our country is expected to become third largest aviation market in terms of passengers by 2024.
As millions of people travels through airway, it is the responsibility of airports to give them the best services as possible. The major airports in India where passenger traffic is more are Delhi, Mumbai, Bengaluru, Kolkata, Hyderabad, Chennai, etc. The demand of better services is going to increase every year. Also there are many passengers who are unaware about some of the services that airport offers.
So, there is a need of tool which can rate the airports according to the services they provide and utilization of them by the passengers which will help passengers and airports for their development in our country.

V. METHODOLOGY

This project aims to develop an Application (Aero Analyst) which will be going to visually demonstrate various Airport Facilities including Delay Report, Special Assistance, Air Traffic, etc. This application will act as convenience to understand visual representation of data in a concise manner. The passengers can utilize the available airport facilities better and encourage them to utilize them more. The simplicity of this application is that normal users can understand it by looking at the analytics in the form of bar graphs, pie charts, box plots, scattered plots and histograms and evidently become aware of the features being provided and utilized at the concerned airport.

Facilities

Fig 1.1. implements various facilities of any airport like Rest & Relax, Parking, Wi-fi in the form of pie-chart

Research Design:

Aero Analyst's frontend part is made on Bootstrap, HTML. Visualization of data is done on Python which consists of pandas, Matplotlib libraries. We have also used codeless visualization tool i.e. Tableau which is not an open source tool. The major focus is on visualization of data since it amplifies the cognition abilities of the passengers and maximum amount of data can be monitored easily.

Research procedures:
The data of different airports having different facilities, reviews, delays, etc. are

collected from major websites. Collected data of around 20 airports at pan India level and state level. The process of visualization consists of different paths Data Collection, Data Cleaning,

Data Prediction. The raw data collected was in unstructured manner then later it was converted to structured data which helps us demonstrate the facilities of the airports.

The visualization will provide answers to these questions:
Which City has the most traffic?
Which city has the least?
Which month is the busiest in the year?
Which airport route is the busiest one?
Which airports have special security management for the passengers?

Selection and access:
The application design consists of major three points i.e. facilities, delays, air traffic. These analyses can be used by the airport authorities for better management of utilities and push forward better airport advertise. Passenger can efficiently manage their time at the airport by knowing the various that are provided by the airport and conveniently use them.

The airport companies can easily demonstrate the monthly and annual delays of their airplanes and can come to a solution in future in
advancement of their techniques. Insightful information in finger tips will make passengers, staff to take the right decision. The dashboard of aero analysis also consists visualization through maps which gives end to end management of security of passengers.

Most of the money on airports are used in better infrastructure and security surveillance of the airports. Passengers invests around 4 hours for security and baggage check in on airports .The workload is reduced by using the dashboard as it contains a special security visualizations that is connected to the airport monitor .Every passenger is rated according to their previous criminal records. The visualization helps to maintain airports secured as shady peoples will be colored" red "on to the scatter plot and normal citizens are colored "blue". The scatter plot will help to secure the airport from inside which reduces the chance of hijacking.

FUTURE ADDONS:
Analytics on passenger data
Cleanliness and efficiency of machinery at airports
Air traffic density and route analysis

BENEFITS FOR THE SOCIETY:
People can easily compare which aviation provides them the fastest arrival to their destination.
It will make the airport authority to easily
enhance their facilities according the users feedback.
Map visualization of all collectively routes
will help the passenger as well as airport authority to predict the future air traffic.

VI. HARDWARE & SOFTWARE REQUIRMENTS

Hardware: This website can be access from any Operating System like Windows, Android, Linux, MacOS, etc.
Software:

ANDROID STUDIO FLUTTER, REACT NATIVE

Front-End:
HTML
CSS, BOOTSTRAP 4
JavaScript

Back-End:
MYSQL Database
PHP
PYTHON with DJANGO

VII. STATEMENT OF LIMITATIONS

There are many booking websites which displays the data like timings, delays etc. But none of them provides information about the services they provide. Till now we don't have such application which can rate airports on the basis of services they provide.

Our research will be beneficial for airports as well as

people who travels through airway. It will help airports to know that where they are lagging in providing services to the passengers and can modify them accordingly. Also it will help passengers to utilize maximum available services at the airport.

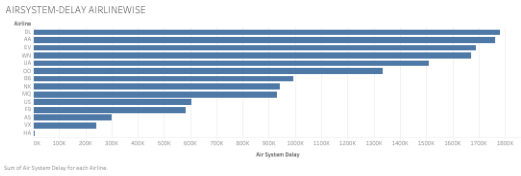


Fig 1.2

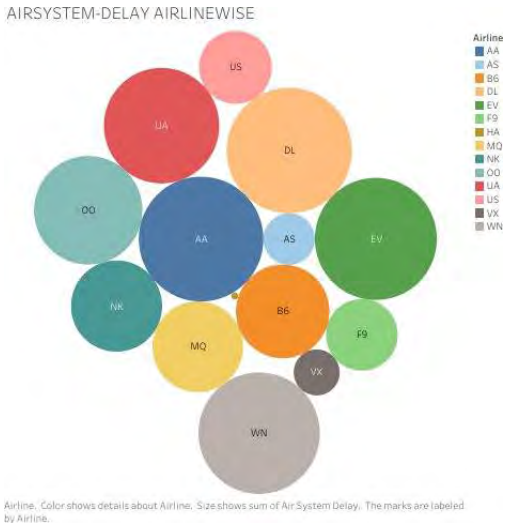

Fig 1.3

Both Fig shows the air-line delay but Fig 1.2 is represented in the form of bar-graph and Fig 1.3 is represented in the form of bubble graph.

VIII. RESEARCH GAPS

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too.
They are as follows:
This website may take more time to load at several places due to less Internet bandwidth
The real-time data may fluctuate as due to the geographical region.

IX. CONCLUSION

The following project helps in the clear visualization of data provided by the concerned associates, which is processed by the algorithms created by our programmers to create extremely easy to understand analytics in the form of graphs and plot. These analytics can be understood by most individuals.

Proper utilization of large data is extremely essential and should be carried out in an efficient manner. The procedures carried out during the project, helps in minimizing complications and ambiguity by reducing it to a visual and comparative study.

The website is beneficial to both passengers as well airport authorities. Passengers can refer it to plan out their trips more efficiently and also become aware of the various facilities being provide at a concerned airport, it promotes higher usage of the facilities as well.

Real-Time Based Facial Recognition Systems.

Jyoti Khare, Aman khairwar, Abhishek Tripathi, Hinal deriya, Mohammad Ali khan
Information Technology Thakur College of Engineering Kandivali(E), Mumbai-400101
jyotirkhare@gmail.com,khairwaraman@gmail.com,Possible.abhishek90@gmail.com, hinalderiya03@gmail.com, sameerjoshi67@gmail.com, Khan907666@gmail.com

Abstract—**Face recognition is used to prove identity across a wide variety of settings. Despite this, research consistently shows that people are typically rather poor at matching faces to photos but, when you work with machine this introduces a new level of identification through a real-time algorithm. How to accurately and effectively identify people has always been an interesting topic, both in research and in industry. With the rapid development of artificial intelligence in recent years, facial recognition gains more and more attention. Compared with the traditional card recognition, fingerprint recognition and iris recognition, face recognition has many advantages, including limit to non-contact, high concurrency, and user friendly However, face recognition skills are subject to wide individual variation, with real time machine showing exceptional ability—a group that has come to be known as 'Bureau of Police Research & Development". The Bureau of Police Research & Development adapt 'Real-Time Based Facial Recognition Systems' from within its ranks, for deployment on various identification tasks. Here we test Facial Recognition Systems from within this Bureau, and ask whether they are really able to perform at levels above control groups. We consistently find that this 'Facial Recognition Systems' perform at well above normal levels on tests of unfamiliar and familiar face matching, with degraded as well as high quality images. Allocating this system not only remove difficulties but also include more automation and efficient working environment.**

Keywords—Deep neural network, face recognition, server-client model, deep multi-model fusion, convolutional neural network.

I. INTRODUCTION:

"Faceprint are one way that technology recognizes individuals"

As the digital world and real-world merge more and more together, how to accurately and effectively identify users and improve information security has become an important research topic. Not only in the civil area, in particular, since the 9-11 terrorist attacks, governments all over the world have made urgent demands on this issue, prompting the development of emerging identification methods. Traditional identity recognition technology mainly relies on the individual's own memory (password, username, etc.) or foreign objects (ID card, key, etc.). However, whether by virtue of foreign objects or their own memory, there are serious security risks. It is not only difficult to regain the original identity material, but also the identity information is easily acquired by others if the identification items that prove their identity are stolen or forgotten. As a result, if the identity is impersonated by others, then there will be serious consequences. Different from the traditional identity recognition technology, biometrics is the use of the inherent characteristics of the body for identification, such as fingerprints, irises, face and so on. 6 Compared with the traditional identity recognition technology, biological features have many advantages, as:1. Reproducibility, biological characteristics are born with, cannot be changed, so it is impossible to copy other people's biological characteristics. 2. Availability, biological features as part of the human body, readily available, and will never be forgotten. 3. Easy to use. Many biological characteristics will not require individuals to corporate with the examine device. Based on the above advantages, biometrics has attracted the attention of major corporations and research institutes and has successfully replaced traditional recognition technologies in many fields. And with the rapid development of computer and artificial intelligence, biometrics technology is easy to cooperate with computers and networks to realize automation management, and is rapidly integrating into people's daily life. When comparing the differences between different biometrics, we can see that the cost of facial recognition is low, the acceptance from user is easy, and the acquisition of information is easy. Facial recognition is the use of computer vision technology and related algorithms, from the pictures or videos to find faces, and then analysis of the identity. In addition, further analysis of the acquired face, may conduct some additional attributes of the individual, such as gender, age, emotion, and et

II. PROBLEM DEFINITION

A complete face recognition system includes face detection, face pre-processing and face recognition processes. Therefore, it is necessary to extract the face region from the face detection process and separate the face from the background pattern, which provides the basis for the subsequent extraction of the face difference features. After detection ,the details will be searched cross various websites and social medias to gain access to information regarding the image. This will make the police bureau easy access to criminal's personal information if available on any of the websites.

III. BACKGROUND:

Pioneers of automated face recognition include Woody Bledsoe, Helen Chan Wolf, and Charles Bisson. This project was labeled man-machine because the human extracted the coordinates of a set of features from the photographs, which were then used by the computer for recognition. Using a graphics tablet (GRAFACON or RAND TABLET), the operator would extract the coordinates of features such as the center of pupils, the inside corner of eyes, the outside corner of eyes, point of widows peak, and so on. From these

coordinates, a list of 20 distances, such as the width of mouth and width of eyes, pupil to pupil, were computed. These operators could process about 40 pictures an hour. When building the database, the name of the person in the photograph was associated with the list of computed distances and stored in the computer. In the recognition phase, the set of distances was compared with the corresponding distance for each photograph, yielding a distance between the photograph and the database record. The closest records are returned. Some face recognition algorithms identify facial features by extracting landmarks, or features, from an image of the subject's face. For example, an algorithm may analyze the relative position, size, and/or shape of the eyes, nose, cheekbones, and jaw. These features are then used to search for other images with matching features.

Other algorithms normalize a gallery of face images and then compress the face data, only saving the data in the image that is useful for face recognition. A probe image is then compared with the face data. One of the earliest successful systems is based on template matching techniques applied to a set of salient facial features, providing a sort of compressed face representation.

IV. IMPORTANCE

When you post a photo on Facebook, and the platform automatically tags the people in the image, you might not give much thought to the technology behind the convenience. However, when you discover that facial recognition technology could track you without your permission while you walk down a street in Mumbai, it might make you question the invasion of your privacy. Just like with any other new technology, facial recognition brings positives and negatives with it. Since it's here to stay and expanding, it's good to be aware of the pros and cons of facial recognition.

Cons of facial recognition: 1. The technology isn't as effective at identifying people of colour and women as it is white males. One reason for this is the data set the algorithms are trained on is not as robust for people of colour and women. Until this is rectified, there are concerns about the ramifications

for misidentifying people with the technology.

2. In order to benefit from the positive aspects of facial recognition, our society is going to have to work through some significant challenges to our privacy and civil liberties. Will individuals accept the invasion of their privacy as a proper cost to being more secure and for the conveniences facial recognition provides?

V. OBJECTIVES AND SCOPE:

1. To track the full face during its motion in a video.

2. To track many faces during conversations.

VI. 3-DIMENSIONAL RECOGNITION A newly emerging trend, claimed to achieve improved accuracies, is three- dimensional face recognition. This technique uses 3D sensors to capture information about the shape of a face. This information is then used to identify distinctive features on the surface of a face, such as the contour of the eye sockets, nose, and chin. One advantage of 3D facial recognition is that it is not affected by changes in lighting like other techniques. It can also identify a face from a range of viewing angles, including a profile view. Three-dimensional data points from a face vastly improve the precision of facial recognition. 3D research is enhanced by the development of sophisticated sensors that do a better job of capturing 3D face imagery. The sensors work by projecting structured light onto the face. Up to a dozen or more of these image sensors can be placed on the same CMOS chip— each sensor captures a different part of the spectrum. Even a perfect 3D matching technique could be sensitive to expressions. For that goal a group at the technique applied tools from metric geometry to treat expressions as isometries a company called Vision Access created a firm solution for 3D facial recognition. The company was later acquired by the biometric access company Bioscrypt Inc. which developed a version known as 3D FastPass.

Vehicle Recognition And Compilation Of Database Software

Abhishek Pandita, Deeksha Rai, Aditi Singh
TCET, MUMBAI
abshek2109@gmail.com, raideeksha809@gmail.com, singhaditi206@gmail.com

Abstract— **Today's age is an age of AI, ML and IOT and it is a digital era where everything is going to be automatic i.e. less need of human work or you can also say no need of humans to do work at all . Most of the human work is done by Hardware machines and Software systems.**
Everything is done in just one click. The only work of humans is to just wait and watch. The same is needed to be done in department/field of Vehicle Recognition and the applications related to it. Taking this into consideration the Vehicle Recognition Software is to be developed which will help in many ways like it will be helpful in parking areas, toll booth, maintaining law and Supressing criminal activities. The System will help in multiple fields and also the work load to humans will be decreased. This system will also help in better functioning of law and desired work. The system will consist of a software and hardware mainly.
Keywords – Vehicle recognition; Number plate; Compilation; RTO, ANPR-Automatic Number Plate Recognition, OpenFace.

I. INTRODUCTION

Vehicle Recognition and Compilation Of Database
is a software that recognises vehicle number from number plate and the face of driver. This technology consists of both software and hardware. Hardware mainly comprises the camera or detector that captures the face of driver and number plate of vehicle. Software will extract the number form number plate and stores it in database, the captured face will also be stored in database where it will be matched with the bio data of people for extracting the information of driver.

This software will help in many ways like it will help to know if the vehicle is over-speeding , if the traffic rules are broken by the driver and the RTO wants to check the registration of vehicle , if the vehicle is overloaded, the software will also help in case of theft, in case of toll on highways .The camera is fast enough that it can capture the number plate of fast moving vehicles.
The database of driver will be created when the vehicle is registered in RTO. The software has a special type of technology that converts the number plate image into text. The number plate should be according to the rules of RTO Terms and Condition. The camera will also have night vision, so that it can capture the images of vehicle in day as well as night.

II. PROBLEM DEFINITION

Design a software for vehicle recognition and compilation of database. The software should get input form hardware i.e. camera and read the image and match the information with database information and to do the task assigned (depends where it is used).The software should be useful in case of law enforcement ,toll booth, parking system, RTO offices etc. The software should use modern Algorithms and searching techniques for fast and accurate results.

III. BACKGROUND

Vehicle recognition is a deep learning based software that is available as computer software. Unlike other license plate recognition software's it has multiple
uses and has an additional face recognition technique which will help in case of theft and other crimes.

The license plate recognition technique algorithm first debuted in 2007 but the ANPR technique was invented in 1976 at police scientific development branch .Since then it is been developed and many new algorithms are introduced and proposed but no system is efficient for proper functioning of the system and the work assigned to it.
The Vehicle recognition uses the best and latest Algorithms for both facial recognition and number plate recognition for best and efficient functioning of the software. This is the best type of intelligent transport system. Previous methods have many names like ALPR,CPR,LPR,VRI and much more but no technique is efficient till now.

IV. IMPORTANCE

Vehicle Recognition has wide range of applications as number plate of vehicles is primary and mandatory identifier for vehicles. Vehicle Recognition helps in automatic content access and management of database of vehicle and drivers information. Some of its important applications are below--

Parking--The vehicle Number plate is recognised while entering in parking lot and the bill will be generated on account of driver, identified by facial recognition.

Traffic Control--The overloaded vehicles will be charged fine and the vehicles which are over speeding or breaking traffic rules will also get charged with challans.

Law Maintenance--Theft of cars from parking lots or garages can be prevented when the vehicle number plate and drivers face is recognised by software. The software will automatically send message to the owner of car if the car is spotted with other driver, also the car can be tracked by other cameras.

Border control--The unidentified vehicles can be spotted on borders and the drivers face can also be identified to alarm the guard's.

V. OBJECTIVES AND SCOPE

The main objective of building the system was to build an effective software and hardware that can help in recognising the vehicle by number plate and drivers face. The software is useful in Traffic control, Parking System ,Law maintenance and Border control.
The software can work efficiently in both day and night modes. The additional feature of the system is to recognise both face ID and number plate at the same time. It can also be used on entry gates of the buildings and apartments or college campus by recognising the face ID of driver or number plate of vehicle. Only the recognized and registered vehicles will be given entry.

VI. PHASES

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: First work to do is to get strong knowledge on this project title and get description preparation on it. After doing survey, some research is needed to be done for better understanding of topic in depth.

Designing: After research and survey, demo model/design will be built so as to read the prototype of project and then design the main project model. This will also help in checking the drawbacks in project.

Phase 2: Testing and Deployment.

Testing: After the model is ready the project will be tested on small amount of data (In a Building or Campus) to check the proper functioning of the system. If any issues are found then the issues will be resolved in the model itself and the model will be tested again.

Deployment: After testing and finalizing the model, the system will be deployed on the main one and the real time testing will be done.

VII. METHODOLOGY

The proposed system will automatically detect the vehicles and take snapshot of their number plate and driver and send the data to the System's software part for further work. The software will extract the text from the number plate and the face ID from the images and check for the information in the database obtained from RTO.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

- Resolution: 1080x720 and above, up to 1080p
- Alarm Center Workstation: Core i9, 12GB RAM, 2TB HDD Windows 10 OS
- Frame Rate: 20 fps and above
- Database: MySQL

- 1 HDMI to VGA converter
- 1 USB cable

IX. XI. OUTPUT

When the software gets the image from cameras the system will start generating information data from that image and start checking for the same matching data in database.

X. BLOCK DIAGRAM

Fig1. Block Diagram[4]

The above block diagram represents the working of the project. Here the input image is given to the software which is processed using the Algorithms.

XI. CIRCUIT DIAGRAM

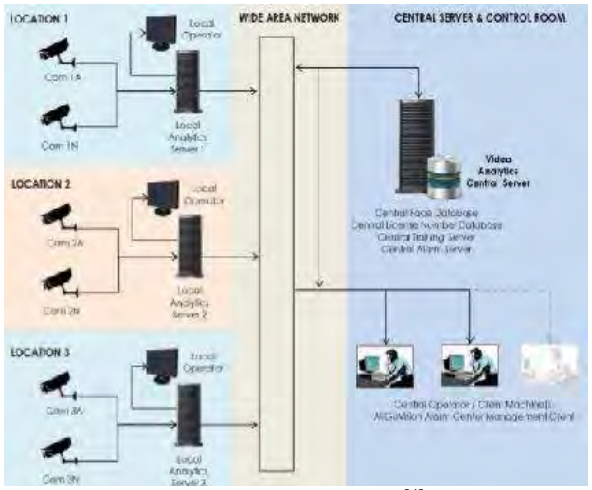

Fig2. Circuit Diagram[4]

This circuit diagram represents the internal working of the system. It consists of Hardware Part i.e. camera, the software part and the server database.

XII. RESULT

The software will match the information collected by the cameras and the information in database and do the useful work assigned to it as per use.

Fig3.Result and Output Diagram[4]

XIII. OUTCOMES

Creating the outline, survey work and research study for the proposed problem statement which will help in design phase of the project.

The work will help in suggesting that what work is needed to be done and what is not.

The research work was done to check the drawbacks of previously proposed systems and what is needed to be done further. Also, the survey and research helped to choose which algorithm is best for the work.

According to Survey work the Segmentation and Extraction algorithm is best for number plate recognition and for face recognition OpenFace algorithm is best.

XIV. RESEARCH GAPS

No project is 100% perfect. This project also has some [4] https://www.allgovision.com/index.php drawbacks. They have been discussed them below:

The system fails to identify the Face ID of drivers who's over speeding or if the vehicles windshield is not clean.

The system will not identify the number plate of vehicle if the number plate is not same as the guidelines provided by RTO office.

The system will fail if the Vehicle will be having a large number of printed characters or numbers on it. The system will get confused.

XV. SUMMARY

The vehicle recognition system software focuses mainly on detecting the number plate area of a vehicle and the windshield of a vehicle then takes pictures of it and sends to the software part of system. There the software uses algorithms for extracting the data from the images and matches it with the data in database which is created while registering the vehicle. After matching the data, the software will do the required and desired task assigned to it. For reference this paper also has an abstract and introduction at beginning. The paper also has importance, objectives and scope outcomes in it.

XVI. CONCLUSION

The Vehicle Recognition and Compilation of Database Software is a system software which uses two modern and efficient Algorithms for number plate recognition and face ID detection and then performs the desired task. It has many applications and future scope. The weakness of the system is also discussed in this paper.

Efficient Chatbot Designing

Akshat Chandel, Darshil Ajudia, Parth Desai, Hinal Kuvadiya, Pratik Bhatt, Manav Agrawal
TCET,MUMBAI
akshatchandel92@gmail.com, darshil1999@gmail.com, parthdesai0849@gmail.com, hinalkuvadiya@gmail.com, pratikbhatt503@gmail.com, manavagrawal12@gmail.com

Abstract— **It is very important to know what a chatbot is. So, a chatbot is a software or an interface to get work done via text messages or voice command-based conversation with computer program which may or may not be aided by a human.**
It can be referred as a conversation of a human with robot. It's very important for today's media and industry to integrate chatbots in their environment and so it's very important that the chatbots should be designed accordingly.
This paper deals with how to design an efficient chatbot that can be used a base template by any user and set some ground rules that should be followed by every user designing a chatbot so that it can be interactive like a human and can even provide responses based on human like thinking.
Basically, we would be emphasising on what chatbots really are and how are they so important in this era and also how to use them and how to create them.
Keywords –, chatbot; efficiency; conversational interactions;

I. INTRODUCTION

"Chatbots represent a whole new trend in how people access information, make decisions, and communicate"
This paper deals with what chatbots are, what they can be used for and how to develop an efficient chatbot. Most of the common people don't know what chatbots are and what potential it bears in todays technology age, so really what is a chatbot? "A robot" i.e. an autonomous program that can

imitate, behave and respond like a human being. So, in simple words CHATBOT can be defined as an automated computer program that can respond to the users in a human way and solve their queries and doubts in real time.
Designing an efficient chatbot requires some thought process about the use and needs of the user. So, there are some steps and rules to be followed which will be discussed later in this paper in designing a chatbot. Designing an efficient chatbot is very significant because it needs to meet the expectations of the company and the customers. Also, most users don't want to waste their time by speaking to a bot rather they prefer to talk a human and so designing an interactive and human-like bot is very vital. According to a survey, 60% of the users have claimed that a chatbot has failed to resolve their issues, so this may be very crucial for any company or an entity as it may lose its potential customers due to their unresolved issues and doubts. A chat bot needs a good script, name, platform and an image for it to work.

II. PROBLEM DEFINITION

Many chatbots are nothing more than glorified flowcharts, their responses fumbling forth from rigid IF/THEN scripts. Even artificially intelligent chatbots, though skilled at detecting patterns in human language, are lacking when it comes to natural language understanding. Inevitably, chatbots that draw replies from IF/THEN scripts will run into a question or request that wasn't accounted for. When this happens, most bots will attempt to recover by asking a clarifying question that redirects conversation back to the safety of their predetermined responses, but problems arise when a bot's corrective questioning leads to a conversational dead-end or places blame on the user, even subtly. Chatbots run the risk of being impersonal if designers aren't keenly aware of their user's practical and emotional needs when seeking help from a bot. Some chatbot designers are attempting to offset the impersonal nature of bot interactions by mining more and more user information. It seems obvious that this is a bad idea, but some companies continue to learn the hard way.

III. BACKGROUND

Chatbot also known as Chatterbots or chatter robots, is the computer system that can communicate with human in the form of messaging app. They can understand multiple question requested by humans. They also have the ability to differentiate between uniqueness of words including emoticons. In order to get the best quality of chatbot conversation, they need to have richness of vocabulary amongst people. Chatbot may look like a normal
messaging app, they have the application layer, a database and also APIs(Application Programming Interface) working at the background . User interface represent the interface to make easy contact with user. While Chatbot is easy to use, at background it has the complexity to achieve. Most of the chatbots have log of the conversation and the developers use these logs in order to understand user requests. The log is then used to improve Chatbot conversation. Chatbot works by matching the questions from user with the help of machine learning. The developer needs to train the chatbot to understand different questions and to deliver the suitable output. Chatbot is being trained through the analysis of thousands of logs from human conversations. More the number of logs the smarter the chatbot will be.

IV. IMPORTANCE

Chatbot applications streamline interactions between people and services, enhancing customer experience. At the same time, they also offer companies new opportunities to improve the customer engagement process. They also yield better operational efficiency by reducing the typical cost of customer service. To be successful, a chatbot solution should be able to effectively perform both of these tasks.

Human support plays a key role here: Regardless of the kind of approach and the platform, human intervention is crucial in configuring, training and optimizing the chatbot system. Even though they are increasingly used, the modern chatbot is still a young technology. With the continuing development of AI, the potential for bots in business and personal lives is unlimited. They can be easy to build. It depends on what you want to achieve.

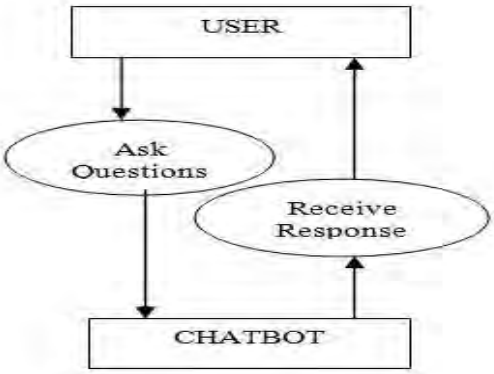
V. OBJECTIVES AND SCOPE

1. The amount of information present on a website is not accessible to an average individual if the visitor cannot find it. Chatbot can helps to make information accessible to all.
2.There is sharp decline in people downloading apps as some app which are not in too much use take to much storage. Chatbots will help get more customers and people who arrive at the website are able to ask queries and be answered more efficiently and quickly.
3.Chatbots can help to schedule meetings and broadcast newsletter.
4.Multilingual chatbots can communicate with people their comfortable in and attend their queries more efficiently.
5.Humans who can only communicate with one person at a time but chatbots can communicate with thousands of people simultaneously.
6. Chatbots are virtually robots hence they do not get tired and because of which they can work 24/7 and it will help to increase people to visit the website more since they get quick replies to their issues.
7.Chatbots helps to save money and are easy to configure for people having different needs and use of it.The cost of keeping them updated is very low.

VI. DESIGN OF CHATBOT

"Designing a bot is like brewing beer; it always takes the same ingredients to make it, but slight changes to the process can transform the whole outcome."

A chatbot is a computer program used to simulate real world communication. The chatbot is implemented to enact a conversation with user. The chatbot effectively responds to question posed by the user. Chatbots are not new invention, history of chatbots can be found during 1950–60s when Alan Turing & Joseph Weizenbaum contemplated the concept of computers communicating like humans do with experiments like the Turing Test and the invention of the first chatterbot program, Eliza. It helps the user by answering the questions asked by them. The program is implemented using Java programming language. Particularly Java applets are used. Applets are used because it is easy to create the dialog box required for the conversation between the user and the bot. The design of a chatbot is represented using the following diagram



The following points must be considered while designing an efficient Chatbot –

[A] *Selection of Platform*

The usage of a chatbot cannot be restricted to a single platform, hence while designing it the developer must really emphasis on making it platform independent.

[B]*Selection of Software*

Java is primarily the most used language to write chatbot for various needs. However, other programming languages such as Python, Closure, PHP, Ruby are also widely used to create robust chatbots.

[C]*Creating a Chat*

The chat is created using a pattern that is known to the user and could be easy to understand. Chat dialog box show up to create conversation. This dialog box is created using java applets.

[D] *Pattern Matching*

This process makes use of Artificial Intelligence to help generate response text for the chatbot. The input provided by user is saved into the database and is subsequently answered with an appropriate response.

[E]*Human Personification*

The way a chatbot responds to a user is hugely responsible for the growth of business or institution where it is being used. The conversation with the customer must reflect that a conversation with a real person is taking rather than computer program. The chatbot should be made witty and entertaining to ensure maximum user satisfaction.

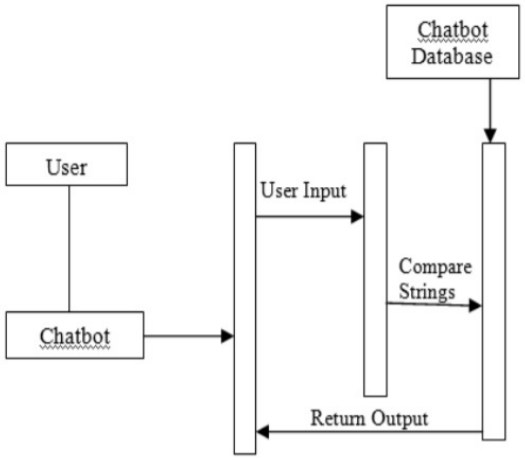
VII. IMPLEMENTATION PROCESS

[A]*Creating the dialog box on display*

All the essential packages required for creating the dialog box are imported beforehand. The size of the dialog box and text area inside the dialog box visible to the user is adjusted and implemented as per the rquirement. Vertical scrollbar is used so that the screen gets scrolled up as the conversation goes on. Horizontal scrollbar is avoided because the size of the dialog box is fixed.

[B] *Creating a database*

2-D string arrays are used for the creation of database. Rows in the array are used for request and response. All the even rows contain the request or questions and all the odd rows contain the response or answers. Columns in the array are applied to save different types of questions that could asked by the user and responses that a Chatbot can answer. There is one row in the array which contains default responses which is used when the matching question is not found in the array.



VIII. SOFTWARE REQUIREMENT

There are various tools that can be used to create a chatbot IBM Watson, Microsoft Azure Bot Service, QnA Maker, Semantic Machines, Recast AI. Once the chatbots are created we need to deploy them, the deployment of a chatbot depends on the user requirement. Some common platforms for deployment of a chatbot are Facebook Messenger, Slack, Skype for business, Facebook Workplace, Kik.

IX. IX. RESULT

Most people are attracted to a system that is human-like. And many users do not know that Chatbot will not only give feedback in the form of text and voice command whereas Chatbot nowadays have an interactive way of serving information using graphical interaction or graphical widget. Th main benefit of using chatbot is it is able to reach broad audience even from great distance only using the messenger apps. Beside that, this automated human-computer conversational platforms works positively to provide efficient service in various field to serve human in many ways. In this paper, the review is based on the design work, features, how it interacts with users and also its interface. Chatbots are actually an innovative approach to automate user-personalized messages. If the chatbots are well designed and implemented, it could be a tool to attract user engagement and provide good user experience between humans and the served field. The development of chatbots should carefully planned, choosing the appropriate platform tools is very important since it can help in boosting the effectiveness and efficiency of the chatbots.

X. X.CONCLUSION

We have successfully shown the importance of chatbot and its uses. It is reconfigurable in any sector and it can also be used for multiple task. Designing of efficient chatbots will meet the expectations of companies and customer. A chatbot i.e. designed humanlike bot will help customers to interact with them properly and get their queries solved. A multilingual hatbot will help users to ask queries in their preferred language and it help them to be comfortable while asking. Efficient chatbot will help in rise in business. As they are cheaper than hiring an employee company can buy them easily and chatbots won't take much time to work according to the company needs whereas employees can even take months. This will also help in making meetings, appointments, and also broadcast newsletters. This will also minimize the workload on humans. Chatbots require relatively low update cost, so it will help to attend more customers than average. This knowledge should help exploring further possibilities of chatbot and it should enable more companies to apply chatbots to new works and thereby also improve human-machine interaction.

App for Online Opd Appointment & Hospital Information System

Ritika Chaube, Rahul Kurmi, Richa Gupta, Neeraj Chauhan, Nilesh Gond, Chaithanya Moozhickal
Thakur College of Engineering and Technology, Mumbai, India
ritikarchaube@gmail.com, kurmirahul557@gmail.com, richag536@gmail.com, chauhanneeraj170@gmail.com, gondnilesh123@gmail.com. binuchaithanya0015@gmail.com

Abstract- **Appointment scheduling systems are used to manage access to service providers. Many factors affect the performance of appointment systems which include arrival and service time. Thus a proper scheduling system has to develop by considering all these factors which will increase patient satisfaction, which in turn increases profit. An online scheduling system allows individuals to conveniently and securely book their appointments online. Compared to the usual queuing method, the web-based appointment system could significantly increase patient's satisfaction with registration and reduce total waiting time effectively.**

Keywords: Online Appointment System, Scheduling

I. INTRODUCTION

The term of "appointment" refer to the period of time allocated in the schedule to a particular patient's visit and "service time" refer to the amount of time the physician actually spends with the patient. Appointment scheduling can be classified into two broad categories. Static and Dynamic. In static appointment scheduling all decisions must be made prior to the beginning of a session, which is the most common appointment system in healthcare. In dynamic appointment scheduling the schedule of future arrivals are revised continuously over the course of the day based on the current state of the system.

The appointment-scheduling process which is either dynamic or static can be viewed as burden in hospitals, which can be eliminated through an efficient online appointment scheduling system. The benefits of implementing this technology touch everyone involved in the scheduling process. Administrators and staff can conduct their tasks more efficiently and accurately, while patients have the ability to book their appointments and reservations quickly and more conveniently Patient can also provide additional information to the doctor, making the doctor aware of their situation and giving the doctor time to prepare the necessary information for when the patient's arrives. For doctors, online appointment scheduling brings a lot of value add services and being able to store patients' data securely for future reference. But the most wonderful and useful advantage is that online appointment scheduling is amazingly low cost.

II PROBLEM DEFINITION

The appointment-scheduling process which is either dynamic or static can be viewed as burden in hospitals, which can be eliminated through an efficient online appointment scheduling system. The benefits of implementing this technology touch everyone involved in the scheduling process. Administrators and staff can conduct their tasks more efficiently and accurately, while patients have the ability to book their appointments and reservations quickly and more conveniently. Producing standard appointments of 15, 30 and 45 minute durations. In contrast, paediatric practices, and some family practice groups, tend to use 10 minute increments with resulting planned visits of 10, 20, 30 and 40 minutes. In this method physicians can reduce down time and the need for double booking by calibrating scheduled time closer to actual visit time. But it increases the complexity for scheduling personnel.

III BACKGROUND

A number of different methods are available to schedule appointments in the medical office. They include the following:

- Double Booking
- Ten Minute Increments
- Modified Wave Scheduling.
- Staggered Starts
- Group Meetings

IV IMPORTANCE

Modified Wave Scheduling: In a modified wave system, patient appointments overlap so that when one finishes early, another patient is waiting to be seen by the physician.

Staggered Starts: If a modified wave schedule is not appropriate, some of the same benefits can be achieved by staggering visits in five or 10 minute intervals.

Group Meetings: By seeing such patients as a group, some physicians have found they can save time, create a highly supportive atmosphere, and devote more time to patient education and health issues than would be possible during traditional office visits

Double booking: Double booking appointments is a basic technique for minimizing down time by ensuring that there always is a patient ready to be seen when the physician is available

Ten Minute Increments: Internists traditionally design schedules around 15 minute time increments, thus In traditional appointment system patients has to come to the hospital and queue at the appointment window to make the appointment. But they usually end up waiting for very long periods of time. The patient can, however decide to schedule an appointment, but this option does not usually work well for all parties

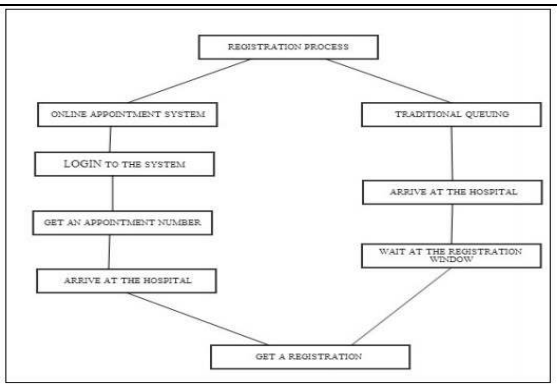
involved. Online appointment System provides the following benefits:-

- Schedule patients for various medical procedures-test, treatment
- View daily, weekly, monthly patient schedule
- Create Patient Records and Appointment reports
- Helps to trace Patient Flow based on arrival, visit and departure time
- Avoid no-show, missing, over- booking patients and other conflicts
- Email appointment schedule reminder
- Provide daily appointment scheduling reports.The flexibility of online scheduling system enables it to be utilized for a variety of different services and activities such as:
- All the appointment can be aggregated from the website, phone enquiries or direct enquiry
- Scheduling patient appointments, treatments and services
- Booking vaccine

V.OBJECTIVES AND SCOPE

The main objective of developing this project was to build a online OPD appointment & hospital informative system. In traditional appointment system patients has to come to the hospital and queue at the appointment window to make the appointment. But they usually end up waiting for very long periods of time. The patient can, however decide to schedule an appointment, but this option does not usually work well for all parties involved. Parties involved includes: the patient, the medical personnel and the hospital. The patient wishes for readily available and convenient appointment times. When they do not find a close enough appointment time they experience long periods of indirect waiting time (time between scheduling the appointment and that appointment becoming available).The patient also wishes to be seen either immediately or within minutes of their arrival (whether they scheduled an appointment or not). The time that the patient waits from the scheduled start time of their appointment to the time that they actually receive service is called direct waiting time. The patients using this method waste much unnecessary waiting time standing in line at the registration window to ensure a successful registration with a certain physician.

VI. PHASES



Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting strong knowledge of the project title and doing exploration on it, we will get our description. Preparation: After we will first study about it and do some research on the project for our better understanding and also getting a rough depiction about what would be our problem definition for this particular project.

Designing: Then we will build the design of the project and agreeing to that, will list down all the necessities needed for the creation for the prototype of our project.

Phase 2: Testing and Deployment.

Testing: After the model is ready we will first associate the hardware with the allotted code and then we will check if it supports the machine or not. If not we will resolve the issues relating to it and will crisscross again.

Deployment: After completion of integration and testing of project, real time testing and operation of the system will be done.

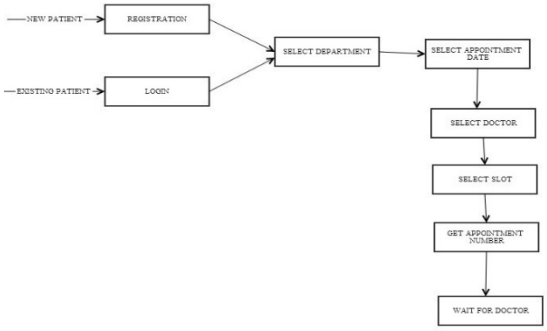
VII.METHODOLOGY

In online appointment scheduling system patients are given an appointment number. At the designated appointment time, patients arrive at the hospital and get the registration that is allotted to their appointment number. These patients need not queue at the registration window. In this way both direct and indirect waiting time can be minimized and hospital's valuable resources can be utilised efficiently.

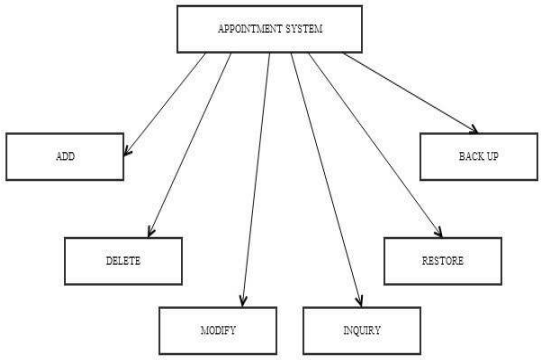
VIII. SOFTWARE ARCHITECTURE

- Schedule daily appointment list of patients
- View patients complete information
- Reschedule the appointment
- Assign time slot to each patient
- Cancel the appointment
- Check Doctors availability for patient's Appointment
- Send reminder SMS to patients

IX. BLOCK DIAGRAM



X.CIRCUIT DIAGRAM



Database Management consist of Appointment Details, Addition of data, deletion of data by the Authority, Modification of data

It also consist of inquiry section, as well as Backup

XI. OUTPUT

As we go on the appointment system, we get the option of registration as well as login option and then only we can go to the appointment section

XII. OUTCOMES

Creating the outline, works survey and achievability study for proposed solution which will act an input to the design phase. Suggesting Statement of work, scope description and scope border for planning the model from the problem definition to decide what needs to be done and what not to be done.

Phase 1 Implementation: Implementation of the online appointment scheduling system with the help commands running it in the Linux environment.

Phase 2 Testing: Testing was done with cases like testing mic and speakers , Testing by asking different queries to the assistant .The testing of the model was a success are mentioned in the above figures.

Phase 2 Deployments: Real time working was done when we asked questions and assistant replied the answers appropriately. Thus the model works efficiently.

XIII.RESEARCH GAPS

Every project has some gaps in it. No project is 100%efficient. There are some gaps in this project too. They are as follows:

Since the Wi-Fi was not working with the online appointment scheduling system ,due to this confusion was raised.

The system cannot control other devices connected on the network right now. It needs to be configured in that manner to do so.

XIV. SUMMARY

The user login and registration requests are processed by the portal server which located in 2- tier. The application server is a component that manages the complete end-to- end appointment tracking and scheduling services. The key functions of application server include: (1) multiple-practitioner scheduling, (2) centralized and consolidated patient appointment tracking, (3) available appointment searching, (4) appointments rescheduling, and (5) appointment confirmation and cancellation. Detailed information about each scheduled appointment slot, such as patient login and contact information, is also stored into the 2-tier database

XV.CONCLUSION

One of the biggest reasons that online appointment scheduling is getting popular day by day is that it helps the patient to make the appointment to their doctor, clinic or hospital in an easier way. It makes it through the computer, access a website or software and makes an appointment, than to go to the hospital, wait in a line for a number of hours, just to make an appointment with the doctor for the next week or next month. And through this, patients can also involve in the health decisions that they have to make. They can make an appointment to another doctor other than theirs, by nothing more than a click.

State Teacher Eligibility Test (STET) Software For Government Of Sikkim

Rohan Sharma, Urvi Sharma, Janhavi shetty, Pratishtha Singh, Smruti Singh, Rohan Vishwakarma
IT Department, Thakur College of Engineering and Technology, Mumbai
rohann20sharma@gmail.com, urvi321.us@gmail.com, janhavi9520@gmail.com, prati3331@gmail.com, singhsmruti2001@gmail.com, rohanvishwakarma@gmail.com

Abstract— **TET or Teacher Eligibility Test is an exam conducted at state levels to determine the eligibility of candidates for their appointment as teachers in central or state government schools. This exam is conducted offline (Pen and paper test) and it consumes a lot of time and labor. As a result we have come up with the idea of online portal of the same. The project entitled "ONLINE STATE TEACHERS ELIGIBILITY TEST" is aimed to conduct examinations for aspiring teachers in an efficient manner without time wasting for the checking of paper. Online examination system is a web-based examination system where examinations are given online either through the internet or intranet using computer system. . The main goal of this online examination system is to effectively evaluate the student thoroughly through a totally automated system that not only reduces the required time but also obtain fast and accurate results. In this automated system there is no need of paper and pen.**

Keywords – Online examination, Employment, Eligibility Criteria, Internet connectivity, Educational Institute.

I.INTRODUCTION

The Teacher's Eligibility Test is a test that is conducted for appointment of eligible teachers into Government Schools. This test is conducted for teachers from class 1 to 8 and is conducted as Paper 1 and Paper 2. Paper 1 for class I to V and Paper 2 for class VI to VIII. These days most states conduct their own TET. Which are conducted in offline or online mode. Today, Online Examination System is considered a fastest developing examination method because of its accuracy and speed. It is also needed less manpower to handle the examination. Almost all organizations today, are managing their exams by online examinations.

TET was introduced by Indian government in the year 2011 to improve the quality of teaching in government as well as private institutes. The teachers already teaching in the institutes were given time duration of 2 years to crack the examination for continuing their profession as a teacher.

The National Ministry Of Human Resource Development handed over the responsibility to Central Board Of Secondary Education (CBSE) to conduct Central Teacher Eligibility Test (CTET). Since, CBSE conducts this examination twice a year. On 8 December 2019, CBSE successfully conducted its 13th edition of CTET examination. This examination covers 110 cities across the country. Over 14 lakhs candidates participate in this examination.

In a country like India, where youths are in majority and are considered as the pillars on which our country's flag will stand to be on top of the world, quality education plays an important role. For our country's development in every aspect, it is necessary that the young generation should be provided with the best education this country has to offer. In such a scenario, teachers act as concrete to this foundation. A good teacher will give rise to an excellent student.

TET was made a necessary and important prerequisite for appointment of teachers all across the country to set a national benchmark for recruitment of teachers. It is also necessary to increase standards of teaching quality and improve performance of teachers, students and institutes.

We, by our project have given a solution to the Government of Sikkim to have their own Online State Teacher's Eligibility Test to ensure that the best and well qualified teachers get appointment as teachers in their state.

II. PROBLEM DEFINITION

Nowadays we have most states in India having their own TET But with the growing population and depleting resources the traditional pen and paper wouldn't be much helpful in the long run also, considering the ongoing digitalization every state is now opting for an online software to take up the task of successful and efficiently conducting the TET. One such government requiring an Online Software for TET is the government of Sikkim.

III. STATEWISE TET CONDUCT

Every year many states all across India conduct TET examination in offline as well as online mode for appointment of teachers. Statistics of this examination of few states are stated below.

A. Andhra Pradesh & Telangana (APTET): CBSE who is responsible to conduct CTET has given accreditation to Andhra University to conduct their state TET known as APTET once in a year for recruitment of teachers in their states. In the recent APTET held in 2019, over 4 lakh candidates from the state appeared for this examination.

B. Uttar Pradesh (UPTET): The Uttar Pradesh Basic Education Board (UPBEB) has the authority to conduct its Uttar Pradesh Teacher Eligibility Test (UPTET) annually. Mode of this examination is offline.

C. Rajasthan (RTET): The Rajasthan Board of Secondary Education has the responsibility to

conduct their state TET examination also known as Rajasthan Teacher Eligibility Test (RTET). Over 9 lakh candidates appeared for the RTET examination in the year 2019. The mode of conduct of this exam was offline.

I

D. Haryana (HTET): Board of School Education Haryana (BSEH) conducts Haryana's TET. The candidate who has qualified the exam has to reappear for the examination every five year. The candidate can give reexam end number of times. Over 2.5 lakhs candidates gave this examination in the year 2019 and only 21,993 candidates could crack it.

E. Punjab (PSTET): The Department Of School Education is responsible for Punjab State Teacher Eligibility Test (PSTET). In the year 2019 about 1.7 lakhs from Punjab and neighboring states appeared for the exam.

Sr. No.	Paper Title	Author	Year of Publication	Key finding	Research Gap
1	Web Based Online Examination System	Prof. Rahul Shahane	2017	This process is focused on removing unwanted vantages and is intellegible and user friendly.	In few Centres it was noted that only those who have registered already can give the exam and this process was done manually which is not appropriate.
2	An analysis on online examinations in college courses	Andrew P. Barkley	2001	Large cost saving of substitution of machines in labour. On spot evaluation of the exam and result display.	Unable to know the indepth theoretical knowledge of the teacher who is giving the exam.
3	Online Examination System.	Muna R. Hameed	2017	Obtain fast and accurate reluts in given period of time through a totally automated system using PHP and web servers.	The changes can be done in the question paper i.e. in an unauthorised way and the database can also be altered.
4	TET Online Examination	Shreya Sareen	2020	TET helps students getting proper knowledge from a educated professor. Professor also need not go to 10 schools or colleges and apply, rather they can give the exams and apply directly.	State TET is done for many states in India but not in Sikkim due to the network and runability issues of software at different places.
5	The Research and Design of Online Examination System	Zhang Yong-Sheng	2015	This system adopted B/S mode and used coding tool combined with MySQL database.	The area where there were network connectivity issues could not be able to give the exams which leads to unemployment of well-educated and hardworking people.

IV. LITERATURE SURVEY

1. Uploading the paper pattern and previous years' question papers on the website.
2. Issuing notices regarding the eligibility criteria to appear for the exam which requires the candidates to be aged between 18-35 and have a Bachelor's Degree in Education (or an equivalent course).
3. Declaring the examination dates.
4. Verifying exam applications which includes authenticating candidate's identification proofs and other important documents that make sure he/she fits the eligibility criteria.
5. Notifying the eligible candidates confirming their registration.
6. Conducting the online examination.
7. Providing the results immediately after the completion of the test.
8. Issuing online eligibility certificates to the passed candidates.
9. Allocating teachers to the educational institutes as per their requirements.

Following are the functions performed by the client:

1. Logging into the website.
2. Registering for the examination by uploading bonafide documents such as identification proofs, degree certificates, etc.
3. Appearing for the examination upon receiving the exam notification.
4. Obtaining result.
5. Receiving eligibility certificate.
6. Raising a grievance in case the candidate is not satisfied with the allocated institute.

V. SUBJECT DESIGN AND CURRICULUM

The website is based on client-server architecture. Here, the Ministry of Studies (Government of Sikkim) is the server and the teachers appearing for the eligibility test are the clients.

Following are the functions performed by the server:

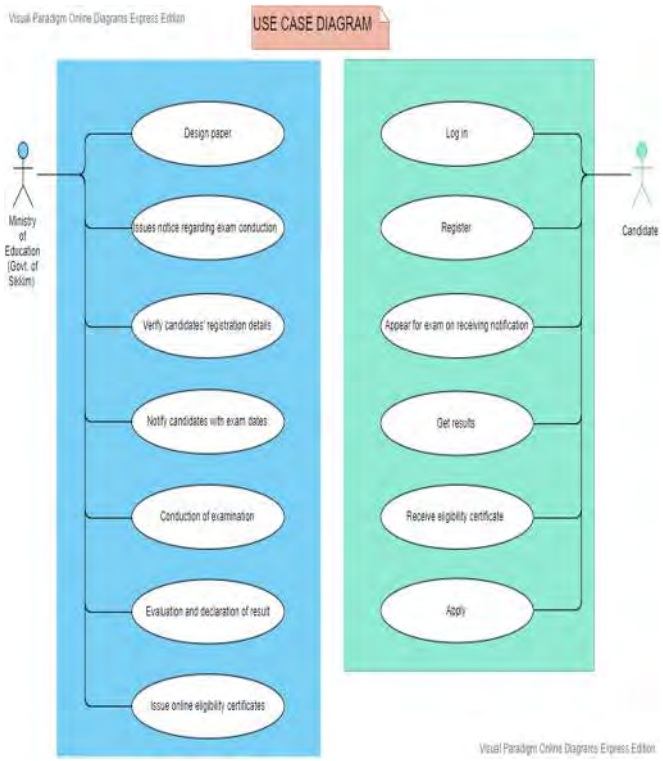

Figure : Use Case Diagram

VI. RESEARCH GAP

The online State Teacher Eligibility Test is conducted in many states across the country except Sikkim due to lack of network connectivity. The eligibility certificate of a particular state cannot be used in other state due to different eligibility criteria and requirements of subject knowledge. Since the mode of answer is objective in online tests, subjective knowledge is not tested which leaves us with a big question mark of whether that candidate is truly eligible or not. Due lack of knowledge of computers in many parts of the country lead, many candidates fail to understand the working of online examination and hence are left unemployed.

VII. EXPECTED OUTCOME

The main purpose of the system is to efficiently evaluate the candidate thoroughly through a fully automated system that not only saves a lot of time but also gives fast results and saves paper. It is a cost-effective and popular means of mass- evaluation system. The faculty prepares the tests and questions for each exam. The candidates can login through the client computers with their registration number given to them and can take the exam. The questions are shuffled in a random order so that possibilities for getting questions in the same order for the students who are beside is very less.

Objective of proposed system

I. Economic feasibility: When an exam is placed online, it results in significant cost savings. The cost of paper and distribution expenses are all reduced or eliminated. The elimination of paper costs alone is extraordinary. The copying and distribution of assignments to a large class are often unwieldy and inefficient. Administrators anxious to reduce expenditures are likely to strongly favor the transition from paper assignments examinations to using online assessment software.

II. Time Flexibility: Online examination systems make use of computers that helps in saving time. With the widespread availability of computers and the internet, there is a general acceptability and endorsement of this system. The lengthy formalities and processes involved in creating question papers, registering candidates for exams, answer sheet evaluation and declaration of results are completely eradicated with the online exam system. Each student is timed precisely and all results are generated instantaneously. In some cases, a candidate may even be able to get an assessment on failed questions.

III. Technical feasibility: A major highlight of using a web based exam software or an online examination system is that it gives a high level of transparency as opposed to the traditional method or remote method. It is almost impossible to compromise exam questions and evaluations because they cannot also be influenced. Most online exams generate their results instantly and it is often possible for the exam taker to get information on his results immediately.

IV. Eco-Friendly System: This is one of the major benefits of online testing. This kind of eco-friendly and forward-thinking approach to daily processes is essential in a world where students can graduate into an environmental crisis caused by climate change. From teachers, exam papers, electricity, etc, all of the cost can be drastically reduced by online tests.

VIII. SOCIETAL OUTREACH

The State TET will directly affect the employability of the teachers of Sikkim. As the teachers will have a proper government job after clearing the exam they would not have to roam here and there to 10 different schools and give all kinds of interviews, the teacher or professor will be all tested once by giving the test. This test is not only useful for the Faculties but also for the students who want quality education. Students in government schools and colleges need professors who are educated enough and can guide the students in the right path. Students will also willingly go to schools and colleges to gain education and stand on their

own. The 2 level examination procedure of STET i.e. Paper-1 and Paper-2 would clarify and distinguish between the faculties that who is eligible to teach higher standard students. The costing of papers and other materials would be cut off which was earlier used for the examinations. The technical growth of the state will also increase. Sikkim would turn more technical and would be able to compete different states at different levels. Since the teachers teaching would be well educated, this will attract the students from other states to study in Sikkim which will increase the economy and overall development of the State.

IX. RESULT

- The result affirms that our software helps overcome the drawbacks of the previous sites that conduct the online examination.
- In online examination process, security is one of the critical challenges. Proper authentication, authorization process is followed to ensure that the right candidate is appearing for the exam in a secure environment.
- In case of electricity cut, this software provides a data backup so candidate can continue the test from the same place as before.
- With improvising the software, we also contribute in saving the nature by building an eco-friendly system where there is no use or wastage of papers.
- Instant generation of results reduce the manual working of evaluation of test and saves the time for declaration of final ranks and further process.

X. CONCLUSION

The website provides facility to conduct online Teacher Eligibility Test for the state of Sikkim. It saves a lot of time, money and effort as paper cost is cut along with no labour charges to physically transport the question papers and collect the answers after the successful completion of the exam. The issue of electricity cut during the online examination may rise up but that is resolved using our software. The result gets displayed after the test is done which is generated by the server and this feature helps the examinee to not be burdened by stress of waiting for the result. The authority also has the privilege to modify and delete questions from the paper in case of any mistakes which ensures correction reaching on time. To sum up in short, the software developed, is a total win-win for both parties, the one giving the exam and the one taking it.

E-Marketplace for Tribals

Vivek Shah, Laxmi Yadav, Rahul Singh, Anita Uniyal, Ashutosh Sanghvi, Riddhi Umap
Thakur College of Engineering and Technology
Mumbai, India
vivekmihirshah@gmail.com, laxmi31520@gmail.com, singhrahulkumar564@gmail.com
Anitauniyal2001@gmail.com, ashutoshsanghvi7@gmail.com, riddhi.umap17@gmail.com

Abstract:
As the trend in the urban areas consumers in the rural areas are also expected to have a hold on online purchase over time. Due to great advancement in technologies already the tribal people are getting access over better telecommunication service and witnessing increasing use of smartphones and computers. Taking advantage of these online portals we have come up with an application for the tribal people for marketing wherein people can do marketing over internet application or website. As 70% of India's population resides in rural area so this application can be useful. This shall reduce the human efforts and load which can serve the task of transporting the goods to the tribal by just relaxing at home. We humans have always looked for new inventions that meet our desire and comfort so this e-marketing for tribal can be beneficial.

I.Introduction:

Most of the forests and mountain regions are occupied by the tribes. Tribal people pay an important role in tribal areas of India by resorting to the sales of their own produce procured free of cost from the forests and mountain and making purchases of their other requirements.

Thus, they help distribute the forest produce to plain areas direct and through Government and other agencies, now they can also sell their
products online through E-commerce websites. The people are accustomed to live in small huts and houses.

Generally, they are below middle. Their cost of living is quite less when compared to that of the plains people. Low literacy rate is common in the tribal communities. The tribal people retain some of their sale amounts for investment required to enhance their business activity.

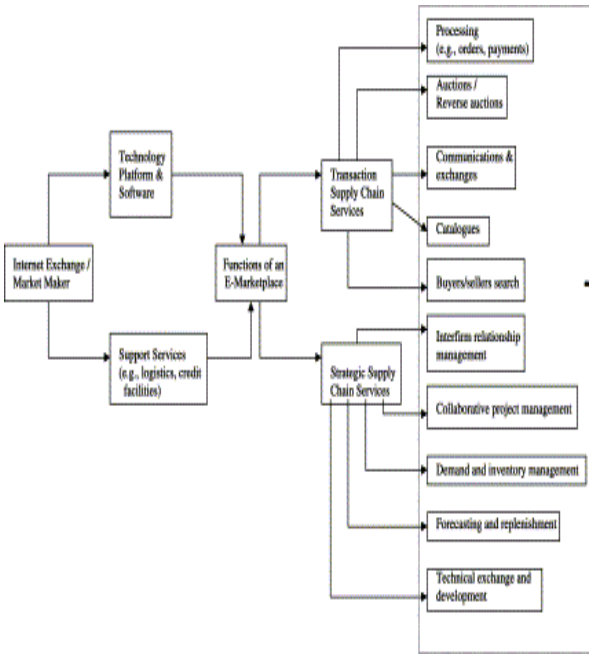
In addition to such savings, they get loans and advances from the Banks, G.C.C., Tribal welfare Department of the State, TRICOR, International Fund for Agriculture Development (IFAD), money lenders, middlemen etc. Financing business operations through these media is a very important aspect of development of business by the tribal people. The minor forest produce is procured and sold by the local tribal people in te weekly markets, along with that we can offer an online portal to sell those things using E-market or E-commerce website/applications

II.Problem Definition

The major wrong advantage taken by higher authorities is due to social backwardness, poverty and lack of digital literacy of tribal people. By which they are wrongly exploited and their trust on such schemes and great digital reforms are hindered. Due to which they themselves are made
to think that they are inferior from other sections of society and they are isolated from this great platform of digital development and transportation. Corruption is also biggest factor due to which awesome facilities and technologies are reaching to remotest of parts of India. Which ultimately doesn't serve the purpose of digital platform background
for every section of society. And this digital
isolation doesn't keep them attached and updated with happenings of world. Tribal regions are very well known for their sculpture, paintings, textile arts and pottery which indeed fascinate different sections of world. But because of literacy and lack of awareness of tribal people and wrong exploitation done by higher authorities the poor sections are made to sell their fine art products cheaply and they are actually are not paid the right price. Tribal areas are still thought of areas of wrong due advantage by world by which they are still thrown deep down in the black hole of under development and poverty.

III.Methodology

The customer first needs to register himself. The home page will contain the pictures of the recent searches of various products. Recent searches will appear with the help of keywords used. If any customer purchases article of more than Rs 500 discount of 10% will be provided.



Survey:

Sr no.	Title	Author
1	Journal Of Humanities And Social Science	Dr. Nirmala Alex1
2	E-Marketing-A literature Review from a Small Businesses perspective	Hatem El-Gohary
3	Tribal marketing: The tribalisation of society and its impact on the conduct of marketing	Bernard Cova and Véronique Cova

IV.Result & Discussion:

The following is the SWOT analysis of the tribal people adopting e-commerce in India:

Strength: Minor forest products are abundantly available in India, which can be used in productive and creative ways. Indian villages have a unique and diversified culture which produces a wide range of exclusive handicrafts. There is an increasing number of skilled artisans and an increasing knowledge about the demands of consumers, positive attitude of the sellers towards the government and non-government agencies and elimination of the middlemen due to e-commerce resulting in low distribution cost.

Weaknesses: Lack of adequate devices and infrastructure; lack of awareness about new designs, innovations and
technological upgradations; highly fragmented industries; limited capital and low investment capacity of artisans; insufficient market information on trends, opportunities and prices; limited access to credit and limited resources for production, distribution and marketing.

Opportunities: Global identity of the product and business and broader customer base due to e-commerce; rising demand from consumers in domestic and foreign markets; direct contact of customers and identity of self; middlemen being eliminated can make them fetch good price of the product in the market; government and NGOs' support and interest in preserving craft and marketing support.

Threats: The lack of authentic data on artisans, including their socio-economic status, livelihood conditions and family details is a major bottleneck which adversely affects planning and policy making for this sector; low infrastructural facilities, issues of logistics and network connectivity; decreasing supply of good quality raw materials; increasing customer sophistication and expectations; threats and exploitation by cyber intermediaries.

V.Conclusion

The Indian economy mostly depends on agriculture, as millions of people are directly orindirectly dependent on agriculture. Besides agriculture, rural arts and crafts give a gainful occupation to a large number of rural populations. They also serve as subsidiary occupation to agriculture and increase their rural income substantially. Major population of our country belongs to rural areas. Any strategy for national development must be associated with the development of rural areas. Every individual
artisan can develop his/her own website or with the help of cybermediaries, they can start e-commerce activities; NGOs' and other private institutions can help the tribal people to market their products online. Thus, e-commerce can provide tribal people an opportunity to reap the advantage of widened markets beyond the limits of geographical boundaries.

VI.Future Scope

Our biggest aim is to make a website to promote the tribal products so that we can overcome social backwardness, poverty and lack of digital literacy of tribal people. As we know e-marketing professionals are highly paid, so this market will increase job opportunities for tribal people as well. E-marketing has resulted in drawing the best possible revenue to the business. Due to high revenues, the discount on the products can be increased which will result in increase in sale of the tribal products. The Reviews on the product can be made mandatory so that product come in the search page and the product will stamp on the consumers mind. As we know the available e-market like Amazon does not sell ship product above 8 kg and does not sell product above 30 kg, we can incorporate the transportation facility to overcome this problem.

Global Tribal Survey for E-market

PotSol

Nidhi Shetty, Avisha Jain, Aastha Shah, Hetansh Shah, Tanisha Rai, Sajjad Shaikh
Thakur College of Engineering & Technology,Mumbai, India
nidz251100@gmail.com, avisha9619@gmail.com, shahaastha8@gmail.com, hetansh403@gmail.com, tanisharainp20@gmail.com, starix456@gmail.com

Abstract— **Potholes on Indian roads are emerging as one of the biggest killers. The scenario is very dismal with more than 1,37,000 people dealing with injuries due to road accidents. Almost 30 deaths every day are caused due to potholes and speed which have claimed over 10,000 deaths for the last three consecutive years. Potholes Don't Just Cause Car Accidents, But Fatal Motorcycle Accidents Too. Potholes also cause major problems to the pregnant women and to other people too that are suffering from bone disorders. So we have come up with the solution called PotSol (Mobile Application for users and Website for admin). The aim is to easily manage the entire process of pothole management, hereby managing and dealing with potholes thus taking a step towards the betterment of the nation. Phases involving Centralized database generation, Image Processing, Pothole Sensing and Geo-tagging will be implemented and the target pothole area will be determined from the images that are uploaded by the users. Further the status associated with the tasks will help to manage potholes in an effective and efficient way thus preventing damage. Use of this proposed system will ease the entire pothole detection and its management thus minimizing the risk of human life.**

Keywords – Pothole, Geo-tagging, Image Processing.

I. INTRODUCTION

Potholes though seem inconsequential, may cause accidents resulting in loss of human life This may affect pregnant ladies as well as the people with cervical disorders. Potholes not only cause damage to the humans. But it also causes wear and tear to the vehicle. Which may lead to depreciation cost to the vehicle? P.M. Narendra Modi stated that "If Potholes aren't treated properly, they may lead to more deaths than cancer ". He has also started a development in the road sector again. He has grand plans to build more than 80,000 kilometers of roads by 2022. This paper, we present an automated system to efficiently manage the potholes in a ward by deploying Geo-tagging technique that overcomes the drawbacks associated with the existing survey-oriented systems. Every year, local authorities come under renewed pressure to maintain and improve the road infrastructure. Indeed, some would argue that public satisfaction with road maintenance is at an all-time low. However, with potholes on the rise, local authorities will have to consider how best to minimize their risk exposure and manage the budgets to ensure long term pothole and road maintenance. Proper risk management processes should therefore be put in place to mitigate both the reputational and financial damages associated with pothole management.

Figure 1.Literature Survey

II. PROPOSED SYSTEM

The proposed system consists of two modules application and a website. User Log's in and acquires the image of pothole. The uploaded image along with the Geo-co-ordinates is viewed by the admin. Admin views the pothole image and Geo-co-ordinates and assigns the tasks which will be visible to both the admin and the user. Also the status associated with the assigned task will be updated.

III. WORKING:

The Proposed system consists of an application (user) and a website (admin).

Images of the Potholes will be uploaded by the citizens through the application along with the automatically fetched location (through geo-tagging) and size (through image processing).

The uploaded image along with the Geo-co-ordinates will be viewed by the Admin (appointed by civic body) on the website.

Workers will be assigned tasks to resolve the potholes; also, the status associated with the assigned task will be updated which will be visible to both the user and the admin.

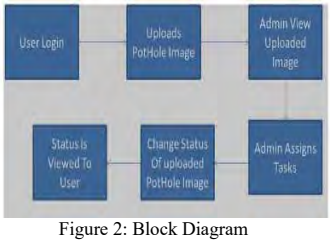

Figure 2: Block Diagram

Application:

- Register/Login: The user needs to register by providing the necessary information. If the user owns a vehicle he needs to provide its details too(for sensors). After successful validation with the help of two factor authentication, the user gets to see the different available options.
- Reporting a Pothole: To Report a pothole, the system provides two facilities:
  - While walking, if the user spots a pothole and wants to report it, the user needs to select the send picture option, click or choose the picture and click on upload; the appropriate location & approximate size are also attached with the help of Geo-tagging & Image Processing features.
  - While travelling, the sensors embedded in the tyres of the vehicles owned by the user will collect the information about the detected pothole and it will pass it to the application, which will then be uploaded.
- Check the Status of the reported Pothole: If the user wants to know current status of the grievance uploaded by him then he can check it by clicking on the Query status option. Here the user will also get to see the resolved pothole's Image provided by the officials.
- Citizen of the Month: The user reporting maximum number of potholes will be declared as "Citizen of the month" and may receive various goodies from the government.

Figure 3: Login page

Figure 4: Query Interface

Website:

- View Queries: Here the Admin(assigned by concerned government bodies) will view the received Queries through application along with the location on the map provided by geo-tagging and will assign workers to resolve the reported grievance.
- Providing Status: The time period will be automatically provided based on the size of the pothole and once the pothole is repaired ,the admin will provide complete status with the help of an image captured at the same location (so that the users cannot be manipulated). The status will be viewed by both user and the admin.

This System thus completes the loop, as the user gets a response to his reported grievance.

Figure 5: User queries

Figure 6: query details Interface

IV. Design Aspects of the System:

- Application (user)-

After launching the application, introduction about the system is displayed. For a new user, create account section and for an existing user, a login section is seen otherwise he/she directly sees the menu containing UPLOAD PICTURE , QUERY STATUS ,CHANGE PASSWORD and LOGOUT SECTION.

- Website (Admin)-

The website contains a home page where total counts about the number of potholes registered , resolved and pending can be seen along with the introduction of the system, it has a menu containing sections like view queries, view users, citizen of the month, logout and change password.

V. Advantages:

- Decreased number of potholes will lead us one step closer of becoming a developed nation.
- Number of Death rates will be decreased.
- Due to the feature of geo-tagging the user does not need to enter the address manually.

VI. Dependencies:

- Internet Connectivity
- Enabled GPS

VII. Conclusion:

Phases involving Centralized database generation, and Geo-tagging will be implemented and the target pothole area will be determined from the images. Further the status associated with the tasks will help to manage potholes in an effective and efficient way thus preventing damage. Use of this proposed system will ease the entire pothole detection and its management.

Tracking Software with Hologram Technology to Secure Goods

Bhavanish Dhamnaskar. Harsh Sharma, Siddeshwari Patil, Dhanashree Shripatwar, Saakshi Pawar, Suyash Sawant
Department of Information Technology, Thakur College of Engineering and Technology, Mumbai
brdhamnaskar@gmail.com, (sharma.harshmukesh271@gmail.com, patilsiddi123@gmail.com, dhanashreeshripatwar@gmail.com, saakshipawar02@gmail.com, suyashsawant11@gmail.com

Abstract— **This paper presents a possible system for online shipment and delivery tracking using RFID technology and robust hologram grid system to ensure the security of the goods placed inside the container and protect it against theft. The software aims to track the location of the delivery at every instant of time, i.e. from the time of shipment to delivery, and using a smart hologram technology increase the accuracy in shipment of the packages as illegal attempt to unload any package would create an alert. So both the goods and their carrier vehicle are being monitored simultaneously. The database of the system is quite robust and provides useful information about the shipment by simply clicking buttons on the application which is available on both mobile and PC. Actual implementation of the software has not yet been tested but the results of the research show us that the system is promising for online goods tacking.**

Keywords: Hologram grid system, RFID technology, delivery tracking

I. INTRODUCTION

The need of tracking softwares is of a greater importance for many manufacturing firms nowadays. It is essential for managing logistics network efficiently and ensures high customer satisfaction. Delays in the shipment delivery of even a few days can cause a great loss to these high manufacturing firms. Coordination problems between shipment dealers and third party receivers causes imbalance in the production department as well as the sales department resulting in poor customer satisfaction. It also breaks the trust in relationships between firms gradually. Hence it is truly important for the third party receivers to know exactly till where their shipment has reached. Some companies have created great softwares used in tracking systems, but some limitations such as non functionality on iOS devices, lack of information displayed in mobile phones, networks issues causing failure in real time display of location. Also, due to minimum security arrangements for the cargo kept on the ports or in trailers or trucks, the risk of theft increases. Cargo theft may cause loss of about billions to the manufacturing firm. Till date no technological advancement has been made to overcome the problem of cargo theft. Without proper and suitable tracking and tracing system, efficient co- ordination of logistic flow would be difficult to acquire. Seeing all the above problems on hand, we have come up with an innovative solution to the tracking systems of the shipment of the goods and along with that ensuring the safety of these goods and ensuring the proper delivery of the goods. Our software aims to solve most of the problems faced during shipment of products by companies and also create a secure application for online order placing and buying or selling. More about the software is mentioned under the "Methodology" section of the Paper.

II. TECHNOLOGICAL REQUIREMENTS

Hardware: Trackimo (Tracking Device), Rrimin 3D Holographic Projector, Fingerprint Sensor

Software: Python, CSS, HTM, PHP, MongoDB, Netbeans IDE, Android Studio

III. LITERATURE SURVEY

Before developing the software design, we searched a list of firms who were making tracking systems. To understand what we should and what we shouldn't include in our software system, we researched about their tacking systems. We noted down the most common features amongst all the softwares of the firms. For any product, the most important thing is customer review, and hence we took the reviews of the customer and important part of the research. From there we got to know all the drawbacks the various softwares were facing. Some of these softwares are listed below:

1. Teletrac Navman Director

The satellite is used for the vehicle positioning by using satellite GPS. The information is transmitted between the vehicle and the telecommunications company (the security system) via a wireless cellular or device connection. The access to the information about your goods that are been tracked is easy.

Drawbacks:

- Satellite does not work in bad weather. Trackers can be disabled easily by easily disabling antenna.
- There is a lot of backend work that remains a big question mark to the end user.
- The system tablets malfunction on a regular basis.

2. ClearPath GPS

They are a no-contract company. The customers pay on a subscription basis for their GPS tracking system that can track vehicle location down to 30 second time-intervals.

IV. METHODOLOGY

V. PROS AND CONS

The benefit of having this software is that it not only tracks the goods along their delivery path but also omits the chances of incorrect cargo being unloaded. This will help in reducing the delays in shipment caused by incorrect unloading of the cargo. It also allows the customer to directly contact with the driver of the vehicle for any problems face. This software still remains helpless in avoiding damage to the cargo as the hologram just sets the alarm in case of movement but does not stop the cargo from moving. Also the hologram grid gets disturbed by the motion of the vehicle, causing false alarms at some times.

VI. FUTURE SCOPE

The future of this technology includes use of laser shields to protect the cargo against damage as well as theft. The limitations of the hologram system was that even after the alarm would be set on, the cargo could still be picked in case of robbery. Also the grid would be insensitive to the jerks of the moving vehicle which could reduce the chances of false alarms. Also offline mode for tracking the shipment would be introduced in the case of network issues. The tracking strength of satellite in case of densely clouded sky is still being worked on. This design promises a revolutionary change in the future of tracking technology for goods.

VII. CONCLUSION

With the help of such tracking software the

Development of an online platform for mentoring startups

Prince Pandey, Nandini Yadav, Aniket Singh, Pratyaksha Ambast, Vishal Singhania, Sudhanshu Rai
TCET,Mumbai
pandeyprince128@gmail.com, nandini976804@gmail.com, Aniket180101@gmail.com, pratyakshaambast2000@gmail.com, vishalsinghania52014@gmail.com, amanrai7757822267@gmail.com

Abstract- **Startup-a company founded by one or more entrepreneurs in an attempt to capitalize on developing a product or service which is unique and bring it into the market. For a startup to enter the major leagues, the innovation and uniqueness in their idea is a must. But the cases where a startup has an excellent idea but fails to make justice to it have been witnessed. Most of these companies either do not have a proper guidance or succumb to the external competitive pressures. The article focuses on providing the startups a mentor who can help them to mould their plan of action in such a way that it meets the industrial demand. The startups provide a short insight of their idea on the platform which the mentors and the potential investors can view and accordingly choose to act. Also the incorporation of Market Trends aid in the evolution of the company. We firmly believe the proposed application will greatly help in the startups to bring about a revolution in the existing industry,**

Keywords- Startup, Mentor, Investors, Market Trends

I. INTRODUCTION

The era of entrepreneurship has started and many students and businessmen are investing their time and money in developing many solutions to market problems which will loosen up the tensed situation in the market [1],[6]. The entrepreneurs need a guide/mentor to teach them the right way to approach to the system/business development and make it successful in the market. The past platforms haven't given all the facilities that a start-up should get and there was no existing platform for mentoring the start-ups online and providing them with a good mentor, in India. The proposed system solves this problem and has come up with a recommendation system which helps students to reach a mentor who will lead them with a purpose and help them with their technical, analytical and business knowledge along with their contacts in the industries to get funds or a sponsor. The stakeholders are the people who'll get benefited from this and time and money of the both parties will be saved by using this system.

II. LITERATURE SURVEY

Startup's are the great way to show out your individuality and create job opportunities for millennials, with the growing population of world with high percentage of technical background, mobile and internet domination have manifested in creating startups. Even the government has initiated for employment , entrepreneurship with 'Make in India' schemes for boosting development in youngsters. Developing sustainability is important in both internal and
external factors with disciplined planned route for the growth. To embark in the journey market trends , revenues, funding,venture are predefined factors to be taken into consideration. Infrastructure , team work, time investment, tenacity for work are the quality elements for entrepreneurial success. But for the development of an individual mentor plays an important role for business development and growth. Depending on the pesronality - traits and decision-making style mentors are needed for proper guide and support. Initiation,cultivation and definition
are much needed guide for startup to workout properly.
As far the reports more than 800 technology startup are being set up. Looking at the persistent growth rate of startups , incubators are much in demand, they act as cataylst
tool for development.
Break-up of Indian Startup BusinessesTechnology

1. E-Commerce - 33%
2. Engineering- 17%B2B - 24%
3. Construction-13%
4. Internet - 12%
5. Agri- products- 11%
6. Mobile apps - 10%
7. Textile - 8%

Challenges of startups to be meet by mentors [2],[4],[5]:

1. SaaS - 8% Printing & packaging – 8% Other – 13% Transport & logistics- 6%Outsourcing & support - 5%Others-32%
2. Challenges of startups to be meet by mentors:
3. Financial resources: Provided by Business developers
4. Revenue generation : Poor revenue generation can lead to failure of startup and due to this focus is deviated towards challeneges , funding, reduced revenues rather than fundamentals of business. capital growth is necessary along with sustainability.
5. Team members: Hiring team mates with talent for business and required soft skills is again an challenging thing. Founders of the startups need trusted members with potential skill set. Each member being specialized in their field of operations.According to the survey , 23 percent startups failed due to lack of member competency to handle the work efficiently.
6. Awareness in marketing : Marketing is ruling the leading world of IT , if market awareness is not created there are much chances of failure at first stage. Building community and firm is necessary for the establishment of the product.
7. Lack of mentorship: Most of the great startups have failed due to lack of proper guidance which is our main objective to implement the system. As an apprentice has no industrial knowledge, business and market trends for launching if product but have a great way for managemnet and implementation of

the product , it is necessary for them to have a mentor.

Already existing system [1]:

1. StartupIndia
2. MUDRA Yojna
3. SETU(Self-Employment and Talent Utilization)Fund
4. E-Biz portal

List of Current Startups and Area of Operations

Area of Operation	Startup Firm Name
Online food delivery	FRESHMENU,SWIGGY
Online fish, meat delivery	FRESHTOHOME
Big data analytics for trade	PEELWORk
Online pharmacy	MYRA
Platform to get local businesses online	NOWFLOATS

III. Research Gap

Through the studies we came to a conclusion that there's no such online platform being available for mentoring of startups as well as domain based filtering of mentors. Thus we propose an online platform for the same and let the upcoming entrepreneur to present their ideas and help them to get the mentors as well as financial assist through business incubators.

IV. Finance

The mentoring process can be a real stressful if the related topic isn't interesting to the client. That requires complete attention of the mentor and the entrepreneur to ensure that the project is being funded and implemented in the right way. Hence they require a perfect balance of time and money that is being invested in the project [9].

Now, the question arises that how will the idea get implemented with proper funding and who will sponsor/fund the project? The Businessman portal on the application will do the exact thing to satisfy both the parties simultaneously [12].

Fig.4.1 Finance

V. Methodology

The proposed application will have the following services/portals in it.

1. Startup – This portal will be focused on a startup's registration and will have the details like the domain, name, address and a mini article which will include the startup's basic idea. Depending upon a startup's mini article it will get the recommendations of mentors which are involved in the same field of interest.
2. Mentor – This portal maintains the details of the mentor. It requires the information regarding a mentor's name, field of expertise, address etc. The mentors will be initially approached as the heads of EDC cell of colleges. A start-up can enrol under multiple mentors and eventually select any one which they feel are the most suitable for them.
3. Market Trends- This will include market being divided as per the domains registered by the startups. With the help of experts there will be a data provided that will display the current business trends in the various market domains.

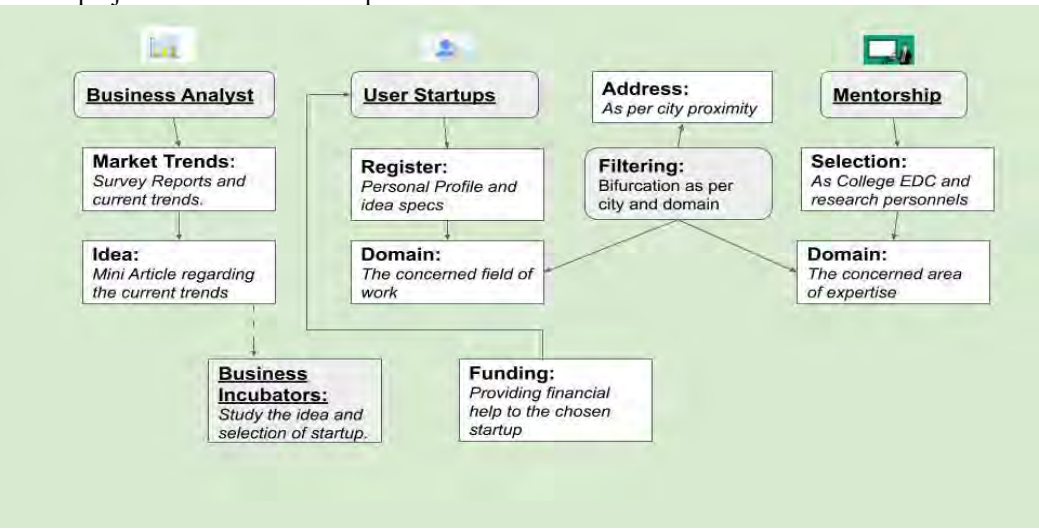

Fig.5.1 Methodology

This application can be used by the following user types

1. Startup personnel
2. Mentors/teacher guides
3. Business analysts

Table 6.1 Use case and scope

Scope

Startup	**Mentor**	**Analysts**
Registering themselves.	Understanding a startup's article and expressing their interest.	Study the market needs and instruct the startups to work in the pattern required by the industry.
Expressing a mini article regarding a startup's basic function.	Interacting with startups and help moulding them.	Interacting with the startups as well as the mentors.
Interacting with the mentors.	-	-
Understand the market trends in their respective domain.	-	-

VI. Results Achieved

Successfully Proposed an application which will act as a great aid for the existing as well as the newly found startups, and will incorporate all the key aspects right from the generation of an idea to seek a proper path for its evolution, a business acquirance opportunity to bring about a revolution in the field of interest and will be sustainable considering its future scope.

VII. Conclusion

The research proposes a conceptual framework for the evolving startups to seek mentorship in their respective domains. This propells a positive feedback as a technoprenuer may know the technology but a mentor ensures a startup to focus its attention on the society as well as the technology. The article also enables a startup to seek funding on an organised E-platform which can revolutionarize the current gruesome process and also the same time analyze the market trends in their field of interest.

Centralized Attendance Monitoring System of Employees of RMDD

Abhishek Mishra, Aditya Shetkar, Ruchit Yadav, Hitarth Patel, Amar Singh

Abstract – **India, on its way of becoming a full-fledged developed country, still has some backlogs in some of its state's key functioning. The RMDD i.e. The Rural Development Department of Govt. of Sikkim has over 37196 workers. Maintenance of attendance of such a huge worker base goes a long way, but the pre-existing attendance systems have some flaws in it. For e.g. some workers tend to substitute anyone else if it's a card punching attendance record. Thus, our new proposal of a Centralized Attendance Monitoring system for those employees, would yield better results as well as help the monitoring officers to maintain, track and resolve any issues in the long run.**

Index Terms: RFID (Radio Frequency Identification), Buddy Punching, RMN (Registered Mobile Number), IRIS scanner, Authenticator code.

I. INTRODUCTION

Today, the attendance monitoring system is used globally. But the motive behind it is to be accurate about the employee's time of entry and exit. As we know, no project is completely flawless and full of pros. Similarly, some of the present and past attendance monitoring systems also have flaws in them. Our project: Centralized Attendance Monitoring System focuses on bypassing those flaws to make the regulation of such things smoother. The design and architecture of this project are such that there should be minimum efforts but maximum impact and output. Also, centralization should be an option available to every organization already using attendance monitoring systems. However, this project also emphasizes the fact that each and every entry marked is available to everyone and anytime within the authority.

II. PROBLEM DEFINITION

A. Review:

First of all, we must understand what **is RMDD of Govt. of Sikkim** to evaluate this problem. Ministry of rural development is a branch of the government of India, which is authorized with the work of accelerating the social & economic development of rural parts of India. It focuses on drinking water, health, housing, education, and roads.

The headquarters are located at Krishi Bhavan, New Delhi. The main objectives of this department ministry are sustainable growth of rural India through a multipronged strategy for eradicating poverty by increasing livelihood, opportunities, and developing infrastructure for growth. The department improves the quality of life in rural India and to correct the development imbalance.

There are currently **37196 employees** working for RMDD. Thus, the main problem sometimes arises regarding the attendance monitoring and updatation on the servers, which could sometimes lead to the compensation of a small number of salaries of people working in rural areas. The main issues in these cases are either of forgery/substitution (getting marked present while being absent) or some serious database issues in servers.

B. Actual In-Depth Problem:

In the 20th century, the need to accurately track employee hours has become an essential part of running a business. Laws were put in place to protect employees and ensure they were properly compensated. Businesses began using various methods of tracking employee time. While these methods allowed businesses to record employee time, they also possessed flaws. Here are the primary disadvantages of these traditional systems.

There is a Potential for Human Error:

When you rely on RFID or timesheets, there is always the potential for error. Employees may inaccurately enter their time into accounting software for payroll. These errors are common in the workplace when using manual time attendance solutions. The HR department would have to spend a large amount of time correcting these errors. The errors that go unchecked could result in incorrect pay for employees and other payroll issues.

Employees Can Commit Time Theft

Timecards/Timestamps and RFID do not prevent time theft or buddy punching. With manual time tracking, an employee could use another employee's RFID card to enter their time data in the system. This is known as buddy punching and is a common problem among large businesses, all around the globe.

Manual Time Tracking is Time Consuming

Handling RFID cards and timesheets takes a lot of time. The employees might need to stand in line to punch the RFID cards or timestamps in or out. The same amount of time is taken by the HR management to manage and maintain these records. This can include the replacement of RFID punch cards, correcting timesheet errors and mistakes, modifying the biometrics of an employee and other problems that arise when using a manual time tracking systems.

They are Inefficient and Outdated

The conclusion is that attendance systems like clock punch, timesheets, and individual data entry are inefficient

and outdated. They can have a large impact on any business or organization's performance. Time clock errors can cost the business time and money. These issues become bigger with large businesses, for example, any corporate giant. Not only for clock punch and timesheets but modern systems like RFID and biometrics can sometimes cause problems while punching, thus disturbing the relay time and inappropriate entries in the data servers.

Also, you can keep the disadvantages of using manual attendance systems solutions to a minimum when you only have a dozen employees. But, with a thousand or more employees, you could be losing thousands of rupees in payroll errors and time theft every month.

C. Background of Attendance Monitoring Systems:

A centralized attendance monitoring system (or CAMS) is a modern attendance management solution, nowadays used worldwide. Attendance management is the method or culture of managing attendance or presence in a work setting to minimize loss to the organisation due to employee downtime.

Attendance control has traditionally been approached using **timesheets, time clocks, and time tracking software such as RFID and Biometrics**, but attendance management goes beyond this to provide a working environment that maximizes and displays employee attendance accurately.

Attendance management takes place not only in all educational campuses but also in each and every single workplace, be it a corporate, business or factory. Nowadays, there are new types of attendance management systems like biometrics, RFID, GPS enabled systems.

These are critically important for any organization to function efficiently and smoothly, throughout its existence.

The first time clock was invented in the late 1800s with the purpose to record the time an employee entered and left the factory. This mechanical employee time clock would stamp day and time information on a thick paper card, hence the name 'time card'. This first time card gave the factory owner an actual record of the hours worked by each employee. This protected the business owner by making sure employees worked the number of hours they claimed, and protected employees by making it much more difficult for employers to cheat them out of their wages.

Since then began the era of attendance management, which has continued to date for decades and centuries.

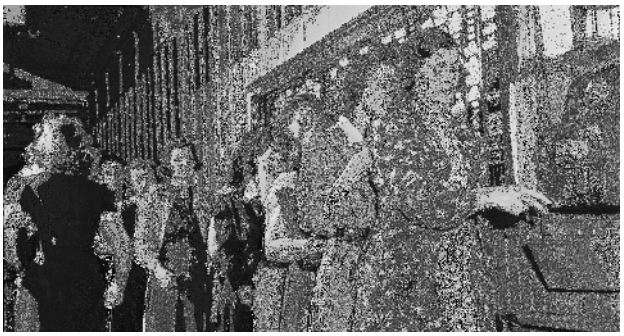

Figure 1: The First Employee Time Clock

D. Drawbacks of Previous Attendance Systems:

Drawbacks of some commonly used attendance monitoring systems are:

1. Time Clock:
a. Time Consuming
b. Time Theft
c. Human Error
d. Buddy Punching
2. Biometrics:
a. Expensive and High Maintenance
b. Complex Integration as compared to password solutions
c. Tend to be Inaccurate Sometimes.
d. Once comprised, it cannot be reset.
3. RFID:
a. Expensive
b. Costly RFID tags. Once lost, the employee has to repurchase the RFID tag which could be inconvenient
c. Prone to manipulation
d. There is a requirement to replace the microchip, radio transmitter, receiver and antenna, and battery which would be tiresome.

III. IMPORTANCE

Our Centralized attendance monitoring system mainly focuses on reducing data redundancy and data inconsistency. Since the project is for the RMDD: Govt of Sikkim, we would be integrating two or more types of a previously used attendance monitoring system to increase not only efficiency but also to increase the technical knowledge of the employees working in extremely rural areas to make them aware of the newest available technology. The following would be the main points on which the project would be mainly focused on:

- High efficiency and accurate time entries.
- Centralized, in order to make the head of the organization keep informed about the situations.
- Data backup on servers, in case of any emergency, arises.
- On-spot reset, delete or modifying options available with HR for convenience of employees.
- Enhanced Security.

IV. THE CAMS

A. Architecture:

The CAMS designed in this proposed architecture will have the following components:
1. Biometrics Scanner.
2. Iris Scanner.
3. RFID Scanner.
4. 2 servers hosted by central govt. of India
5. 1 server hosted by govt. of Sikkim.

B. The Working:

Since there were so many drawbacks in each and every individual attendance systems, we decided to collate them and make a comprehensive and complex, yet the most accurate and secure solution.
The employee whose data is to be entered would first place his finger on the biometric scanner. If it reads it successfully, then he may proceed to the RFID scanner. If the RFID reading process is successful, then his time-stamp is entered to the local database of the system in that office, which with no delay would be uploaded automatically to the state database server, which would be stored there for 14 days and then directed to the Central Govt's Main Server and Backup Servers.
In case, the employee is unable to complete their verification either by Biometrics or RFID, then he may proceed to the IRIS scanner. After they verify themselves with the IRIS scanner, they may enter the UID provided to them on their RFID and enter an authenticator code that would be delivered to them via SMS onto a computer screen which would be touch-sensitive. Thus, this proposed architecture is a 2-Step verification attendance system that is not only secure but would also have no redundancy in the entire process.
There is a necessity that the employee complete two verifications from any of the available options. The entire procedure takes less than 18 seconds to complete if there are no complications mid-authentication. These are the available options for the employees to validate their entry at the organization:

- Biometrics & RFID
- Biometrics & IRIS Scanner
- Biometrics & Authenticator
- RFID & IRIS Scanner
- RFID & Authenticator
- IRIS scanner & Authenticator.

The data entered on the systems & local database will be directly passed on to the servers of the Organization's current office which subsequently will be transferred to the state govt's servers, in order to protect the data from infringement and from getting it compromised. The Servers could either be hosted by govt or be rented from technological giants such as Amazon Web Services, Tata Technologies, Reliance, etc.

The employees would also be able to view their routine and performance with the help of an ERP system, which would be directly synced with the State Govt's records. Thus, any discrepancies noticed could be directly rectified with the HR management team within 14 days, after which the records would be uploaded to the Central govt's Main and backup servers. As soon as the state servers are updated with any discrepancy rectification, the Employee's ERP would also reflect the changes. Only the highest ministers of the state govt. would be able to view the status of the organization including the Authorities of the RMDD.

In case, any of the details of the employee needs to be updated in case of emergency or accidents, the HR of the local office could do so just by Resetting the particular field or entry in the device the employee needs to make changes in. For e.g, due to some accident, an employee loses their RFID. So, in that case, the HR can issue a new RFID along with a new authenticator code to verify at that very instant and then proceed with the issue. Let's take another example where an employee loses the eye which they registered as their verification for the IRIS scanner. The HR could simply delete that particular Employee ID' code from the database and propose the employee the option of either scanning the other eye for validation or not use that system at all.

Since the literacy rate of Sikkim is over 90%, implementing these systems in RMDD would not only increase the technology available in the area but also enhance their technological skills.

C. The Flowchart and Algorithm of working:

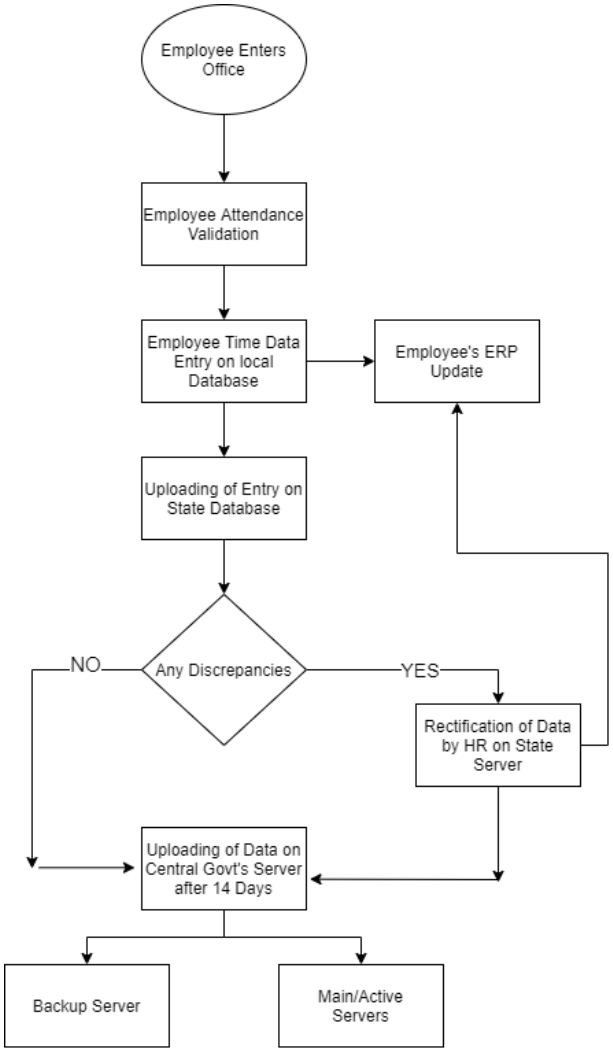

Figure 2: Main Flowchart

The above flowchart describes the general working of the Centralized attendance monitoring system. In the next flowchart, we have discussed the in-depth working of the validation process of the employee to enter their timestamp in the database.

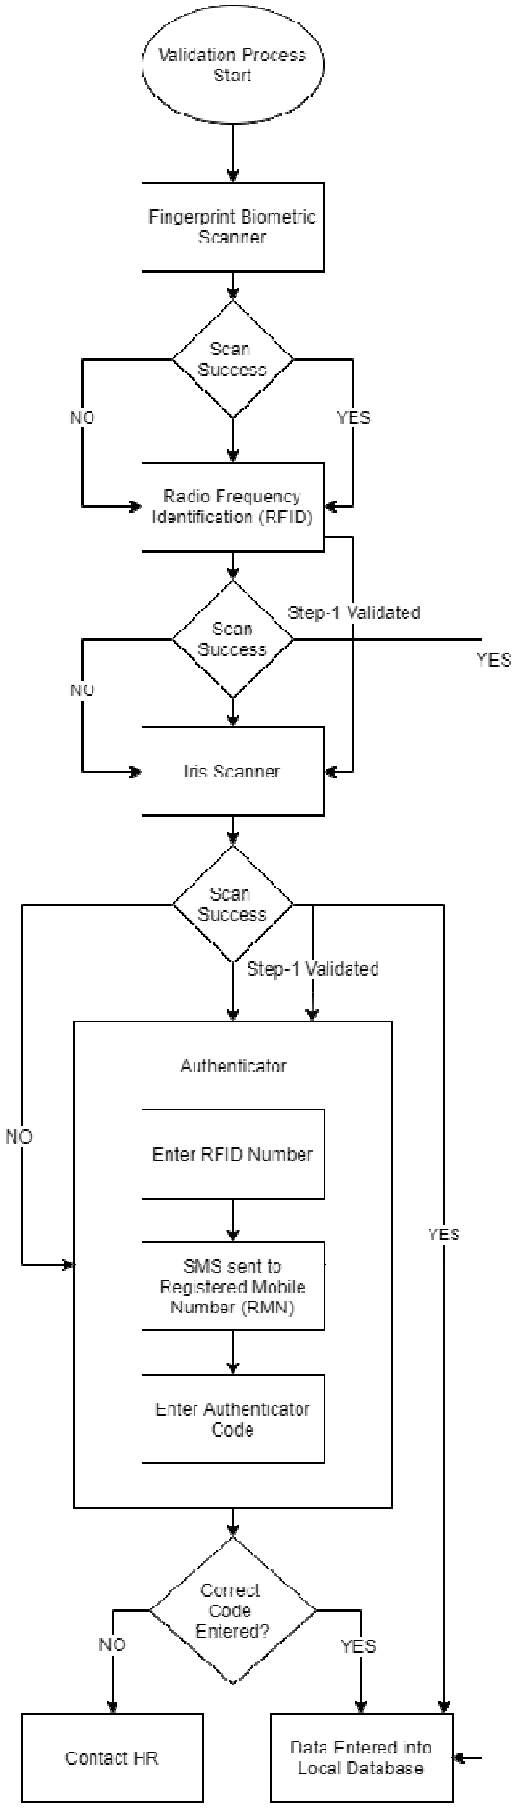

Figure 3: Employee Attendance Validation Process

V. HARDWARE & SOFTWARE

The Hardware proposed in the architecture are as follows:

- ZKTeco Biometric Fingerprint Scanner
- Matrix RFID attendance Monitor
- Cogent Radium Iris Scanner
- Touchscreen Inbuilt CPU Monitor.

The proposed Software to be associated with the hardware is as follows:

- MySQL Database
- Kronos Attendance Management Software
- Microsoft Windows 10
- Google Authenticator
- Microsoft Authenticator

The Total cost of this equipment would be around Rs.30,000/- INR considering the fact that the state and central govt's servers pre-exist.

VI. RESEARCH GAPS & DRAWBACKS:

As we said earlier, every project has some gaps in it and none of them are 100% efficient. Even our's has some drawbacks and these are the following:

- This project was designed not only for RMDD of Govt. of Sikkim but also for keeping in mind the corporate organizations. Thus, there could be some differences in the amount the organizations want to spend in a single attendance monitoring system.
- The hardware and software are expensive and so is their maintenance.
- The entire project revolves around the fact that both the state govt and the central govt own their own individual servers.
- The project would conclude efficiently, provided a good internet or broadband connection in the locality or the area of the RMDD offices.

VII. OUTCOMES

The outcomes of this project are expected to be positive as there might such a secure and appropriate solution for reducing redundancy, inconsistency and data loss. The operation of the project is simple, even though it's algorithm is a little complex. With this type of employee validation and verification, none of the employees could buddy punch the systems or manipulate the data to their convenience. Also, the central govt's data backup provides some additional safeguard measures for this project. The govt. of Sikkim had an annual budget of 7,051cr INR in FY 2018-2019. Thus even a small part contributed towards the IT team of RMDD could make this project possible.

VIII. SUMMARY:

A centralized attendance monitoring system is an attendance system that is linked to a central server and requires 2-step verification for the employee to mark themselves as a present. This is done in order to protect the RMDD govt. of Sikkim from employee's data tampering as well as manipulation. This 2-step verification is the best and the most secure type of attendance marking scheme. Also, if someone tries to delete some data about a month back, he couldn't do it, since the backup of all the attendance would be available in the central Govt's backup servers, which are installed in the first instance in case of some emergency.

IX. CONCLUSION

Thus, from a state budget of 7051CR INR, an efficient and accurate attendance monitoring system can be built. No organization in the entire world uses multiple linked attendance systems, due to which there arise problems of each individual system. Thus to cover those up, a combination of very those systems should be used along with some additional security measures.

Computerized Fee Collection System and Transfer Certificate Module

Vaibhav Kumar, Nidhi Gupta, Suman Gupta, Pratik Jain, Priyansh Jain, Jainam Jagani
TCET,MUMBAI
chikkalkarvaibhav@gmail.com, guptanidhiabc@gmail.com, sg1198959@gmail.com, pratikmjain17@gmail.com, priyanshjain625@gmail.com, jainamrj6@gmail.com

Abstract— **The Fee Collection Module is the one of the most automated fee calculation module on hand in the market. Apart from being automated it is, at the same time, flexible enough to accommodate the varying nature of fee payments that most of the educational institutions come across. Fee calculation is done on the basis of Category selected for the student.**

The module automatically calculates the pending fees, previous fee payment details, deductions and concessions if any applicable to the selected student. In addition to the above, the user is also given the option to allow payment of more than one month/fee-cycle either applicable.

User-defined fee structure and category can be maintained. Automated bill generation option enhances the system dependability. Fee Receipt can be accepted by the system with few mouse clicks. At any point of time, user can verify collections made and outstanding with single click.

For any school to register a child legally, it is mandatory that they receive a Transfer Certificate (TC) from the child's current school in which he is studying. Registration at any school without a TC is not possible. When a child is leaving a school or applying for a new one, he ought to have a TC for the future need and the school generates a TC with all the relevant details pertaining to the date of admission and date of leaving. The school also needs to maintain a record of the date of admission and fee due report of all the students before it could generate a TC. Hence Transfer Certificate Module will make one's task easier to generate transfer certificate without any delay.

Keywords–Fee, Transfer Certificate, Net Banking, School Administration

I. INTRODUCTION

In Fee Collection Module, you can effortlessly manage student Fee Collection
and maintain fees related data. You can view school wise total fee collected in a selected date range. This module displays total fee collected in particular date range by cash, card, cheque, Bank Transfer etc. You can also export the complete data to an excel file.

II. II. PROBLEM DEFINITION

Define different Fee groups for transportation Fees, Nursery to UKG Fees, Primary section fees (I to IV), Secondary section fees(V to X). Define penalty or late payment fees that get applied daily, weekly etc. Accept Fee in installments.

At a glance get to view the cash, card, cheque, bank transfer, Advance amount or disc. Obtain Fees in cash, credit card, NEFT, Cheque. Swiftly update enhancement in fees. Apply the different fees defined to the students as necessary.

III. III. BACKGROUND

When schools and colleges
are filled with stacks of loose papers and folders, you're overwhelmed with errors, late payments, slow pace of approvals, and forgotten invoices. Here is how to automate student fees so you can minimize careless mistakes and maximize your profitability.

IV. IV.OBJECTIVES

The specific objectives of this project include:

1. To provide a reliable and transparent system devoid of personal inclinations and interest
2. To provide a system that will relieve the staff and works of the academy the stress of searching files or data manually
3. The new system will bring an end to the issues of lost receipts or of any kind as the records and data will be stored in the new system's database which is safe and reliable for use and operation.
4. The new system gives a quick access to data and modification of records if necessary.
5. To save time (fast inputting and accessing of records)
6. To design a system that will be capable of generating the student receipt when payment is made and recorded with all the corresponding awaiting bills is incurred
7. To ensure accuracy in record keeping.
8. To ensure safety of the documents/records, because the system will be password aided to enhance security.

V. V. KEY FUNCTIONS

The main objective for developing this project is not only to achieve the targets and objectives set up by the computerized fee module but also to create the awareness of this programme among the various institutions.

1. Online Payment Method: The Fee collection module should furnish a provision to pay the school fee online. With digital transactions being

the current trend, every fee module should provide the above facility for online fee payment.

2. Integrated SMS Alert: The entity should be integrated with SMS feature i.e, timely alerts should be sent to parents about the due date and also an intimation or notification upon successful fee payment.
3. Receipt Generation: It should be able to generate an automated receipt after fee payment and also generate previous fee receipts. It should be compatible with both laser printers and dot matrix printer enabling you to use your
4. existing print technology rather than investing in new one.
5. Mode of Payment: The system should offer different modes of payment to parents like payment through debit card, credit card and net banking. It should allow the parents to pay the fee at their comfort and feasibility.

VI. VI. PHASES

Phase 1: Planning, Analysis, Designingand Implementation.

Analysis: We will collect the data about different fee collection transaction histories and Transfer certificate logs from data repositories of different schools and analyze them.

Planning: After we finish the analysis, we will use the statistics obtained, get a defined result and then build a plan based on the result.

Preparation: Based on those results, we will conclude which domains of educational institutions need more emphasis and will try to prepare the website on that real.

Designing: We will build the design of our project according to our analysis and accounting to that, we will list out all the necessities required for the creation of the prototype of our project.

Implementation: The design can now be implemented through web application frameworks like AngularJS and the required databases can be handled through software like MySQL.

Phase 2: Testing and Deployment.

Testing: After the prototype is ready, we will test the UI/UX of our website and will try to ensure that it is feasible with our targeted audience and creates the impact as expected.

Deployment: After completion of integration and testing of the project, the project will be deployed with real-time databases and real-time & operation of the system will be done.

VII. VIII.HARDWARE AND SOFTWARE REQUIREMENTS

Hardware: Any computer System or smartphone.

Software:

IDE Eclipse JAVA

1. Front End

a. HTML

b. CSS

c. JAVA

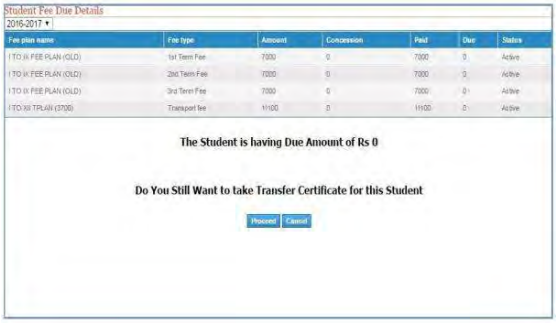
d. JAVAScript

2. Back End

a. MYSQL Database

b. PHP

VIII. IX.PROPOSED UI SCREENSHOT



TRANSFER CERTIFICATE

Affiliation No.:130105 School Code:06158

Book No.: Sl.No.: Admission No.:NIL24

1. Name of the Pupil: VEDIKA RAJPAL

2. Mother's Name:

3. Father's/Guardian's Name: PRUSHOTHAM S

4. Date of Birth(in Christian Era) according to Admission & Withdrawal Register (in Words & in Figures): Thirteen -November-Two Thousand 1(13.November

5. Nationality: Indian

6. Whether the candidate belongs to Scheduled Caste or Schedule Tribe or OBC: OBC

7. Date of first admission in School with class: 17 June 2014

8. Class in which the pupil last studied(in figures and in words): Class ISec F

9. School/Board Annual examination last taken with result:

10. Whether failed,if so once/twice in the same class:

11. Subjects studied:

12. Whether qualified for promotion to higher class (if so,to class(in fig & words): Yes

13. Month upto which the pupil has paid School dues:

14. Any fee concession availed,if so, the nature of such concession:

15. Total No. of working days in academic session:

16. Total No. of working days pupil present in the school:

17. Whether NCC Cadet / Boy Scout / Girl-Guide (details may be given):

18. Games played or extra-curricular activities in which the pupil usually took part(mention achievement level therein):

19. General Conduct:

20. Date of application for certificate: 01 Feb 2017

21. Date of issue of certificate: 01 Feb 2017

22. Reason for leaving the school:

23. Any other remarks:

Signature of Class Teacher | Checked by (with full name and designation) | Signature of Principal with date School Seal

The Fee Collection page is designed as follows which shows the fees collected and fees paid. The Transfer Certificate page shows the details already entered from before and the process is a single click application for submission.

IX. X.OUTPUT

The focus of our project lies on the smooth working of educational institutions by providing better solutions to avoid haphazard situations related to fee collection systems. Also provide a better plan to develop software for the generation of transfer certificates. Users of the fee collection software will have a platform to raise issues related to delay in fee submission, to ask for extensions,etc. directly to the authorities in-charge.

X. XI. OUTCOMES

Phase1 Implementation:
Implementation of a website with proper database and no failure.

Phase 2 Testing: Testing was done considering the feasibility of UI of the website among the users and the portability of the website on different devices

Phase 3 Deployment: Real-time working was done with teachers and parents from different schools and they were found to be comfortable with our website, they shared good user experience. Thus, the project works efficiently.

XI. XII. RESEARCH GAPS

Every idea was once a dream, so research gaps go hand in hand. The research gaps in this project are as follows:

- Due to poor connectivity this system may not work efficiently for rural areas. Websites may load at a slower pace and may pop errors a lot of times.
- There will be a need to provide training to parents as well as educational authorities and to all the people that will access the website so that it functions smoothly.
- All the people dealing with the website need to have a basic knowledge about how transaction is done safely to avoid blunders.

XII. SUMMARY

This website will act as a platform between the parents of the students and the school administration staff. The main purpose of this website is to make the fee collection easier and efficient while also making it easier to auto-fill in details while filling out transfer certificates for the students. It will also contain all the information of the school administration and general information such as school location, timings, etc. This website is purely made to decrease crowds in school during the manual fee collection timings and to make it easier to pay online.

XIII. CONCLUSION

We have successfully shown the implementation of our website. Technologies used to design this COMPUTERISED FEE COLLECTION SYSTEM AND TRANSFER CERTIFICATE MODULE are mentioned. Thus effective execution of the project is done. The concerned data will be reported to the concerned person on time and all should get the benefits of this computerized module.

Software Tool to Aid Search and Rescue of Aircrafts

Shubham Jain, Aman Gupta, Hridyansh Gupta, Dev Jindani, Manu Khandelwal
Thakur College of Engineering and Technology
Mumbai, India
Shubham.Aryanjain@Gmail.Com, Avgupta3100@Gmail.Com, Hridyanshgupta@Gmail.Com, Devjindani68@Gmail.Com, Manukhandelwal20@Gmail.Com

Abstract— **Aircrafts are a boon for mankind, allowing us to travel long distances in short time, but they do come with certain risks like pilot error, mechanical failure, harsh weather, sabotage and other types of human errors. Thus, it is very important to create a software tool to aid in search and rescue of aircrafts. This paper deals with the features of software tool required to aid in search and rescue of aircrafts.**
A software can be created which inputs the flight route of the aircraft and stores details like fuel left, average speed of aircraft before it went missing, altitude.
An enhanced black box which communicates the inputs mentioned before to the software at fixed intervals is developed.
Thus, the software takes into account all the inputs and weather factor and runs various algorithms and provides with a probability circle of position of missing flight.
Hence knowing a close approximate of the missing aircraft will help in speedy search and rescue operation.

I. INTRODUCTION

"Aircraft search and rescue operation priority is at a all-time high "

This paper basically deals with the problems faced by the search and rescue team of airport authority of India. Firstly, the question is" What is a search and rescue (SAR) team?". Search and rescue team is basically a group of professionals who work on helping and rescuing the people on board a flight which is in trouble during crisis such as plane crashes, plane missing and highjacks and work on tracking down the missing aircraft.
SAR teams today have various software but they are in-efficient to provide the probable location of aircraft which increases the search time and thereby delaying rescue.
Designing an efficient software requires some thought process about the use and specific needs of SAR teams. So, there are some steps and rules to be followed which will be discussed later in this paper in designing a search and rescue software Designing an efficient software is very significant because it needs to meet the expectations of various aircraft agencies and governments.
The software created should have the potential to be equipped with future technologies and not become obsolete.

II. PROBLEM DEFINITION

The primary problem faced by the search and rescue team (SAR) of airport authority of India but also by most of the airport authorities is that they are unable to track down the location of the missing aircrafts within timespan required to execute their rescue operation. Due to this many of the aircrafts have gone missing, leaving no traces which indirectly affects the families of the people onboard and also the reputation of the country leaving everyone in distress. To resolve this problem, we can create a software that predicts accurately the location of the aircraft and during the time of distress it shows the last detected location of the aircraft and guides the SAR team to the most probable location of the aircraft.
Thus, creating a software which overcomes the limitations of previous software used by SAR teams is the desired solution.

III. BACKGROUND

Researchers have developed technologies that has reached new heights but still need work. Airport authority of India and other countries have their search and rescue teams which are doing their best with the resources they are provided with. They can achieve a higher success rate by working with better and improved technologies. The basic goal of every search and rescue team is to complete their task successfully and execute the rescue operation and save as many lives as possible, but they are not able to do it with a higher success rate. SAR teams also have to provide with answers as to why they were not able to perform more efficiently and the answers all point to one thing i.e. time-consuming search process.

IV. IMPORTANCE

It is very important for an airport authority of every nation to provide comfort and safety to every passenger on board. But during a time of crisis i.e. during a crash

or sabotage it becomes very difficult for them to regain the access to the missing aircraft or to locate it at the right time and rescue each and every passenger safely. Sometimes due to harsh weather conditions or due to some technical reasons the pilot or the particular aircraft loses its contact with the air traffic controller. It is very much important to develop a kind of software aiding tool that predicts the last detected location of the aircraft so the SAR teams can work on it immediately and help everyone in distress or evacuate the area if unfortunately, the aircraft has to crash land.

V. OBJECTIVES AND SCOPE

1.Previous software used by SAR teams do not efficiently aid in locating the aircraft hence the software proposed greatly reduces the time and manpower required for search operations.

2.Though there is a decrease in rate of the missing aircrafts, many of them are not found.

3.We only find the remaining parts of aircrafts which wash onto the shores.

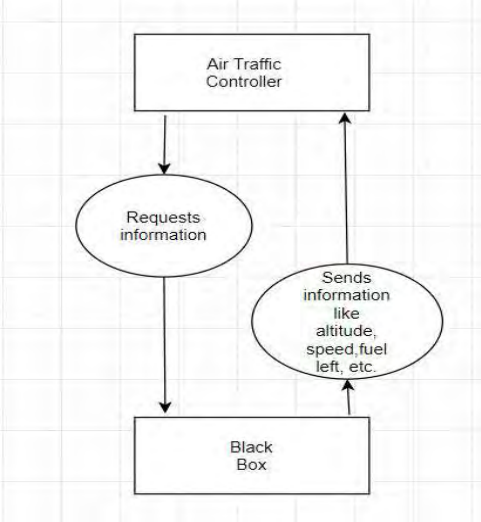
4.The proposed software greatly reduces time consumed to search the missing aircraft and start the rescue operation.

5.The software provides the probable location perimeter of aircraft when it goes missing taking into account the amount of fuel left, aircraft speed, wind direction, altitude and many factors.

6.The main objective is search and rescue and the most important factor while travelling by an aircraft is tracking which the software ensures.

VI. DESIGN OF SOFTWRE

A software basically consists of a front end and back end. The logic of the software is written in the backend and the frontend which is basically what a user sees and operates on. The user interacts with the frontend and then the logic is worked upon and the data is linked to the backend hence providing the required information. This software consists of a link which connects it to the chip in black box located in the aircraft, which provides the software various details like speed, altitude, overall health of aircraft, route of aircraft, turbulences faced and the conversation the pilots are having. The GPS chip and software combined in the aircraft provides the live and predicted locations of the aircraft. This can be linked by satellites to provide accurate and satellite images of the probability circle of plane crash. So when a crash occurs the application shows the last position of the aircraft runs algorithms and various simulations using the details provided by the black box and outputs the probability circle of plane crash and the SAR team can trace down the location and execute the operation thus saving much time as compared to earlier practice



The following points must be considered while designing the software –

[A] *Selection of Platform*

The usage of the software cannot be restricted to a single platform, this software should be made such that it can be operated on any system such as mobile phones as well as computers, tablets.

[B]*Selection of Software*

Java is primarily the most used language to create an application for various needs. However, other programming languages such as Python, PhP, Ruby are also widely used to create robust applications. For front-end JavaScript is preferred.

[C]Compatibility with the system

The software should give the appropriate details required of the aircraft using location trackers, GPS, etc. The system should be able to work in symphony with the back end with least possible lag.

VII. IMPLEMENTATION PROCESS

[A]*Creating the frontend*

All the essential packages required for creating the frontend are imported using the required programming languages, the black box is set into the aircrafts. On the frontend there will be an option to enter the flight to be tracked and by confirming the details all the required information is displayed to the authority of airport.

[B]*Creating a database*

All the necessary details are mentioned on the database in the backend which is linked to the application ,so when the required search is made all the details are tracked down, it will the calculate and plot the area where the search should be conducted from the last known location of the missing aircraft using the flight details and information provided by the black box.

VIII. SOFTWARE REQUIREMENT

There are various tools that can be used to create this software like the basic compatibility systems,the GPS trackers in blaackbox so that we get the live location continuously and this software can be implemented on the system of airport authority of India also the other airports.

IX. RESULT

Most people are scared to use airways as an option of transport mainly due to safety issues and due to some crash incidents reported in the past. Before it was very difficult for the search and rescue team on Indian airports like : Antonov An-32 twin engine turboprop transport aircraft of the Indian Air Force disappeared while flying over the Bay of Bengal... The search and rescue operation became India's largest search operation for a missing plane on the sea in history. This problem persists not only in India but also for an other instance in past: Malaysia Airlines Flight 370 disappeared on 8 March 2014, after departing from Kuala Lumpur for Beijing, with 227 passengers and 12 crew members on board. Malaysia's former Prime Minister, Najib Razak, stated that the aircraft's flight ended somewhere in the Indian Ocean, but no further explanation had been given. These aircrafts were not found at the right time or were never found due to lack in the resources and technology, through this application the exact search plot of the aircraft can be determined so that there is no confusion and rescue operations can be done on time and successfully and there are no further casualties.

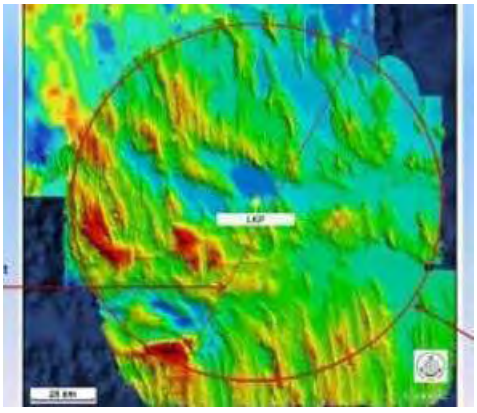


Fig: Probability circle of aircraft crash

X.CONCLUSION

We have successfully shown the importance of this software, that can be implemented by the airport authority of India ,that can act as an aiding tool for the search and rescue team to conduct the search when an aircraft goes missing by plotting a particular area where the search should be conducted so that the team reaches that area quickly without wasting the essential time in searching the whole area instead. This will help in the search and rescue operations very efficiently. Thus the importance, need and working of this software is successfully implemented and understood.

Alumni Tracking System

Anurag Mishra, Pranali Darekar, Ashutosh Mishra, Kripa Damania and Raj Jadhav

Abstract – **The information system for communication with alumni embodies one of many ways how university can keep tracking with its graduates. Except for communication between university and its graduates, the information system should allow communication between graduates themselves and their personal presentation in public. The system also should collect actual information about working experience of graduates, which can improve faculty credits and teaching process. The presented information system includes all these points and focuses on usability and comfortable user interface.**

The aim of this project is to build an Alumni Tracking System university online dashboard, it is intended to manage especially the Alumni of college with their respective fields.

The project mange the fresh as well as old graduate students with their respective information in actively participating in making registering, searching, managing the alumni information for sharing their expertise, network, jobs opportunities and resources. This participation has evolved into multiple dimensions; and is now eager to formally enter into the domain of mentorship to students through a regular program. Alumni registration management system (Alumni Dashboard) is a step towards this, creating multidimensional interactions between current and past students of College

I. INTRODUCTION

The greatest asset any Institution can have is the Alumni system. Alumni are the people who represent the Institution in the real world.

Alumni website is created for the students that have graduated from the Institution. This is a web based application that allows former students to take advantage of the benefits and services that a Institution offers after graduation. The alumni network is becoming important in the development of the institution because of their vast potential that benefits both the Institution and the students. There are many benefits for being an alumni member of a college or Institution, some of these benefits are: keeping a person inform on the events that are organized by the Institution, and when some important events will be holding in the Institution. Another benefit is that information concerning a former student can easily be received and other members of the alumni community can be located without much stress. The student and alumni can communicate each other.

II. LITERATURE REVIEW

This project is aimed at developing a Repository and each Engine for alumni of the college, which is of importance to a college. The Alumni Information Database is a web based application that can be accessed throughout the World. Anyone can access the search Engine to know about any Alumni of that college .

This system can be used as an application for the Alumni Information

This project is aimed at developing a Repository and each Engine for alumni of the college, which is of importance to a college. The Alumni Information Database is a web based application that can be accessed throughout the World. Anyone can access the search Engine to know about any Alumni of that college but can't able to add.

This system can be used as an application for the Alumni Information

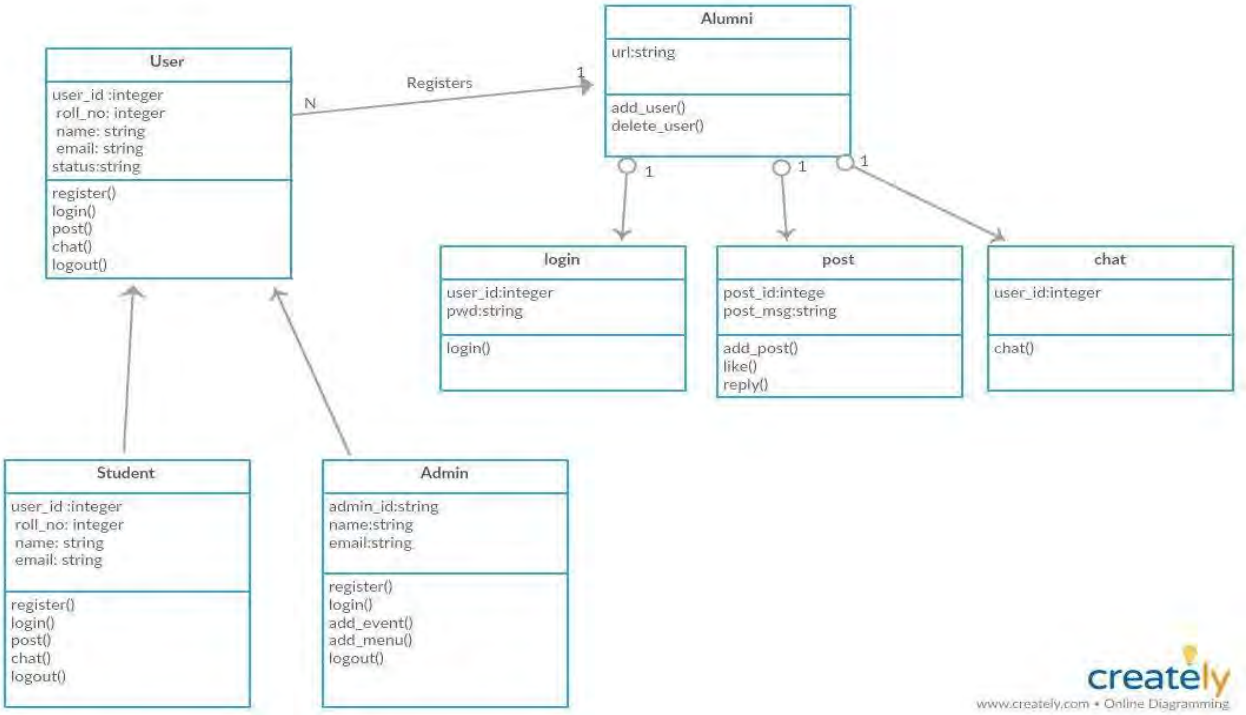
III. IMPLEMENTATION

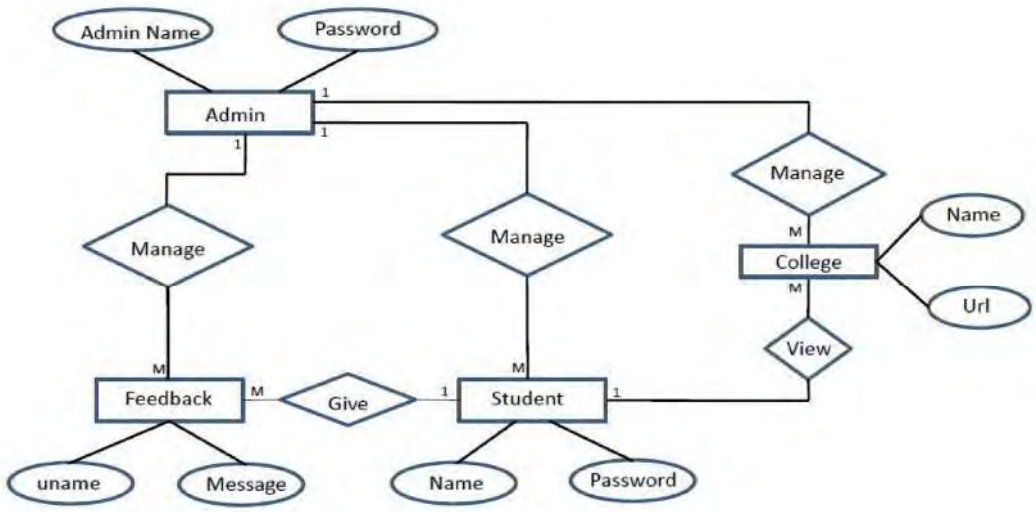
The Department of Graduates Follow-up is responsible for monitoring the affairs of graduates.

It is proposed to be administratively linked to the Principal, where the administration mentors the transfer of students from the academic education environment to the operational environment. The Department also monitors the graduates and learns the news of the university's keenness to maintain a permanent and strong contact with the graduates.

Graduation is the end of the relationship with the university, and try to find jobs for university graduates.

One of the most important objectives of the establishment of the administration is to link the bridges of practical life with the academy and to support continuous communication between the university and its graduate, benefiting the university and its graduates, as well as conducting research studies on academic developments in order to meet the requirements of the labor market. There are now more than one million unemployed, so the technology will be integrated into a database on a website so that information can be accessed in a flexible and easy way





IV. CONCLUSION

This system will be available for general public use through the web interface. A non-registered visitor can look at the list of graduates according to year of graduation or a field of study. He can also look at graduates profiles. The level of profile details shown to the public is limited. By default, a public visitor can only see name and surname of a graduate, year of graduation and a field of study. The faculty endeavors to propagate its graduates.

Therefore graduates can also add some information about themselves into the system during the study such as working experience, knowledge. Graduates can enable to display this information in their profiles for public visitors. Inserted information can be used as an input for generating graduate's curriculum vitae in pdf format, which isprovided automatically. It is in a graduate's competence, which information will be searching pages with their crawlers. A graduate can use it for the building of his virtual web identity on the internet.Our Alumni system solves the problem concerned with graduate's feedback to the faculty with an inquiry module. In this module the faculty can define questions with answers which active graduates can respond. This module should be used for collecting data which are not included in graduate's profiles and have high information value for the faculty

Deep Learning Techniques For Detecting Deepfake: A Review

Anushree Deshmukh, Sunil Wankhade
TCET, MUMBAI

Abstract – **Deepfake algorithms can make forged pictures and videos that people can't differentiate them from true ones. The suggestion of technology that locate and prove the truth of virtual visual media is as a result essential. This paper offers a survey of tools and algorithms used to make deep fakes and, additional significantly, methods to locate deep fakes. We present large discussions on challenges, studies developments and guidelines related to deep fake technologies. By reviewing the history of deep fakes and cutting-edge deep fake detection strategies, this gives a comprehensive assessment of deep fake techniques and helps the development of latest and more robust strategies to deal with an increasing number of tough deep fakes.**

Keywords: deep fakes, deep learning, auto encoders, generative adversarial networks (GAN).

I. INTRODUCTION

Deepfake (stemming from "deep learning" and "fake") is a technology which creates fake images or videos of targeted humans by swapping their faces another character saying or doing things that aren't absolutely done by them and humans start believing in such fake, as it isn't always recognizable with the everyday human eye. Deep learning models such as autoencoders and generative adversarial networks have been applied widely in the computer graphics vision to solve various issues [1,2]. These models have been used by deepfake algorithms to examine facial languages and actions of a person and synthesize facial images of another person making equivalent expressions and movements [3]. Deepfake algorithms usually require a large dataset to train models to make realistic images and videos. As public figures such as legislator or celebrities may have a large number of videos and images available online, they are probable targets of deepfake. Deepfakes were used to superimpose faces of legislator or celebrities to bodies in porn images and videos.

The first deepfake video found in 2017 where face of a celebrity was superimposed to that of a porn actor. It is threat to world security when deepfake procedures can be employed to make videos of world leaders with forged speeches for false purposes. Deepfakes therefore can be abused to cause political or religious misunderstanding between countries, to fool public and affect results in election campaigns, or create confusion in financial

markets by creating fake news. It can be even used to

create forged satellite broadcasting images of the Earth to hold items that do not really exist to create chaos in military
There is also advantages of deep fakes such as creating voices of those who have lost theirs voice or updating episodes of web series without reshooting them. However, the number of venomous uses of deep fakes largely dominates that of the positive ones. The growth of advanced deep learning networks and the accessibility of big amount of data have completed the forged images and videos almost unique to people and even to algorithms. The method of creating those forged images and videos is also much easy today as it wants as little as a self-photo or a small video of a targeted individual. Less effort is required to produce an impressively substantial tempered footage. Recent advances can even create a deep fake with just a motionless image. Deep fakes therefore can be a threat affecting not only community figures but also ordinary people.

Finding the fact in digital domain therefore has become gradually critical. It is even more interesting when dealing with deepfakes as they are majorly used to help venomous drives and almost anyone can create deep fakes these days used with present deepfake tools.

Therefore, here have been abundant methods proposed to detect deepfakes. Most of them are also based on deep learning, and thus a battle between malicious and optimistic uses of deep learning methods has been rising.

In Section 2, we present the ideologies of deepfake algorithms and how deep learning has been used to enable such riotous technologies. Section 3 reviews different methods for detecting deepfakes as well as their advantages and disadvantages. We discuss challenges, investigation movements and directions on deepfake recognition as well as interactive program and forensics issues along with research gap in Section 4. Section 5 concludes the paper.

II. DEEPFAKE CREATION

Deepfakes have become popular due to the quality of tampered videos and the easy-to-use skill of their applications to a wide range of users with various computer skills from expert to beginner. These applications are typically developed based on deep learning practices. Deep learning is well known for its ability of instead of complicated and high dimensional data. The first attempt of deepfake creation was Fake App, developed by a Reddit user using autoencoder-decoder blending structure. In that method, the autoencoder extracts hidden features of face images and the decoder is used to reconstruct the face images. To swap faces between source images and target images, there is a need of two encoder decoder sets where each pair is used to

Train on an image set, and the encoder's parameters are joint sandwiched between two network sets.

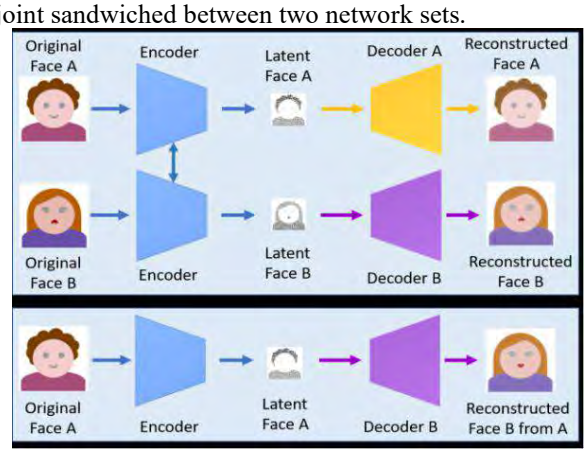

Fig. 1: A deepfake creation model.

This approach enables the common encoder to find and learn the comparison between two sets of face images, which are comparatively unchallenging because faces normally have similar structures such as eyes, nose, mouth places. Fig. 1 demonstrations a deep fake making procedure where the feature set of face A is linked with the decoder B to rebuild face B from the original face A. Table 1 shows some tools for deep fake creation along with its algorithm used and key features

Table 1: Summary of notable deepfake tools

Tools	Algorithm used	Key features,
DFaker	GAN with DSSIM	Reconstruction of face is done by DSSIM loss Function. Keras library-based implementation
Faceswap-GAN	GAN v2.2 with MTCNN	the auto-encoder architecture is provided with adversarial loss and perceptual loss (VGGface) are added to.
Faceswap	GAN with MTCNN and DFL-H128	Parameters of the encoder are shared and pairs of Encoder-decoder.
DeepFaceLab	GAN-er with MTS3FD	Expand from the Faceswap model with new models, Uses multiple face
DeepFake-tf	GAN with DSSIM	Like DFaker but tensor-flow is used for Implementation.

This segment gives a review of deepfake detection methods where we categorize them into two major classes: fake image detection approaches and fake video detection approaches as shown in Fig. 2. The latter is distinguished further: visual artifacts within video frame-based methods and temporal features across frames- based ones. Whereas most of the approaches based on temporal features use deep learning recurrent classification models, the methods use visual artifacts within video frame can be executed by either deep or shallow classifiers.

III. DEEPFAKE DETECTION

Deepfake finding is normally deemed a binary arrangement problem where classifiers are used

between reliable videos and interfered ones. This kind of method requires a large database of real and fake videos to train classification models. The number of fake videos is progressively available, but it is still limited in terms of setting a level for validating many discovery methods.

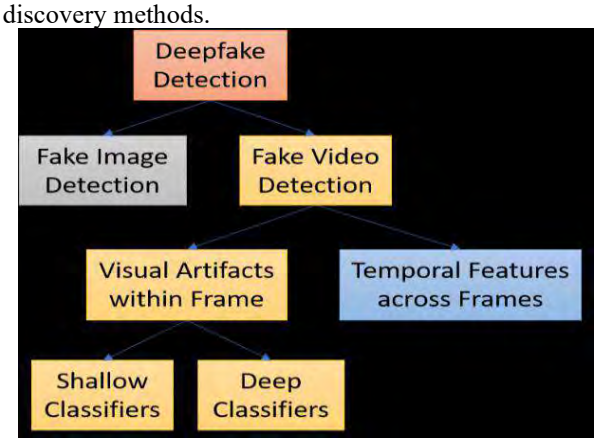

Fig. 2: Classification of deepfake detection.

.

To report this matter, Korshunov and Marcel [6] produced a distinguished deepfake data set containing of 598 videos based on the GAN with the open source code Face swap-GAN. Videos from the openly available VidTIMIT database were used to produce low and high quality deepfake videos, which can efficiently emit the facial features, mouth actions, and eye blinking. These are then used to test various deepfakes. Test outcomes show that the general face recognition systems supported VGG and Facenet [6] are incapable to detect deepfakes successfully. Additional approaches such as lip-syncing and image quality metrics with SVM makes very high error rate when allied to detect deepfake videos from this newly shaped dataset. This increases fears about the serious need of upcoming development of more strong systems that can detect deepfakes from the original.

3.1 Fake Image Detection

Face swap has a few convincing applications in video compositing, transformation in portraits, and especially in individuality safety as it can swap faces in photos by ones from a group of typical images. However, it is one of the approaches that fake attackers enter authentication structures to gain access. The usage of deep learning such as CNN, GAN, SVM, Random forest and multi-layer perceptron has exchanged face images more challenging for forensics as it can reserve pose, facial appearance and light of the photos. Among deep learning produced images, those produced by GAN are possibly most tough to notice as they are genuine and good quality based on GAN's ability to learn supply of the input data and gives novel outcomes with same input distribution.

Maximum works on recognition of GAN produced images do not consider the capability of the recognition models although the development of GAN is continuing, and Several new extensions of GAN are often introduced. Xian et al. [7] used an image preprocessing phase. This rises the pixel level statistical comparison between actual image and false image and needs the forensic classifier to study additional essential and meaningful features, which has better simplification competence than preceding image forensics methods or image stag analysis networks.

Additionally, Agarwal and Varshney [8] company the GAN-based deep fake recognition as a hypothesis challenging issue where a statistical outline was presented by means of the information theoretical study of verification. The least distance among deliveries of genuine images and images produced by a specific GAN is defined, explicitly the vision fault. The logical outcomes demonstrate that this distance rises when the GAN is fewer correct, and in this situation, it is easier to distinguish deep fakes. In case of high-resolution image, a very accurate GAN is required to produce fake images that remain tough to detect.

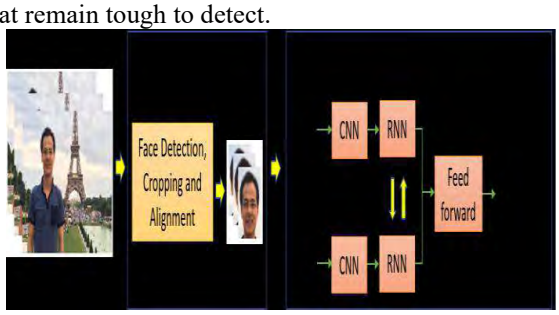

Fig. 3: A two-step process for face manipulation detection.

3.2 Fake Video Detection

Maximum image based deep fake recognition approaches cannot be used for videos because of the robust deprivation of the frame data after audiovisual compression. Also, videos have chronological features that are diverse amongst sets of frames and thus challenging for approaches intended to sense individual fake images. This subcategory emphases on deepfake video recognition approaches and classifies them into two clusters: approaches that uses chronological features and those that explore visual artifacts inside frames.

3.2.1 Temporal Features across Video Frames Based on the opinion that temporal coherence is not imposed efficiently in the procedure of deepfakes, Sabir et al. [10] use of spatio-temporal features of audiovisual streams to sense deepfakes. Video manipulates to carry out on a frame-by-frame basis so that low level objects formed by face manipulations are supposed to further clear themselves as temporal artifacts with irregularities among frames.

A recurrent convolutional model (RCN) was projected based on the combination of the convolutional Network Dense Net and the gated recurrent unit cells to exploit temporal inconsistencies across frames see Fig. 3. The proposed technique is verified on the Face Forensics++ data set, which contains 1,000 videos, and displays promising outcomes.

Guera and Delp [11] detailed that deep fake videos comprise intra-frame conflicts and temporal conflicts among frames. Then they proposed the temporal-aware pipeline technique that uses CNN and long short term memory (LSTM) to detect deep fake videos. CNN is employed to extract frame- level features, which are then fed into the LSTM to create a temporal sequence descriptor.

A Fully-connected network is used afterwards for classifying doctored videos from real ones based on the sequence descriptor (Fig. 4).

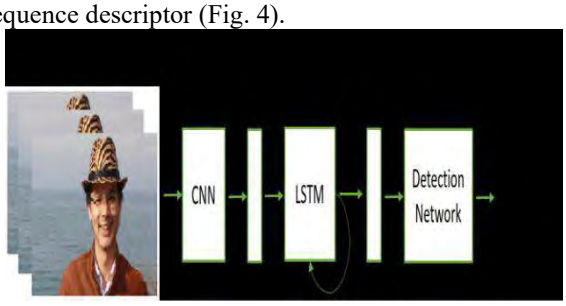

Fig. 4: A deep fake detection using CNN and LSTM.

Similarly, the use of a physical signal, eye blinking, to notice deep fakes was planned in [9] based on the opinion that a individual in deep fakes has a lot fewer frequent blinking than that in original video. A fit adult human would usually blink somewhere between 2 to 10 seconds, and every open and close the eye would take 0.1 to 0.4 seconds. Deepfake procedures, however, frequently use face images existing online for training, which usually demonstrate persons with open eyes. Therefore, without blinking images of persons, deep fake algorithms do not have the ability to produce fake faces that can blink typically. To distinguish actual and false videos, Li et al.

[9] Initially decompose the videos into frames where face areas and then eye region are mined based on six eye signs. After some stages of pre-processing such as aligning faces, extraction and scaling the bounding boxes of eye sign points to generate new arrangements of frames, these cropped eye area arrangements are distributed into long-term recurrent convolutional networks (LRCN) for dynamic state prediction. The LRCN contains of a feature extractor built on CNN, a sequence learning built on long short-term memory (LSTM), and a state prediction built on a fully connected layer to forecast probability of eye open and close state. The eye blinking illustrates robust temporal dependencies and therefore the application of LSTM helps to capture these time-based patterns efficiently. The blinking rate is calculated built on the predicted outcomes where a blink is defined as a highest above the threshold of 0.5 with interval less than 7 frames. This technique is assessed on a dataset collected from the

internet containing of 49 videos and their matching fake videos produced by the deep fake algorithms.

3.2.2 Visual Artifacts within Video Frame

As observed in the preceding subsection, the approaches using temporal patterns across video frames are typically based on deep recurrent network models to sense deep fake videos. This subsection inspects the additional method that usually decomposes videos into frames and explores visual artifacts within single frames to get distinguished features. These features are then dispersed into either a deep or shallow classifier to discriminate between false and true videos. We thus assemble approaches in this subsection based on the categories of classifiers, i.e. either deep shallow.

3.2.2.1 Deep classifiers

Deepfake videos are usually formed with few resolutions, which need a face warping method (i.e., rotation and shear) to matches the original ones. Because of the resolution contradiction between the warped face part and the nearby context, this procedure leaves objects that can be noticed by CNN methods such as VGG16, ResNet50, ResNet101 and ResNet152. A deep learning technique to spot deepfakes based on the objects observed throughout the face warping step of the deepfake generation algorithms was proposed in [12]. The proposed structure is assessed on two deepfake datasets, i.e. the UADFV and Deepfake TIMIT. The UADFV dataset [15] contains 49 actual videos and 49 forged videos with 32752 frames in total. The Deepfake TIMIT dataset contains bad quality videos of size 64*64 and another good quality videos of 128 x 128 with 10537 unique images and 34,023 forged images mined from 320 videos for each set. Performance of this technique is associated with other predominant approaches such as the face tampering recognition technique two-stream NN, Head Pose [15], and two deepfake recognition MesoNet methods, i.e. Meso-4 and MesoInception-4 [13]. Advantage of the proposed technique is that it need not to produce deepfake videos as forged examples before training the detection methods. As an alternative, the false examples are produced dynamically by mining the face area of the unique image and aligning it into several scales before applying Gaussian blur to a scaled image of chance choice and warping back to the unique image. This decreases a huge time and computational resources associated to other approaches, which need deepfakes are produced in advance. Recently, Nguyen et al. [14] proposed the usage of capsule networks for distinguishing doctored images and videos. The deepfake face swap dataset created by Afchar et al. [13].

IV. RESEARCH ISSUES

Deepfakes are gradually damaging to confidentiality, society safety and democracy. Diverse approaches for detecting deepfakes are proposed by many researchers as soon as this menace was familiarized. Initial efforts were based on handcrafted features gained from objects and on social context in which deepfake is revealed. This is serious as deepfakes are getting more photorealistic and it is extremely projected that recognition software will be lagging behind deepfake creation techniques.

4.1 Limitations of Existing system

In the technique where the recognition is done by eye blinking technique [9] the dataset used was very small thus system accuracy will be reduced. The experimental outcomes show great performance of the planned technique in detecting false videos, which can be further enhanced by seeing dynamic pattern of blinking. Detection is done by frame by frame basis so there might be chances of inconsistency [10]. RNN gives better result than CNN [11][12][13].

4.2 Effects of Deepfake

Misinformation: Folks are more probable to have a response to misinformation in the form of forged image, audio, and video content, which allows the doctored media to spread more rapidly than purely written fake data. Additional, images and video have been recommended to generate a Mandela effect, the formation of memories that never happened.

Exhaustion of serious thinking: It will take more effort for people to determine whether data is true, especially when it does not originate from reliable actors. Uncertainty around content reliability might also put off an distinct from sharing correct content, dropping the distribution of true information.

The deceiver's dividend: The presence of entirely artificial content offers an avenue for actors to deflect charges of impropriety based on footages and video, by appealing the source material has been faked.

These results are troubling and will be most persistent in the future, as deep fake excellence increases and social alertness lags

V. CONCLUSION

Deep fakes have started to wear down trust of people in media contents as seeing them is no longer corresponding with believing in them. This is critical nowadays as the technologies for creating deep fakes are progressively approachable and social media platforms can spread those fake contents rapidly. This paper has revised the state-of-the-art methods and a summary of typical approaches are provided. It is noticeable that a fight between those who use progressive machine learning to create deep fakes with those who make effort to detect deep fakes is rising. Deep fakes' good quality has been increasing and the Performance of discovery methods needs to be enhanced consequently. Detection methods are still in their early stage and various methods have been suggested and evaluated but using fragmented data sets. An approach to progress performance of detection methods is to create a rising updated standard data set of deepfakes to authorize the

ongoing development of discovery methods. This will simplify the training process of discovery models, particularly those based on deep learning, which involves a large training set. The current detection methods mostly focus on disadvantages of the deepfake generation pipelines, i.e. finding weakness of the participants to attack them. This kind of information and knowledge is not always available in adversarial surroundings where attackers usually attempt not to reveal such deepfake creation technologies. This is a real challenge for detection method development and a future research needs to focus on introducing more robust, scalable and generalizable methods.

Review of an Indoor Navigation System Using NFC Technology

Heeth jain ,pratik gupta,pritesh jain,ravindra chabhadia ,shubham gadia
TCET, Mumbai

Abstract— **There are many problems faced in the existing navigation system. Here we present a NFC (Near Field Communication) based indoor navigation system called NFC Internal in order to improve and enhance the current Indoor Navigation System. NFC Internal enables an easy data transfer for indoor navigation systems just by touching tags spread over a building or a complex. This review has some pros and cons but is definitely improved then previous systems. The system requirements were discussed and necessary upgradation were done to the previous technology.**

Keywords- NFC, NFC Internal, Indoor Navigation

I. INTRODUCTION

Navigation is the thing that helps one to reach from one point to another. While one is traveling on an intended route, navigation systems provide reading, controlling and updating the movements of one's position and orient. The demands and usage of outdoor navigation systems are increasing incredibly today as all people use PDAs, mobile devices or personal navigation assistant and navigation systems can run on those devices.

Global Positioning System (GPS) is generally the base of outdoor navigation systems, it provides reliable location information in almost all weather conditions and at all times on or near Earth as it is a space based global navigation satellite system. It is a well explored and standardized area of research. But due to the absence of line of sight to the satellites the GPS receivers cannot perform well indoor environments. So because of the unavailability of GPS indoor environment, the indoor navigation system has become a recent research area. In order to circumvent the lack of excellence, variety of technologies are tested and new designs are generated for indoor navigation.

For indoor navigation systems the existing solutions are grouped as network based navigation system that are based on networking technologies such as sensor networks[4], and an Independent navigation system providing autonomous user position. Technologies such as Bluetooth, Ultra Wide Band (UWB), WiFi or Radio Frequency Identification (RFID) are used by network based navigation systems.Wifi and UWB technologies provide higher position accuracy than Bluetooth and RFID technologies.

The position accuracy of a Bluetooth depends on the amount of cells used, it is a simple, compatible short range Communication technology. The same for RFID technology depends on the type of tags, which can be either active / passive, and also the amount of these tags. The RFID based indoor navigation solutions up till now are generally based on usage active RFID tags and require extensive usage of active RFID tags to get good position accuracy. Opposite to the passive tags, to increase the transmitting distance active tags contain embedded batteries. The high cost of the active tags is the major drawback of using active RFID tag based solutions. Studies in this area also indicate that it does not provide an efficient tracking system. WiFi and UWB technologies have their own limitations as well. WiFi requires expensive access point in any area where the person needs to be tracked. Due to some technical problems of technology (e.g. antenna mismatch, low power emission, and possible external interference from other systems) an efficient indoor navigation system cannot be ensured in case of UWB. Independent navigation systems based on dead reckoning (DR) methods are the other popular systems. There are 2 types of positioning defined when marking position of a person on a map. I.) By making use of help from enough number of assisting devices such as satellites, the FIX position determines the location. I.) Whereas the current position is determined using the last fix position, the speed of the item, the route and the time required to calculate the last fix position.
This methodology is used by navigation systems based on DR methods. They use Micro Electro-Mechanical Sensors (MEMS) that include electronic barometers, magnetometer and accelerometers. When the calculation of new position is based on previous DR position, the errors of the estimation process are cumulative. The performance of the system is affected by the large errors, so this acts as a major drawback of DR method based navigation system.

Assisted GPS (A-GPS) systems which enlarge the working area of GPS technology is another independent, existing technology. With A-GPS systems, through an assistance data server the indoor GPS. signals are processed efficiently. The assistance data server is connected to reference receiver. However, the strength of the signal indoors is sometimes too

low. The high installation cost and the complexity of the system design are the major drawbacks of the indoor navigation system. Also, the other existing positioning systems are far from providing an accurate position in large buildings [4],[5]. Therefore inside large buildings consisting of many rooms, floors and large halls there is a strong requirement of an efficient and low cost indoor navigation system. At any time the navigation systems for indoor environments are desirable.

For some instance, a person is entering a building for the first time and he may want to go to an office inside the building. Such cases are very common at University, airports, complexes, hospitals, and shopping centers etc. In such cases, a user friendly navigation system guiding people through huge buildings consisting of thousands of rooms can be helpful. This idea presents an innovation of Low cost indoor navigation system called NFC communication technology.

The main idea is to orient users by NFC enabled mobile phones, which also have an embedded indoor navigation application. While this application is oriented by the user by gathering destination point. The mobile devices gathers the current position from NFC tags and shares the coordinate data with the application. The user can now determine the current position inside the building by a simple touch on the device to tags which are spread inside a building.

The remainder of this paper is organized as follows:

In section 2, solutions to indoor navigation based on NFC are presented together with the system design and it's implementation. Section 3 consists of the conclusion of paper as well as highlights the future work.

II. NFC INTERNAL

NFC is bidirectional short range, wireless communication technology. This communication occurs between 2 devices within the range of few centimeters. 13.56MHz signal with a bandwidth not more than 424kbit/s is used. This technology is based on Radio Frequency Identification (RFID) technology. It can be operated on acrd emulation, reader/writer. It is also used in peer to peer operation modes where communication occurs between a mobile phone on one side and an NFC reader, a passive RFID tag (NFC tag), or a mobile phone on the other side. It is very simple and easy to use technology. The user only needs to carry and use an NFC enabled mobile device.

Indoor Navigation application must be OTA(over the air) preloaded to the smart card. The user just needs to simply touch the URL tag that contains the URL of the indoor map information just before entering the area or building. The map present on the site is OTA downloaded to users mobile from Mapserver . This map information is afterwards used by the device as the Indoor Navigation application starts automatically. So as the person selects destination of his voyage inside the building, the indoor navigation application provided the most optimized route to the destination. As the user navigates through the halls, they have the option to touch to the Reference Tags (NFC tags) spread over the building to fix their current positionon the map, & then get instructions to reorient their position to destination or to create a new optimal route to the destination is necessary. For indoor navigation systems, NFC technology is a coherent solution then all the current ones. The use of NFC can be extended to Internal and more other cases. The existing outdoor navigation systems and the NFC Internal can be combined and such kind solution provides higher functionality.
For example, if a new student is currently staying in their home and has to meet his advisor for some work, but they don't not know where the office of their advisor is in the campus. In this case, user will need an mobile device with NFC enabled which has a GPS-based mobile navigation system for outdoors as well as indoor navigation application. The student starts the process by entering the name of the university campus and name of the advisor. GPSbased mobile navigation application will help the student until they reache the respective university campus.

Map of the surrounding area is shown on the mobile device screen, which the help of student’s current position and a route to the campus are also indicated as well [1]. As student moves to the destination, the mapped area and the student’s position are dynamically updated on the map. GPS based mobile navigation systems can also provide audio guidance to the student . When student reaches to the university campus, they need to simply touch the URL Tag on the entrance in order to get indoor map information and navigate inside.

After the map is downloaded from MapServer, the outdoor application quickly shares the destination information with the indoor application on the mobile device which is a seamless solution. So, the student does not need to enter the destination address again. Now, user can start to navigate inside the campus by touching to the Reference Tags as described above.

II System Design

Spatial Information Maps:

Current Indoor map database is generally based on 2D graphical representations which are developed by CAD (Computer-Aided Design) systems [3].

In order to [7], the CAD drawings of an indoor environment can be separated into floor maps of each floor in the building, and each CAD drawing of floor

plan can further be converted into separate spatial information maps that annotate structural features such as walls, doorways, elevators, and staircases. In each separate spatial information map, the reference points are also expressed in form of vector spatial data structure which uses the 2D Cartesian coordinate system and each map is stored in the Map Server for the Indoor Environment with a unique floor identifier, and also a unique building identifier if the indoor is a complex or campus.

Reference Tags for NFC Internal:

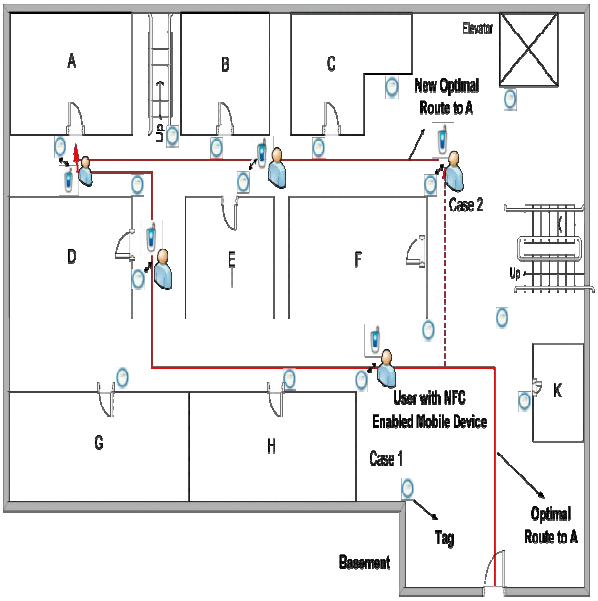

Fig. 2. Navigating to Destination

There is a possibility that the user might get out of the NFC technology in indoor navigation systems has a potential

Vector spatial data structure is used instead of raster data structure. Use of vector spatial data allows efficient encoding topology and also network linkages can be efficiently employed [9]. Thus it is more useful for accurate positioning.

B. How NFC Internal Works

This section shows how NFC Internal works in detail. The NFC Internal is comprised of two phases: initiating the indoor navigation system and navigating to destination. As described before, the main problem starts with the user who needs to reach to an intended point, but does not know the exact location of the place. In such situation, the user who has an NFC Internal system on her an NFC enabled mobile device is only required to follow the phases hereunder.

1) Initiating NFC Internal:
1. As seen in Figure 1, the user touches to the URL Tag which contains the URL of the indoor's map information on the MapServer. This tag is placed on the entrance of the building. The NFC enabled mobile device gets the address as it touches to the URL Tag.

2. Mobile device connects to the URL via OTA and requests the map information from the map Server, and the map information is loaded to the mobile device afterwards.
3. After loading the map, indoor navigation application on the smart card automatically starts and converts the map data into link-node model as 2D network with topological relationships.

4. The application asks the user to enter the destination point.
User specifies destination point just by choosing the person's name.
5. The application quickly computes the best route by using
Dijkstra's shortest path algorithm.

2) Navigating to Destination:
After the route is computed, the application starts to orient the user towards the destination. As the user navigates along the path, she can touch to any Reference Tag to validate her navigation. User is only required to touch to a tag on her way to get this valuable help. The location data on the Reference Tag is transferred to indoor navigation application at this moment. It is obvious that information on the tag also shows the user's current location. The application uses this information to check whether the user is on the intended route or not. The application forms simple plain instructions as forward, left, right, backward etc. to orient the user which can be easily followed by the users. Also there are instructions to use stairs upward / downward or to use elevator up / down to a specific floor. These instructions are displayed on the screen of the mobile device.
Let's concentrate on the simple case shown in Figure 2. According to the scenario, user wants to be directed to Office A, and starts navigating inside the building for this purpose. She touches to the first Reference Tag that she sees on her way, after which the location data on tag is transferred to the application on mobile device (Step 1'). So, the application figures out that she is on the intended route and gives user the first instruction as: "go straight ahead for 25 meters, turn right". Similarly user touches to another Reference Tag on her route

and application finds out that user is still on the correct
route, so gives instructions to the user (Step 2').
route, towards Office A for example, and touches to a Reference Tag which is not on her route (Step 1"). With the transfer of location data, the application figures out that the user is out of route and calculates a new shortest path to Office A and gives user a new instruction as: “go straight ahead for 50 meters”. Similarly user touches to another Reference Tag on her new shortest route to Office A and application figures out that user is on the intended route indeed, and gives instructions to the us (Step 2"). As the user arrives the destination point, Office a (Step 3), the application tells user that she reached the destination, and ends the ongoing process.

III. CONCLUSION

This paper presents a new, reliable, and seamless indoor navigation solution that helps to create smart and contextaware environments. The use of NFC technology in indoor navigation systems has a potential to increase the usability of these systems. Comparing to other existing indoor navigation solutions, NFC Internal has many advantages hereunder:

• Reduces the cost of indoor navigation systems by using cheap passive tags,
• Minimizes response time, because the time required to transfer data from NFC tag to mobile device and the time required to generate application’s new path is little,
• Provides accurate position and orientation information, so the orientation of the user to the destination is facilitated,
• Eliminates the need for a server or a terminal to orient position, so location privacy of the user guaranteed,
• Provides exclusive control over her location data for the user. On the other hand there is a limitation of the proposed system.

In the system, on the go position information cannot be provided,
since user can learn her position information as she touches an
NFC tag.

Overall, we think that the proposed system is very simple to use and has several benefits to users.

Abstract— **Wireless Sensor network (WSN) facing many issues in due implementation in vulnerable environments. Various researchers has already defined a systems for data transmission with WSN, still such system having high data loss issues, maximum packet delay as well as packet overhead during the data transmission. Different parameters has to consider to improve such losses like cluster network generation, data aggregation, secure data encryption and data transmission using distribution approach produces effective outcome and eliminate such issues. Moreover implementation with cluster network and selection a cluster head (CH) based on trust which produces much effective results and provides flexibility to system. This is research we proposed secure data transmission in cluster network and investigate the Quality of Service (QoS) parameters of entire execution. Initially we create different clusters with collaboration of multi sensor nodes while each node consist individual battery power as energy. According to highest energy we calculate the trust and such node defined as CH, Data Aggregation (DA) and Broadcast Tree Construction (BTC) two different techniques have been used for eliminate network lifetime or cut generation in system. In partial experiment analysis system shows improve QoS parameters like Throughput, delay, packet overhead etc respectively. It also enhance the network life because of proposed energy conservation approach.**

Keywords - Cluster Network, WSN, Data aggregation, Broadcast Tree Construction, QoS.

I. INTRODUCTION

In this era, the dagger development of mobile computing expedients that primarily embody laptops, personal digital assistants (PDAs), as well as hand-held digital devices, is driven by a revolutionary change in the computing world. Security approaches to eliminate different network attacks like wormhole attack [1] in untrusted environment. To identify intruder or threats from large traffic defined in [2]. Computing will not simply place trust within the power provided by private computers, and the idea of gift computing often arises and becomes one within the applied science society at every research hotspots [3]. Throughout this environments a path behalf of the two hosts might contains steps through one or extra nodes inside the painter. an important draw back in associate degree passing mobile ad-hoc network is finding and maintaining routes since host quality can

cause topology changes [4]. Several routing algorithms for MANETs are proposed inside the writings which they differ inside the painter. New routes square measure set up and existing ones square measure modified. Basically MANET networks square portion extra susceptible to suffer from the hateful performances. This paper we proposed an wormhole attack detection and prevention approach using secure mechanism of detection such malicious behaviour. This paper we proposed an various attack detection and prevention approach using secure mechanism of detection in malicious behaviour [5] and investigate the proposed experimental analysis.

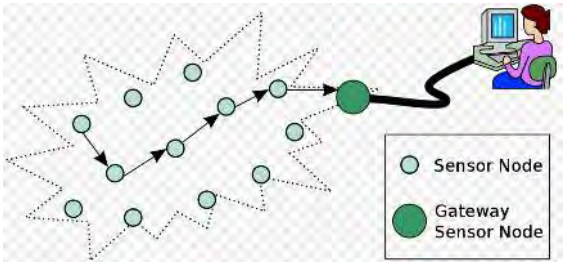

Figure 1 : Representation of a wireless sensor network [6]

The above figure 1 shows basic WSN view in sensor network, which is basically similar to wireless ad hoc networks in the intelligence that they rely on wireless connectivity and unstructured establishment of networks so that sensor data can be ecstatic wirelessly.

RELATED WORK

Yashpal sinh Gohil et. al. [1] proposed a true Link verifies whether or not there's an immediate Use truelink to link a node to its adjacent neighbor. The main disadvantage is that TrueLink only works on IEEE 802.11 devices that are backward compatible with an update to the computer code. An approach to trip time (RTT) is emerging to beat the problems of further hardware exploitation. The RTT is that the time taken to deliver RREQ to a supply node and to collect RREP from endpoint. A node should calculate the RTT between its neighboring nodes and itself. The malicious nodes are priced higher for RTT than different nodes. This method will determine the supply of its real and misbehavior neighbors. This detection technique is efficient only in the case of hidden attacks.

Vikaskumar Upadhyay and Rajesh Shukla [2] describes Numerous methods are planned to be used to identify wormhole attacks using a leash method for the packets. Packet leash is the technique that guards against wormhole attack. The leashes are either spatially or temporally categorized. All nodes inside the network should have data from their own position and stable synchronized clock in spatial leashes. This

requires its own current location when a sender sends the data packet and UTC accepts wormhole nodes. Directional data are exchanged between source and destination during this technique. Destination by scrutiny will find the wormhole the Received signal from malicious nodes and gave directional info. The relation to the wormhole is observed if the supply signals and intermediate nodes are distinct.

Amit Kumar and Sayar Singh Shekhawat [3] describes, in Authors have criteria of contact that are primarily focused on a paradigm of research to ensure safe communication. Another such assault is a wormhole attack, in which two or many nodes are often flustered together to gain knowledge calculation and communication. A wormhole compromised network is illustrated during this post, and the research model can be used for secure communication within the network being targeted. The network model is designed to identify the secure communication node, so that connectivity is maximized. Additionally, in mostly mobile network based attack, the writers address a way of generating the safe path. The model eventually provided the optimized parameter for reconciliation communication. Results show the improved performance of model in terms of the communication throughput and reduced the loss.

Ashish Kumar Jain and Ravindra Verma [4] authors To search for aggressive or legitimate nodes inside the network, build calculative confidence values for the nodes. Authors propose a way to defend against victimizing wormhole attack combination of parameters such as energy, connection range and node buffer length. A node's confidence value is calculated backed by these parameters. This node confidence value is then compared with the threshold value of network faith. This comparison was supported and one can find out if The selected node is either malicious or valid, or is not. The planned methodology consists of two phases: first, the analysis of the network parameter and the calculation of the threshold, and second, the implementation of the protection on the routing protocol that prevails. Results area unit assessed by expanding the AODV protocol as well as evaluating the efficiency of the proposed routing protocol and matching it to the insecure AODV. The performance of the proposed confidence-based approach, based primarily on defense, is cost-effective and reasonable against comparative findings wormhole attacks in MANET.

Rajan Patel Anal Patel, Nimisha Patel [5] this Survey is The different techniques used to identify authors of wormhole attacks suggest an approach for the identification and prevention of wormhole attacks. A projected defensive approach against wormhole attack based primarily on the Hash-based Compression Function (HCF) that is really mistreatment of any secure hash operates to chip a hash field for the RREQ packet and the projected approach looks terribly promising compared to other proposed solutions in literature.

Dhruva Patel et. al. [7] system describes various safety hazards which affect different levels of safety. Because of its simplicity and self-routing nature, MANET is responsive to various threats, and various attacks can breach separate layers within the network. There are numerous attacks and each attack has its own impact on different layers since some can only affect a single layer of the network while others can hit other layers, i.e. depending on the nature of the intrusion on how it reacts. Wormhole assault is now a network layer intrusion capable of crippling the communication network entirely. all the attacks.

Juhi Biswas et. al. [8] system present AODV With the implementation of the MANET and Wormhole Attack Detection and Prevention (WADP) technique on this revamped AODV, the routing protocol is modified to detect and prevent wormhole attacks in real world. So that fraudulent nodes are found within the network and the false positive limitation node authentication function is eliminated. Simulation tests also indicate that node authentication does not eradicate false positives although it helps to chart the actual location of the hole jointly and could be a relatively double test for hole attack detection. This algorithmic rule doesn't use any special hardware for police work wormhole attack.

Kapil Raghuwanshi et. al. [9] take Initiative to eliminate or minimize the impact of a hole assault by offering a solution within the initial route setup point that could sense the presence of a void. Such resolution is based on the hop count analysis approach, i.e. hop count is used as a parameter for characteristic shapes involving tunnel space. Hop counts are evaluated to detect hostile nodes. Simulation of the planned work is completed in many node and traffic situations in the presence of a wormhole attack. The simulation results The predicted strategy demonstrates superior performance as PDR and attendance decreases however, in fact, "normal end-to-end gap" rises. It has been noticed within the analyzed state of affairs that the MAODV has a superior performance than AODV. Modified AODV is ideal for wormhole attack identification and bar detection. This strengthens the insecure circumstances of the packet distribution level, with a borderline reduction in turnout and a reasonable raise in end- to-end delay.

System [10] Throw light on a weak wormhole attack, during which two or more malicious nodes type a tunnel as a relay mechanism into the packets themselves. Such an attack may result in the packets sent being selectively diverted, fabricated and changed. During this paper AN identity is planned on the side of the clusters to shield the network from hole attacks based primarily on the signature theme. The designed theme need not transmit any credentials between nodes, thereby overhead calculations. Cluster During which cluster heads area unit selected in such a way that they cannot be harmful, specifically focused architecture is employed. This style works in 3 steps. The effects of the simulation indicate the improved performance of the theme in

terms of throughput, packet delivery ratio and end-to-end delay. According to [11] proposed protocol is based on Neighbourhood overhearing and frequent analysis of key and different tables and expected procedure information was found to be safe and a few region assault units are checked on it. Wormhole assault is observed by nodes being overheard. The results show that M-AODV has been strengthened in terms of the packet transmission magnitude relationship and the latency has therefore been lowered further, however the overhead amount has been raised. M-AODV jointly improves network reliability and stability. Thus, the planned protocol is proven to be protected in simulations alongside wormhole and blachole attacks.

Luo It. Al. [15] Fixes problems with WSN because every node is created to handle all the information from a forward-looking and network management-friendly, autonomous system to all levels, from the appliance layer to the appliance layer. This works very well, especially thanks to the algorithms developed with the short-shortcut WSN, they do not create simplicity and completeness when trying to implement widely and widely distributed different and low-energy WSNs at the same time.

Gante et al. [16] for example announce good organization of SDWSNs to boost potency and Overcome the inherent difficulties of common WSNs. The management theme is predicated on a Base Station Design for WSNs with Associated Integrated Controllers. The controller creates forwarding rules that area units stored in flow tables from location knowledge acquired through the localization technique processed in the layer layer application layer of the design.

Olivier et. al. [17] projected gradable design referred to as software package outlined Clustered detector It is believed that multiple base stations network (SDCSN) are used as controllers which additionally play the role of cluster head. Clusters of large nodes are divided into clusters, and each has a cluster head. The cluster head controls and coordinates the detector nodes in each cluster, and the knowledge processed in each cluster is diverted to the cluster head.

Oliveira et al. [18] style associated implement associate design supported Even within the framework many controllers in WSN referred to as Tiny-SDN supports Tiny-OS with a style structure consisting of SDN-enabled detector nodes and SDN controller node. This fixes issues such as in-band management, high communication delays and restricted power offers.

Tootoonchian et. a. OpenTM [19] projected associate very Put a little effort into this technique or work for new techniques observation SDN-based WSNs associated remains an exposed analysis space. Freshly but, work has been conferred on a network mensuration design supported SDN for observation of WSN data like routing path per- packet, the ratio each Link and hence the delay in each ointment-hop configuration.

East-West Apis modify supervisors that area unit within the similar dominion or neighbouring dominions to express with one another [20]. it's vital to say here that SDN isn't concerning SDNs have been shown to have the ability to change network management and allow innovation through network programmability, rather than enhancing network performance.

The challenges to think about once integration a quality management theme contains management the impact of nodes coming In the network and therefore the nodes perform network functions, implement functions, and different network attributes on QoS. A number of solutions and process steps have been provided by Zhou et al to stop the problems associated with the SDN controller nodes and offer WSN efforts. [21].

II. PROPOSED SYSTEM DEISGN

Figure 1 describes the cluster creation process and transmission between source and destination node. At the end of each TS network nodes verifies sensed data and broadcast messages to nodes within given Cluster Distance (CD) for cluster creation. Cluster creation uses the Relay Node (RN) and CD to group the sensor in same cluster. Upon accepting the broadcasted message each node verifies the value of RN. If its value is within RN it stores in its memory and compares CD with each node's distance. If the distance between nodes is same or less to CD and sensed value is within given RN then those group of nodes forms a cluster. The nodes NID which are related they will not broadcast message for cluster creation. Nodes which are not participate in cluster creation process based on *RN* and *CD*.

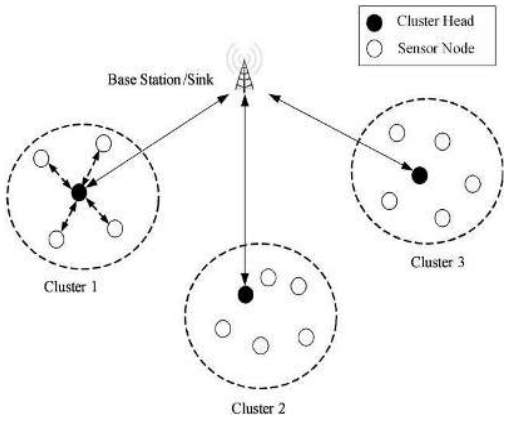

Figure 2: Proposed system cluster scenario

III. CLUSTER HEAD SELECTION :

Input: Cluster set with nodes.
Output: Ch selection with remaining sensor node.
Step 1: select all nodes as initial population.
Step 2: Select evaluation set
Step 3: Apply crossover on similar power nodes. **Step 4:** Apply mutation on each sensor node. **Step 5:** Apply fitness on all nodes power
Step 6: select best node using rout let wheel selection.
Step 7: Check GA evaluations

Step 8: Select final max energy node as CH node.

IV. DATA TRANSMISSION USING BTC

A dynamic cluster it will be designed when the goal reaches several cluster boundaries. A difficult role problem is how the device identifies the situation, particularly in a fully distributed environment, when the goal reaches the boundaries. We use boundary nodes to solve this problem in a fully distributed way.

The following assumptions are taken in order to design the proposed algorithm.

In this work we have carried out an algorithm which is wormhole attack identification has been through in a cluster based network creation manner to eliminate the wormhole attacks. Basically AODV routing protocol is utilized as the fundamental network topology. A multi-layer method is used to determine if a node is participating in a wormhole attack. Introduces the layered approach to decrease the capacity of dispensation on respective cluster heads. Due to safety point of view, this also decreases the risk of a cluster head should be hacked by attacker.
The complete network is separated in clusters sets illustrated in figure 1. Sometimes clusters might be corresponded or separate. Every cluster contains a single cluster head as well as number of cluster member nodes. Member nodes forward on the data only to the cluster head when any nodes want to send data to Cluster Head (CH). The CH is responsible for forward on the collective data to all its other cluster members. The CH is selected enthusiastically and preserves the routing information.

Input: Primary source node *Sender_node*, Destination node *Dest_node*, Group of nearest nodes Neigh_node *[],* node id as *N_id,* node energy *N_eng;*
Output: From source to destination way based on the given algorithm.

Step 1: initially system select the *Sender_node* and *Dest_node* on dynamically

Step 2: select the packet or file f for info broadcast.

Step 3: if (*file or data* ! =null)

Step 4: read each byte *bytes* form *file or data* when reach null

Step 5: send data, initialize *cost_filed_1, cost_filed_2, parent_filed_1, parent_fileld_2*

Step 6: while (nd[i] when reach NULL)

cost_filed_1=node[i]_eng parent_filed_1= node[i]_id

cost_filed_2 =node[i+1].eng parent_filed_2= node[i+1] _id

Step 7: if (*cost_filed_1*> *cost_filed_2*) *cost_filed_2*=null *parent_filed_2*=null

Else

parent_filed_1= parent_filed_2 cost_filed_1= cost_filed_2; *parent_filed_2*=null *cost_filed_2*=null

Step 8: end of while loop

Step 9: reiteration till when extent at the sink node

V. RESULTS AND DISCUSSION

After In this section we present experiment analysis using log file, Once simulation has finished it will create trace file at background, which contains all information of node communication as well as other log information. we have created a database of 5 text files which contains reading of 5 ms each till 25 ms as our simulation time is 25 ms. After that, we read the text file in a program created for the trace in Netbeans IDE 8.2. We got readings of various events in Netbeans from which we have plotted the graph of various parameters such as Drop rate(DR),Throughput and Packet Delivery Ratio(PDR) calculate d according to equation (1), (2) and (3) respectively. The evaluation has done with various WSN as well as cluster network existing protocol [12] [13] [14].

Table 1. The simulation parameters has used which is described in below table

Parameter	**Values**
Simulator	NS-allinone 2.35
Simulation time	25 sec
Channel Type	Wireless Channel
Propagation Model	Two Ray Ground
Standard	MAC/802.11

Simulation Size	1000 *1500
Max packet Length	1000
Ad hoc routing	AODV
Traffic	CBR

Table 2: shows the basic difference between the proposed and existing WSN.

Parameters	**WSN [21]**	**Proposed (cluster base with AODV)**
Data Aggregation	No	Yes
Data Security	Yes (selective)	Yes
Energy Conservation	No	Yes
Packet Loss	High	Low
End to End delay	High	Low
Packet Overhead	High	Low

1. Drop Rate:

It is defined as the number of packet lost per number of packet sent. The smallest
amount value of drop rate states superior performance of the protocol.

$$Drop\ Rate = \sum_{i=0}^{n} \left(\frac{packet\ received\ [i \ldots n]}{sent\ packet\ [i \ldots n]} \right) \quad \ldots\ldots (1)$$

2. Throughput:
It is defined as the total number of packets supplied over the entire simulation era.
This is a mix of TCP's total number of packets and the total number of packets sent. The higher throughput value means higher performance of the protocol.

$$Throughput = \left(\frac{\sum_{i=0}^{k} received\ packet[TCP]}{\sum_{i=0}^{l} sent\ packet[TCP]} \right) * 100 \quad \ldots\ldots (2)$$

3. Packet Delivery Ratio (PDR):
The PDR is defined as the ratio of the data packet numbers to the number of packets
produced through the network. The higher value of the packet distribution ratios represents greater efficiency of the protocol.

$$PDR = \sum_{i=0}^{n} \left(\frac{packet\ received\ [TCP]}{packet\ sent\ [TCP]} \right) * 100 \quad \ldots\ldots (3)$$

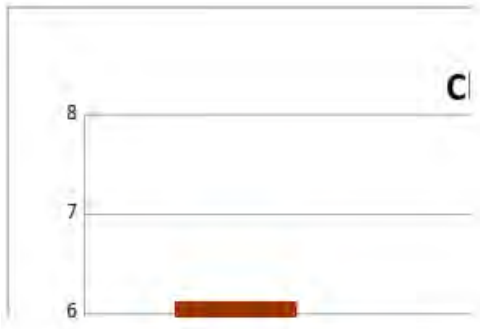

Figure 3: Drop rate of proposed vs existing
This figure 3 will provide the drop rate overall simulation during the communication with other protocols. The above graph has calculated based on various experiment analyses in NS2 environment. All defined protocols has used with different number of nodes in cluster network. The graph shows minimum packet drop rates of proposed AODV than other protocols.

Figure 4: Throughput of proposed vs existing
This figure 4 will provide the throughput of system during the communication with other protocols. Throughput s the most vital parameter the measure the QoS of any network. Similar as first experiment .tr files has utilized for evaluate the throughput
for all protocols. This figure also shows our approach produces highest throughput
than all three protocols.

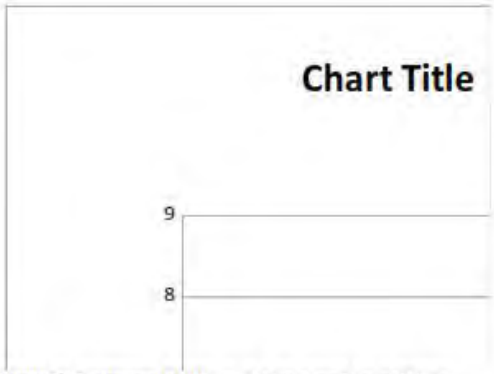

Figure 5: Network lifetime of proposed vs existing
This figure 5 will provide the how system will increased the actual time percentage of simulation due to proposed energy conservation protocol. Network lifetime has calculated based on after applying the energy conservation protocol, conservation s the technique during the data transmission eliminate unnecessary energy utilization by sensor, receiver as well as internal nodes respectively. In proposed system BTC has
used for best path selection as well as energy conservation protocol.

VI. CONCLUSION

This proposes an aggregation of the HMAC and data in WSN. The CHs are
initially chosen based on the connectivity of the node, which acts as a Data
Aggregator. The proposed techniques provide the ad hoc network with greater security and also prevent different types of network attacks. It supports in the direction of
escalations the packet delivery ratio (PDR) as well as decreases the network directly above by cultivating the enactment of the respective routing protocol. In the future, for faster detection of wormhole nodes, it will also need to modify the table entries in the receiver node. And also improved the security of the wireless ad hoc network. By means of set up such effective approach to prevent various kin fog network attacks with new defined algorithm. It also exposure and

elimination of wormhole attack throughout data communication. The proposed Techniques offer greater security for various types of ad hoc networks and also deter network assaults. This facilitates the elevation of the packet distribution ratio (PDR) and reduces the overhead network by encouraging the enactment of the respective routing protocol. To get the detection of wormhole nodes faster, the table entries at the receiver node need to be improved in future plan as well. And the security of ad hoc wireless networks is also improved. By applying such an effective approach, the kin fog network will deter various attacks with new defined algorithm.

Hybrid Cryptography Approach For Secure Sharing Of Data using AES, ECC & SHA256

Pooja Patil, Dr. Rajesh Bansode
Information Technology, Thakur College of Engineering & Technology
ppatil879@gmail.com, rajesh.bansode@thakureducation.org

Abstract— **Nowadays, the networks have gone global and information has taken the digital form. Critical information now gets stored, processed and transmitted in digital form on computer systems and open communication channels. Since information plays such a vital role, hackers are targeting the computer systems and open communication channels to disrupt the critical information system. Different cryptographic techniques like symmetric and asymmetric algorithms are used to hide any confidential information from the attacker. Symmetric key algorithms are simple and faster, but easily cracked by attacker. Asymmetric key algorithms have higher security, but lack in time efficiency. But, when symmetric and asymmetric algorithms combines together, they provides better result, and this technique known as hybrid cryptography. Using the concept of hybrid cryptography technique, we proposed hybrid system which combines symmetric algorithm (AES) and asymmetric algorithm (ECC) together, that can provide greater security and less execution time for encrypting and decrypting plaintext. Also cryptographic hash function (SHA256) implemented to evaluate the integrity of data, authentication control and other security mechanisms.**

Keywords— Cryptography, AES, ECC, SHA256, Encryption, Decryption.

I. INTRODUCTION

The spectacular growth of the Internet has make an increased awareness of an interest in security issues. Security of data is primary aspect when it transfer over the internet and protecting over data from unauthorized access is very necessary. To keep information secret, a widely used method is an encryption and decryption. Basically, encryption/decryption are the fundamental functions of cryptography In encryption, a simple message (plain text) is converted into unreadable form called ciphertext. While in decryption, a ciphertext is converted into the original text (plaintext)[1].

Different Cryptographic techniques were implemented for securing data during various communications. Cryptography algorithms mainly divided into two categories such as Symmetric key cryptography and Asymmetric key cryptography. In the symmetric key encryption, same key is used for both encryption and decryption process. Symmetric key algorithms are AES, DES, 3DES, Blowfish etc [1],[2]. Asymmetric key encryption is the technique, in which the different keys are for the encryption and the decryption process. One key is public and second is kept private. Asymmetric key algorithms are RSA, ECC, ElGamal, DSA etc [1],[2]. And the concept which combines both symmetric and asymmetric cryptographic techniques is known as hybrid cryptography. A hybrid cryptosystem is a protocol using symmetric and asymmetric cryptographic technics together, each to it's best advantage.

The main objective of cryptographic algorithms is that to transmit the data speedily and in a secure manner with confidentiality, authentication and integrity [2]. The another objective of the research is to provide encrypt & decrypt data efficiently and effectively protect the transmitted data along with improved performance parameters.

Also, Hash functions are important cryptography building block. They combines strengths of both methods (symmetric and asymmetric-key cryptosystems) [3]. Hash functions are used to assure integrity and authentication. This system will provide better security to data transfer over the internet.

II. LITERATURE SURVEY

Survey of various research papers done in this section. Different cryptographic algorithms and Hash functions are analyzed with different parameters by various researchers.

In paper [1], different types of symmetric and asymmetric algorithms are explained in detail. Also, Different parameters analyzed such as key generation time, encryption and decryption time etc. Performance evaluation can be improved in future.

In paper [2], the main objectives of cryptography such as confidentiality, integrity, authentication are explained. Comparison of different types of algorithm is done on the basis of performance parameters and it is concluded that ECC provides better security with high speed.

In paper [3], SHA and MD5 algorithms are explained in detail. It is concluded that SHA1 is more faster than MD5, and SHA2 is even more secure than SHA1 and MD5. Hash functions can be implemented with hybrid cryptography to improve performance & security in future.

In paper [4], encryption and decryption of text using AES is explained. It provides security to multiple accounts, multiple files which have confidential data. Security can be improved in future.

In paper [5], encryption and decryption of text using ECC is explained. Encryption and decryption time analyzed for text. It is concluded that ECC has low power consumption, less memory requirement, small key size and high security.

In paper [6], Image encryption and decryption using AES algorithm is implemented to secure the image data from an unauthorized access. The original images can also be completely reconstructed without any distortion. It is concluded that it has extremely large security key space & can withstand with attacks like the brute force attack, cipher attacks and plaintext attacks.

In paper [7], Image encryption and decryption using ECC algorithm is implemented to provide authenticity and integrity. Also, speed analysis & correlation analysis discussed.

In paper [8], hybrid cryptography approach implemented to provide encryption to the multimedia data
such as text, image, audio, video which resulted in an
output with 100 percent accuracy without any loss of information.

III. PROBLEM DEFINITION

Cryptographic techniques provides the secure data transmission, but there are some complexities in existing systems. Most of the cryptographic techniques are time consuming processes. Some techniques does not includes the integrity checks on transmitted data. The amount of cipher text is higher than the original text. Another issue is lack of security during key exchange.
In order to implement an effective cryptographic algorithm all these aspects has to be considered in order to make it robust. There is need to implement the technique which helps to overcome such complexities in such existing system.

The proposed hybrid cryptographic technique uses the best features of symmetric (AES) and asymmetric (ECC) cryptographic technique with hash function (SHA256). So that, this technique will help to reduce space and time complexity. It will provide the validation of data integrity. Also, data transmission can be more efficient, if cipher size is reduced.

IV. DISCRYPTION OF AES, ECC & SHA2

A. Advanced Encryption Standard(AES)

The Advanced Encryption Standard is a block cipher which takes as input a 128 bit plaintext, which is subject to an encryption with 128 , 192 and 256 bit key depending upon the number of rounds i.e 10,12 or 14 respectively [9].
Fig.1 explains the various internal rounds that take place for encryption and decryption using AES. It broadly consists of Substitution i.e bit by bit substitution, shifting of rows i.e transposition, mixing of columns based on modular arithmetic multiplication followed by adding of round key till n-1 rounds. Mix column round is omitted in
the final nth round. After the nth round a 128 bit cipher text is obtained.

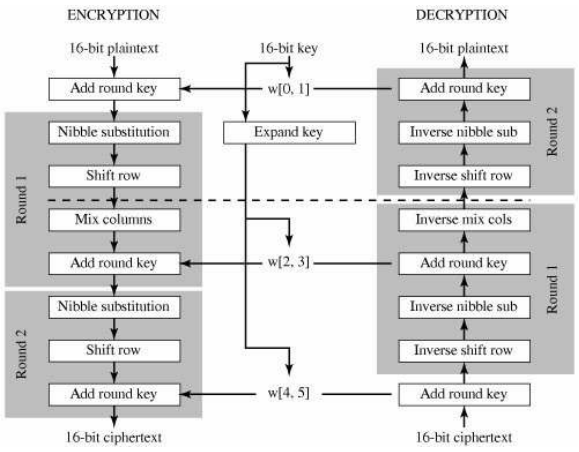

Fig.1 Block diagram of Advanced Encryption Standard (AES) for encryption & decryption

B. Elliptic Curve Cryptography(ECC)

ECC provides better security with a smaller key size if we compare it with other asymmetric algorithms.. High level of security can be achieved using a small key size. ECC works on elliptic curve equation [10]. Elliptic curve equation for binary field is written as- $y^2+xy=x^3+ax+b$ Where a and b are two constants, different elliptic curves will be shaped with different values of these two constants. Elliptic curve equation for prime field is given as- $y^2=x^3+ax+b \bmod p$

Here a and b are constants and p is a prime number. Grater the value of number p more will be the number of points generated on the elliptic curve. Large number of points on the curve gives high level of security. Elliptic curve is shown in figure below-

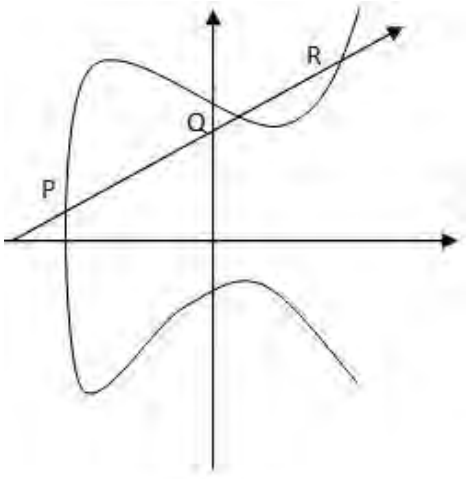

Fig.2 The algebraic structure of elliptic curve on which Elliptic Curve
Cryptography (ECC) is based on

C. Secure Hash Algorithm 256 (SHA256)

SHA-2 is a set of cryptographic hash functions the variants of SHA-2 are SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA-512/256. SHA-2 includes a significant number of changes from its predecessor,

SHA-1. SHA-2 currently consists of a set of six hash functions with digests that are 224, 256, 384 or 512 bits [11].

V. PROPOSED METHODOLOGY

The proposed system consists of two processes such as encryption process and decryption process. It uses symmetric algorithm AES and asymmetric algorithm ECC along with hash function SHA256. They are explained as follow:

ECC a public-key algorithm can be used for encryption as well in digital signature processes. The key management is an essential feature of ECC algorithm. ECC provides better security with small key size [12]. The security of the method used in ECC is based on the difficulty of factoring large numbers.

AES is not only a secure cipher but it offers a very high performance and makes better use of resources. Operational cost is less and less memory requirement. It is strong enough to be certified for use by the US government for top secret information Encryption Process. Not a single successful brute-force attack on AES has been found till date, the only possible known attack against AES.

SHA-256 a message digest function with a block size of 512- bit generates 256-bit message digest. All major SSL certificate issuers now use SHA256 which is more secure and trustworthy than SHA1. SHA256 is currently much more resistant to collision attacks as it is able to generate a longer hash which is harder to break.

So all the essential features of these algorithms are made available in our hybrid algorithm [13]. Better encryption of AES, most efficient key management by ECC along with the digital signature by making use of SHA-256 are included in a single hybrid system.

A. Encryption Process

1. An AES key 'K' of 128-bit, 192-bit or 256-bit is chosen.
2. Encrypt message (M) using AES algorithm and above selected key K.

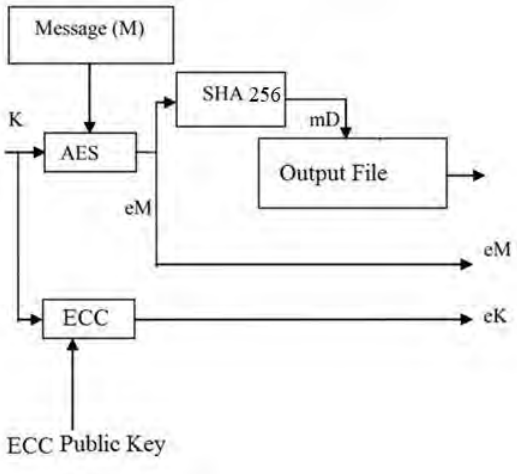

Fig. 3 Encryption process of proposed system

B. Decryption Process

This process is the reverse of encryption process and is having following steps:

1. The encrypted AES key (eK) is decrypted with ECC algorithm.

K = ECC-decryption (eK)

2. Similarly the encrypted message (eM) is decrypted by

AES algorithm using key K

M = AES-decryption (eM)

3. The message digest of encrypted message (eM) is computed using SHA256.

mD = SHA256 (eM)

4. Thus we get message (M) of sender eM = AES-encryption(M)

3. AES key K is encrypted by making use of ECC algorithm.eK = ECC-encryption (K)

4. The cipher text (eM) is fed to SHA256 algorithm which generates a message digest of 256-bit.

mD = SHA256 (eM)

5. The encrypted message (eM) and AES encrypted key (eK) is transmitted to the user over a network.

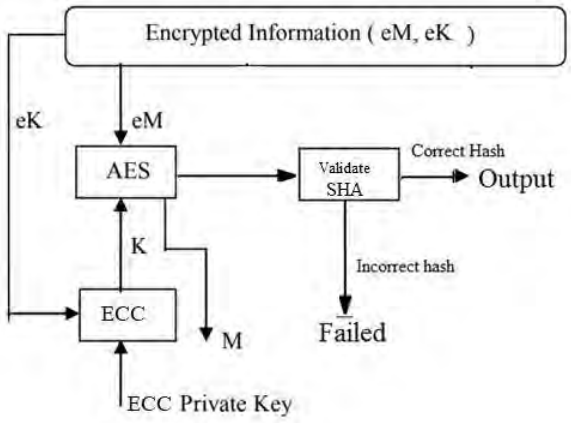

Fig. 4 Decryption process of proposed system

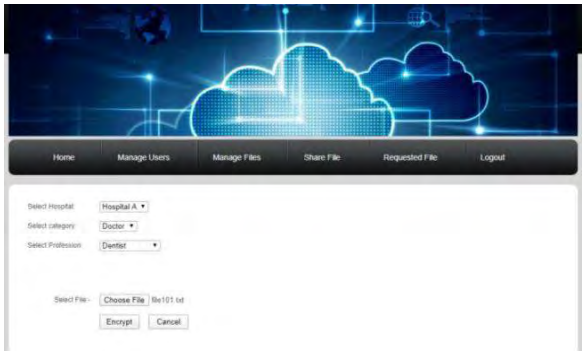
Proposed hybrid cryptography method is implemented for secure sharing of patient healthcare information on website. Encryption and decryption time taken for different text and image files are calculated. Also, hash matching is performed.

There are following steps:**Step 1:** Admin login into website using login credentials such as username and password

Step2: After successful login, multiple users added by the admin. So the admin can share files with user.

Step3: File is selected by the admin for uploading purpose.



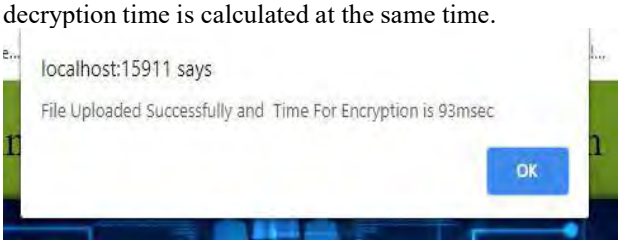
Step4: File is uploaded on website and encryption time is calculated.

Step5: File is successfully shared with user by the admin.

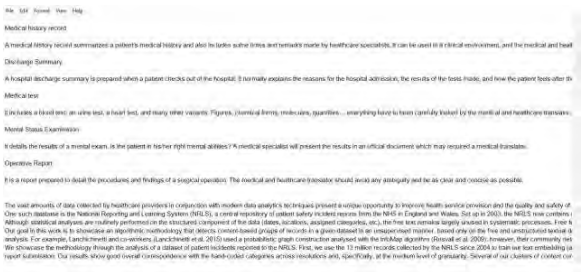
Step6: User login into website using login credentials such as username and password.

Step7: User can view shared files which are sent by the admin.

Step8: User enters the secret key to decrypt the file and decryption time is calculated at the same time.



Step9: After successful decryption, file can be downloaded.



Step10: To perform hash matching, hash is generated to check whether it is matching with its hash value or not.

VI. RESULT AND ANALYSIS

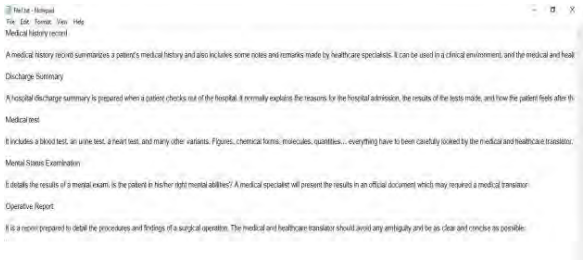
This methodology implemented for secure sharing of healthcare data and can be used for another web applications also. Different types of text (txt, docx, pdf) and image (jpg, png) files are taken as input. Encryption is performed on original file and it sent to the intended receiver. Receiver decrypted that file using secret key and matching of hash is performed.

Text and Image files:

1. Text File:

(a) Original text file

(b) Encrypted text file



(c) Decrypted text file

2. Image File:

(a) Original Image

(b) Encrypted Image

(c) Decrypted Image Encryption and Decryption time of different types of files are calculated and mentioned in following table:

TABLE I
Encryption And Decryption Time

File Type	File Size	Encryption Time (ms)	Decryption Time (ms)
.txt	4KB	50	107
.docx	24KB	57	86
.pdf	1880KB	390	142
.jpg	296KB	92	91
.png	7KB	62	92

VII. CONCLUSION

The limitations of various cryptographic techniques are analyzed and we proposed this hybrid model which is the combination of the AES, ECC and SHA256. This system performs encryption and decryption for better security of confidential data. It provides enhanced time and validation of data integrity.

Securing IoT Devices Generated Data using Homomorphic Encryption

Mrs. Anita Caudhari, Dr. Rajesh Bansode
Mumbai University
rajeshanitac@sjcem.edu.in, bansode1977@gmail.com

Abstract –.**Cloud computing is emerging trends Cloud service provider provides services like,network,application,storage etc.Peoples use Clod storage for stor- ing and retrieving their data for future use. Internet loT devices have memory and power constrained .So, all data generated by these devices are outsourced on cloud .But sharing private data to cloud is risky. Though it is in encrypted format. Processing data on cloud is import task .Our Research focuses on processing on Encrypted data .we had developed GSW scheme to perform computation an en- crypted data.Our scheme takes data from IoT devices and encrypt it using GSW algorithm. Computation is performed on encrypted data like addition and multi- plication.**
Keywords: HE,Cloud,Operation

I. INTRODUCTION

Homomorphic encryption method carried out on encrypted data that is cipher text instead of plain text .The main thing in homomorphic encryption is after performing computation on encrypted data ,generated result should match with the computation performed on plain-text data. In following figure, we are performing simple design of homomorphic addition where plain-text is 4 and 7 and generated result 11 when we do encryption of 4 and 7 by using simple method just multiply plaintext by 3 we will get encrypted result 1 and 21. at decryption side we will use method cipher-text divide by

3 we will get original result. IoT devices delegate encrypted data to cloud ,If some computation are required on data, user has to download data and perform computation. This problem can be solved by using homomorphic encryption on cloud side[1,2]. For Preserving privacy of data when sending data to cloud has to encrypt plaintext before sending data to cloud. This might bound the value of the information , but current trends in cryptography permit probing on encrypted information and execution of different actions on encrypted data, without revealing secret information [3]. An encryption system which permits random actions on ciphertexts known as a Fully Homomorphic Encryption (FHE) scheme. The initial FHE system was constructed by Gentry, and several succeeding systems have quickly developed more practical, with enhanced performance and parameters. Subsequent FHE systems have called Somewhat Homomorphic Encryption (SHE) system as an fundamental structure and use a method called bootstrapping to spread in FHE scheme[4]. computation on encrypted data is ongoing research different authors propose different algorithm to reduce computational cost. This type of model can be used in healthcare application to secure patient data[5].

II. LITERATURE SURVEY

Public key encryption with keyword exploration based homomorphic encryption in multi user situation. In this method DGHV homomorphic encryption applied cloud server generate reversed encryption directory structured. DHGV not uses query trap door. Permits several users to achieve encrypted keyword search over encrypted data. If number of queried keyword is 300 takes 9 s[6].The encoded information can be considered as a good solution to forget over these impediments on computing. Researchers have proposed another encryption form, homomorphic encryption (HE), that the third-party have the capacity to complete tasks on encrypted information. The homomorphic property makes HE schemes helpful in a extensive scope of protection saving applications by the homomorphic property, for example, electronic voting and advanced human services. The Homomorphic encryption method was presented in 1978.

From that, numerous HE schemes have been proposed. HE plans can be isolated into two classes: somewhat and fully homomorphic encryption. The first categories give one homomorphic property[7]. A few homomorphism properties are offered by the full

homomorphic. Since re-appropriated scrambled information under homomorphic schemes can be put away for a long-lasting, more often not by the equivalent key, in CC conditions and since the cloud customers frequently access to cloud services utilizing asset restricted gadgets. These plans should be advanced as far as security level and running time to work successfully. Designed FPGA homomorphic encryption co- processor [8].

Cloud computing is used to convey on-request facilities (e.g., capacity, applications, networks, servers) using the Internet. This is because of a few benefits given by cloud providers containing low costs, high administrations, power calculations flexibility and adaptability. Regardless, failures over the privacy of sensitive information are as yet the main drawback constraining the adoption of Cloud computing services[9]. Translating algorithm that can run on encrypted data. translate basic operators like bitwise, arithmetic and relational operators. Also discussed decision making, loop handling data structures like stack, queue, in that how these algorithm can be applied on encrypted data. Processed each algorithm and measured time required to process encrypted data[10,11].

Hybrid homomorphic encryption model that combines public key encryption and somewhat homomorphic encryption for reducing storage requirement. Here message are encrypted using PKE and computation carried out using FHE or SHE. Uses public key size 3TB,multiplicative depth 20,comparative analysis of proposed algorithm with SHE only and AES with SHE[12]. Homomorphic proxy re-encryption scheme permits different users to share data they outsourced homomorphically encrypted using separate public key. Uses Damgard -Jurik cryptosystem. Evaluated the performance of proposed model in terms of time computation and encrypted data volume. Delegator will take

0.004 sec ,proxy ,i.e cloud 120sec ,delegator 30 sec for 92x122 pixel[13].

Secret keys implemented a lattice-based Key-Policy Attribute-Based Encryption (KP- ABE) scheme. The specific KP-ABE plan can be utilized straightly for Attribute-Based Access Control (ABAC) applications. Graphics Processing Units (GPUs) is the state- of-the-art implementation and demonstrates that the homomorphic open key and ciphertext evaluation activities, which command the execution time of the KP-ABE plot, can be performed in a sensibly short measure of time [14].

Privacy-Preserving Data Processing (PPDP) framework with the help of a Homomorphic Re-Encryption Scheme (HRES). The HRES expands fractional HE from a solitary client framework to a multi-client one by offering ciphertext re-encryption to enable numerous users to get handled ciphertexts. PPDP system can maintain seven essential activities over ciphertexts, which incorporate Addition, Subtraction, Multiplication, Sign Acquisition, Comparison, Equivalent Test, and Variance [15]. Implemented optimized RLWE scheme in Bayesian spam filter, Decision tree, secure multiple keyword search.

Alhassan Khadr et,al(2017) developed model for securing healthcare data

.maintaining patient data privacy is important. Focused on NTRU based implementa- tion on GSW HE and results shows improvement of 58x in CPU performance. Per- formed Operation on blood pressure data, person goodness of fit test[16]-health.to se- cure patient data proposed secure privacy preserving data aggregation scheme. Based on bilinear pairing .Here focused on improving data aggregation efficiency and data privacy. Reduced communication and computation overhead.

ECIECS,KP-ABE,CP-ABE,PAILIER ,FHE algorithm used in securing healthcare data but main limitation is computation time[17].Provided solution to protect users data di-rectly into the cloud while preserving the user privacy

.uses cardiac risk factor algo- rithm on encrypted data.to execute this algorithm it take 3.2 second.FHE is imple- mented on healthcare data .perform computation on encrypted heart rate, provided av- erage heart rate ,LQTS,Min,Max Heart rate[18].

III. METHODOLOGY

Homomorphism If (F1, ∗) and (F2, ⊗) are two groups, then a function f : F1 → F2 is a group homomorphism if f(a ∗ b) = f(a) ⊗ f(b) for all x, y ∈ F1 Examples: f(a) = e a , f(a) = log(a),...

GSW:

A ciphertext C encrypts a message m if the following holds:

$$C\text{iphertext} * vco = m\text{message} * vco + err \quad (1)$$

where err is a small error term
Can decrypt if vco has a "big" coefficient vi by rounding

$$A=\{< Ciphertext\ i, , vco >\} \quad (2)$$

$$B=\{< message * vcoi + err >\} \quad (3)$$

$$A \div Vcoi = B/Vcoi \quad (4)$$

where Ciphertext i denotes the i th row of Ciphertext

Ciphertext 1 encrypts message1 and ciphertext 2 encrypts message2,

3.1 Addition:

Ciphertext1 + Ciphertext2 encrypts $m$essage1 + $m$essage2 (5)
Ciphertext1 + Ciphertext 2 vco = $m$essage1 + $m$essage2 vco + err1 + err2 (6)

3.2 GSW Key Generation

Secret Key: $t \xleftarrow{\$} Z_q^n$

Public Key A:

$$B \xleftarrow{\$} Z_q^{m*n}$$
$$err \xleftarrow{\$} X^m$$

A*s = Bt + err− Bt =err (10)

Encryption:

For plaintext message € Zq

Ciphertext<- F($m$essage · IN + BitDecomp (R ·A)) (11)

IV. EXPERIMENTAL RESULTS

A Homomorphic Encryption is the transformation of data into ciphertext that can be examined and functioned as if it were still in its unique form. Homomorphic encryption shows a significant part in cloud computing, permitting patients to store encoded PHR files in a public cloud and take advantage of the cloud provider's analytic services. The scheme prevents rogue insiders from violating privacy and avoids unintentional leakage of private data. Homomorphic Encryption schemes are utilized to achieve processes on encoded information without knowing the private key (i.e., without decryption), the client is the only holder of the secret key. Once the result of the process is decrypted, it is the equivalent as if it had carried out the calculation on the raw data.

In this section we will discuss about results of homomorphic encryption on data set. Collected from IoT devices and performed GSW encryption on it .

Table 1.Time Taken for encryption and Decryption based on Record size(in Second)

Record Size	Encryption Time(First Field)	Encryption Time(Second Field)	Decryption Time(Addition)
50	2.40	2.43	2.46
100	111.97	111.98	112.00
200	233.42	233.43	233.45
300	382.32	382.33	382.37
500	648.47	648.49	648.50

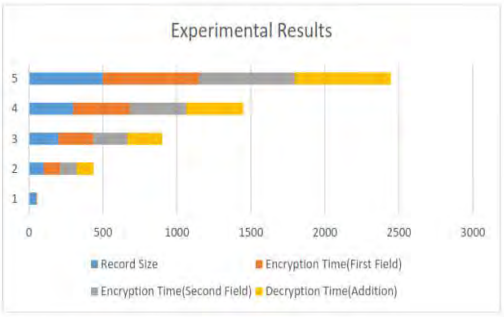

Figure 1. computation time based on record size
If we increase security parameter, there will be exponentially increase in time for performing operation.

V. Conclusion

In this research, we had collected data from IoT devices and after encryption uploaded it on to cloud server. User sends query to cloud for performing operation on encrypted data. Computation will be performed once query will be fired on cloud. Here we are using only addition and multiplication operation .Computation time varies based on data set and

security parameters. If noise will be more then ,not getting proper result. In future focus will be on comparative operators.

arunaapavate@gmail.com[1] , rajesh.bansode1977@gmail.com[2]

Abstract – **Tremendous advancement in machine learning over the last few years lead to use of deep neural networks in many applications from weather prediction to safety critical applications like disease diagnosis. Latest work observed that deep neural networks are vulnerable to the perturbed input samples as known as adversarial examples, very small changes considering single pixel can cause neural network models to make mistakes in predicting the output, this growth in safety concern of deployment of applications in safety critical environment. It is observed that the adversarial examples are transferred from one neural network model to another neural network model with considering adversary knowledge either black box which is similar in a real-life scenario with the adversary not aware of knowledge of the neural model to be attacked, white box or gray box. Adversarial attacks can be categorized by various characteristics. This paper provides a good inclination of adversarial examples in the context of computer vision and provides detailed discussion on different types of adversarial attacks on various types of neural network architectures and also elaborate the different metrics applied to validate the system performance. We conclude that adversarial learning is a factual threat to application of machine learning not only in the physical world but also during training the model and testing the model. There are some certain countermeasures exits but none of them can act as an individualistic solution for all the challenges. It remains an extensive challenge for the machine learning community to deal with robustness.**

Keywords:Deep neural network,adversarial attack, machine learning,computer vision

I. INTRODUCTION

Machine learning system gained remarkable success in almost all the applications. Machine learning used in many safety critical applications including self driving cars[1] [2], robots[3][4],Natural Language processing[5],speech recognition[6][7][8][9], malware classification[10][11],anomaly detection[12] and many more . Most machine learning algorithms are considered to map from an input domain to an output domain by detecting sample pairs of inputs and outputs from these domains. Lately machine learning algorithms are known to be vulnerable to adversarial attacks. In computer vision algorithms object detection, object segmentation, object classification is known to be vulnerable to adversarial attacks, by adding small perturbations to the input. In recent times the number of approaches have been implemented and examined to produce adversarial examples for different neural networks architectures and updating the parameters of the model to apply optimization techniques to find the optimal solution[13][14][15][16][17][18][19]. Szegedy et al. were first introduced the concept of adversarial samples , applied over image classification and misled the neural network with high confidence[13]. Deep neural network is noticed as blackbox as neural network works well with limited knowledge [20][21].

In this paper, we have explored the different attack approaches for creating adversarial examples. Most of the adversarial examples are created across the computer vision domain . we emphasis on one pixel attack as a one of the important adversarial attacks that demands very few adversarial information to deceive the various network architectures because of the immanent properties of the evolutionary algorithm and generates the low cost adversarial attacks to evaluate the robustness of the classifier based on Differential Evolution(DE). Using the available framework , implemented an experimental attack on image classification models using CIFAR-10 , CIFAR-100 data sets.

1.1 Discussion About Basic Terminologies

In this section, we highlight some major terminologies used during the work that are related to the generation of adversarial examples on Deep neural networks in the Computer Vision field.

Informal framework

General Framework for adding perturbation to the input sample that helps to generate the adversarial examples

Consider a Classifier K(X)= $\hat{Y} \in \{1, \ldots, N\}$ Let L(x) be the labels that belong to the class and M(X) be the logits.

$$arg\ max\ Li(X)_{i\epsilon\{1,\dots,N\}} = \hat{Y} \quad (1)$$

$$\sum_{i=1}^{N} L_i(X) = 1 \quad (2)$$

$$L(X) = softmax(M(X)) \quad (3)$$

Adversarial Example

Definition: An adversarial example is a sample input to the model such that perturbed input sample x' addressed at L(X') ≠ L(X) and the distance between || X'- X || being narrow i.e. sometimes unnoticeable to human eyes. Figure 1 represents the generation of adversarial sample.

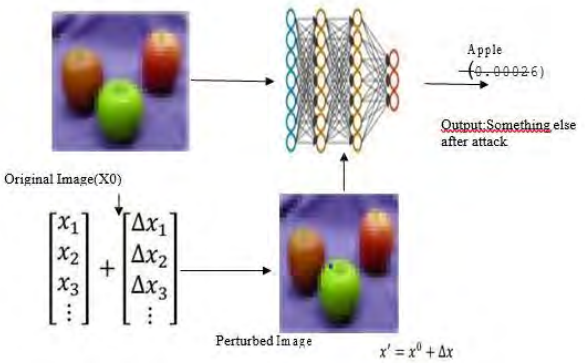

Fig. 1 An illustration of adversarial examples developed on Lenet. The predicted label belongs to something else than the actual class after the attack. The prior confidence was 0.00026. The actual class is an Apple. Here perturbed image x' is the smallest modification of an image by changing single pixel. X0 is the original image.

Threat Models:

Practically, the main objective of an adversarial attack is to alter the input sample as small as possible of a classifier in such a way that is not correctly classified. The attacker's knowledge can be considered as 1. Black- box 2. White box 3. Grey box

Black - box: The adversary has access to the input data and observers the output. A typical strategy of the attack is to use a proxy model for crafting an adversarial attack and adversarial samples tested on different architectures[22]. Another method is zero order optimization to generate adversarial samples without accessing model gradients[23]

White box : Here , the adversary is aware about the neural network model , network architecture type , number of hidden layers, activation functions , hyperparameters [15].

Grey box: Any variation between the white box and black-box attack is considered as grey - box attack where adversary has access to the architecture, training [24].

Most of the adversarial attacks are white box attacks where advisory knows all the details, but these attacks are can be converted into black- box models due to the transferability property of the adversarial examples[22]

Attacks Specificity:

Attacks can be either targeted or untargeted

Targeted attacks manipulate deep neural networks to misclassify the input to a specific class.Targeted attacks mostly applied on multiclass classification problem. E.g. Here Model misclassified an 'Apple' sample to ' bowl' class.

Non-targeted Attack: The output of the model can be represented arbitrary i.e. output does not assigned to specific class. These types of attacks are easy to craft and apply. E.g. Model misclassified an 'Apple' to as any other class

Attack Frequency : Attack can be one time or iterative . One time attack is generated only single time whereas iterative attack can take many attempts to generate adversarial examples. For some rigorous algorithms (reinforcement learning) , one time attacks are more suitable. Iterative attacks need many queries to be posted to success the attack so the computational cost is more to generate them as compared to single time attack.

Attack Measures : There are many measures useful for evaluating the performance in terms of efficiency and effectiveness of the proposed system. The following measures utilized here to evaluate system performance.

1. *Confidence:* This measure specify the intermediate probability of the labels of the expected class output to the successfully altered class label of an input sample from expected to target.
2. *Success Rate:* This measure specify that the observed probability of the original image that can be successfully changed to another targeted attack and non-targeted attack by modifying the original image
3. *Average Distortion:* Average distortion for a single pixel is computed by considering average modification of the channels (R,G,B) to evaluate the cost of the attack. If the value of the average distortion is

eminent such that it can be easily visible to the human eyes then the cost is high.

II. RELATED WORK

This section highlights different approaches for generating adversarial attacks. In the recent studies there are many approaches in the below described defeated by countermeasures. The presence of these approaches needs to be studied which improves the transferability and thus robustness of the neural network models.Szegedy et al. proposed box-constrained L-BFGS adversarial examples. Author discovered that mapping of input to output in deep neural networks interrupted to some extent. It is possible to cause the network to present an image belonging to another class by making certain perceptible perturbation which can be possible by exaggerating the network's prediction error. Also it is possible that the same perturbation can cause other different networks , trained using different dataset to analyze the same image belonging to a different class. The proposed concept applied on different networks like AlexNet,QuocNet,FC [15].

The Fast Gradient Sign Method(FGSM)[15] is an efficient solution tried for both targeted and nontargeted label attack. Fast gradient sign method computes the gradient cost function corresponding to the input of the deep neural networks.

S. Moosavi et al. proposed an accurate and simple method which computes the distance by adding small perturbation to the input sample to provide robust classifier. Deepfool computes the nearest distance from the input sample to the decision boundary of the perturbed input. The attack is applied iteratively to avoid the problem of nonlinearity in high dimension space. Deepfool proved on both binary and multiclass classifiers[17].

Papernot et al. proposed Jacobian-based Saliency Map Attack (JSMA) which is estimated as an expensive method as it runs much slower than the fast gradient sign method where Jacobian matrix computed for the input sample. The adversarial success rate 97 % achieved by applying small perturbation of 4.02% input features per sample[18].

Tom B. Brown et al. introduced a targeted universal attack using image patch and tried over the real world problem without knowing the knowledge of the type of classifier, scene- independent, angle of the camera etc.Trained patch retrieved using Expectation over Transformation(EOT) framework[25] where the expectation is applied over locations, random images and transformations. The attack evaluated across different Imagenet models like resnet50,inceptionv3, xception, VGG16, and VGG19. Here attack is examined and shown that small perturbations are not sufficient, large , local can also be possible to break classifiers. Confidencance 99%[26].

Universal perturbations were developed in [27] for targeted attacks by changing each pixel in the input image with high probability but the attacks were not tried in the physical world. This attack is an iterative attack that presents observations on the geometry of the decision boundaries of neural network.

Pin-Yu Chen et al. [28] proposed an elastic Net attack by introducing set of adversarial examples with small L1 bias and proved the similar performance like the other advanced methods in vaiours attack frameworks like FGM,C&W attack, IFGM. The developed attack enhanced transferability of attack and the capacity of adversarial training for the deep neural network.

Wieland Brendel et al.[29] proposed real world stable attack by considering adversary knowledge as blackbox. The implementation is based on boundary between adversarial and non-adversarial samples,and needs final class prediction. This attack is simple, does not require a substitute model, flexible in terms of adversarial criteria, and requires limited hyperparameter tuning .Author claimed that the decision boundary attack is more robust than gradient based attacks,score based attacks and transfer based attack.

Nicholas Carlini et al. proved that,providing defensive distillation doesnot improve the robustness of the classifier by developing new attacks for L0,L2 and L∞ which are much more powerful than the previous one.These attacks are successful with 100% transferability success rate between the secured model and unsecured model. These attacks were evaluated on three different datasets:MNIST,digit-recognition task, and CIFAR-10[30].

III. METHODOLOGY

In computer vision research, adversarial examples are original images that are input to the deep neural network that have been specially crafted to miss classify the input by the model. It is proved that deep neural networks can be fooled by an attacker by simply modifying the color of a single pixel [31] this approach is referred to as " one pixel attack". In many cases attackers can even cause the network model to generate the output of what they want i.e. targeted attack. We demonstrate this work into three different directions 1) Appling one pixel attack on CIFAR 100 dataset 2) Generation of the low cost adversarial attacks to evaluate the robustness of the classifier based on Differential Evolution(DE) 3) Analysis of one pixel attack on different network models. Our implementation is based on [31] uses a basic Convolutional Neural Network as shown in Figure 2.

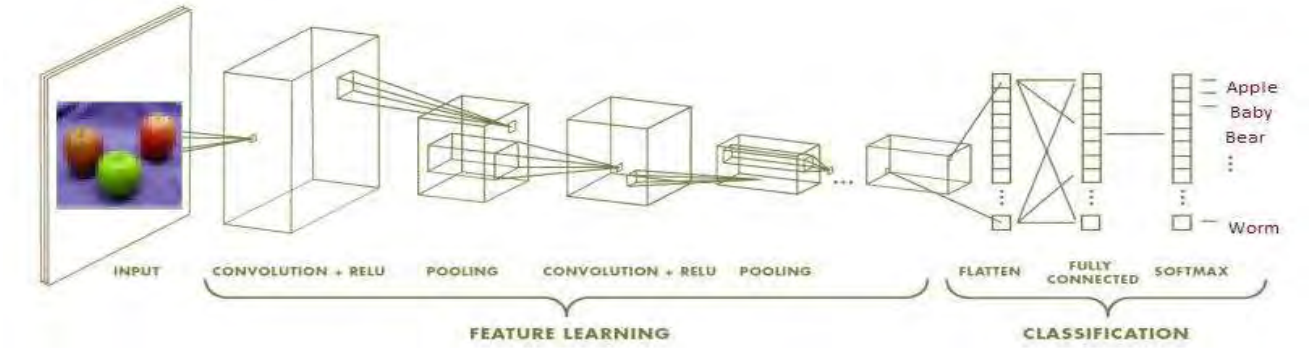

Fig. 2. Basic Architecture of Convolutional Neural Network applied on [CIFAR 100 dataset [32]]. The output of the convolutional Neural Network belongs to one of the class label among 100 labels.

One pixel Attack:

J. Su, et al.[31] proposed the approach that causes neural networks to misclassify an input sample by just crafting single pixel in the input sample. The attack is developed using genetic algorithms without crossover operation and is referred to as Differential Evolution (DE). The attack is generated for both targeted, untargeted attacks,Image specific which perturb single pixel to cause a misclassification . Our implementation is based on convolutional neural networks with different architectures.

Algorithm 1: One_Pixel in Pseudocode

```
1.  procedure perturb_image( (x,y,R,G,B), img):
2.    for x,img in zip((x,y,R,G,B), imgs): do
3.  perturbation pixels: pixels = np.split(x, len(x) // 5)
4.      for pixel in pixels:do
5.      At each pixel's x,y position, assign its rgb value:
                x_pos,  y_pos, *rgb = pixel
6.       img[x_pos, y_pos] = rgb
7.       return imgs
```

Input samples are encoded into vectors of five elements(x,y,R,G,B). Here x,y indicates the position of an image and the next three values represent the channel for the image. Here in this case R,G,B i.e. color value. Attacks are developed using differential evolution.**Differential Evolution:**

To find out the pixel which helps in providing successful attack, the problem is considered as optimization problem. Here the problem is either minimization of confidence in case of non targeted attack and maximization problem in case of targeted attack Differential evolution is a type of stochastic algorithm useful for global optimization problems.

Algorithm 1: Differential Evolution

1. Initialize population with random positions in search space :popsize=400
2. Until termination : adequate fitness reached do
3. For each solution in the population do:
4. Xs= x0+0.5(x1-x2)
5. Calculate fitness of each child if fitness[Parent]<fitness[child]:do
6. Replace: fitness[Parents]=fitness[child]
7. Repeat 100x , reating the updated solution as the parent solution
8. best= trial_denorm
9. Yield best, fitness[best_idx] : Best fitness is the "winner"

Targeted Attack: The main objective of the targeted attack is to minimize the confidence of the correct class and maximize the average of the probabilities of the other classes. This type of attack is very hard to implement as constrain the classifier to predict the wrong class than that of the actual one. There is no guarantee of success of attack , after several iterations the confidence of the classifier increases. Figure 3:

shows that letnet model to classify an image of an apple to an image of aquarium_fish

Fig. 3 Targeted Attack :One pixel attack implemented on trained on CIFAR-100 different types of DNNs :The right side image represents targeted attack for single sample with confidence 0.4634. The predicted output is aquarium_fish whereas the image belongs to Apple class

Untargeted Attack:

The objective of the Non Targeted attack is to classify an input sample to as given target class.To design a successful non targeted attack , the input sample is perturbed as to maximize the probability of the selected class. For CIFAR 10 and CIFAR100 we evaluated randomly drawn 100 samples from the validation set.

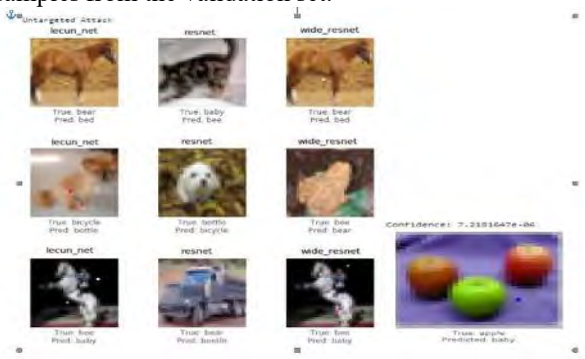

Fig. 4. Untargeted Attack :One pixel attack implemented on trained on CIFAR-100 different types of models of DNNs : The right image indicates Non-Targeted attack for single sample with confidence 7.21. True class is an apple whereas the predicted class belongs to baby

Fig. 5. Shows confidence of the model changes after adding small perturbation into the image . The middle image shows the success of attack on a single image for untargeted attack prior confidence 9.6221505e-05 & the attack successful

IV. RESULT AND ANALYSIS

We demonstrate the evaluation of one pixel attack with an original CIFAR-10 test dataset [31]. We have used 100 random images for non-targeted attack and 100 random images for targeted attack. It has been observed that the target DNNs have higher accuracy and confidence. All settings are kept the same as in the implementation of attack on CIFAR-10 dataset. The results of the attack shown in Table 1. The limitation of this attack is it works finest on low- resolution images. After implementing one pixel attack on various models on 100 different randomly selected samples it successfully generates100 adversarial images and calculated the success ratio. Multiple

experiments run by varying the number of pixels(here 1,3, 5) and the results were analyzed. The attack showed on CIFAR 10 works with an average accuracy of 88.08% and on CIFAR 100 with an average accuracy of 91% .

Table 1. Attacks on different CNN Models with 1,3,5 pixels perturbation

			CIFAR [0][3][]			CIFAR 100		
Model	parameters	Pixels	test accuracy	attack success (untargeted)	attack success (targeted)	test accuracy	attack success (untargeted)	attack success (targeted)

		5		36.0	4.44		35.0	5.44

V. CONCLUSION

The final aim of this work is to propose an attack over the Convolutional neural network. The applied attack shows that CNN is sensitive to adversarial attacks generated using stochastic differential evolution algorithm of optimization problem. It has been observed that the Convolutional neural network is susceptible to low cost and low dimension attack. The characteristics of neural networks have a major impact on the attack both in terms of success rate and the average distortion. The accuracy of the CNN models are not robustly related with the attempt of implementing a successful attack on an input sample. Perhaps it is most robust to the type of attacks. It has been observed that the CapsNet has the minimum attack success rate as compared to all other models both in case of CIFAR10 and CIFAR 100 dataset however the model is still vulnerable to attacks.

Iot based application device for mentally challenged patients

Namdeo Badhe , Khushali Tank, Riya Rana, Saloni Verma' Sheetal Yadav
Information Technology, Thakur College of Engineering and Technology, India

Abstract: **Census 2001 has revealed that over 21 million people in India as suffering from one or the other kind of disability. This is equivalent to 2.1% of the population. Among the total disabled in the country, 12.6 million are males and 9.3 million are females. Although the number of disabled is more in rural and urban areas. Such proportion of the disabled by sex in rural and urban areas. Such proportion has been reported between 57-58 percent for males and 42-43 percent females. The disability rate (number of disabled per 100,000 populations) for the country as whole works out to 2130. This is 2,369in the case of males and 1,874 in the case of females. The treatment for mentally challenged patients can be very troublesome and difficult for the doctors and the patient's family as they have to be attended to constantly which is quite tiresome for the patient's family and doctors. Also, the patients may be unable to express any type of discomfort that they may be feeling, therefore, we create a device and supporting application to help locate the patient and monitor the patient's heart rate. The problem that the patient's family and doctors face is that they have to constantly attend the patient which is not always possible, even when they are not attending the patients they are always worried about the patient. They can never let go off the patient. This process is quite tiring and can be harmful for both patient and others if not done properly. Hence, there is a need for a device that can constantly track the patient and his condition. The device will monitor the patient's heart rate constantly so if there is any drastic variation in the patient's heart rate a list of emergency contacts can be notified. The device is connected directly to Web site so that the doctor and patients can easily track the patients' data.**

Keywords: IOT, RFID, IBAMP

I. INTRODUCTION

The Internet of Things (IOT) is the network of physical devices, vehicles and other items embedded with electronics, software, sensors, actuators, and network connectivity which enable these objects to collect and exchange data. Each thing is uniquely identifiable through its embedded computing system, but is able to interpolate within the existing internet infrastructure. Sensors should be installed to gather the data from surrounding of the patient and GPS tracking module must be implemented to trace the patient's location. Tracking system for mentally challenged people is an application which is primarily aimed to help mentally challenged people by continuously monitoring their location and notifying the emergency contacts in case some unusual behavior is seen. Addressing the people with issue with mental illness through single aiding system. In this project we are creating an environment for mental patients so that they can stimulate it. All these activities would be co-ordinated by using Raspberry Pi . The mental patients, who would use this system, would be able to recognize the environment and would get aware of any danger around.

A radio frequency identification reader (RFID reader) is a device used to gather information from an RFID tag, which is used to track individual objects. Radio waves are used to transfer data from the tag to a reader.

II.. LITERATURE SURVEY

In the Paper [1] it refers to motion detection, raspberry pi video recorder. Here accuracy can be increased up to 99% and system sized is decreased. In Paper [2] The Angel Sensor then transmits this data via Bluetooth low energy (BLE) to the user's mobile device and an associated mobile application. but the problem is Bluetooth is short range. Refers to raspberry pi temperature, humidity measurement, camera WiFi.. In paper [3], Tracking is focused either entirely on indoor or entirely on outdoor by using different devices and techniques .By using multiple wireless devices we have increased the efficiency of fetching the location over a long distance.

III. PROPOSED WORK

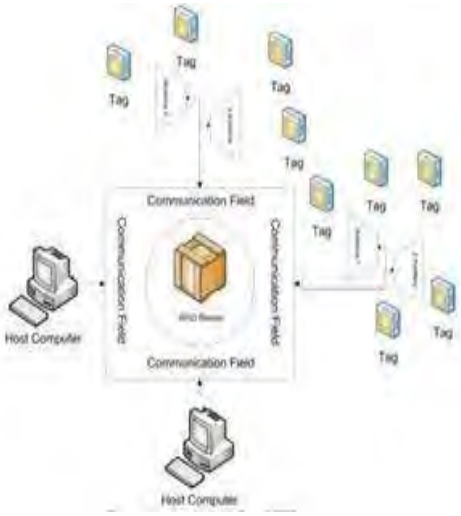
The proposed system will able to design a device which is a all-rounder i.e. it helps not only mentally challenged patients but also to the physically handicapped patients , the doctors, the guardians of the patient and other staff of the hospital to keep a track of the authentication, authorization, proper health and location of the patient. The device could be used in asylums, hospitals and also house. The RFID tags, RFID readers, temperature and humidity sensors, LED light, e-tracker, UNO R3

Development for Arduino and GPS Tracker which would help us in developing an environment where the patient, guardians and doctors would be able to keep track of health, location and authenticate and authorize themselves to use the facilities provided.

Besides we are also using Touch screen LED display which would act as a server for controlling all the operations mentioned above.

IV. METHODOLOGY

The idea is to use RFID chips embedded in, say the wrist of the patient, and as the patient passes through any dangerous kind of situation such as fire accident or facing any kind of obstacle in the environment, the chip is scanned by RFID readers mounted on either end. The tag ID is then sent to the server via an on board Wi-Fi module. The corresponding data is fetched from



the database, identification parameters are mapped, the status of the patient is detected and the situation of the patient is sent to their guardian or parents via text messages. All this should happen in "real-time", as the patient passes through the dangerous situation. The aim of our proposed innovation is to provide a Implantation of Access Control System, and take care of the mentally challenged person.

In our project, two levels of users are maintained
Administrator Level- owner/Guardian/Parent User Level- mentally challenged patients
In public places, we need to get the information about mentally challenged people in particular time and collect it by various means, like RFID (as part of Smart card based ticket), location aware mobile system, Wi-Fi membership) etc.
Multidimensional input data from any RFID system or other means as discussed, about its user, location,
current timestamp and RFID tag/card
After collecting and storing the current status of the patient immediately the status is sent to their guardian/parent so that they come to their ward and save them before any catstrophy takes place At the granular level, with the support of high computational power we even can able to track individual person movements.Fig.2 RFID Reader and tags Communication

V. RESULTS AND DISCUSSION

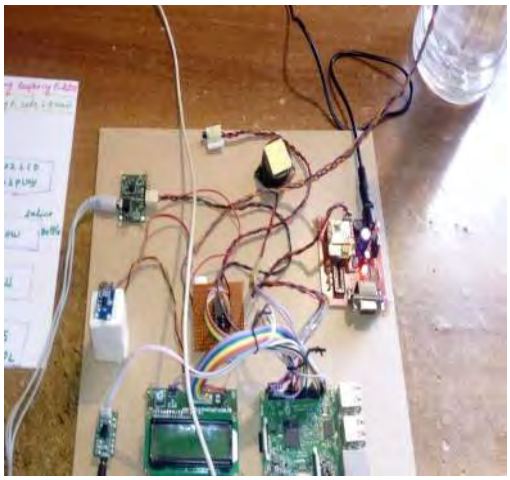


Fig 3 Working Model of the proposed system

VI. CONCLUSION AND FUTURE SCOPE

Thus by this, we conclude that the proposed device [Iot Based Application for Mental Patient (IBAMP)] and boost the mental patient's confidence by e- monitoring. It will also reduce the burden of guardian of patient.
In future, this device can be further used in multi-specialty hospitals.

VII.RESEARCH GRANT

Received Minor Research Grant by University of Mumbai of rs.30000/-

Heart Beat Measurement Using IoT

Sukesham Bissa, Gangadgar Chauhan, Nitin Bangar
Information Technology, Thakur College of Engineering and Technology, Kandivali Mumbai, India

Abstract: **There are many heartbeat sensors available in the market in watches and mobiles. We aim to present to you an affordable heartbeat monitor, which will help you keep your heart rates in check on a regular basis. Sometimes there is possibility of the monitor not giving accurate results due to some errors. We from our research found that the "Instant Heart Rate Monitor" received the highest accuracy and "Cardiograph" received the lowest. From this study we can easily conclude that the "Instant Heart Rate Monitor" is more accurate application when compared to the digital heart rate monitor and other such applications. Instant Heart Rate doesn't require heart rate straps and it monitors blood circulation with accurate heart health monitor. It detects the change in your finger nerves to provide accurate heart beat measurements. It measures your heartbeat in BPM accurately in less thna10 seconds. Heart rate can be affected by stress, workout, depression, emotions, training, fitness level, body composition, and medication use.**

I. INTRODUCTION

A heart rate monitor is a personalized monitoring device that allows individuals to measure their heart rate in real time and record the same for later study. It is mainly used by performers of various types of physical activities. Heart rate is the number of times the heart beats per minute and reflects different physiological conditions such as workload, stress and concentration on various tasks, drowsiness and the active state of the nervous system. The heart rate rises gradually during exercises and returns slowly to the normal value after exercise. Lower than the normal heart rates are usually a strong indication of a condition known as bradycardia, while the higher is known as tachycardia. Heart rate is simply measured by placing any finger over the person's arterial pulsation, and feeling, timing and counting the pulses normally in a 30 second period. Low-cost devices such as wrist watches are also available nowadays for the measurement of the heart rate. Such devices can give accurate measurements but their cost is usually as high as several hundred dollars, making them uneconomical. So this heart rate monitor with an optical sensor is a very useful instrument in knowing the pulse the patient.

II. MATERIAL AND METHODS

This project was carried out using patients body data.

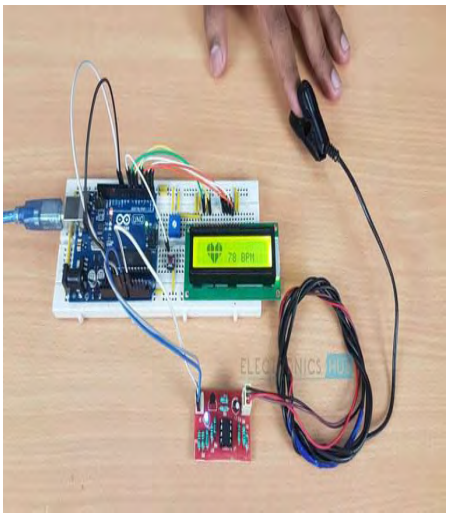
Study Duration: July 2018 to November 2018.

In this project are going to measure the heart beat using the pulse oximetry logic. The timer we will be setting for counting the heart beat is 30 seconds. There will be a set point we can decide, after 30s the heartbeat will be shown on the LCD. The code written in Arduino IDE takes the pulse of user and then simply divide it with the time constraint. After this calculation the pulse rate of user is shown on the LCD in beats per minute or simply BPM.

Resources Required: Programmers, Arduino. Software required: Thing Speak, Arduino IDE Hardware required: PC for development, hardware components for implementation.

III. RESULT

We were able to build a GUI for the web implementation using bootstrap. System is implemented using Django framework. The web has input interface where user will enter his parameters which we have mentioned. Our system will tell that whether user is diabetic or not.



The project intends to correctly analyze the input data on the basis of heart rate parameters to correctly judge the presence of any abnormality

IV. DISCUSSION

Thus, after the implementation of prototype we finally come to a conclusion and discussion that the cost of our project or system has to be reduced and efficiency has to

be improved as well. The main change to focus on is the size of the system. It has to be compact and easy to use in daily lives of users. So, in next phase our primary goal is to focus on size and efficiency of the proposed system.

V. CONCLUSION

- Currently the project focuses on gathering a structured authentic data.
- With reference to reviewed work we were able to find and define the problem definition we were able to find and define problem definition.
- We are clear with the idea of problem definition, algorithms, tools (front end, back end) required to implement the same.
- In the future, this project can be extended to give better health benefits and awareness to various classes and will be affordable for every middle-class person by using simple IoT and sensor technologies for sensing and sending data over the internet to a user friendly and device friendly websites.
- It can also be extended in health industry and hospitals as doctors will be able to monitor individual patients on regular basis and the risk of heart diseases can be easily reduced in such way.

IOT based Smart Greenhouse

Amarjeet V. Singh, Rahul C. Yadav, Abhishek D. Singh, Neha Kapadia
Department Of Information Technology, Thakur College of and Technology
Mumbai, India
amarjeet952@gmail.com, rahulsince1997@gmail.com, abhishe216@gmail.com, neha.kapadia@thakureducation.org

Abstract – **In the recent era, with the rapid surge of growth in areas of automation and digitalization, our lives are improving as almost everything is undergoing mechanization which is replacing the primitive manual, intensive labour systems. Today, as Internet has become a vital integral part of our day-to-day lives, all the electronic devices also need to be brought on the network. This is the main aim of Internet of Things (IoT), which is one of the new upcoming technologies that helps in establishing connection, control, and management of standalone intelligent objects which are connected to Internet via different functions and protocols. In our project the main intention is to focus on incorporating IoT technology in the field of agriculture, specifically in the greenhouse system. Using several electronic components such as Intel Galileo, Arduino, and multiple sensors connected over the internet, the greenhouse parameters will be monitored and controlled with the help of different electronic devices like smart phone, computer etc.**

Keywords: Internet of things, sensor, automation, smart greenhouse.

I. INTRODUCTION

This proposed model of a Smart Greenhouse, helps the greenhouse workers to carry out the work in a greenhouse automatically without using much manpower. Greenhouse, a closed environment protects the plantations from harsh weather conditions and animal, pest attacks. The irrigatio n of smart greenhouse is done by the usage of mechanized drip irrigation, which operates on the parameter of soil moisture specified as optimal to the plants. Based on parameters from soil health card and data nitrate sensor proper amount of minerals can be applied by using drip irrigation techniques. Proper water management tanks are constructed and they are filled with water after measuring the current water level using an ultrasonic sensor. Plants are given the appropriate amount of light when it gets darker using adjustable led lights. The temperature and humidity sensor are used to monitor them**.**

The current architecture only supported the input data from sensors & display on web portal & only monitoring will not be efficient solution for maintaining Greenhouse, We propose monitoring and controlling the greenhouse components with the help of IOT. The current model water tank for irrigation, water tank is not a feasible solution our model uses drip irrigation. Most of the existing greenhouses have improper ventilation with lack of humidity control. We have proposed movable flaps which function for controlling the humidity & temperature of the greenhouse.

1.1 GREEN HOUSE

Even though India receives plenty amount of precipitation and has numerous large river systems, but one third of the total land for agriculture is attached via canal irrigation system. Rest majority of the portion relies on monsoon or tube-wells for the growth of plantation. There are places having excess water but face issues of land salinity, because of over irrigation and water-logging.

The Greenhouse, being a closed-frame structure safeguards
the plants from vigorous weather conditions such as hurricanes, Ultraviolet radiations, hailstorms, and insect & pest attacks. Here, the irrigation of agricultural field is carried out with the help of an automated drip irrigatio n process, which functions in accordance with the threshold soil moisture that is being set in such a way that an optimu m amount of water is given to the plants on a regular basis. Based on the data from soil health card, appropriate amount of nutrients, water and other requisites may be supplied by making use of drip irrigation techniques. Water management containers are also employed in the greenhouse, as they are filled with sufficient amount of water after determining the current level of water with the help of an ultrasonic sensor. The plants are provided with the requisite light wavelength in the form of glowing LED during the night time. Inside the greenhouse, air humidity and temperature are monitored by the humidity & temperature sensors respectively, and can be controlled with the help of movable roof flaps which function automatically as it reaches the threshold temperature and humidity.

1.2 BACKGROUND

In India, agriculture is still carried out in the traditional way and lags behind in utilizing the modern technologies available to mankind. This model aims to improve the preexisting agricultural practices by incorporating smart modern technologies for efficient and better production of greenhouse. The project provides a model of a smart greenhouse, which will aid the farmers in carrying out the farm work automatically, in an unmanned manner.

At present, there are numerous greenhouse models
which function in an automated manner, but most of them lack in minor parameters, which have an impact on the production of greenhouse. With the help of the proposed model, these shortcomings can be efficiently overcome, thereby improving the production of the greenhouse. Our project aims to bridge all these gaps which will help in efficient and less time of user being used in performin g redundant tasks. At present, with the advancement of technology there have been a lot of improvements in the greenhouse, but still there's ample room for further improvement to increase the efficiency and production rate of the greenhouse. There are greenhouses which have drip irrigation systeminstalled in them, sensors

that only collect data but are not programmed to perform any trigger- mechanism based actions, so we aim to overcome these shortcomings with the help of our proposed model. Production rate is fair in the existing greenhouse systems and can be boosted with much efficiency. Also, many of the greenhouses have been dependent on manpower or human assistance in some or the other way, which can be modified into a completely automated process by 24/7 Real-time monitoring of the green house.

1.3 IMPORTANCE

India being an agro-based country, agriculture is still being carried out in a traditional manner, and thus lags behind in the integration of modern techniques and technologies. About 57% population in India has been actively engaged in agricultural and associated activities, which make for about 15% of the country's GDP. Thus, it is very important in today's time for the involved stakeholders to leave behind the old conventional practices of agriculture and get ahead by modernizing the agricultural process with the help of better and efficient newer technologies.
The pecuniary contribution of agricultural activities to the
GDP of India is firmly decreasing with the country's wide- ranging growth in economy, although a large number of people are still persistently engaged in the agricultural sector.

1.4 OBJECTIVES & SCOPE

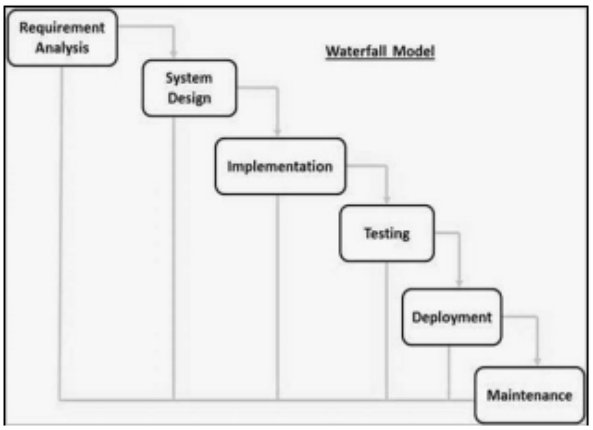
The greenhouse should be able to create multiple micro - climates with precision that favors custom condition for a variety of plants. The greenhouse will be fail-proof because all the components will be able to work independently so there is no single point of failure. The greenhouse should be able to conserve resources there by cutting costs of the plantation process and could lead to multiple growth cycles in a short span of time, increasing the productivity and revenue for the client.

The automated greenhouse in this project is meant for domestic use but can also be scaled to be implemented for bigger plantation. This project focuses on one plant only. However, this reference can be changed into any other plant.
The greenhouse has the ability to create a microclimate suitable for the growth of the plant,
which was achieved by controlling the factors such as humidity, temperature, moisture, light source.

To create a versatile greenhouse in which any conditions can be created just by altering soil properties, and using the IoT based monitoring and control to create other favourable conditions.
Wide area and safe monitoring available by authorised personnel.

II. METHODOLOGY USED

WATERFALL METHODOLOGY:



3.1 SUMMARY

Only monitoring will not be efficient solution for maintaining Greenhouse, We propose monitoring and controlling the greenhouse components with the help of IoT.A LAN based website would be area-limited. We can use a web portal & application which can be accessed from anywhere. Water tank is not a feasible solution; instead drip irrigation should be used. In earlier systems, there was improper ventilation with lack of humidity control. We propose movable flaps which function for controlling the Greenhouse humidity & temperature. Normal glass absorbs more heat. We can replace glass with acrylic material for efficient temperature management with the help of movable flaps using precise Servo Motors.

4.1 BLOCK DIAGRAM

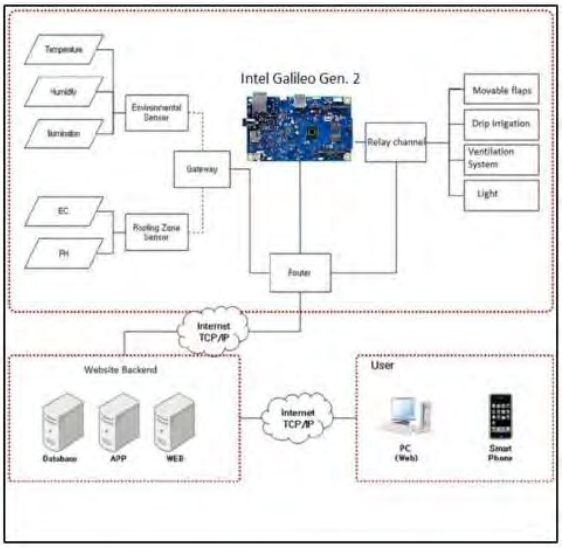


Fig. 4.1.1 Block Diagram

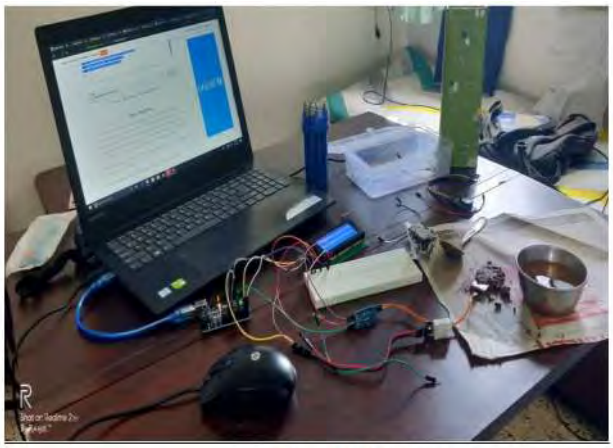

Fig. 4.1.2 Setup

cutting costs of the plantation process and could lead to multiple growth cycles in a short span of time, increasing the productivity and revenue for the client.

With the help of our proposed project, following features can be implemented and better results can thus be achieved:

Easy monitoring & control of the greenhouse through IoT.

Standalone operability of each & every sensor and modules.

Wide area accessibility with the help of web- based portal & applications.

Built-in movable flaps for proper ventilation of Greenhouse.

User-friendly interface of the web portal for monitoring the Greenhouse.

Advanced drip irrigation mechanism instead of conventional water tank method.

Adjustable light emitting diode (LED) lights for better growth of plant.

Fig. 5.1.1 Sensor Reading

The model not only overcomes the biggest challenge of deadlock situation but also increases the total efficiency of the whole object detection and obstacle avoiding system. Now assessing the Range of Application: The proposed model is capable of operating in military zones and areas where human presence is impractical, such as deep manholes for cleaning purposes, narrow places where movement is impossible for human. It can be an important asset to the government rescue programs and also oil industry.

III. CONCLUSION

Thus the results of an IoT based Smart Greenhouse allows precise position real time measurements and data transmission from the greenhouse to the interested farmer. Using the Intel Galileo and multiple sensors in an IoT based internet accessed agriculture application. All collected data can also be stored on a computer and day/time based reports and graphics are accessible for analysis at any time. The very specific data collection, easily adjustable sensor
The greenhouse should be able to create multiple micro - climates with precision that favors custom condition for a variety of plants. The greenhouse will be fail-proof because all the components will be able to work independently so there is no single point of failure.
The greenhouse should be able to conserve resources thereby positions and storage of data allows thorough analysis that can reveal even the most intricate trends in the farmin g process, thus directing the farmer how to improve the process for the next farming cycle. Furthermore, the long term collected data can be used by agriculture specialists to create more specific timetables and directions for growingspecific crops. Hence we use the actuators (motors/moving parts) as well, thus providing not only monitoring and data analysis but also precise control for the smart greenhouse.

Internet of Things – Managing Projects

Vikrant Sankhe *Siemens Ltd.*
vikrant.sankhe@siemens.com

Abstract—**Excitement about invention and technology is omnipresent. Digitalization has made us believe in realities which were distant some years ago. Case in point, IOT. Imagine what life would be like when everything is connected. Where there is a surge in machine-to-machine communication making life simpler and to an extent more virtual, when everything from a streetlamp to a seaport becomes 'smart' in the true sense of the word, how every aspect of our lives and business will change? And who would make that possible? Internet of Things!**

The internet has made it possible for seamless collaborations across countries. IOT devices enhance the efficiency and effectiveness of communication and collaboration even more, as information and data is shared automatically between team members regardless of their location. In fact, it was one of the biggest predicted project management trends.

Keywords—IOT, OTA, Edge,

I. INTRODUCTION

Picture a client discussion scenario, "Just connect the device and get it on-line!" is often asked by the client manager while defining the use cases. During customer and user interactions, the primary IOT functions are defined: "We want to receive alarms, read-status, asset-control and verify the communication. All secure of course! Oh, by the way the project needs to be ready in 2 months and we need to have a demo next week for the investors." Does the situation sound all too familiar?

Now the value of IOT is not technology, but, lies in the creation of new propositions and potential revenue systems. The real value of IOT is at the intersection of gathering data and leveraging it. The information gathered isn't of much use unless there is an infrastructure in place, to analyze it in real time. Currently, the data used today is mostly for anomaly detection and control, not optimization and prediction, which provide the greatest value. This has resulted in a fundamental shift to approach and strategy. Intelligent and smart devices are ones that carry potential to source new products and services with high degree of efficiency.

The challenges associated with this digital transformation are significant. The vast new sums of data that these technologies generate will hold little value if suitable analytics techniques are not developed and implemented to inform intelligent decision-making across the enterprise. Moreover, to effect this transition companies will likely have to oversee and manage widespread changes relating to staffing, skills development, organizational structure and culture, and supplier relationships. This paper focuses on the challenges related to project implementation.

II. CHALLENGES

Some of the biggest challenges faced in the implementation of IOT are end-to-end services covering sensors, communication and application. Sensors measure, it evaluates; in short, it gathers data. To put things in perspective, the Internet of Things really comes together with the connection of sensors and machines. Coming back to the challenges faced, managing installations of sensors at field locations and managing these assets post implementation with respect to repairs, warranty, replacement etc. are crucial and should be always given serious thought and consideration.

III. THINGS TO REMEMBER

Often we ignore the power of the 'Platform' in a hurry to deploy 'Pilots'. The essence is missed out as the pilot calls for only few of the 'Things' to be connected. However, at the end state, there are millions of things that are connected along with associated multiple applications. Another big thing missed, is the firmware updates of these millions of devices in field. Hence, one needs to consider Firmware update OTA (Over The Air) functionality within integrated Platform.

As millions of devices get connected, the amount of data generated will also be BIG! Such massive amounts of unstructured data are of no use to anyone, unless it can be utilized well or has a context. To develop a model that forecasts behavior, data scientists require context and time-series data. Otherwise it becomes very difficult to consume this information and truly see what is happening now and what could happen in the future. People need real-time data to make the best possible decisions. With pervasive monitoring, this information is captured and delivered for business intelligence analysis. This BIG data also calls for the fundamental shift from on-premise to Cloud with Mobile integrated Applications.

One can make technology work efficiently in limited scaling in a 'point solution' with isolated business benefit. To scale up to an application having a positive effect on wider business performance requires a concrete plan backed with technological prowess. To be able to build on your initial success, consider the business strategy of your Internet of Things (IOT) project at the start. To effectively deploy IOT within this strategy, planning for robust network infrastructure is critical to be successful. Edge computing provides a means to assure reliability of the service to avoid unplanned downtime with high customer satisfaction. End-users at plants adopting IOT for near real-time predictive maintenance, process optimization and visibility also need a robust architecture with edge computing to assure high data integrity and avoid missed alerts. On the other

hand, the automatic transmission of a vast amount of data makes things automatically measurable and analyzable. This in turn, increases the efficiency of processes as decisions can be made quicker. The decisions will also be more accurate because they are based on empirical data. The biggest challenge of having so much data available is data security.

IV. SECURITY

IOT is all about physical "things", hackers that gain access cannot just perform the usual digital attacks like stealing data, moving money, or shutting down websites — they can cause havoc by tampering with infrastructure like electrical grids and traffic signals, or put lives at risk by meddling with healthcare devices, airplanes, or elevators.

In the recent past, Hackers used stolen credentials to gain access to the Ukrain Power Grid and cut power of 30 sub-stations and 225,000 customers. The attack included installation of custom firmware, deletion of files including master boot records, and shutting down of telephone communication.

In another instance, a team of researchers were able to take total control of a Jeep SUV using the vehicle's CAN bus. By exploiting a firmware update vulnerability, they hijacked the vehicle over the Sprint cellular network and discovered they could make it speed up, slow down and even veer off the road.

These examples are demonstration of emerging Internet of Things (or Threats) hacks: While companies often ignore the security of peripheral devices or networks, the consequences can be disastrous.

Security needs to be defined on 4 broad aspects:

1. Applications - Evaluate the specific threats w.r.t. applications. The risks associated with wearable fitness band are different to those facing a smart grid.
2. Integration - evaluate risk w.r.t. End-to-End integration. Security needs to be considered at various stages including, Platform, Communication, Sensor Security eg. Embedded malware and Third-Party Integration Security, especially connecting with third party solutions eg. Car data with Maps etc.
3. Availability - assess the impact due to non-availability of the security measures and
4. Confidentiality - the impact of losing out the confidential data.

We need to build IOT Solutions which are 'Secured by Design'. Plan for what to do if something goes wrong. Understand that compromise will happen, and plan a workflow for getting compromised credentials out of the system.

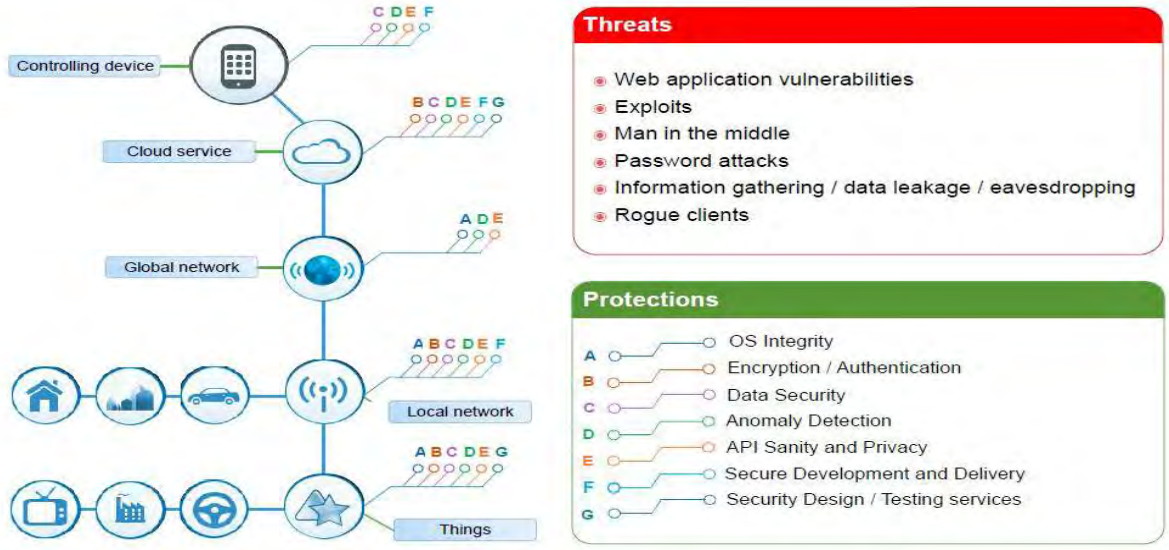

Fig. 1. Typical Security Architecture

V. ARCHITECTURE

We need a scalable Open Cloud Platform with data analytics and connectivity capabilities, tools for developers, applications and services covering end-to-end Security.

When we begin making things intelligent, it's going to be a major engine for creating new products and new services. We need to evaluate and utilize data and to gain breakthrough insights, drive the performance and optimization of assets for maximized uptime and also establish feedback for design improvisation as an ongoing process.

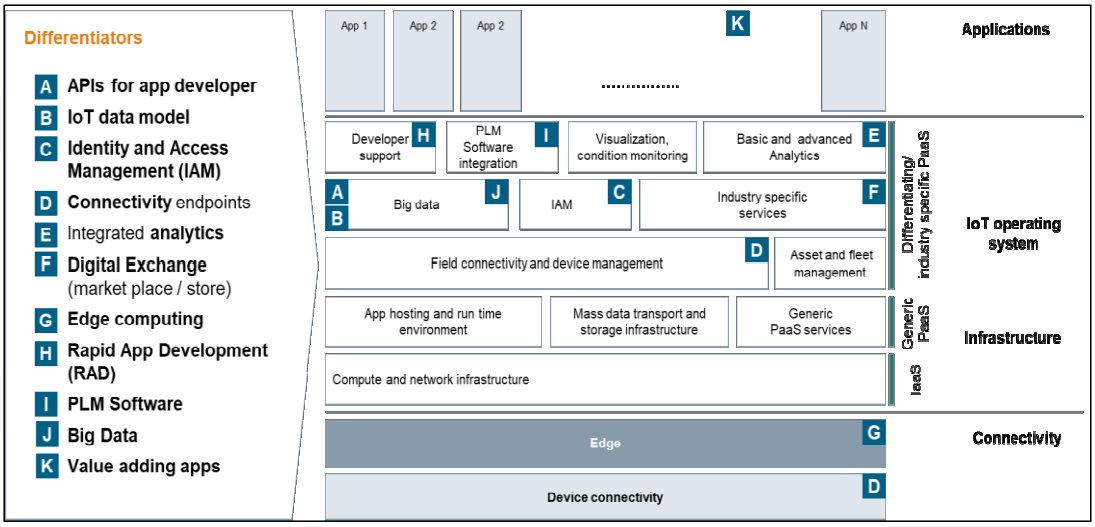

Fig. 2. IOT Architecture

VI. Conclusion

The Internet of Things is probably the biggest trend that's taking place in the world of technology as we speak. It is one that is going to give us the most disruption as well opportunity over the next few years. And hence managing the scale by design is utmost important.

U.S. economist Warren Bennis, who once quipped: "The factory of the future will have only two employees, a man and a dog. The man will be there to feed the dog. The dog will be there to keep the man from touching the equipment." Although intended as a joke, this statement certainly has a grain of truth. The fears and concerns that many people have in this regard are not unjustified.

Abstract – **Every day, a big amount of trash is released into the urban drainage which contributes to serious water pollution. Existing techniques are using a manual process for cleaning the trash which causes serious health issues and diseases. Existing trash collector boats are used only in big areas like river and sea for cleaning the surface water. The proposed system is sanitary and economical which automatically detects, collects and accumulates the floating trash using a conveying machine which can be controlled remotely from any location and this reduces human efforts. The proposed system is designed to collect trash from small and narrow space areas like drainage systems. The proposed system uses an augmentation technique for data preprocessing and Wireless sensor networks to control command remotely. It uses a convolution neural network for the detection of the floating trash. Once the floating trash is detected, the system calculates the position of the floating trash by the use of the high-resolution camera. The proposed system uses a CNN-based algorithm to extract image attributes and a multilayer perceptron's method to merge image attributes information to classify the floating trash. The proposed system is trained and validated against the physically labeled elements, expecting final classification accuracy more than 90% confidence under different testing approaches in real-time. Finally, a robotic conveying machine controlled by the microcontroller is used to pick up the floating trash and places it in the trash bin.**

Keywords: OpenCV, CNN, Deep Learning, IoT, Data Augmentation, ReLU Layer, Pooling Layer, Fully Connected Layer

I. INTRODUCTION

Water is the most precious gift to the humanity of nature and it is a very crucial element that supports life on earth. Today, the exponentially expanding number in the urban populace and boom of industries, water is experiencing the contamination issue. A big amount of floating trash is locating its manner into the urban drainage structures from where it's miles capable of travel through the city drain, streams, rivers, lakes, and estuaries till it subsequently reaches the open sea. Floating solids including refreshments/beverages can, plastic bottles, meals packaging, container, straws, and Styrofoam cups are a number of the most vital solid waste that may be found in the surface water, worsening pollution every day [1]. The undesirable presence of those wastes within the surface water will also contribute to environmental troubles, including drain logging and flash flood as well as potential diseases consisting of malaria and typhoid. On the other hand, for small streams and drainage, the manual cleaning method is frequently used. This scenario is undesirable since it can lead to health troubles and diseases to the operator due to the variety of impurities present in the water [2]. Hence, to overcome this situation a prototype robotic trash boat proposed system was expected to develop which can harvest floating trash from the urban drain and can be operated online/remotely.

Now a day, the trash collector boat has been widely used for cleaning of the surface water. Most of them are mostly targeted at massive place applications such as river and sea. The commercially accessible design of a trash collector boat calls for excessive manpower to function the system. In addition, the huge length of the trash collector boat makes it not possible for use in cleansing small regions consisting of small streams and drainage [3]. Therefore, a smaller length of trash collector boat has been designed to accumulate waste and floating solid from a slender and small place which includes small streams and drainage systems. The robotic trash boat proposed system was expected to design with automated detection, collection, and conveyor machine to accumulate the floating solids trash and can be remotely controlled from a distance. The proposed prototype is also portable, user-friendly, easy to understand and environmentally pleasant [4].

The objective of this proposed prototype is to design and build up a prototype of a transportable, robotic trash boat to collect trash from small and narrow space applications. The proposed system was conducted using open computer vision (OpenCV), convolutional neural network (CNN), deep learning and internet of things (IoT). In addition, it will be attracted and encourage the tourist to drive the boat across the surface water and make a contribution to keep it clean. The performance of the proposed system was examined and evaluated to determine the effectiveness of accumulating floating solids from surface water.

Fig. 1. Floating solids waste over the surface water.

II. RELATED THEORY

P S.H.Y.S. Abdullah et al. [1] the boat system works properly with the movements and speed corresponding to the collecting process of floating solids. But, the radio connection isn't strong that will bring about a connection loss sometimes at some point in the testing. It also wants to improve the quality of the image for better tracking of the trash collector boat. Mainly it offers the wireless remote control using radio waves, however, this results in connection loss in some scenarios, also needs the quality of the image for better monitoring and this problem can clear up by the usage of net connection, OpenCV, and convolution neural network and make it autonomous.

Sridhar Thiagarajan et al. [3] in this proposed system cups, trash was collected with the help of the classification algorithm. By using the fully connected neural network easy to identify the number of floating solids that provide more accuracy to the robot.

Abdoulaye Saadou-Yaye et al. [8] the compensation mechanism provided the ability to complete tasks in lower instances, but additionally gave the users enough control to perform finer movements. The compensation mechanism does have its boundaries, the system always continues to transport within the direction it was moving before the packet losses took place. To overcome this limitation, computer vision, object detection and object tracking used for determining the most likely direction to move in case of losses.

Shinji Fukui et al. [9] this paper proposed a new approach for object tracking. The tracker is primarily based on the particle filter. The object detector is used for monitoring the target object robustly. The proposed detector can come across similar objects with various sizes that exist near the target object. The positions of the similar objects are used in the procedure for calculating the likelihood and that for judging the situation under which the target object exists. Using statistical information makes the method robust tracking. The experimental results display that the proposed system can track stably the target objects. The problem is not about tracking stable objects, but the moving or floating solids over surface water live video streaming from the camera.

Prof. N.G.Jogi et al. [12] proposed a system targeted on modeling, design, and control of a pedal-operated boat, with emphasis on lightweight, portable appliances. Although this system able to acquire the rubbish from the lake with human intervention. To function the proposed system needs excessive manpower and this problem can be solved by using the solar panel the sufficient power can provide to the boat instead of pedal operating and Expending manpower. By making the prototype automatic using IoT and small enough to travel and collect trash from small and narrow space areas like drainage systems, also portable and lightweight.

III. PROPOSED METHODOLOGY

The proposed methodology is divided into two major systems I) Local System and II) Remote System as shown in Fig. 2. The identification of floating solids on the surface water could be accomplished from numerous points of view. This operation can be made seems easy by using image processing. The three-dimensional nature of the floating trash and the randomness in shape, size, and conditions of the floating trash and surrounding atmosphere situations like low light and their limitless possibilities, application of convolutional neural network with deep learning seems to be the only way out [1]-[3]. This would give the proposed system the ability to self-learn dependent on the experience they gain while they work.

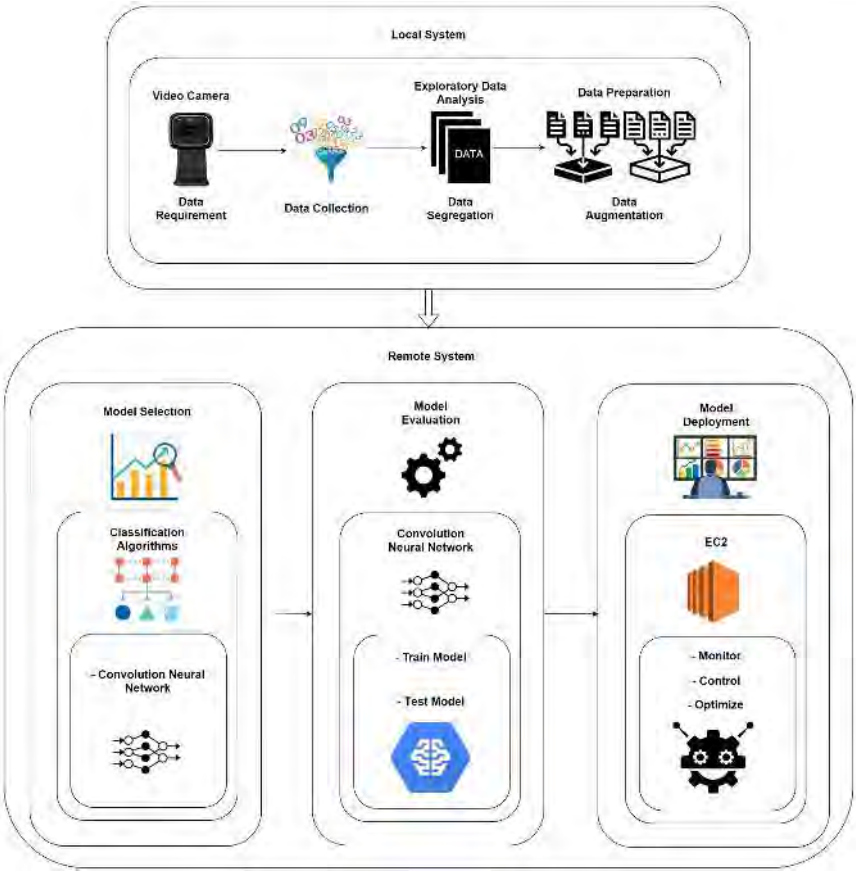

Fig. 2. Proposed system architecture.

1.1 Local System

There are billions of trash substances that are constantly being produced by the humans. The proposed system is meant for figuring out and clearing the seen floating solids. Examples of seeing floating solids include polystyrene blocks, plastic cups, bottles, and other plastic wastes, corn cobs, twigs, leaves, etc. are major concerns and for that, the "Data Collection" process plays an important role. OpenCV is a library of programming functions mainly used for image processing; the OpenCV read, write and display images functions/techniques are helps in data collection. This type of images was gathered at varying lighting conditions, some of them containing litter. It is further segregate into different labelled classes, this process is performed manually and called as "Data Segregation". Some of this labelled classes have many images while some classes have few images, which leads to imbalanced dataset. In the imbalanced dataset where some classes are contained more data as compared to other classes now at any given class the probability that this class is mathematically represented as follows using basic Bayes rule:

$$P(C0|x) = P(x|C0)*P(C0)/P(x) > P(x|C1)*P(C1)/P(x) = P(C1|x) \quad (1)$$

This is clearly show the effect of the priors and how it can lead to a situation where a class is always more likely than the other, so, that the classifier can't do a good prediction on the minority class. Now, in this kind of situation "Data Augmentation" techniques are used to generate more data and equalize the dataset [3]. But before applying data augmentation techniques each image must be resized and convert in grayscale form. The resize function from the OpenCV library is used to resize an image to the desired shape. The parameter here is the shape of the recently resized image. The images with a fixed-sized to train the model, take less processing power. In order to make a powerful floating trash classifier, augment the images via a number of random transformations, so that our model would never see the duplicate images. This has to be feasible through the "Image Data Generator" technique. Data augmentation is one approach to overcome overfitting, but it isn't sufficient since the augmented samples are still highly correlated. The model needs to concentrate on the most important features in the data, which is more relevant and helps to generalize the dataset in a better way. Finally, the proposed system used data augmentation to balance the dataset to improve the accuracy of the proposed model.

1.2 Remote System

After data preprocessing on the local system, the proposed system performs a model selection, model evaluation and model deployment task on the remote system. The "Model Selection" becomes the main task to identify which "Classification Algorithm" is fitting in the proposed system. The model selection task is done by using a "Cross-Validation" technique. The cross-validation technique is a simple and useful method for model selection and it is necessary to obtain an estimate of the error of model selection.

$$J_{cv}(\theta) = \frac{1}{2m_{cv}} \sum_{i=1}^{m_{cv}} (h_\theta(x_{cv}^{(i)}) - y_{cv}^{(i)})^2 \quad (2)$$

This process is willing to take large processing power and also it is very time-consuming. At the "Model Evaluation" the "training and testing" phase is performed with "Convolution Neural Network" and the data of the number of images is passed through the following process:

Convolutional Neural Network, In the case of CNN the neuron in a layer, will only be connected to a small region of the layer before it, instead of all of the neurons in a fully-connected manner. Convolutional Neural Network (CNN, or ConvNet) is a sort of feed-forward artificial neural network in which the connectivity pattern among its neurons is inspired by using the organization of the animal visual cortex. The visible cortex has small regions of cells that are sensitive to unique areas of the visual field. Some individual neuronal cells in the brain respond (or fires) only in the presence of edges of a certain orientation. For example, some neurons fire when exposed to vertical edges and some when shown horizontal or diagonal edges. A computer understands an image using numbers at each pixel. CNN compares the image piece by piece. The pieces that it looks for are known as features. By finding rough feature matches, in roughly the same position in two images, CNN gets a lot better at seeing a similarity than whole-image matching schemes. The feature moves to every other position of the image and will see how the feature matches that area of the image.

$$h_w(x) = g\left(\sum_k w_{2,k,1}\, g\left(\sum_j w_{2,j,k}\, g\left(\sum_i w_{1,i,j}\, x_i\right)\right)\right) \quad (3)$$

ReLU Layer, Rectified Linear Unit (ReLU) transform function only activates a node if the input is above a positive quantity, while the input is below zero, the output is zero, however, whilst the input rises above a sure threshold, it has a linear relationship with the based variable. In this layer, remove every negative value from the filtered images and replaces them with zeros. This is done to avoid the values from summing up to zero.

$$f(x) = \begin{cases} 0, & x < 0 \\ x, & x \geq 0 \end{cases}$$

Pooling Layer, In this layer the image shrinks stack into a smaller size.

$$C = [c1, c2, c3, c4, \ldots .cn\ ]$$

$$C_1 = max\{C\}$$

Fully Connected Layer, This is the very last layer where the actual classification happens. Now, the filtered and shrank images are put into a single list.

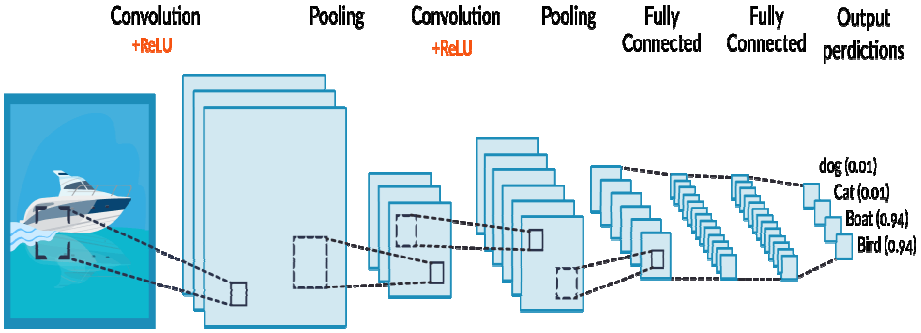

Fig. 3. Convolutional Neural Network.

Each prediction by way of the proposed system is compared with the manually classified label, and the "Confusion Matrix" helps to show the hits and misses of the classification of the proposed system. The system overall performance is evaluated with accuracy, precision, and recall. The accuracy of classification is defined as the percentage of images that are efficaciously classified:

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} * 100\% \quad (6)$$

The precision represents the correctness of classification prediction of the proposed systems.

$$Precision = \frac{TP}{(TP+FP)} * 100\% \quad (7)$$

The recall represents the effectiveness of the classification prediction of the proposed systems.

$$Recall = \frac{TP}{(TP+FP)} * 100\%$$

After creating a trained model, it's time to load the model on the boat. The boat has a processor of its own that does all the detection and gives us information about the location and size of the object with the help of OpenCV and CNN. An image is just some number of pixels that get by using computer vision, it also gives the "x-axis, y-axis, height and width" of the identified object (floating solids in surface water). The identified object is marked in a square box and the value above the square box represents the confidence that the algorithm

determines the floating trash. With this information, it is easy to find the center point of the identified object.

$$Center(x,y) = \left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2}\right) \quad (9)$$

This center point plays an important role to determine in which direction boat needs to move to come back to the vision center point and also set a threshold value that helps to control the speed and rotation of the motor.
The final fully tested proposed system is deployed on the cloud which helps to get the robotic vision with the visualization result of the analysis. The "Model Deployment" also helps to monitor, control and optimize the proposed system.

IV. PROPOSED ALGORITHM

Proposed System work in the following way:
Step 1: Get the data (the data in the form of images)
Step 2: Perform the segregation operation on the dataset
Step 3: Perform the aggregation operation on the segregated dataset
Step 4: Apply the classification algorithm for model selection
Step 5: Visualize the model accuracy
Step 6: Select the algorithm for model evaluation
Step 7: Split the dataset into the train and test set
Step 8: Train model on convolution neural network
Step 9: Test model on convolution neural network
Step 10: Predict the data from the boat
Step 11: Model deployment on cloud

V. RESULT AND DISCUSSION

The proposed system which is trained using an augmented image dataset is evaluated under the floating trash is placed with fixed and random orientations. The model performances are compared with a standard CNN model that takes the images as the input. The classification results are presented in Table 1.

Table 1. Expected result of confusion matrices for different classification models.

Evaluation Metrics	Standard CNN Model		Proposed CNN Model
	1st Test	2nd Test	Expected To Achieve
Accuracy (%)	87.7	80.0	83.85
Precision (%)	88.6	85.9	87.25
Recall (%)	96.8	89.2	93.00

The expected evaluation results show that the proposed system outperforms standard CNN model in terms of all three matrices (accuracy, precision, and recall), particularly for the floating trash.

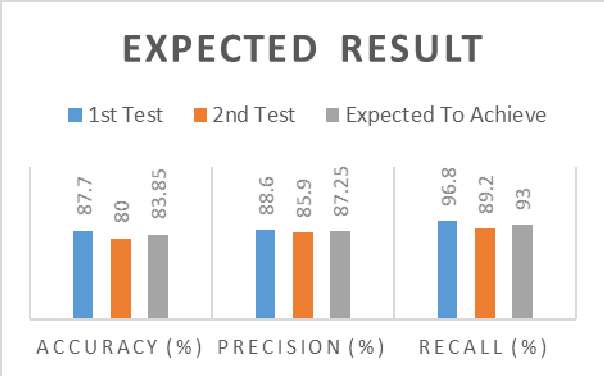

Fig. 4. Expected result of confusion matrices for different classification models.

VI. FUTURE WORK

To get, the more precious result, plan to include further classes of floating solid objects in our dataset and expect similar/better performance from the Deep Learning Algorithms. Also, try to segregate biodegradable and non-biodegradable floating waste using the Convolutional Neural Network.

VII. CONCLUSION

The computer vision combines with deep learning algorithms like the convolution neural network embedded and deployed on a robot, in order to successfully harvest floating trash from the urban drain.

Certificate Assurance through Block Chain

Sachin Sadare, Raja Choudhary
Founder & Director, Digital Dojo India, Mumbai, Manager - Digital, Digital Dojo, Mumbai India
sachin@digitaldojo.eu, raja@digitaldojo.eu

Abstract. **In the world today, there exists a need to mitigate fraudulent certificates and manipulation of records to ensure honest and seamless trade. Recently, modifying certificates and contracts for deceiving, misconstruing or fake anything is a commonplace happening. This is a clear breach of ethics. It takes our society to deeper darkness as a whole. Hence we need a system of issuing digital certificates on Blockchain technology that provides the following advantages - (1) leverage immutability of block chain technology to avoid certificate tampering, (2) public record mechanism to provide endorsement of the certification and (3) universal validation to prevent fraud and mutilation of records by involved entities. This paper presents the need, the solution, the high level architecture and the next research steps to make a digitally block chained certificate mechanism a universally accepted process.**

Keywords: digital assurance, digital certification, Certificate accreditation, Block chained certificates.

I. INTRODUCTION TO BLOCK CHAIN

To begin, we should discuss the historical backdrop of the Block chain. Before it was ever utilized in digital currency, it had humble beginnings as an idea in software engineering — especially, in the areas of cryptography and data structures. The specific primitive form of the block chain was the hash tree, otherwise called a Merkle tree. This data structure was protected by Ralph Merkle in 1979, and worked by checking and dealing with data between PC frameworks. In a shared system of PCs, approving data was essential to ensure nothing was adjusted or changed amid exchange. It additionally guaranteed that false data was not sent. Generally, it is utilized to keep up and demonstrate the respectability of information being shared.

In 1991, the Merkle tree was utilized to make a "secure chain of blocks" — a progression of data records, each associated with the one preceding it. The most current record in this chain would Contain the historical backdrop of the whole chain. And thus, the block chain was made. In 2008, Satoshi Nakamato conceptualized the conveyed block chain. It would contain a safe history of data exchange, use a shared system to time stamp and check each trade, and could be overseen self-governing without a focal specialist. This way, the block chain we know today was conceived, and the universe of cryptocurrencies. Block chain allows you to keep decentralized and distributed records of digital transactions. The first implementation took place in 2008 in the context of bitcoin as a digital currency, and although the Blockchain technology is no longer only in bitcoin, bitcoin is an example that will be used as paradigm of block chain. In bitcoin transaction occurs between anonymous users using public key cryptography. That means each user has its own private key that only he or she knows and one public key which will be shared with other users. All transactions are communicated to all nodes on the network. The nodes check transactions and group them in blocks. Each block is identified as a hash: a cryptographically unique value calculated on the content of the blocks and includes a reference to the hash from the previous block. So that blocks are linked. This chain of blocks is nothing but record of transactions or public accounting look shared by all the nodes in the network. In this way, all nodes can verify that the keys used are correct and the bitcoins transferred are from a previous transaction and they had not been spent already. However, transaction is only considered confirmed when it is part of a block added to chain. To add a block, it is important to undermine it, in other words, calculate its hash, which requires solving a unique mathematical problem of great difficulty that consumes some very considerable computing resources. As the power of the connected computer increases, the difficulty of the problem grows.

As a result, modifying its content is nothing but modifying its hash value, so link to the next block would fail and would break the chain, which, combined with the difficulty of repairing it, and with the fact that the rest of nodes have a copy of original string, makes the information contained in the block unalterable.

II. 2. Block Chain Decentralization

Blockchain is a public log or open registry that consequently records and confirms transactions. This open registry also known as the Distributed ledger technology (DLT) powers many virtual currency companies. Use cases for a transparent, verifiable register of transaction information is vast because of the fact that DLT works through a decentralized platform keeping it safe from fraud.

Fig. 1. Block chain Decentralization

The decentralization idea of block chain technology implies that it doesn't depend on central point for control. An absence of a single authority expert makes the framework more attractive and considerably more secure. The manner by which information is recorded onto a block chain encapsulates its most progressive quality: its value of decentralization. Rather than depending on a central authority to safely execute with different clients, block chain uses innovative consensus protocols over a network of nodes, to approve transactions and record information in a way that is incorruptible. As a block chain is a record of data it is critical that the data/information being stored is real and accurate. A consensus protocol is a set of rules that describe how the communication and transmission of data between electronic devices, such as nodes, works. Decentralization isn't to be mistaken for conventional distributed storage. Information which is stored on cloud is not directly stored on devices but kept on one central server somewhere else. Unlike block chain, it is very much centralized solutions. Information that is put away on the block chain isn't stored on a single server network, but rather distributed across wide range of devices over a P2P network.

III. Block Chain in Education

In all of the world's developed countries, the field of education is a central focus. This is due to the fact that the future of other important areas, including science, medicine, agriculture, industry and almost all others, is dependent on the country's education levels. Despite the remarkable developments in robotics and Internet and IT technologies, human resources are still the most precious resource to almost any business. Contrary to popular opinion, advanced technologies help to improve the sphere of personnel training and solve a lot of problems. Not only private but also in many state educational institutions are either getting ready to implement block chain-based tools, or they are conducting research to identify the areas where they need block chain implementations.

3.1 Problems in Education

Learning is no longer an activity that is performed during an initial period of formal mode, and which is enriched by experience in professional and vital practice. Lifelong learning has become a labor necessity; Human learning is a requirement of twenty- first century Citizenship which affects both the social framework in which we move and social learning. Formal education has soon transferred part of their programs to the temporary post-formal space; Post graduate studies and refresher courses became upgrade and specialization programs. The question that arises for years is how we can overcome the difference between formal education i.e. with accreditation and informal education i.e. without accreditation. However, accreditation of learning is not only complicated because of the diversification of the field from which training is offered, but it is increased by teaching methods and curricular elements which are materialized in an ideal pursuit personalized learning. The formal academic qualifications such as degrees and postgraduate, even with the correct documents it is not enough to major the capacity and knowledge of one person in particular subject. The kind of knowledge that we get in informal/non-formal education institute is appreciated and needed in industries or in everyday life. Due to this reason they are also counted in formal education when industries are recruiting. When industries are hiring they always asks for resume and if it is complemented with corresponding certificates then there are some challenges that industries will face to authenticate the documents and certificates. The traditional solution to for this problem is to contact the authority to cross validate the documents but this solution do not solve the problem of knowing the actual practical skills and knowledge acquired outside the formal education program in that particular subject.

3.2 Utilization of block Chain in Education Paper-based higher education diplomas, school certificates and extra training course certificates get lost and the original can be lost over time. Once put in block chain, the information about a student's grades and the courses that have been undertaken will not get lost, and it is impossible to change or falsify the information. At the same time, one can easily access this information with the owner's consent. Nowadays, the field of education is in need of central authorities to focus on checking certificates. Every day, educational institutions have to process thousands of requests from different educational organizations for sending copies of documents. They want to make sure the person has in fact graduated from a certain university. Putting information about education into block chain will remove doubt for employers about an employee's level of knowledge. Using block chain technology for storing information about one's level of education will make faking a diploma impossible. It is effective because it will solve the problem of low qualification levels of doctors, lawyers, engineers, economists and other popular occupations for which a formal education is required. A database can be established, which will include a person's skills, courses or training which have been completed, Assignments which are done and lectures which have been attended. Employers will be able to obtain and filter information about an employee's knowledge quickly and easily, with no doubt as to its relevance or reliability. Nowadays, recruitment for specific positions is a time-consuming and complex process. There is no single algorithm able to narrow the search down to only those applicants with the required knowledge. Rather than accumulating papers and certificates in education over their lifetime, people will be able to record information in block chain, which will make it available to employers anywhere in the world. In addition to the issuance of diplomas and certificates, educational institutions have to keep a paper record of students' progress for the entire duration of their study, thus creating a burden on the teaching and

administrative personnel as well as a lot of bureaucratic impediments. Non-official institute, Digital Dojo India provides Blockchain certificates for their courses which is a great technology to use for educational startups to gain trust from the people who are learning from them. This block chain certificates includes assignments, completion certificate and some other things about that particular person that will help the recruiter to know the knowledge of that person in the particular subjects. Block chain certificates or mostly known as Blockcerts consist of four basic components: Issuer or the institution that creates the certificates. Certificates adjusted with the requirements of the open badges initiative which contains a wide range of statements about skills, achievements or characteristics of the student, all recorded in a chain of blocks. Verifier is someone who will verify the certificates to see if it has been altered, and that it has been issued by a particular institution and belongs to particular individual, without having to depend on the distributor. Wallet is where each student can store their certificates and also share with others.

Fig.2. Block chain certificate structure.

IV. Critical View

The passion with which some sectors of education system have been pursuing block chain has raised alarms, both by the origin of the enthusiasm, as well as the consequences that an actual application of technology as we know it could have. As this time speaking of the consequences of an implementation is to move into the field of speculation as much as the literature that is promoting it. Despite this there are few challenges posed by the block chain in following four points:

(1) It is not about easy and immediate implementation for social, technological and economic reasons.
(2) It can lead to unacceptable consequences depending on the direction it is working and intentions with which it is made.
(3) It presents challenges in areas such as privacy, transparency, functionality and value of the certification, as well as official and public institutions.
(4) It concerns citizen who have seen in these years as some technological changes not always desirable. In coming few years, we will come to see if we are moving towards more economical and easier to use systems with this technology or not.

The three key elements of the imagined future in the discourse on block chain in education that deserves special attention:

(1) The anti-institutional disposition of Block chain. (2) Its dependence on decentralization that does not necessarily implicate democratizes, but sometimes means dismantling the public sector (3) The invocation of trust as a key social behavior mediated by technology.

V. Conclusion

Block chain is a disruptive technology that, after a few years of implementation as the basis of digital currency, is showing itself to be an open resource with possibilities in different field. The key to the interest in the technology lies in its ability to move from a system of centralized data logging to a distributed system that ensures no alteration of information and maintenance of privacy. However, concept of learning certification can also be applied in relation to training projects that strengthen the personalized itineraries of each student, and that at the same time, try to solve some basic problem such as fair and equitable grades or the accreditation of the progress made. It is likely that in coming year we see a growing interest in this technology.

Emerging Wireless Technologies: A Comparative Study

Sowmyashree, Chitvan Mehrotra
Thakur College of Engineering and Technology, Kandiviili (E), Mumbai, India

***Abstract*—With increasing demand for high speed wireless communications, many wireless technologies have emerged in the recent years. Wireless communications provide faster transmission of information, easy access without the need of cords, greater flexibility and mobility to the users. This paper contains comparative study of emerging wireless standards defined by Institute of Electronics and Electrical Engineers (IEEE) such as WLL, Wi-Fi, Wi-Max, Bluetooth, Li-Fi and Zigbee and GiFi technologies.**

Keywords: Emerging Wireless technologies, WLL, Wi-Fi, Bluetooth, Zigbee, Li-Fi, Wi-Max, Gi-Fi

I. INTRODUCTION

Wireless network is a network which uses wireless data connections between nodes within the network. In wireless networks devices can stay connected to the network but roam untethered to any wires. Whereas, the wired networks is used to establish a connection between two or more nodes or components at earlier time. It would work when an application needs short range communication containing smaller number of nodes. But when number of node increases or the range between them increases, the wired method becomes very untrustworthy, untidy and complex method. The main limitation of wired technology is mobility or portability, and the major reasons for this are need of power outlets to run them and the physical length of the wires which makes it a very bulky system and a really difficult manage it. Get damaged easily, so frequently there is a need for replacement. In addition, it is an expensive method and too much time consuming. To overcome limitations of the wired technology, the wireless communication technologies came into existence.

Wireless communication uses mediums like radio waves, microwaves, infrared waves, and satellite communications. Radio waves are the first wireless communication medium which permit a user to speak over short distances. Microwave wireless communication is an efficient sort of communication, mainly this transmission uses radio waves, and therefore the wavelengths of radio waves are measured in centimeters. Satellite communication is one sort of self-contained wireless communication technology, it's widely spread everywhere the planet to permit users to remain connected almost anywhere on the world. When the signal (a beam of modulated microwave) is sent near the satellite then, satellite amplifies the signal and sent it back to the antenna receiver which is located on the surface of the earth. Satellite communication contains two main components like the space segment and the ground segment. The ground segment consists of fixed or mobile transmission, reception and ancillary equipment and the space segment, which mainly is the satellite itself. Infrared wireless communication communicates information during a device or systems through IR radiation. IR is electromagnetic energy at a wavelength that's longer than that of red light. It is used for security control, TV remote and short range communications. In the spectrum, IR radiation lies between microwaves and visual light. So, they will be used as a source of communication

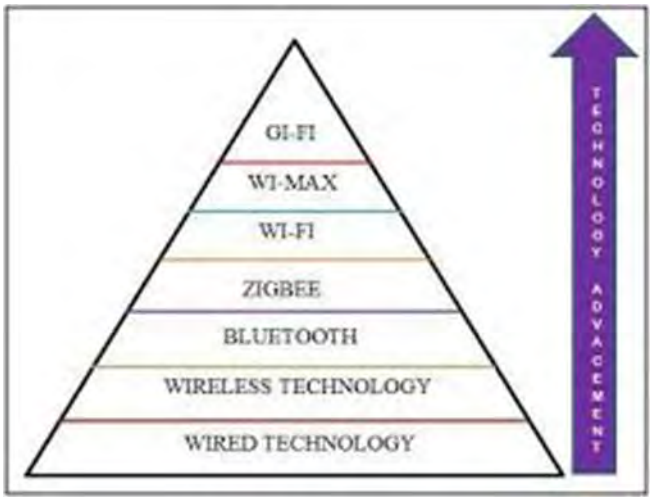

Figure 1: Network Evolution

Figure 1 shows technology advancement from wired network to Gi-Fi technology[9]. With the assistance of wireless technology we will send data over long distances with none quite trouble and which is more trustworthy and expedient compared to wired methodology. In industry, several sorts of devices, sensors, data collection devices and lots of more are connected in several ways via various protocols, if this is often done using wireless technology than it can replace all the physical limits of wires.

The advantages of wireless networks include increased efficiency, availability, flexibility and security. A variety of IEEE standards and protocols are used for wireless communication like Bluetooth, Zigbee, RF modules, infrared and lots of more. It is utilized in many areas like industrial, commercial, home use, health care, Smartphone, laptops and lots of other fields. The particular wireless standard is being chosen as per the need and specification of the merchandise or the appliance. For example, Bluetooth is employed in Smartphone, laptops, home automations, music players, etc. where several meters of range and data transfer in tens of MBs are required.

II. WIRELESS TECHNOLOGIES

A. WLL

Wireless local loop (WLL), is that the utilization of a wireless communications link because the "last mile / first mile" connection for delivering plain old telephone service (POTS) or Internet access (marketed under the term "broadband") to telecommunications customers. Wireless local loop (WLL) provides two-way calling services to the stationary or “fixed” users, which is meant to exchange its wireline counterpart [1]. WLL systems can be based on satellite based, cellular based, and microcellular based and fixed wireless access technologies.

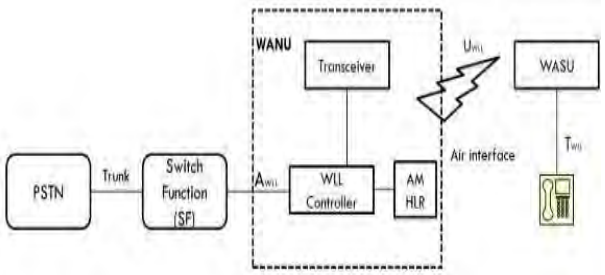

Figure 2: Typical architecture of WLL

The given architecture consists of three major components i.e WANU, WASU and SF. The WANU consists of various components which include several base stations transceivers or radio ports (RP), Radio port control unit, an Access manager (AM), an HLR. It provides various functionalities like authentication, Air interface privacy, over-the-air registration of subscriber units, Operations and Maintenance, Routing, Billing, Switching, functions, Transcoding of voice and data.

Wireless access subscriber unit (WASU) provides an air interface UWLL towards the network and a standard interface TWLL towards the subscriber. The power supply for it is provided locally. The interface includes protocol conversion and transcoding, authentication functions, signalling functions. The TWLL interface are often an RJ-11 or RJ-45 port. The UWLL interface are often AMPS, GSM, DECT then one.Switching Function (SF) is related to a switch which will be digital switch with or without Advanced Intelligent Network (AIN) capability, an ISDN switch or a Mobile Switching Centre (MSC). The AWLL interface between the WANU and therefore the SF are often ISDN-BRI or IS-634 or IS-653 or such variants.

Limitations of WLL involves, the technology is more costly due to the need for research and development. The technology has not been tested over an extended term of your time for reliability and repair costs. Certain technologies aren't available altogether areas, which leaves people with the unsupported technology disconnected. Wireless technology requires that data be sent over open space, which makes it vulnerable to interception and reduces the safety of the transmission.

B. Bluetooth

Bluetooth is a short range data communication platform. This helps in the connection of devices for different applications. It is not a perfect form among the latest, emerging wireless technologies while there's a requirement to transfer large amounts of knowledge. They usually carry the data at speeds of upto 721 Kbps. Bluetooth uses frequency hopping techniques with the carrier modulation using Gaussian Frequency Shift Keying (GFSK). [2][7].

Up to eight devices are often connected together using this technology. In this system one will act as a master and seven others as slaves. A network of devices connected together is named Piconet or PAN (Personal Area Network). Bluetooth uses unlicensed ISM band frequency of 2.45 gigahertz (GHz). Devices in Piconet are synchronized to a standard clock and frequency-hopping pattern, with the master device. In frequency hopping technique, the transmission frequencies are adjusted automatically by the paired device.

Spread spectrum frequency hopping uses frequency within the range of 2 .4 to 2.485 GHz. Signal is transmitted in 79 individual frequencies within the given range with a niche of 1MHz. Frequencies are randomly chosen and Bluetooth transmitters change frequencies 1600 times every second, such that, chances of two neighboring signals transmitting at same frequency is extremely less. Bluetooth 2.0 can manage a speed up to 3Mbps and is backward compatible with Bluetooth 1.0 devices, which features a transfer speed of 1 megabit per second (Mbps). Bluetooth connectivity is meant for devices within the range of about 10m radius. Bluetooth technology is employed in devices like headphones, speakers, wireless mouse, data exchange between mobile phones etc.

Figure 3 shows the architecture of bluetooth. The radio layer is responsible for Modulation/Demodulation of data for transmitting (OR) receiving over air. The baseband layer is liable for Controlling the physical links via radio assembling the packets and controlling frequency hopping. The link manager protocol controls and configures links to other devices. The host controller interface(HCI) handles communication between the host and therefore the module. For this purpose, it uses several HCI command packets like the even packets and data packets. The L2CAP layer converts the info obtained from higher layers into packets of various sizes. The RF COMM provides a serial interface with wireless application protocol (WAP) and object exchange(OBEX). WAP and OBEX provide interface to other communications protocols. The TCS(Telephone control protocol specification) provides telephony service. The SDP(Service discovery protocol) allows the devices to get the services available on another Bluetooth enabled device. The applications present within the application layer can extract the services of the lower layers by using one among the various profiles available.

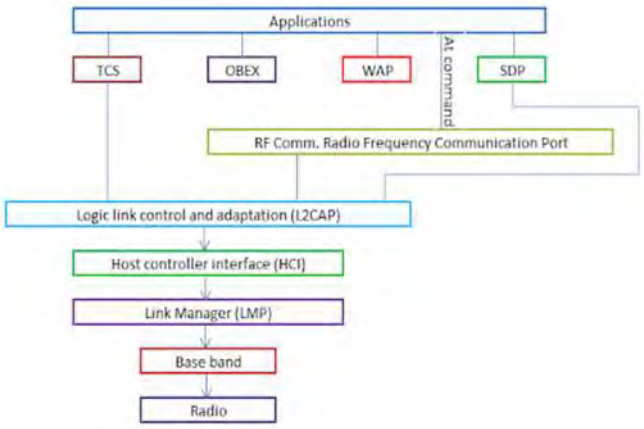

Fig 3: Architecture of Bluetooth

Advantages of bluetooth are, Bluetooth avoids interference from other wireless devices. It is easily upgradeable and consumes low power. Bluetooth provides better range than infrared. Bluetooth is employed for voice and data transfer. Bluetooth devices are available at very cheap cost. Free to use if the device is installed with Bluetooth. The technology is adopted in many products like head set, in car system, printer, web cam, GPS system, keyboard and mouse.

There are certain disadvantages like low bandwidth compared to Wi-Fii, losing connections in certain conditions and security issues.

C. ZigBee

ZigBee works in 2.4 GHz frequency. Basically it uses mesh, star and cluster topologies. They are inexpensive, general purpose, self-organizing and a robust wireless technology. Usually, ZigBee networks need a number and a coordinator for its operation. ZigBee is based on IEEE 802.15.4 standard. To achieve low power consumption, transmission distance is restricted to 10-100m distance. Also to transmit the data over long distances, we normally pass the data through a mesh network of intermediate devices. Commonly ZigBee is employed in applications that have long battery life and network security[7].

Some of the characteristics of ZigBee includes, Various transmission options, Security mechanisms, and operations in 2.4GHz frequency. ZigBee operates in the 915 MHz (Americas) and 868 MHz (Europe) and includes Power saving mechanisms. Z.igBee Operating over 16 channels. ZigBee works in 2.4 GHz frequency. Basically it uses mesh, star and cluster topologies. They are inexpensive, general purpose, self-organizing and a robust wireless technology.. ZigBee is based on IEEE 802.15.4 standard. To achieve low power consumption, transmission distance is restricted to 10-100m distance. Also to transmit the data over long distances, we normally pass the data through a mesh network of intermediate devices. Commonly ZigBee is used in applications that have long battery life and network security.

Working of ZigBee: The physical layer of ZigBee is supported by the 802.15.4 specification. The particular may be a bundle based radio convention planned for ease, battery-worked gadgets. The convention permits gadgets to impart during a mixture of system topologies and may have battery life enduring a couple of years. The Zigbee convention has been made and endorsed by part organizations of the Zigbee Alliance. In more than 300 heading semiconductor producers, engineering firms, OEMS and administration organizations contain the Zigbee Alliance enrollment. The Zigbee convention was intended to offer an easy to-utilize remote information result portrayed by secure, solid remote system architectures. The Zigbee convention is meant to impart information through unfriendly RF situations that are normal in business and modern applications.

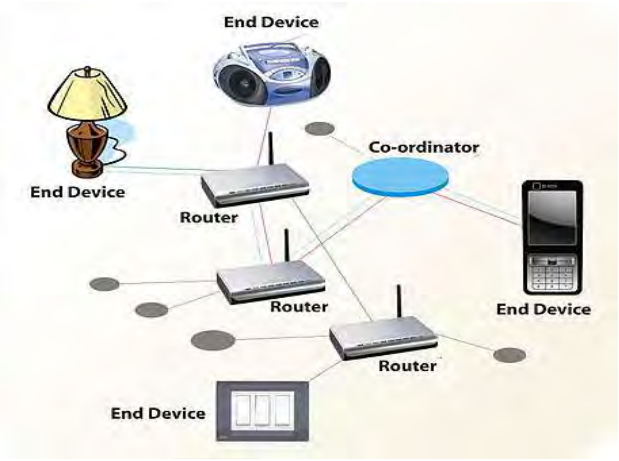

Fig 4: Operating modes of Zigbee

Figure 4 shows three operating modes of Zigbee: Zigbee router, Zigbee Coordinator(ZC) and Zigbee end device (ZED) Zigbee Router: this is often an intermediate format of application that acts sort of a data router, where the info are often transferred from one device to a different using the wireless networks.

Zigbee Coordinator (ZC): The ZC is recognized to the basis of this network tree because it acts a bit like a bridge for this suite with the opposite networks. Using ZC one can explore a plethora of data about network, which makes it the last word Trust Centre where users can get answers about their queries that are related to Zigbee.

Zigbee End Device (ZED): This is entitled with a set of characters that helps the user to connect to the parent node of the system (the parent node can be either the router or the coordinator). Only thing about ZED is that it doesn't have any functions for relying the info from other devices, but the inter-relationship of nodes allows you to get sleep mode where one can significantly increase the battery lifetime of the

device.

The Advantages of Zigbee is it is cheap and easy to utilize networks. Zigbee has a very long battery life. Zigbee is secured and used globally. Zigbee network supports >64000 nodes in network with low latency. The product, accessibility to broader markets, interoperability and vendor independence. Zigbee is employed in industrial quite environment and also for building automation. Zigbee has very long primary battery life, also dynamic and static mesh and star network.

Disadvantages of Zigbee is it cannot access in mobile phones because of its hardware size. Zigbee network only supports 20-250 bandwidth size. Zigbee only supports those application which has only short range area. Zigbee network supports large number of nodes. Zigbee stack size is very less [3] [4]

D. Wi-Fi

Wi-Fi (Wireless Fidelity) is a technology that allows many electronic devices to exchange data or connect to the internet wirelessly using radio waves. The Wi-Fi Alliance defines Wi-Fi devices as any "Wireless Local Area Network (WLAN) products that are supported the Institute of Electrical and Electronics Engineers' (IEEE) 802.11 standards. The key advantage of IEEE 802.11 devices is that they permit less costly deployment of Local Area Networks (LANs). For places where running cables to each device isn't practical, like outdoor areas and airports, they will host wireless LANs. Wi-Fi uses Wireless Adapter of a PC to translate data to radio signal and transmits it using antenna. Wireless router is used by Wii-Fi to receive and decode the signal. Also, it helps to send the information to Internet using physical and Ethernet connection. Figure 5 shows architecture of wiFi.

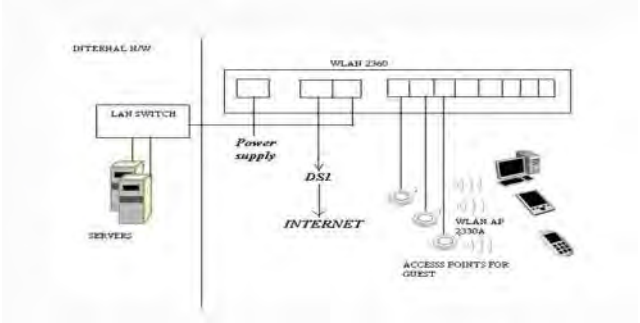

Figure 5: Architecture of WiFi

Wi-Fi uses very high frequency in comparison to other wireless communication methods, lies within the range of two .4 GHz or maybe higher frequency, such as, 5 GHz and thus the signal can carry more data. The 802.11 standard in which Wi-Fi is defined, has a few sub versions [7].

(a). 802.11a

Transmission frequency in 802.11a standard is 5 GHz. It improves the data speed up to 54 megabits per second. 802.11a standard uses orthogonal frequency-division multiplexing (OFDM). In this technology, radio wave is split into several sub-signals before they reach a receiver.

(b). 802.11b

This is the slowest and least expensive method. In 802.11b, the quality transmission frequency is 2.4 GHz and features a rate of 11 megabits per second.

(c). 802.11g

802.11g uses same transmission frequency as that of 802.11b, that is, 2.4 GHz. But its rate is extremely high since, it uses orthogonal frequency-division multiplexing (OFDM), that is, 54 megabits of knowledge per second.

(d). 802.11n

802.11n is the most widely used standard. It supports a data rate of 140 megabits per second. The technology is backward compatible with all the standards mentioned above.

Advantages of WiFi

• Convenience

The wireless nature of such networks allow users to access network resources from nearly any convenient location within their primary networking environment

(a home or office). With the increasing saturation of laptop-style computers, this is often particularly relevant.

• Mobility

With the emergence of public wireless networks, users can access the web even outside their normal work environment. Most chain coffee shops, for instance, offer their customers a wireless connection to the web at little or no cost.

• Productivity

Users connected to a wireless network can maintain an almost constant affiliation with their desired network as they move from place to put . For a business, this suggests that an employee can potentially be more productive as his or her work are often accomplished from any convenient location.

• Deployment

Initial setup of an infrastructure-based wireless network requires little quite one access point. Wired networks, on the opposite hand, have the extra cost and complexity of actual physical cables being run to numerous locations (which can even be impossible for hard-to-reach locations within a building).

• Expandability

Wireless networks can serve a suddenly-increased number of clients with the prevailing equipment. In a wired network, additional clients would require additional wiring.

• Cost

Wireless networking hardware is at the worst a modest increase from wired counterparts. This potentially increased cost is nearly always quite outweighed by the savings in cost and labor related to running physical cables.

Disadvantages of WiFi

• Security

To combat this consideration, wireless networks may prefer to utilize a number of the varied encryption technologies available. Some of the more commonly utilized encryption methods, however, are known to possess weaknesses that a fanatical adversary can compromise.

• Range
The typical range of a standard 802.11g network with standard equipment is on the order of tens of meters. While sufficient for a typical home, it'll be insufficient during a larger structure. To obtain additional range, repeaters or additional access points will need to be purchased. Costs for these items can add up quickly.
• Reliability
Like any frequency transmission, wireless networking signals are subject to a good sort of interference, also as complex propagation effects that are beyond the control of the network administrator.
• Speed
The speed on most wireless networks (typically 1-54 Mbps) is way slower than even the slowest common wired networks (100Mbps up to many Gbps). However, in specialized environments, the throughput of a wired network could be necessary.

D. WiMax

WiMAX (Worldwide Interoperability for Microwave Access) is gaining more popularity because it is faster and does not require any sort of wired connections[5]. WiMAX techonology provides 30 to 40 megabit-per-second data rates. It makes use of OFDM (Orthogonal Frequency Division Multiplexing) and MIMO (Multiple Input Multiple Output) technology for its function. WiMAX applications Provides mobile broadband connectivity, Telecommunications, Data, and ITPV services. WiMax can be used as a source of Internet connectivity and is better for Metering and Smart grids

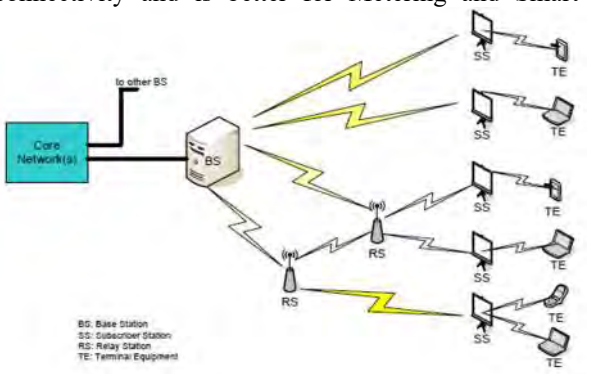

Figure 6: Wi-Max network architecture

WiMAX architecture [8] consists of two types of fixed (non mobile) stations i.e.Subscriber Stations (SS) and Base Stations(BS). Subscriber station serves as a building (business or residence) and Base station (BS) Provides connection to public network and provide Subscriber Station with first-mile access to public networks The communication path between SS and BS has two directions: Uplink direction (from SS to BS) and Downlink direction (from BS to SS)

Advantages of WiMax

A very high speed voice and data transferis supported over longer distances by WiMax. A Single WiMax BS serves hundreds of users. Using WiMax high speed can be achieved. Higher coverage range and cellular like performance are achieved with mobile wimax.

Disadvantages of WiMax

LOS (Line of Sight) connection is needed for subscribers located at the far distant from the WiMAX BS.Bad weather conditions such as rain will interrupt the wimax signal and often cause loss of connection.
Wimax is high power consuming technology and requires significant electrical support. High initial cost is required because it isn't backward compatible with any of the wireless cellular technologies..

E. Gi-Fi

GiFi (Gigabit wireless) is a wireless communication at data rate of about one million bits (gigabits) per second.GiFi is the first integrated transceiver integrated on one chip that permits transfer of videos and audios at a speed of 5 GB per second. GiFi is understood to possess ten times the present maximum wireless transfer rate during a range of ten meters [6]. GiFi as a wireless technology features a number of applications are often utilized in different places and devices that include wireless networks, smartphones, mm-waves and media access control. Due to high power consumption, low range frequency operation and slow rates of Wi-Fi and bluetooth, GiFi is used. GiFi as a wireless technology makes use of a really tiny antenna which will be employed by mobile devices and it's an excellent tool for wireless home equipment. GiFi aims at solving the low rate problems because it has an integrated receiver and transmitter on one chip. Gi-Fi provides better data transfer rate with minimum power consumption. GiFi offers the deployment of service within a few minutes, where other technologies may take hours.. GiFi wireless technology incorporates one subscriber station that's made available for various access points. It supports IEEE 802.15.3C standard millimeter wave wireless networks that are used majorly for communication between computer devices.

The subscriber station basically comprises of a little antenna that's mounted on the highest so as to support the sunshine of sight operations. In order to avoid any interference, it transmits multiples signals across the trail of transmission, at an equivalent time having different frequencies.

Working of GiFi.

Using time division duplex for receiving and transmission the data files are converted to RF 60GHz range by making use of two mixers from an IF range. The output is then stored during a power amplifier, that stores a millimeter wave antenna within. The RF incoming data is first converted to IF signal at 5GHz then converted to a traditional data range. A heterodyne construction is employed for this procedure to avoid any leakage due to direct conversion. With the supply

of a 7GHz spectrum, the info gets transferred during a matter of seconds. GiFi is small sized. The chip measures approximately 5mm on each side, incorporates a small antenna and makes use of a 60 GHz spectrum. Therefore, GiFi offers high mobility and portability. It also provides better coverage area. GiFi can be used in several applications like, household and office appliance, inter vehicle communications etc.

III. COMPARATIVE STUDY

Table 1 shows compassion of wireless technologies like, Buetooth, Zigbee, Wifi, WiMax anf Gi-fi with respect different parameters such as IEEE specification, frequency range, data transfer rate, coverage, cost, topology, type of modulation and application areas and amount of power consumption. We cannot draw a conclusion of which one is better, as superiority of these technologies are application dependent.

Table 1: Comparative study of emerging wireless standard

Features	**Bluetooth**	**Zigbee**	**WiFi**	**WiMax**	**GiFi**
IEEE specification	802.15.1	802.15.4	802.11a/b/g	802.16	802.15.3C
Frequency Range	2.4 GHz to 2.483 GHz	2.4 GHz	57 to 64 GHz	2.5 to 3.5Ghz/5.8Ghz	2.4 GHz and/or 5 GHz
Data transfer rate or speed	1Mbps	250kbps	11Mbps	1Ggbps	5 Ggbps
Operating range or coverage range	10 meters	10-100meters	100 meters	50Kmeters	10 meters
Cost	Low	Medium	Low	High	High
Operating frequency	2.4GHz	868/915MHZ ; 2.4 GHz	2.4GHz;5GHz	2.3-3.5GHz	57 to .64GHz
Network topology	Adhoc, P2P, star,Mesh	Mesh, star,cluster	Infrastructure, Ad Hoc,IP&P2P	Infrastructure IP network	Infrastructure; Ad Hoc,Mesh, star,cluster
Modulation type	FHSS/GFSK	BPSK; QPSK	DSSS	QAM	BPSK
Application	WPAN	WPAN	Wireless LAN, Internet	Wireless MAN, Internet	WPAN, inter vehicle communications
Power consumption	5mW	10.2mW	10mW	~5mW	<2mW

IV. CONCLUSION

In today's world, emerging wireless technologies are used in numerous applications with strong and faster information transmission. In this paper, overview of different wireless standards are discussed along with their advantages and limitations. Suitability of these standards depends on the applications. Comparative study of technologies is shown with respect to various parameters.

Internet of Things (IoT) and Radio Frequency Identification (RFID) Technology- A Survey

Mrs.Apeksha Waghmare
Thakur College of Engineering & Technology, TCET, Mumbai, India

Abstract— **The significance and futuristic deployment of the Internet of Things (IoT) are broadly reviewed and conveyed in this paper. The "Internet of things" (IoT) is fetching an increasingly growing topic of discussion everywhere around the world and has a huge impact on our lives. Radio Frequency Identification system (RFID) on the other hand is the usual technology that supports identifying objects through radio waves. This technology is called the Internet of Things (IoT). RFID is often seen as a prerequisite for the IoT. This paper introduces the technologies of RFID and IOT along with its applications and challenges.**

Keywords- Internet of Things (IoT), Radio Frequency Identification(RFID),Future Technologies

I. INTRODUCTION

In the IoT, environmental and existence things, additionally named "things", "objects", or "machines" are increased with computing and communication technology and be a part of the communication framework. In alternative words, the net of Things (IoT) is that the network of the physical objects or things embedded with natural philosophy, software, sensors, network property, that permits these objects to gather and exchange information. The interactions are tired varied ways in which i.e. machine to machine (M2M), person to person, person to machine, machine to person and then on. Connecting objects may be wireless, like the frequency identification (RFID), or sensing element radio technologies that provide, severally, identification of things and sensing of the setting. The affiliation could also be wired, like transmission line communication (PLC). PLC offers information transport over electrical media and has pioneered the in-home networking property of electronic client devices e.g. good fridges, smart TVs, good heaters, etc. In the IoT, distinguishing, sensing and mechanically deciding and causative are the newest functionalities that may alter present computing and networking. Therefore, sensors and RFID, among alternative technologies, are progressively deployed and can so permit integration of the real-world setting within the networked services. IoT can connect heterogeneous devices and can be dense, connecting billions of objects. An Internet-, IP- (Internet protocol) or TCP/IP (transport management protocol/Internet protocol) -based model stands in the middle of the IoT.

II. RFID TECHNOLOGY

Radio Frequency Identification system (RFID) is associate automatic technology and aids machines or computers to spot objects, record information or manage individual targets through radio waves [1]. The RFID technology was initial appeared in 1945, as associate spying tool for the state, that retransmitted incident radio waves with audio data. Similarly, the IFF (Identification Friend or Foe) electrical device developed within the UK was habitually utilized by the allies in war II to spot craft as a friend or foe. A generally RFID system has consisted of tags (transmitters/ responders) and readers (transmitters/receivers) [2]. The tag may be a semiconductor unit connected with associate antenna, which might be connected to associate objects because of the symbol of the article. The RFID reader communicates with the RFID tag victimization radio waves. The most advantage of RFID technology is that the automatic identification and information capture that guarantees wholesale changes across a broad spectrum of business activities and aims to scale back the price of the already used systems like bar codes. Though RFID technology was discovered a few years ago, it's advanced and evolved solely throughout the last decade since the price has been the most limitation all told implementations. As foretold [3], RFID is one of the massive opportunities in data technology, which can modify the planet broadly speaking and deeply. Once the RFID readers abided by applicable communication protocols area unit connected to the terminal of the web, the readers distributed throughout the planet will determine, track and monitor the objects connected with tags globally, mechanically, and in the period, if needed. This can be the alleged web of Things (IoT). The IoT refers to unambiguously classifiable objects (things) associated with their virtual representations in an Internet-like structure. The IoT initially became widespread through the Auto-ID Center and connected market analyst's publications. RFID is commonly seen as a necessity for the IoT. If all objects of the standard of living were equipped with radio tags, they may be known and inventoried by computers.

III. IoT AND RFID TECHNOLOGY

Internet of Things Internet of Things (IoT) is a global network infrastructure, linking physical and virtual objects through the exploitation of data capture and communication capabilities. It will offer specific object identification, sensor, and connection capability as the basis for the development of independent cooperative services and applications.

These will be characterized by a high degree of autonomous data capture, event transfer, network connectivity, and interoperability.

The IoT system architecture is generally divided into three layers: the perception layer, the network layer, and the service layer (or application layer), as shown in Figure.1

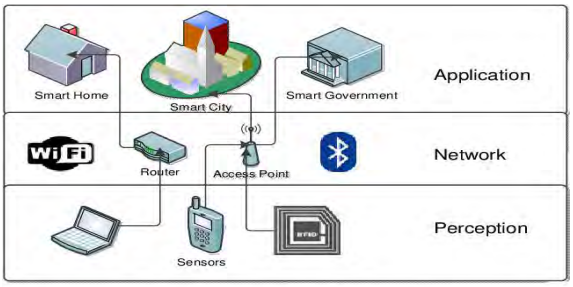

Figure 1. Three-layer IoT architecture.

Perception layer: It is the information origin and the core layer of IoT. All kinds of information of the physical world used in IoT are perceived and collected in this layer, by the technologies of sensors, wireless sensors network (WSN), tags and reader-writers, RFID system, camera, global position system (GPS), intelligent terminals, electronic data interface (EDI), objects, and so like.

Network layer: This layer, also called the transport layer, including access network and core network, provides transparent data transmission capability. By the existing mobile communication network, radio access network, wireless sensor network (WSN) and other communications equipment, such as global system for mobile communications (GSM), general packet radio service (GPRS), worldwide interoperability for microwave access (WiMax), wireless fidelity (WiFi), Ethernet, etc., the information form perception layer can be sent to the upper layer. At the same time, this layer provides an efficient, reliable, trusted network infrastructure platform to the upper layer and large scale industrial application [4].

Service layer: This layer, also called the application layer, includes the data management sub-layer and application service sub-layer. The data management sub-layer provides processing complex data and uncertain information, such as restructuring, cleaning and combining, and provides directory service, market to market (M2M) service, Quality of Service (QoS), facility management, geomatics, etc. by service-oriented architecture (SOA), cloud computing technologies, and so on. The application service sub-layer transforms information into content and provides a good user interface for upper-level enterprise applications and end-users, such as logistics and supply, disaster warning, environmental monitoring, agricultural management, production management, and so forth.

IV. APPLICATIONS OF RFID TECHNOLOGY

The functions of the RFID system generally include three aspects: monitoring, tracking, and supervising. Monitoring generally means to be aware of the state of a system, by repeated observing the particular conditions, especially to detect them and give warning of the change. Tracking is the observation of persons or objects on the move and supplying a timely ordered sequence of respective location data to a model. Supervising is the monitoring of the behaviors, activities, or other changing information, usually of people. It is sometimes done in a secret or inconspicuous manner. The RFID applications are numerous and far-reaching. The most interesting and successful applications include those for supply chain management, production process control, and object tracking management. Now RFID has been gradually and broadly used in the following fields.

Logistics and Supply
Manufacturing
Agriculture Management
Health Care and Medicine
Marine Terminal Operation
Military and Defense
Payment Transactions
Environment Monitor and Disaster Warning
Transportation and Retailing
Warehousing and Distribution Systems
Other applications in many walks of life businesses

For instance, in Manufacturing, RFID technology offers several applications in the automotive industry. An RFID based antitheft vehicle immobilizer is a protective device installed in many cars. RFID also holds great promise for the assembly and manufacturing processes of automobiles, in particular, for flexible and agile production planning, spare parts, and inventory management. RFID technology not only helps to automate the whole assembly process in which a significant reduction in cost and shrinkage can be achieved, but it also offers improved services to automobile users that include more efficient replacement part ordering and automated generation of maintenance reminders. The benefits that RFID offers to the automotive industry, both to the production process as well as to end-users, are visibility, traceability, flexibility, and added security.

V. CHALLENGES OF RFID TECHNOLOGY

Although promising, RFID is not without its challenges, which arise from both a technological and usage point of view. The functions of the RFID system usually embody 3 aspects: observance, tracking, and management. observance usually means that to remember of the state of a system, by continual observant the actual conditions, particularly to notice them and provides warning of the amendment, following is that the observation of persons or objects on the

move and supply a timely ordered sequence of various location information to a model. Management is that the observance of the behaviors, activities, or alternative ever-changing data, typically of individuals. It's generally worn out a secret or invisible manner. The RFID applications square measure various and extensive. The foremost fascinating and productive applications embody those for provide chain management, production method management, and object following management. Currently, RFID has been rising by step and broadly speaking employed in the subsequent fields.

Production
Agriculture M
Health Care and medication
Marine Terminal Operation
Military and Defense
Payment Transactions
surroundings Monitor and Disaster Warning
Transportation and marketing
deposit and Distribution Systems
alternative applications in several walks of life businesses

For instance, in producing, RFID technology offers many applications within the automotive business. RFID based anti-theft vehicle immobilizer protecting device can be installed in cars. RFID conjointly holds nice promise for the assembly and producing processes of vehicles, specifically, for versatile and agile production coming up with, spare components, and inventory management. RFID technology not solely helps to change the entire assembly method within which a major reduction in price and shrinkage will be achieved, however, it conjointly offers improved services to automobile users that embody additional economical replacement half ordering and automatic generation of maintenance reminders. The advantages that RFID offers to the automotive business, each to the assembly method furthermore on end-users, square measure visibility, traceability, flexibility, and other security.

A. Collision Problems

Communication between tags and readers area unit inherently prone to magnetism interference, coincidental transmissions in RFID result in collisions as readers and tags usually treat identical wireless channel. Therefore, economical anti-collision protocols for distinctive multi-tags at the same time area unit of nice importance for the event of large-scale RFID applications [1]. Many anti-collision protocols for RFID tag identification are projected, like question tree protocol (QT), binary tree protocol (BT), frame slotted ciao protocol (FSA), etc., however, most legendary protocols exhibit associate overall identification potency diminutive than five hundredths. Besides, uniform ID distribution has continually been assumed within the past. What is more, it helps remark the simplest performing arts options of RFID tag identification protocols, and for planning new and higher protocols. In [1], we tend to gift a unique and economical anti-collision protocol for RFID tag identification, i.e., collision tree protocol (CT), that outperforms all the opposite anti-collision protocols projected up to now.

B. Security and Privacy issues

Security and privacy problems [5] of RFID tags will affect each organization and people. Unprotected tags could also be at risk of eavesdropping, traffic analysis, spoofing or denial of service and plenty of additional. Even unauthorized readers will affect privacy by accessing tags while not enough access management, albeit the tag content is secure then additionally it is often caterpillar-tracked by the certain tag responses; "location privacy" is often stricken by a traffic analysis attack. the associate aggressor may also threaten the safety of systems, which depends on RFID technology through the denial of service attack. Due to its value and resource constraint limitations, RFID several researchers and scientists work to implement affordable security and privacy protocol to extend the relevance. Countless light-weight solutions are projected for RFID, however, they're still dear and at risk of security and don't resolve the safety problems. Thus there's an honest analysis scope within the field of planning associate economical ultra-lightweight scientific discipline protocol for affordable RFID systems.

VI. CONCLUSION

The IoT uses a spread of data sensing identification device and knowledge process instrumentation, like RFID, WSN, GPRS, etc. combining with the net to make an intensive network to info and intelligence the entities or objects. This paper analyzes the applications and challenges of RFID technology, which is the necessary and foundational element of IoT.

Responsible and Scalable Approach for Secure Multi-Owner Data Sharing for Dynamic Groups in the Cloud: A Survey

Swati Abhang
Thakur College of Engineering & Technology, Mumbai, India
swatiabhang@gmail.com.

Abstract: **In Today's world Cloud Computing which moves the application software and databases to the centralized large data centers, where the management of the data and services may not be fully trustworthy. Several trends are opening up the era of Cloud Computing, which is an Internet-based development and use of computer technology. One of the biggest concerns with cloud data storage is that of data integrity verification at untrusted servers. To preserve data privacy, a basic solution is to encrypt data files, and then upload the encrypted data into the cloud. To resolve this problem recently the best efficient method MONA presented for secured multi owner data sharing in However we identified some limitations in the same approach in terms of reliability and scalability. Hence in this paper we are further extending the basic MONA by adding the reliability as well as improving the scalability by increasing the number of group managers dynamically.**

Keywords– Cloud Computing, dynamic groups, data sharing, reliability, integrity, scalability.

I. INTRODUCTION

A) What is cloud computing?

Cloud computing is one of the greatest platform which provides storage of data in very lower cost and available for all time over the internet Cloud computing is Internet-based computing, whereby shared resources, software and information are provided to computers and devices on demand. Several trends are opening up the era of Cloud Computing, which is an Internet-based development and use of computer technology. Cloud computing means more than simply saving on IT implementation costs. Cloud offers enormous opportunity for new innovation, and even disruption of entire industries. Cloud computing is the long dreamed vision of computing as a utility, where data owners can remotely store their data in the cloud to enjoy on-demand high-quality applications and services from a shared pool of configurable computing resources.

B) Basic Concept

Maintaining the integrity of data plays a vital role in the establishment of trust between data subject and service provider. Although envisioned as a promising service platform for the Internet, the new data storage paradigm in "Cloud" brings about many challenging design issues which have profound influence on the security and performance of the overall system. One of the biggest concerns with cloud data storage is that of data integrity verification at untrusted servers. What is more serious is that for saving money and storage space the service provider might neglect to keep or deliberately delete rarely accessed data files which belong to an ordinary client. Consider the large size of the outsourced electronic data and the client's constrained resource capability, the core of the problem can be generalized as how can the client find an efficient way to perform periodical integrity verifications without the local copy of data files. To preserve data privacy, a basic solution is to encrypt data files, and then upload the encrypted data into the cloud [2]. CS2 provides security against the cloud provider, clients are still able not only to efficiently access their data through a search interface but also to add and delete files securely. Several security schemes for data sharing on untrusted servers have been proposed secure file system designed to be layered over insecure network and P2P file systems such as NFS, CIFS, Ocean Store, and Yahoo! Briefcase.

C) Advantages and Disadvantages of Cloud Computing:

Advantages: -
24/7 Support
Easy to Maintain.
Secure Storage and Management
Location Independent
Less cost (Pay-as-per-you-Use).
high level computing
Personalized Backup and recovery.
Remote access.
Green computing.
Disadvantages: -
Lack of control
Security and privacy.

b) S. Kamara and K. Lauter [3] in this paper consider the problem of building a secure cloud storage service on top of a public cloud infrastructure where the service provider is not completely trusted by the customer. They describe, at a high level, several architectures that combine recent and non-standard cryptographic primitives in order to achieve our goal. Survey the benefits such architecture would provide to both customers and service providers and give an

overview of recent advances in cryptography motivated Higher operational cost.Reliability

II. LITERATURE SURVEY

In the literature survey we are going to discuss some existing technique for cloud.

a) M. Armbrust, A. Fox, R. Griffith, A.D. Joseph, R.H. Katz, A. Konwinski, G. Lee, D.A. Patterson, A. Rabkin, I. Stoica, and M. Zaharia [2] the data centers hardware and software is what we will call a cloud. When a cloud is made available in a pay-as-you-go manner to the general public, they call it a public cloud; the service being sold is utility computing. They use the term private cloud to refer to internal data centers of a business or other organization, not made available to the general public, when they are large enough to benefit from the advantages of cloud computing that we discuss here. Thus, cloud computing is the sum of SaaS and utility computing, but does not include small or medium-sized data centers, even if these rely on virtualization for management. People can be users or providers of SaaS, or users or providers of utility computing. They focus on SaaS providers (cloud users) and cloud providers, which have received less attention than SaaS users.attribute-based encryption (ABE), proxy re-encryption, salient properties of user access privilege confidentiality and user secret key accountability.

d) E. Goh, H. Shacham, N. Modadugu, and D. Boneh [5] the use of SiRiUS is compelling in situations where users have no control over the file server (such as Yahoo! Briefcase or the P2P file storage provided by Farsite). They believe that SiRiUS is the most that can be done to secure an existing network file system without changing the file server or file system protocol. Key management and revocation is simple with minimal out-of-band communication. File system freshness guarantees are supported by SiRiUS using hash tree constructions. SiRiUS contains a novel method of performing file random access in a cryptographic file system without the use of a block server. Extensions to SiRiUS include large scale group sharing using the NNL key revocation construction. e)R. Lu, X. Lin, X. Liang, and X. Shen [6] in this paper secure provenance is of paramount importance to the flourish of cloud computing, yet it is still challenging today. In this paper, They formally defined the secure provenance and the corresponding security model in cloud computing. Then, in proposed a concrete secure provenance SP scheme based on the bilinear pairings, and used the provable security technique to prove its security in the standard model. Due to its comprehensive security features, the proposed SP scheme provides trusted evidences for data forensics in cloud computing and thus pushes the cloud computing for wide acceptance to the public.

f) B. Waters [7] presented the first cipher text-policy attribute-based encryption systems that are efficient, expressive, and provably secure under concrete assumptions. All of our constructions fall under a common methodology of embedding an LSSS challenge matrix directly into the public parameters. Our constructions provide a trade off in terms of efficiency and the complexity of assumptions.

g) V. Goyal, O. Pandey, A. Sahai, and B. Waters [8] they develop a new cryptosystem for One-grained sharing of encrypted data that call Key-Policy Attribute-Based Encryption (KP-ABE). In cryptosystem, cipher texts are labelled with sets of attributes and private keys are associated with access structures that control which cipher texts a user is able to decrypt. They demonstrate the applicability of our construction to sharing of audit-log information and broadcast encryption. Our construction supports delegation of private keys which subsumes Hierarchical Identity-Based Encryption (HIBE).

h) A. Fiat and M. Naor [9] they introduce new theoretical measures for the qualitative and quantitative assessment of encryption schemes designed for broadcast transmissions. The goal is to allow a central broadcast site to broadcast secure transmissions to an arbitrary set of recipients while minimizing key management related transmissions. They present several schemes that allow centers to broadcast a secret to any subset of privileged users out of a universe of size so that coalitions of users not in the privileged set cannot learn the secret.

i)B. Wang, B. Li, and H. Li, [10] in this paper, we propose Knox, a privacy-preserving auditing scheme for shared data with large groups in the cloud. They utilize group signatures to compute verification information on shared data, so that the TPA is able to audit the correctness of shared data, but cannot reveal the identity o f the signer on each block. With the group manager's private key, the original user can efficiently add new users to the group and disclose the identities of signers on all blocks. The efficiency of Knox is not affected by the number of users in the group.

j) D. Pointcheval and J. Stern [11] As Explained in the Introduction, there w ere several proposals for pro v ably secure Signature schemes. However, in all cases, the security was at the cost of a considerable loss in terms of efficiency. Concerning blind signatures, Damgard, Ptzmann and Waidner and more recently at Crypto '97, Juels et al. Have presented some blind signature schemes with a complexity-based of security. Again, the security y is at the cost of inefficiency. In the weaker setting by the random oracle model, we have provided security arguments for practical and even efficient digital signature schemes and blind signature schemes. On the ground of our reductions, one can justify realistic parameters, even if they are not optimal. Further improvements are expected particularly in the case of blind signatures where it should be possible to

obtain a reduction polynomial in the size of the keys and in the number of interactions with the signer

III. EXISTING SYSTEM

In the literature study we have seen many methods for secure data sharing in cloud computing, however most methods failed to achieve the efficient as well as secure method for data sharing for groups. To provide the best solutions for the problems imposed by existing methods, recently the new method was presented called MONA [1]. This approach presents the design of secure data sharing scheme, Mona, for dynamic groups in an untrusted cloud. In Mona, a user is able to share data with others in the group without revealing identity privacy to the cloud. Additionally, Mona supports efficient user revocation and new user joining. More specially, efficient user revocation can be achieved through a public revocation list without updating the private keys of the remaining users, and new users can directly decrypt files stored in the cloud before their participation. Moreover, the storage overhead and the encryption computation cost are constant. Therefore practically in all cases MONA outperforms the existing methods.

Fig 3.1 Existing System Model

3.1 Disadvantages of Existing System

However as per reliability and scalability concern this method needs to be workout further as if the group manager stop working due to large number of requests coming from different groups of owners, then entire security system of MONA failed down.

IV. PROPOSED SOLUTION

Thus to achieve the reliable and scalable MONA approach, in this project we are presenting the new framework for MONA called as RS-MONA (Reliable Scalable-MONA). In this method we are further presenting how we are managing the risks like failure of group manager by increasing the number of backup group manager, hanging of group manager in case number of requests more by sharing the workload in multiple group managers. This method claims required efficiency, scalability and most importantly reliability.

Fig 4.1 Proposed System Model

4.1Advantage of Proposed System

To overcome the disadvantage of existing system MONA, the proposed RS-MONA is if the group manager stop working due to large number of requests coming from different groups of owners, then backup group manager will remains available.

V. SYSTEM REQUIREMENT & SPECIFICATION

5.1 Software Requirements:
Front End: Java
Tools Used: Eclipse/Net beans
Operating System: Windows 7
5.2 Hardware Requirements:
Processor: Pentium IV 2.6 GHz
Ram: 512 Mb
Monitor: 15" Colour Hard Disk: 20 Gb Floppy Drive: 1.44 Mb Keyboard: Standard 102 Keys Mouse: 3 Button

VI. CONCLUSIONS

In conclusion, cloud computing is very attractive environment for business world in term of providing required services in a very cost effective way. However, assuring and enhancing security and privacy practices will attract more enterprises to world of the cloud computing In Thus to achieve the reliable and scalable MONA approach; in this paper we are presenting the new framework for MONA called as RS-MONA (Reliable Scalable-MONA). In this method we are further presenting how we are managing the risks like failure of group manager by increasing the number of backup group manager, hanging of group manager in case number of requests more by sharing the workload in multiple group managers. This method claims required efficiency, scalability and most importantly reliability. Extensive analyses show that our proposed scheme satisfies the desired security requirements and guarantees efficiency as well.

Error Control in Data Link Layer-A Roadmap

Chitvan Mehrotra, Sowmyashree
Thakur college of engineering and technology, Mumbai, India
chitvanmehrotra@gmail.com, sshree87@gmail.com

Abstract—**In today's world, accuracy is the most important key of any data transfer on a computer network. We access a network on this parameter only and we expect that the receiver receives the same data as sent by the sender. If the data is changed while sending or is hampered when the data is sent from one station to the other we would not accept that computer network as a reliable one. In this paper we would highlight the datalink layer of the OSI model and would discuss in detail the error control mechanisms in it. When data is sent from one node to the other how do we detect errors and how do we correct it in case the data has been hampered.**

Keywords – Error control; Error detection; Error correction; Data link layer error control mechanisms.

I. INTRODUCTION

Data link layer has two main subparts or sublayers having different functionalities, they are namely logical link control (LLC) and media access control (MAC)

Logical Link Control: It deals with the various protocols of the network, flow-control mechanisms, and error control techniques on the network. It tries to establish the best possible link between the users or stations [1]

Media Access Control: It deals with actual control of media, how the data has to be sent on the network and in case of any clashes on the network which station would get access on the transmission media is decided by this sublayer of the data link layer.

Data link layer handles very complex functions on our computer network. First of all it works for abstraction and hides the complex details of the hardware from other layers, various other functions served by the Data link layer are as follows:-

- Framing

The data link layer receives the packets of the above network layer and changes them into frame structure, after the frames are made this layer has the responsibility of passing these packets to the hardware which lies beneath in the system.

- Synchronization

When the frames made by this layer are sent over in the computer network it has the responsibility to make sure that the receiver and sender are both synchronised.

- Error Control

When we are sending data there are chances that some bits of the data may change during the transmission from one station to the other because there are various errors which can be introduced in the system. So the data link layer has the responsibility to try identifying these errors which have occurred and try correcting them as well [2] [3]
Flow Control

The speed of the data sent over the channel should be same as the speed the receiver receives because if there will be difference in the speeds there can be problems in the system and congestion can also take place.

- Multi-Access

When a single channel is being used by multiple users in the system then various multiple access protocols can be used which are monitored by this layer. CSMA/CD is used for this purpose.

In this paper we would discuss about the error control functionality of the data link layer in detail. So to understand error control we first need to understand what kind of errors can be introduced when we are sending data from one end to the other Types of Errors [4]

There may be three types of errors:

- Single bit error

If only single or one bit of the frame of data is hampered or changed then it is a single bit error**.**

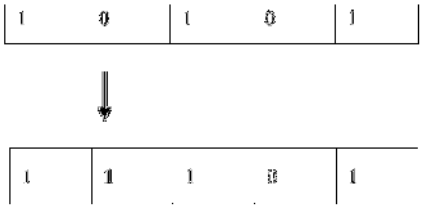

Figure 1: single bit error in the data stream

- Burst error

If there is error in more than one bits in the data being sent then it is called burst error where the

length of the burst is from the first bit where the data got corrupted to the last bit.

If we have such corrupt data being received by the received we have to apply certain mechanism to detect these errors and finally correct them [5]

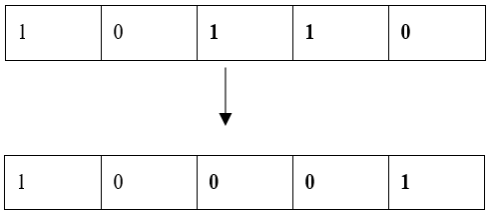

Figure 2: burst error in a data stream

II. ERROR DETECTION

Error control mechanism may involve two possible ways:

- Error detection
- Error correction

There are three most common types of error detection techniques or schemes:-parity check, checksum and cyclic redundancy check (CRC).We would now discuss them one by one

a) Parity check

Parity of a string can be determined by the number of 1's present in any data string or rather binary string which consists of 0's and 1's.The total number of 1's determine the parity of that string.[6]

We add a bit known as the parity bit or it is sometimes also called a check bit to make sure that the total count of the 1's is either even or odd number.Parity bits is the simplest way to detect error although it cannot be used to correct error it can only be used to detect it.Let us take one example:-

if a system checks the data 0111001 for even parity, the parity bit should be 0 if the data is correct because in this case the number of 1's is already even.If we had to produce the same data with odd parity then the parity bit would be 1 to make the number of 1's odd in the string

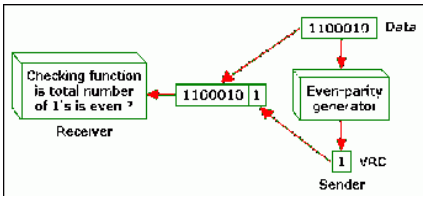

Figure 3: Checking even parity in the data

Here the data at the sender side was 110010 and we are using even parity as the number of 1's in the above string are 3 to make it even we will add 1 to the data and transmit it to the other end. [7]. The receiver will also

Original Data	Even Parity	Odd Parity
00000000	0	1
01011011	1	0
01010101	0	1
11111111	0	1
10000000	1	0
01001001	1	0

Figure 4: Parity checker

b) Checksum

- In this scheme we first divide the data string into K segments each of them having M number of bits.
- The next step is to add these segments together using the 1's compliment method, in 1's compliment method if a carry is generated by the addition then it is also added with the sum. So like this we will calculate the sum of all the frames or segments made in step 1.
- Now the sum is complemented and is then sent to the receiver.[8][9]
- At the receiving end again all the data frames are added along with the checksum value. Now this
- Final sum is complemented, if we get all zeroes we say that no error has occurred during transmission of data and the data is accepted. If we do not get all zeroes the data sent by the sender is discarded.

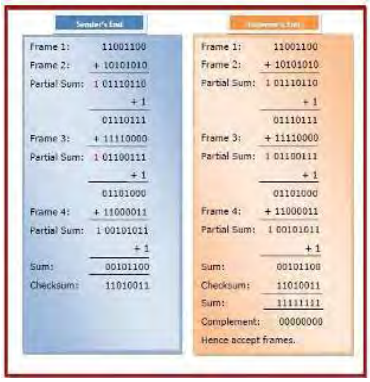

Figure 5: Checksum at sender and receiver

c) CRC

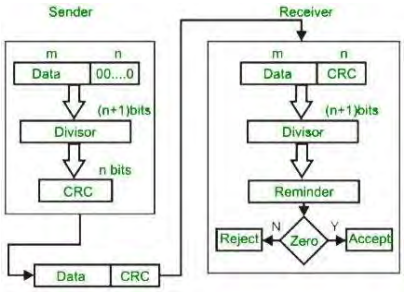

Figure 6: CRC procedure

Another error control technique is cyclic redundancy check in which we mainly perform modulo-2 binary division.
Steps of CRC are as follows:-

Step1-first of all we have to mutually decide a divisor, the sender and the receiver agree to a common divisor which is shared among the parties involved.
Step 2- add (n-1) zeroes at the end of the dividend
Step 3-the data to be sent appended with the the zeroes forms the final dividend
Step 4- Perform the modulo 2 division which is rather an XOR operation and finally we get the result as the remainder. So the remainder of this division is called the CRC. It is added to the data in the end and the whole block is sent to the receiving side.
Step-5 At the receiving end again a modulo 2 division is performed with the data and the divisor predecided by the sender and the receiver.
Step-6 The final step of this entire process is to verify whether the data received was correct or not. If after division we get all zeroes the data received is correct and therefore the data was not hampered during transference. On the other side of this if we do not get all zeroes and we get some other remainder at the receiver end we can easily say that the data was changed during the transmission from one end to the other and it is hampered. But we cannot correct the data from this method we can just tell that the data received is correct or not .[10]

III. CONCLUSION

In this survey paper we have discussed the various error detection techniques in detail. By error detection we actually mean that the data sent from the sender side to the receiving side is correct or not.
[11] As we all know due to noise in the channel or other interferences the data can be hampered when it is being sent over the network. Even the safest of media cannot guarantee 100%error free transfer, because of this reason the role of error detection and correction techniques is important. We have tried to analyse these techniques to understand that even if the data is changed over the network how can we actually detect that the error has occurred.

Framework for Blockchain based Land Registration System.

Sandip Bankar, Neerajkumari Khairwal
Thakur College of Engineering and Technology, Kandivali

Abstract – **Land registration leads to registration of all land transac- tions/deeds undertaken in any geographical jurisdiction of a governing authority. In most countries, these records are maintained with various government and local bodies which at times leads to title disputes and costly litigation. The current land registry system is widespread with corruption and inefficiencies.**

There are many citizens who don't have confidence in the system. There are some situations, where the disaster like fire, flood, and earth- quake destroyed paper records. While many countries and organizations did their best to help to rebuild the nation, there were thousands of plots of land where the rightful owner could not be identified, and in many instances ownerships were in dispute. Hence, there is need of real time record maintenance.

Keywords: Land Records, Blockchain, Revenue Departments.

I. INTRODUCTION

Land is an important resource as its one of a unique due to its location, area, and with increasing population, its interest continues to expand, while its supply is restricted. Access to land (or land rights) has a wide-going effect on jobs, modern, financial, and social development. It has been noticed that individuals with broad rights to arrive are in an ideal situation than the landless, because of better access to business sectors and other financial open doors that accompany arrive rights.

Land ownership is comprehensively characterized by the entrance to a land title. Land title is an archive that decides the responsibility for a resolute property. Having an unmistakable land title secures the privileges of the title holder against different cases made by any other individual to the property. In India, arrive proprietorship is re- solved through different records, for example, deal deeds that are enrolled, property charge papers, government overview records, and so on. [1]

Be that as it may, land record titles in India are indistinct because of different reasons, for example, heritage issues of the zamindari framework, holes in the legitimate struc-ture, and poor organization of land records. This has prompted a few legitimate ques- tion identified with land proprietorship, and influenced the farming and land areas. Such issues have additionally featured the significance of having clear land titles, and an efficient land records system

Land registration for the most part describes matters concerning proprietorship, own- ership or different rights in land can be recorded (normally with an government office or division) to give proof of title, encourage exchanges and to prevent unlawful trans- fer.

Land Administration as characterized as is the way toward deciding, recording and maintaining data about possession, cost and utilization of land, when executing land registration strategies. This incorporates procedures of land enrollment, valuation and the land register. Governments seek to enhance benefits in Land Administration keep on presenting innovation and new advancements in techniques of land registration systems. Different governments have started using various technologies for easy and secure land registration systems [2].

Land registration system becomes successful when there is equal trust in all partners involved in the system. In some countries people have less trust in current land regis- tration system. There are some cases where frauds and corruptions happening in cur- rent land registration systems. [4]

1.1 The requirement of clear land titles

1. *High prosecution*: A World Bank analysis from 2007 states that total land related cases represent 66% of all pending court cases in the country.[5] These land prob-lems incorporate those identified with the legitimacy of land titles and records, and legitimate proprietorship. A NITI Aayog paper recommends that arrive debate by and large take around 20 years to be resolved.[6] Land related cases add to the weight of the courts, tie up land in prosecution, and further effect divisions and tasks that are reliant on these debated land titles.

2. *Agricultural importance*: Land is regularly utilized as guarantee for acquiring loans by people. It has been seen that debated or doubtful land titles restrain supply of capi-tal and credit for agriculture.[7] Small and peripheral farmers, who represent the greater part of the all-out land possessions, and may not hold formal land titles, can't get to systematized credit.[8]

1.2 The Need of Real Time Record Maintenance System

Land records are important from a perspective of land title with one owner, trail of all transactions done regarding the unit and trustworthy system to provide shares of own- ers of units.

Trustworthy system: Many citizens simply don't have confidence in the system. Some are unsure if they legally own a piece of land, even if they have a legitimate sale deed. Others who want to buy a piece of land are not sure if the seller legally owns it.

Fast process: Current system takes one or two months to complete the transaction. There is need of system which could complete transaction in less time.

Decentralized rights: There should be decentralized rights of the sale transac- tions/deeds.

Risk of Multi-owner units: There have been instances where an owner sells same property to multiple buyers at same time, hence, leading to ownership dispute

1.3 Current Challenges:

Data Integration: Currently government officials have data records of only respective zones. Moreover, data formats and procedures differ across various zones. There's no uniformity across country for land records.

Ownership according to share: In case of property having multiple legitimate owners, it is a challenging task to maintain the information that how much share of property is owned by each individual.
Scalability: Current land record maintenance system is not scalable enough to main- tain record of entire country.
Security: Land Records need to be securely maintained for ownership integrity as they
are widely used by other departments such as land acquisition departments, banks and many more.
Accessible to different departments: Since land records are used by various depart- ments mentioned above, authorized departments need to have easy access and appro- priate rights to these land records.
Automatic Ownership/ Checking: Current land record maintenance system lacks the functionality to validate ownership of property or user wise owned properties.
User Friendly Access: Users are currently dependent on government officials and/or agents to retrieve land ownership records. Hence there is need for easy access to users [10].

II. TRADITIONAL LAND RECORD MAINTENANCE SYSTEM

Traditional land registration system consist of following steps as shown in figure
1,where physically user needs to go to the offices to carry out pro-cess.

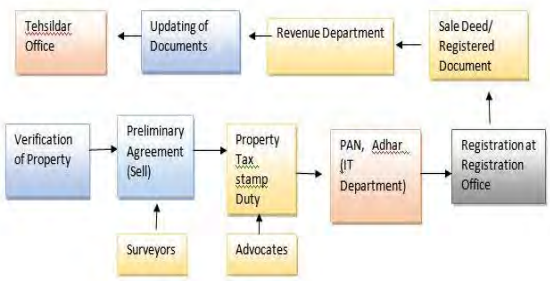

Fig. 1. Traditional land Registry system

2.1 Procedure for registration of land property in India

Registration process in India has become simple as the introduction of computerized system are used. This computerized system can help users to eliminate the middleman and it brings transparency in execution

However introduction of computerized system it has not completely replaced the manual paperwork and in some states it is necessary to submit the application manual- ly to the respective department or authority. The users need to download application form from the website of the concerned department or the concerned office.
The registration process comprises of paying registration fee for sale deed and it is necessary to record all the documents legally with the sub registrar office.it varies based on property is purchased directly from developer or secondary sale. Because in the other case process involves stamp duty and registration of transfer deed.

2.2 Steps:

Verification of the property:
Buyer needs to verify the property by physically visiting or any other option. It is based on whether property is purchased from secondary seller or developer.

Preliminary agreement:
Once property is verified then buyer and seller collectively prepare the preliminary agreement with the help of an advocate

Property tax stamp duty:
After completion of preliminary agreement it is required to pay stamp duty charges and registration fee. It varies from state to state. It may range from three to seven percent of property value. Property value can be decided from the annually ready rancor register.

Submission of documents:
Buyers and sellers with 2 witnesses need to submit their identity proofs and necessary documents.

Execution and registration of sale deed:
Next step involves execution of sale deed and register the sale deed. It needs to visit sub register office and require to submit the photographs, relevant documents like photograph of plot, 7/12 document or property card.

Property Mutation:
This is last step to complete registration process which involves getting mutation of property done in the land and revenue records. For this it is required to visit local municipal authorities.
This complete process may takes 20 to 30 days to complete

III. PROPOSED REAL TIME RECORD MAINTENANCE PROCESS:

Blockchain technology can be used to develop immutable distributed ledger. Every Department interacts with the blockchain using a public-private cryptographic key combination as shown in figure 2.

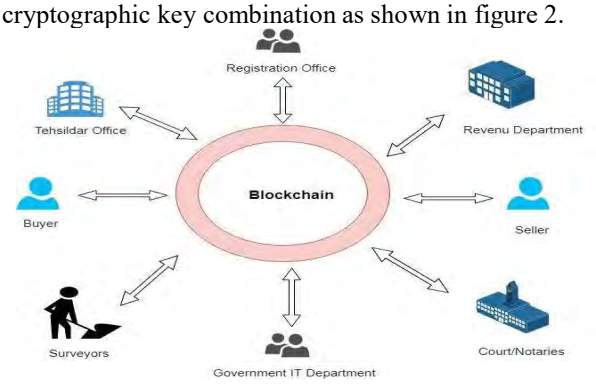

Fig. 2: Property Buying & Selling Process through Blockchain.

3.1 Process:

Step-1 Buyer searches a property on Blockchain platform.
Step-2 Buyer verifies the selected property.
Step-3 Buyer completes the payment to seller bank. Step-4 Registration will be done at office.
Step-5 Then seller initiates the blockchain transaction and broadcast the transac- tion.
Step -6 transaction will be verified by users on blockchain.
Step -7 block will be created and added to blockchain.

IV. PROPOSED SYSTEM

The proposed system, which we have proposed here incorporates many key benefits of blockchain technology, such as Immutable transaction records so no one can doubt the authenticity of transactions, records are permanently stored on the blockchain so no one can tamper these transaction records and there transaction records can be seen by anyone, anytime based on the privileges. Blockchain is a form of distributed ledger where data is stored on distributed network of computers. With blockchain anyone can access the network which automatically receive changes made to any database.

4.1 Smart contracts:

Smart contract is computer program which allows parties that are under certain condi- tions to directly control the transfer of assets or digital currencies.

These are self-executing programs used in blockchain to handle specific task. Actions that are kept in smart contracts are executed based on some events triggered.
They help you to facilitate, verifies and enforce negotiation or performance. Smart contracts are able to track performance in real life and can be used save the cost very effectively.
They can be used to:

1. To minimize the transaction cost.
2. Greater security.
3. To reduce overburden on trusted intermediaries.
4. To turn legal suggestions into automated processes.

Blockchain can be used in land registry to record all the transactions that happened in land record system. As blockchain is tamperproof and it cannot be modified by any illegitimate user as the system only consists of legitimate users who are allowed to transfer the property to other user.

Here smart contract can be used to automatically transfer the property when buyer deposits money into seller accounts.

ESCRO account:

This account can be used as intermediary account to temporarily hold the amount. It will then transfer amount to the seller account once the deed is done. If any stake-holder disallows the transaction then money will be deposited back to buyer account.

V. PROPOSED ARCHITECTURE

Our proposed system involves inclusion of departments like registration office, reve- nue department, court/notaries, surveyors, Tahsildar office as shown in above archi- tecture.

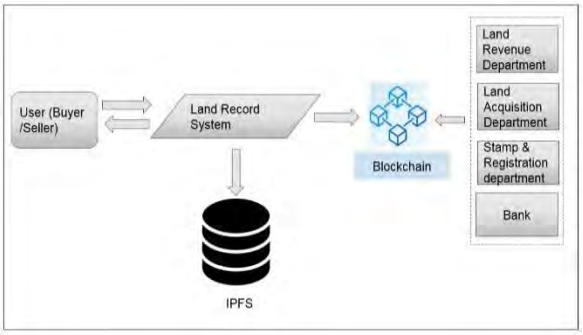

Fig 3: General Architecture of system

The proposed architecture consists of :

1. User: User is the one who is going to use the application in order to register his/her property or can a buyer or a seller of a property.
2. Land Record System: It is the graphical user interface which interacts with both the end user and the system kernel
3. IPFS: IPFS stands for Interplanetary File system is distributed system which is used for storing and accessing files, websites, applications and data. IPFS is used to store the scanned documents and id proofs in the system. It returns the cryptographic hash value of the file which is then passed to the block- chain to store it with the other data.
4. Blockchain: It is a chain of blocks which contains transactions which are linked to its previous node with the help of hash value of the previous block. The transactions of the related to lands will be stored in the blockchain.
5. Stakeholders (validators): Stakeholders are the validators of the transaction based on the authenticity of the documents the stakeholders will validate the transaction. The stakeholders include the Land Revenue department, Land Acquisition Department, Stamp and Registration Department and bank.

5.1 First time registration

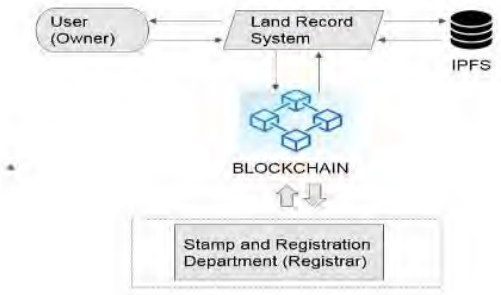

Fig 4: First Time Registration Architecture

Every user or the land owner need to register his property in the Land Record system for the first time irrespective of his interest in selling or buying any property.

First Time Registration is required in order to maintain the record of the land owner- ship. The stakeholder who is responsible for validating the transactions will be the registrar from the Stamp and Registration Department. Registrar will validate the transaction only after testing the authenticity of the documents which are uploaded by the User. Only when the registrar finds that the documents are authentic then and only then he will validate the transaction and block will be created and appended to the blockchain network.

Steps involved in the first time registration are:
Step 1- User will click on the create account and an account number will be generated Step 2- User should enter the personal details which includes name, address, contact details, government ID number etc. along with account that he has received in Step 1. Step 3- User then will enter the property related information which involves survey number, area, owner name, taluka, village, type of occupancy and documents of proof of ownership (property papers) along with document of ID proof will be uploaded by the User. Documents will be stored in the IPFS and cryptographic hash will be send to the LR system.
Step 4- User will click on the Validate button
Step 5- On clicking block will be created and transferred for validation to the regis- trar. Registrar will validate the property and Identification documents along with de- tails for its authenticity.

Step 6- If the documents are found to be authentic then validation status "true" will be displayed to the user and Block created will be broadcasted and appended to the blockchain. Else if documents are not authentic then "false" status will be displayed and the block will be dropped.
Step7- Stop.

5.2 Transfer of property

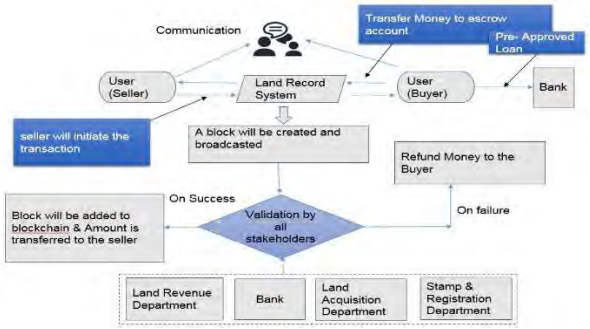

Fig 5: Architecture of Land transfer

The other type of the user is the buyer or the seller who are going to us the Land Rec- ord system for the transaction. In this case the seller and the buyer of the property has already communicated about the deal of the property. Here the seller is supposed to initiate the transaction and the buyer will have a pre-approved loan as shown in figure

5. Here all together there will be all 4 validators which include

1. Land Revenue Department: LRD will check whether the owner has not paid the property tax or does not have any previous dues left.
2. Bank: Bank will check whether the property is currently mortgage by the owner for some loan or not. Also it is responsible to validate that all the in- stallments related to mortgage are being paid by the current owner or not.
3. Land Acquisition Department: LAD will check if the property is the govern- ment property or is in the list of the Land to be acquainted or acquire by the government
4. Stamp & Registration Department: SRD will validate the Survey No and documents for selling the land.

5.3 Steps involved in selling the land

Step 0- The seller and the purchaser has previously communicated and Purchaser has a previously approved loan from the bank.
Step 1- The seller will initiate the transaction by providing the Account no. of the buyer on blockchain and block will created. The Buyer will transfer the Money to the Escrow account of the Registrar from the Stamp and Registration Depart- ment.
Step 2- The created block will be validated by the 4 stakeholders on parameters mentioned above.

Step 3-
1. After block is successfully validated and status is success then the transaction is successful. After which the amount from the Escrow account will be trans- ferred to the seller's account and property will be transferred on the name of its buyer. Then new block will be added to the blockchain.
2. In case the validation status is fail then the amount from the escrow account will be transferred back to the buyer and block will be dropped.

Step 4- Transaction Complete.

5.4 Technology Stack: Ethereum, Solidity, Remix.

VI. RESULTS AND DISCUSSION

We have implemented the proposed system using Ethereum environment with solidity language and stored records on IPFS as discussed in proposed system.Some screen- shots are shown below Figure 6 indicates login screen where first time registration of users is possible while Figure 7 indicates Ethereum accounts list .

Fig 6:Screenshot for First time registration form

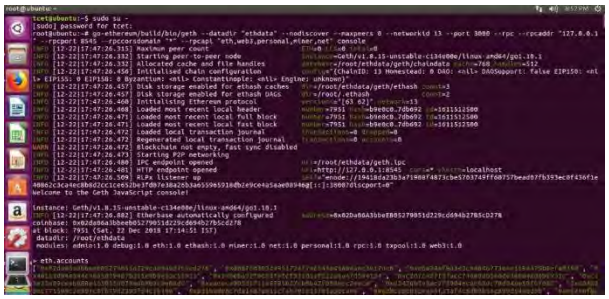

Fig 7: Screen shot for ethereum accounts

VII. CONCLUSION

Blockchain technology in land registry brings transparency in administration. Prove- nance of land can be maintained easily which can also help to find the real owner of the land and thus helping to solve the land ownership cases. Land records across country can be easily integrated and validated – For an owner having multiple proper ties in different regions integrating those data together will help to find the total num- ber of land assets under that owner data integration and overall validations can be done. Synchronization among various concerned departments can be achieved – In case of blockchain based system for land records various stakeholders i.e. various concerned departments acts as the validators during each process because of which the inconsistency that used to be present in the earlier system gets removed and thus synchronization in the departments will be achieved. Common man do not need to move to different offices – Earlier the common man had to move to different offices in order to transfer the property ownership and also had to hire an agent to make the process more faster. This thus leads to frustration to common man. Blockchain thus helps to reduce the activities by bringing them to a common platform. Reduction in corruption: There are people those used to perform bad practices which involves brib- ing the government officers in order to buy or sell the properties. Blockchain based system will reduces the flow the black money from the system and everything will be legally done. Thus Blockchain based record system helps in reducing the corruption.

VIII. Future Scope:

Geographic information System (longitude & latitude): Geographic information sys- tem implies to storing land into the system with help of virtual reality using the coor- dinates longitude and latitude and Google API one can generate the real time land area virtually inside the system. This will help to recognize the land area when there are disputes related to land area between two land owners having lands side by side. Also it helps to recognize the land in case of any natural calamities.Multiple owner (family Tree): Multiple owner implies to land or a property having ancestral owner- ship and storing their family tree to the blockchain will help to ease of transfer of property in case of sudden demise of the owner who do not have pre-prepared will or power of attorney. Family tree will help to decide the next owner or the new owner of the property.

Engineering knowledge as Graduate Attribute Attaining Assessment of Program Outcome

Dr. Rajesh Bansode, Dr. Sangeeta Vhatkar, Mrs. Pranjali Kasture, Mr.Vikas kaul
Information Technology, Thakur College of Engineering and Technology,
Mumbai, India
rajesh.bansode1977@gmail.com, vhatkarsangeeta@gmail.com, kasturepranjali@gmail.com, mvjvikas@gmail.com

Abstract – **Graduate attributes are the qualities, skills, and knowledge every graduate engineer needs to acquire and develop from time to time. Engineering knowledge is considered to apply knowledge of mathematics, science, engineering fundamentals and an engineering specialization to the solution of complex engineering problems. The accrediting bodies for engineering qualifications have developed outcomes-based criteria for evaluating programs through the graduates engineering knowledge. The engineering regulatory body that maintains quality of technical education across nation (AICTE) have developed the process of building competency-based standard with performance indicators for setting up question papers based on Blooms taxonomy which supports verification and validation of engineering knowledge gained by students which is tested through continuous evaluation. In the current paper the evaluation of Program Outcome /Graduate attribute-1 is done as Engineering Knowledge attainment which satisfies knowledge of computing, mathematics, science and engineering fundamentals for SE, TE & BE students with direct and indirect assessment tools.**

Keywords: Engineering Knowledge, Program Outcome, computing, mathematics, science and engineering fundamentals

I. INTRODUCTION

Engineering Program outcomes describe about the learning of students' measurement during their 4 years of graduation. The skills, knowledge students acquire in each semester is measured through two major modes namely direct & indirect tools respectively. The direct tools include continuous evaluation, end semester exam result, practicals' and assignments whereas the indirect tools include student validation, course and exit survey. Program Outcomes are related to outcome based education (OBE) which is student centric activity. Instructions during semester focus on measuring student performance i.e. outcomes. Outcomes include knowledge, skills and attitudes [1].

Outcomes focus on actions that signify student's learning by using concrete, measurable blooms taxonomy verbs. Benefits of OBE is the focus on outcomes that creates a clear expectation of what needs to be accomplished by the end of the course. Flexibility, Comparison, Involvement, Definition, Assessment problems, Generality, Involvement. Faculty members are responsible for learning and motivation among students to inculcate engineering knowledge through delivery of technical contents in practicals, theory lectures, tutorials, assignments etc [2]. Students use engineering knowledge to prepare for competitive exams through self-learning, collaborative & peer learning mode. The purpose of OBE is practiced by gathering and analyzing feedback of the knowledge and skills acquired by students.

The **advantage** of perculating engineering knowledge is that **outcome based education** teaches thinking skills and engages students in more diverse technical learning skills [3]. The learning skills include participation in national level technical events viz. coding competitions, hackathons, domain competitions etc.

The first program outcome (Graduate attribute) is based on engineering knowledge. It is about an ability to apply knowledge of computing, mathematics, science and engineering fundamentals appropriate to the discipline [4]. The courses under Information and Technology curriculum intend to deliver, the fundamentals of Set Theory Function and Relation, enable students to understand and apply the fundamentals to explain the concept of pigeon hole, recurrence relation and generating function, lattice, arithmetic modulo, Laplace transforms and Inverse Laplace transforms. The course also intends to deliver the fundamentals of data structures and analysis of various algorithms by providing a platform to learn, compare and apply different data structures in real world scenario. It is about fundamental knowledge of Digital logic, number system, conversions and Boolean algebra, apply and analyze the concept to create and troubleshoot a broad range of combinational circuits using digital ICs, flip-flops, counters, and registers, to prepare students to perform the analysis and design of various digital electronic circuits. It focuses on fundamentals of database management systems, understand & create Entity Relationship Model with application of relational algebra and basic SQL. Create systematic database and logical design through normalization,

recovery techniques and analyze query processing and optimizer. It emphasizes the fundamentals of object oriented programming features, building blocks along with constructors, and to learn the principles of inheritance, interface and exception handling mechanisms, multithreading and GUI Programming.

II. Related Work

The following section highlights different domain wise subject detailing with the objectives and expected outcomes. The engineering knowledge gained is by segregating the domains and detailing the required expected outcomes from each domain as mentioned in table 1. The engineering knowledge learning is diversified through various activities viz. conduct of technical seminars, industrial visits, activity based learning, bridge courses, online courses through NPTEL, MOOCs, Coursera, Udemy. etc.

Table 1-Domain wise objectives and expected outcomes

Domain Name	**Name of the Subjects**	**Domain Objectives**	**Expected Outcomes**
Software Programming & Development	Java Programming Lab, Operating System, Python Lab, Computer Graphics & Virtual Reality, Software Engineering &Project management, Software Design Lab, Cloud Service Design Lab, Cloud Computing & Services, Usability engineering , Ubiquitous Computing, Software Project Management, Software Architecture, Cloud Computing services, Computer Simulation & Modelling, Software Testing Quality assurance.	1. Build intelligent systems defining interactions with & within system. 2. Design self-managed (autonomous) systems based on awareness of context (environment). 3. Implement distributed system based on Smart DEI Model which in turn shall Quantify stakeholders & operations. 4. Construct systems which is pervasive while being distributed by hiding underlying operations and automating interactions. 5. Construct systems which shall be serving changing needs by being aware of resources & decide operation distribution in this multitenant system. 6. Develop Program applications for various types of operating systems using modern SDKs and Frameworks	1. Build systems which are intelligent while being capable of change flow of interactions. 2. Design context aware autonomous systems. 3. Implement systems based on Smart DEI model. 4. Construct system which appears to be one by defining transparent distributed environment. 5. Construct system which are scalable and incorporates multi features. 6. Design and implement applications for different devices including Servers, PCs, Mobile Phones etc.
Machine Learning & AI	Data structure & analysis, Applied Maths, Automata theory, Advanced data structures & analysis of algorithms, Image Processing, Multimedia systems, Intelligent System/Artificial intelligence	1. Devise systems that are intelligent. 2. Build systems following heuristic approach in operations. 3. Build system that learn from observation with and without human intervention. 4. Build system that can process one dimensional signals, image and video data.	1. Develop Systems which can take decisions, which can mimic human behavior and thinking 2. Build systems which can process and classify data on their own whether or not they know the outcome 3. Build system that can operate on electrical signals, image, audio and video data. 4. Build systems which are able to learn from the training data and improve their intelligence with every execution

Database Technologies	Database Management System SQL Lab, Advanced Data Management Technology, OLAP Lab, Data Mining & Business Intelligence, Business Intelligence Lab, Big Data Analytics, Geographical Information System	1. The students will be able to store, process, manage and retrieve the data from database. 2. The students will be able to segregate the data based on its worthiness. 3. The students will be able to understand the Volume, Variety and Velocity of the data. 4. The students will be able to understand the use of mapper and reducer in the HDFS. 5. Student will be able to explore the different technologies of database technologies.	1. The students will be able to fire the queries and manage the database efficiently. 2. The students will be able to differentiate between the relevant data and irrelevant data. 3. The students will be able to store the data in HDFS and process it using Map Reduce. 4. The students will be able to write programs on mapper and reducer in the HDFS. 5. The student will be able to identify various mini project, research based project ideas based on the database technologies.
Web Technology and E-commerce	Internet programming, E-Commerce& E-Business, Enterprise Resource Planning	1. Get knowledge of broad range of Internet tools 2. Design dynamic website using advanced web technologies. 3. Understand the concept of E-banking, electronic payment system 4. Describe different Business models, and develop an online Business Plan	1. Development of Web applications. 2. Introducing e-business applications in an organization; e-business technology and infrastructure. 3. Develop dynamic and interactive e-business applications and websites.
Information and Communication Technology	Logic Design, Principles of Communications, Digital Design Lab, Computer Organization & architecture, Computer Network, Networking Lab, Microprocessor Programming Lab, Cryptography & Network Security, Security Lab, Microcontroller & Embedded System, Internet Of Things , Robotics Wireless Networks, Sensor Network Lab, Wireless Technology, Storage Network Management & Retrieval, Wireless Sensor Networks	1. Develop an understanding of the data communication in networks, security issues related to data communication in networks and network applications. 2. Study comprehensive background in Network Systems and Data Communications procedures and latest technologies related to network security. 3. To Show students how to properly conduct research for recommending network and data communications hardware and software solutions. 4. To provide the skill sets to analyze, design, test, and evaluate network systems. 5. To Study concepts in Network Systems, network management and Data Communications Analysis and related fields. 6. To study and implement traditional as well as modern day computer networks - wireless and mobile, multimedia-based.	1. Describe security risks associated with computer networks and implement w3 mitigation strategies 2. Design and construct a network application that facilitates communication between computers on an intranet and the Internet. 3. Applies networking concepts to design, implement and maintain LANs and WANs to support modern implementations including internetworking and data convergence 4. Analyzes and applies security in computer and networking infrastructures while detecting any legal and ethical breaches 5. Demonstrates the management of IT infrastructures and projects

III. Methodology

Step 1- To test and measure the engineering knowledge based on academic results (2016-19 batch) as below**:**

Table.2 - Academic result (2016-19 batch)

May 17 (SE)	**End sem result**	**Dec 16 (SE)**	**End sem result**
Information Theory & Coding	97.39%	Analog and digital circuits	88.13%
Computer Networks	98.68%	Applied mathematics-III	82.29%
Automata Theory	99.34%	Data structure & algorithm analysis	98.04%
Computer Organization & Architecture	97.39%	Database management systems	95.45%
Web Programming	100.00%	Object oriented programming methodology	98.69%
Applied Mathematics IV	93.71%	Principles of analog and digital communication	92.86%
May 18 (TE)	**End sem result**	**Dec 17 (TE)**	**End sem result**
Advance Internet Technology	99.33%	Advanced database management systems	96.82%
Data Mining & Business Intelligence	100%	computer graphics & virtual reality	98.06%
Distributed Systems	99.35%	Microcontroller & embedded systems	95.54%
Software Engineering	99.35%	Open source technologies	99.36%
System & Web Security	100%	Operating systems	100.00%
May 19 (BE)	**End sem result**	**Dec 18 (BE)**	**End sem result**
Storage Network Management & Retrieval	100%	Software Project Management	99.35%
Big Data Analytics	100%	Cloud Computing	100%
Computer Simulation & Modeling	100%	Intelligent System	99.35%
Enterprise Resource Planning	100%	Wireless Technology	100%
Soft Computing	100%	E-Commerce & E-Business	100%
		Ubiquitous Computing	100%

Step 2- The process used for calculating the attainment **with H, M, L** (H-High, M-Medium, L-Low) is as follows:

1. H, M, L mapping for each subject has been taken depending on the relevance of CO's with PO's.
2. For each subject in all semesters the tools have been used with 80% weightage to direct tools like Semester end exam (SEE), Internal assessment test (IAT), Assignments, Practical's etc. and 20% weightage to indirect tools like course survey, student validation & exit survey.
3. The attainment for each subject is calculated and the final single value on scale of 3, as average for every subject is calculated.
4. The single value average of the subject is put up in the HML mapping of each subject as following:
   H: average value * 1
   M: average value * 2/3
   L: average value * 1/3

5. The average of all the subjects starting from the third semester to the eight semester is taken according to the H,M,L values in each of the subject's table for individual PO attainments.

6. After getting this attainment, 20% of exit survey is added to 80% of the above calculated average of semesters to get the final PO attainment

Step 3- Differential Evaluation: PO1 Attainment with result

PO 1 mapping for 2015-19 batch

Table 3- PO 1 attainment of S.E A.Y 2016-17 odd sem courses

Subject	ADC	DMS	DSA	Maths	OOPM	PADC
SEE	1.15	1.76	1.83	1.25	1.78	1.44
COURSE SURVEY	2.73	2.58	2.62	2.94	2.79	2.28
Avg	1.47	**1.93**	**1.99**	**1.59**	**1.98**	**1.60**
Total Avg.	**1.76**					

Table 4- PO 1 attainment of SE A.Y 2016-2017 even semester courses

Subject	AT	CN	WP	ITC	COA
SEE	2.19	2.40	2.25	2.34	2.16
COURSE SURVEY	2.58	2.82	3.00	3.00	2.94
Avg	**2.27**	**2.48**	**2.40**	**2.47**	**2.32**
Total Avg.	**2.39**				

Table 5- PO 1 attainment of TE A.Y 2017-18 Odd sem courses

Subject	MCES	ADMS	CGVR	OST	OS
SEE	2.28	1.55	2.13	2.12	2.12
COURSE SURVEY	2.81	2.77	2.77	2.78	2.76
Avg	1.93	**2.06**	**2.19**	**2.21**	**2.22**
Total Avg.	**2.12**				

Table 6- PO 1 attainment of TE A.Y 2017-18 Even sem courses

Subject	AIT	DMBI	DS	SE	SWS
SEE	2.60	2.42	2.74	2.80	2.69
COURSE SURVEY	**2.99**	**2.94**	**2.79**	**2.8**	**2.84**
Avg	**2.55**	**2.50**	**2.45**	**2.49**	**2.58**
Total Avg.	**2.51**				

IV. Result and Analysis

The final average P.O attainment is calculated for SE, TE and BE which is from above step 3

Program Attainment Class wise:

Table 7- Average PO1 attainment of 2015-19 batch

Class	PO1 Average Attainment		Average
	Odd sem	Even Sem	
SE	1.76	2.39	2.075
TE	2.12	2.51	2.315
BE	2.68	2.77	2.725

Table 8- PO 1 attainment with Direct and Indirect Tool (2015-19 Batch):

Direct tools	Final Attainment	Indirect tools	Final Attainment
Internal assessment test	**2.17**	Course Survey	2.47
End sem result	2.49		
Assignments	2.36	Exit Survey	2.76
Practicals	2.67		
Avg. Attainment	2.42	**Avg. Attainment**	2.61

The final attainment is carried out with 80% weightage of direct tools and 20% weightage from indirect tools. That is 80% of 2.42 and 20% of 2.61. Therefore the final attainment is 1.936 (direct tools avg. attainment) & 0.522 (indirect tool avg. assessment) totaling to **2.458** as final attainment**.**

Analysis:

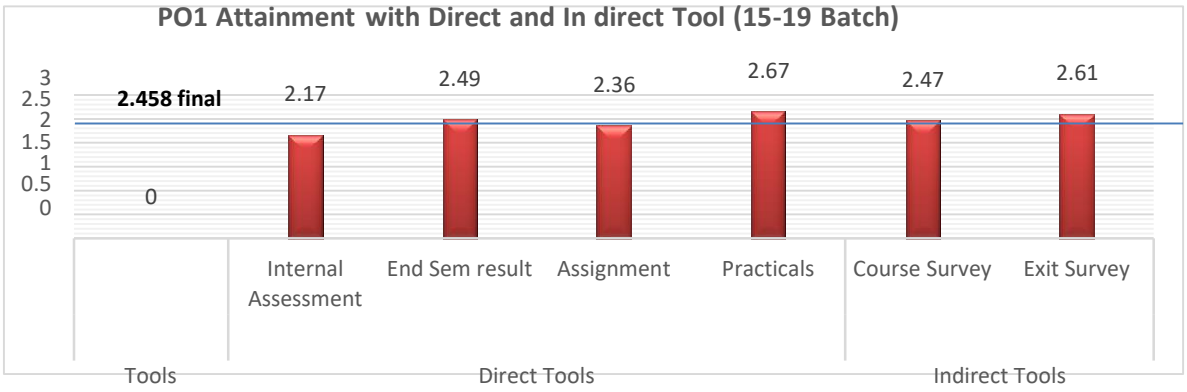

Fig.1 PO1 as Engineering Knowledge attainment using direct and indirect tools

V. Conclusion

The PO1 as engineering knowledge is proved to be beneficial concept of learning in attaining the PO attainment of 2.458 on the scale of 3 to mention that graduates can apply knowledge of mathematics, science, engineering fundamentals and an engineering specialization to the solution of complex engineering problems. Thereby, for better clarity the attainment is measured using direct and indirect tools for the students of batch 2015-19. The attainment tables indicate for students of batch 2015-19 is from academic year, A.Y 2016-17 from second year to final year of their core engineering department.

Knowledge based tool for Academic Strategies and Analysis

Dr. Rajesh Bansode, Dr. Sheetal Rathi
Department of Information Technology, Department of Computer Engineering,
TCET, Mumbai

Abstract—**Educational institutions have a pivotal role in molding young, fertile and enthusiastic mindsets which in turn influences the society at large. This micro-chip society truly understands the importance and value of Knowledge which makes Knowledge Management (KM) essential for every educational organization. This can be identified and made use of at various levels such as administrative, academic (teaching and learning processes), research and student & staff welfare. Deployment of systematic KM enhances the quality of contribution made by an individual thereby encouraging them to co-operate and share their inputs, and to effectively challenge, negotiate and learn from others. In this paper we have applied knowledge management to categorically segregate students in low, medium and high categories using student validation tool. The results of systematic implementation of these categories on students evidently show that over the past four years, students go from low to medium to high category.**

I. INTRODUCTION

Knowledge Management is "A process by which the assimilated knowledge undergoes a cycle of knowledge generation, sharing and exploitation enabled by technology in order to achieve its objectives. The organizational goals are achieved through strategy-driven motivation and an approach providing knowledge to employees to enhance and use their capability to interpret data and information, and skills thereby infusing knowledge management practices into the daily work of the Academic Operation Area.

KM demands a mixture of skills, creativity, technical expertise and innovative capabilities of people; which form the base of KM. Knowledge is made available at three stages: before, during, or after KM-related activities.

Thakur College of Engineering and Technology has initiated KM activities at all levels viz. student, faculty as well as departmental level. In order to achieve results and outcomes to measure the innovative practices to convert them into best practices; all Departments including both academic (All branches) as well as Sections (Exam, T&P, Library etc.) have been assigned with different tools and tasks.

The case study discussed for KM is based on regular practice of student validation at department level. This validation is done at entry level of each year based on various parameters such as previous marks, attendance, term test, learning attitude etc.

The three fundamental pillars of knowledge management are as follows: (1) Knowledge Acquisition. The process of acquiring, gathering, developing and creating insights, skills, and relationships. (2) Knowledge Sharing. The process of disseminating and making accessible what is already known. A perfect example of knowledge sharing would be a decision support system that provides a novice teacher the best teaching practice by providing knowledge. Possibly, optimization of this sharing process must be done on the specific context; (3) Knowledge Utilization. Learning of broadly available knowledge is generalized, applied and integrated into the organization.

Effective knowledge management encourages the usage of more collective and systematic processes, which reduces our tendency to 'make the same mistakes' which otherwise is extremely costly and inefficient. Therefore, Effective knowledge management can enhance and dramatically improve quality of products and/or services. A complete, clear and thorough understanding of the stakeholder needs, customer needs, employee needs, industry needs, always has an obvious immediate effect on relationship management. Thus, accelerated knowledge creation, is the driver for innovation which forms the cornerstone of Effective Knowledge Management.

Steps taken to make proper use of acquired knowledge:

1) Faculty members are advised to come up with innovative practices every semester for overall development of students. The introduction of each of these innovative practices requires measurement forit is effectiveness which can be disseminated to all the departments if proven effective.

2) Suggestions from external stakeholders are very important for development which can be efficiently done by using various knowledge management tools.

3) Prediction of the possible problems that could arise if the internal/external benchmarking requirements are not met.

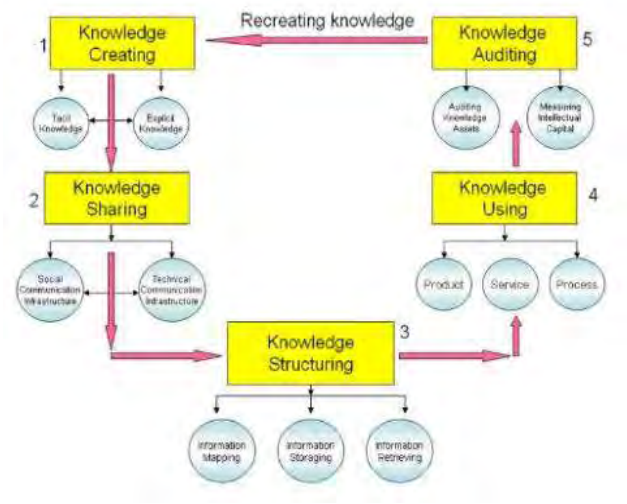

Fig 1. Knowledge Management Lifecycle

II. OBJECTIVE& SCOPE OF KM IN STUDENT VALIDATION

Knowledge is the key for decision making and strategy creation. Knowledge should transfer into an action but unfortunately it does not happen always. In order to sustain in competitive world all educational institutes should implement effective tools for knowledge management.

Following assignments should be activated for effective KM:

Mobilize the hidden implicit/tacit knowledge
Integrate knowledge from organization and make it accessible to all
Identify the missing knowledge
Create new knowledge
Make knowledge more accessible and usable
Create knowledge sharing culture to experiment and learn
Evaluate and reflect learning processes
Codify new knowledge.

KM helps educational institutes to improve their capacity of assembling and sharing of information and knowledge along with application of these to problem solving and support the research and repeated improvement of their work. KM of the educational system must reproduce and encompass information at all levels starting from management level to student level in order to improve professional knowledge of employees, to achieve quality of lecturers and students.

The Objectives of KM can be as follows:

1) To find the root cause of untraceable problems.
2) To foresee the requirements of Institute and be equipped enough for handling any dynamic requirements.
3) To develop optimal practices for holistic student development.
4) To inculcate all the suggestion and feedback from all stake holders into innovative and new practices.
5) To disseminate proper knowledge from time to time to concerned stakeholders.

III. DEVELOPMENT OF BEST PRACTICE

The practices of teaching learning which requires critical /problem solving skills, initially considered as innovative practice to categorize students learning based on their academic performance using continues evaluation with positive outcome as desired is considered as best practices.

The need to implement student validation as regular practice in teaching learning amongst students is to fully engage in their learning, for which validation of students is carried out to measure learning in 3 major categories High-H, Medium-M,LOW-L through which student diversity is measured. So is diversity among college students. The challenge is how to harness that strength, and how to unleash the creativity and exuberance for learning that is present in all students. Applying KM in student validation is one of the key factors for improving the categories of students who are lacking behind.

Student validation (SV) is considered for segregating students in 3 major categories based on their academic performance as High (H)- CGPA 7.75 and above, Medium (M)- CGPA ranging between 6.75 to 7.74 , whereas Low(L) – CGPA below 6.75. SV is prepared based on previous semester performance as SGPI, current sem.: term test marks, attendance, term work. The practice is carried out with a rigor practice to convert students from L to M & M to H category.

The Low (L) category students are informed to write remedial, assignment and practice the lab conduct to improve the academic performance.

The medium (M) category students are asked to update their technical skills by attending and gaining technical hands on training from the bridge courses and try to register and clear online certification courses viz. MOOCs, Coursera, NPTEL, Udacity etc.

The High (H) category student's performance is boosted by giving them inputs to clear the certification courses, internships, domain expertise, program specific research with placements etc.The measurement of student's growth signifies students performing better in the academics.

IV. IMPACT STUDY

The impact study provides an analysis of the student validation for the academic Year 2018-19.

Before: The student's performance was monitored categorically as H, M, L based on their academic performance. The institute followed the criteria of Mumbai University for A.Y 2018-19. The results are seen in fig. 2, fig 3, fig.4, fig 5.

After: In the A.Y 2019-20,TCET was awarded the status of Autonomy, due which there was improvementin student's academic which is reflected in their resultsas can be inferred. Due to various enlighteninginitiatives engaged by TCET such as Smart India Hackathon (SIH), technical seminars as per domain, professional bodies 'seminars& various workshops,students have imbibed the practical knowledge to exceltheir academics.

The measurement is done for consecutive batches where students' progression is perceived from the number of students shifting from L to M and M to H, whether there is a negative or positive trend in the growth of students. The respective processes are retuned as per students need, to meet higher benchmarks and try to get majority of the students in M, H category so that students are globally employable.

V. RESULTS

From the deployment of student validation, the faculty members get an idea of slow learners and can accordingly use various pedagogical teaching learning methods for such students. The figures below depict the growth in student's results from A.Y 2018-19 to 2019-20. There is a subsequent improvement in the results of students before and after the implementation of Autonomy for Information Technology & Computer Engineering departments.

Case A (IT Dept): Table -1: Student validation for A.Y 2018-19 Odd Sem-IT

Percentage of student in High , Medium and Low Category in A.Y 2019-20 odd sem –I.T			
Programme Avg	High (%)	Medium (%)	Low(%)
S.E	53	43	4
T.E	68	29	2
B.E	72	27	1

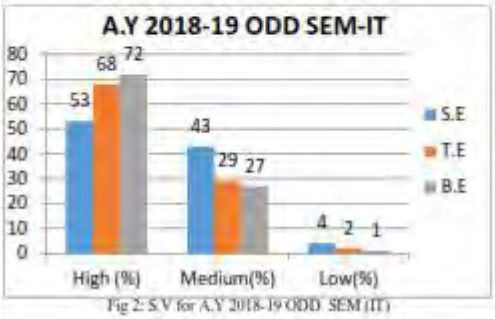

Fig 2: S.V for A.Y 2018-19 ODD SEM (IT)

Table -2: Student validation for A.Y 2018-19 EVEN SEM –IT

Percentage of student in High, Medium and Low Category in A.Y 2018-19 EVEN SEM -IT			
Programme Avg	High (%)	Medium(%)	Low(%)
S.E	54.83	40.91	4.20
T.E	67.01	30.20	2.40
B.E	71.92	26.70	1.38

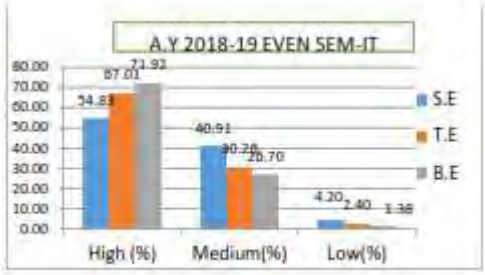

Fig 3: S.V for A.Y 2018-19 EVEN SEM (IT)

Case B(COMP Dept) Table -3: Student validation for A.Y 2018-19 ODD SEM-COMP

Percentage of Student Count in High, Medium and Low Category in A.Y 2018-19 ODD SEM -COMP			
Programme Avg	High (%)	Medium(%)	Low(%)
S.E	85.8	8.6	4.8
T.E	75.04	10.13	14.83
B.E	69.62	22.76	7.62

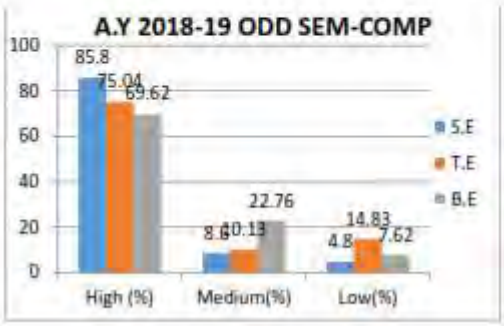

Fig 4: S.V for A.Y 2018-19 ODD SEM (COMP)

Table -2: Student validation for A.Y 2018-19 EVEN SEM –COMP

Percentage of Student Count in High, Medium and Low Category in A.Y 2018-19 EVEN SEM -COMP			
Programme	High (%)	Medium(%)	Low(%)
S.E	56.78	39.87	3.34

T.E	67.34	30.26	2.4
B.E	71.92	26.7	1.38

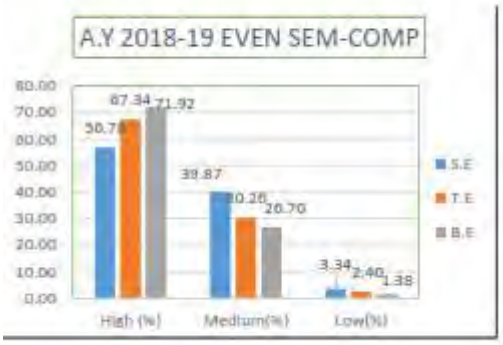

Fig 5: S.Y for A.Y 2018-19 EVEN SEM (COMP)

From the above demography, it is quite evident that the Student Validation Tool has proven to be the most efficient method of precisely gauging and continually measuring an individual's academic performance so as to measure/indicate overall growth of students. In order to convert students from L to M & M to H category for the overall improvement of student's performance at all levels (Curricular, co-curricular & extra-curricular), it refers to various minute calculations of each student categorize based on continuous evaluation (term work), internal assessment test, term work etc which gives a measure/ mechanism. The % of students moving from L to M & M to H are closely monitored for subsequent batches and inference is drawn for next subsequent batches about the various types of practices students to be given.

VI. CONCLUSION

In conclusion, the author has attempted to demonstrate the positive influence of Knowledge Management on studentteacher learning process and how effectively it has been implemented using a Student Validation tool to enhance oveall performance of an individual. The student validation tool is indeed, a foolproof system, however with asmall window for improvement for all the students irrespective of their category, asthe process to apply it on the students for measurement of their performance can be adaptive and not rigid,as it would vary based on various internal and external factors.

Evolution to Sustenance of Information Technology Academic Curriculum to Adhere to Industry Practices

Aniket Ladukar, Advait Maduskar, Divyam Choudhary, Dr. Rajesh Bansode
Department of IT, Thakur College of Engineering and Technology
ladukaraniket@gmail.com, advaitmaduskar.1@gmail.com, divyamchoudhary@hotmail.com, rajesh.bansode@thakureducation.org

Abstract – **The domain of Information Technology has been growing exponentially since the introduction of IT- Enabled Services in the industry since early 2000's. The IT infrastructure of any organization plays a crucial role in the processes of information management, processing, retrieval and communication. This article serves to provide insight into the radical growth of Information Technology over the course of the past few decades and to inspect the direction in which it is headed. Furthermore, the article also discusses about changes in Information Technology curriculum to bring sustenance as per industry practices. The current case study discusses about the paradigm shift in nature of IT-Enabled services which is reflected as per academic instructions being provided at the department.**

Keywords – Information Technology, Curriculum, Academia, Industry, IT-Enabled Services

I. INTRODUCTION

Information technology can be broadly defined as the use of computers, software (operating system/tools and application), communications, and networks to ensure that the information needs of an organization are being satisfied [1].

The department of Information Technology Engineering at the institute structures its curriculum in accordance with the industry trends pertaining to IT-Enabled Services and Applications. The undergraduate syllabus is compartmentalized into five sub-categories as domains and aims to provide a holistic technical education in a manner that promotes student interest in the domain. This part of the article is focused on analysing the domains into which the academic curriculum has been distributed.

The first of the domains is Software Programming and Development. The syllabus covered under this domain includes subjects such as Object-Oriented Programming, Structured Programming, Software Engineering and Project Management, among others. No doubt one of the most crucial skills required of an IT engineering undergraduate, Software Programming and Development serves as a basis on which to build skills that will allow students to specialize in any other software-related domains that they may be interested in.
The Department has 137 students registered under this domain with 9 faculties allotted to it. The subjects thoroughly cover the nuances required by students to gain a complete understanding of Software Engineering concepts as well as Process Models, both of which are fundamentals in any project taken on in the software industry.

The second domain is Artificial Intelligence and Machine Learning. Process automation and the usage of intelligent systems has seen an exponential rise over the course of past decade. Machine Learning and Artificial Intelligence are two of the technologies that are at the core of this boom. The demand for engineers who can build efficient intelligent systems – be it chatbots, intrusion detection systems, predictive models, or any such application – has seen an upward trend and is only likely to increase in the coming decade. Gartner Inc. has named 'Hyper automation' – a culmination of machine learning, packaged software, and automation – as one of the top 10 IT trends of 2020 [2].

168 students have registered for this domain and will be guided for 9 faculty members. The subjects covered under this domain serve to cover the basic concepts of machine learning and data mining. However, the depth of chapters in subjects such data mining and soft computing is often compromised to accommodate the vast breadth of topics. The converse of this is seen in subjects such as Data Structures and Algorithms. To address these shortcomings, the department has introduced electives such as Soft Computing and Advanced Data Structures and Algorithm Design. However, the lack of laboratory sessions for these electives leaves a need of practical understanding while being somewhat heavy on the theoretical aspects.

The third domain is Database technology. It forms the backbone of information technologies by defining storage and access methods. For a long time, the database industry has been dominated by giants such as Microsoft and Oracle with heavy focus on structured, SQL-driven databases. However, recent trends are indicating that the number of organizations that use hybrid databases (NoSQL + SQL) is rapidly increasingand the instances of pure SQL databases is steadily declining. The curriculum provides extensive training in the concepts of database management and SQL programming. Subjects such as Advanced DBMS also serve to introduce database security concepts along with the fundamentals of data warehousing. 194 students have opted for this domain and will be guided by 10 faculty members.

The fourth domain of Information and Communication Technology is an amalgamation of Telecommunications and Information technology. Its primary focus is to provide access to information using Internet, mobile phones, wireless networks and various other communication technologies. It encompasses all the devices and services which allow people and organizations to communicate digitally [3] [4].

We live in a world which is largely information driven. It has a great impact on our daily lives. Making all this information available to is the primary task of ICT. ICT has become an integral part of everyone's lives. For example, everyone with a cell phone and an internet connection can have access to enormous amounts of information right at their fingertips. Services such as Video conferencing, VoIP have turned out to be revolutionary in domains like Education, Healthcare etc. It has made it possible for people to obtain education from teachers present at remote locations. It has enabled patients living in remote areas to receive medical facilities such as consultation etc [5].

The curriculum offered under the domain of Information and Communication Technology covers a wide range of subjects that cover both wired and wireless communication systems. It would be apt to discuss that the syllabus, which covers computer networks, principles of communication, wireless networks, IoT among other subjects, is at pace with the requirements of the telecommunication industry. The 9 allotted faculty proficiently instruct the 145 students that have opted in for the domain while ensuring that no gap is left in the standards of the academic curriculum.

Overall, ICT is a platform that can be used for cross domain research that can involve the integration of database analytics, remote artificial intelligence, cloud- based data management, etc.

The fifth domain is Web Technology and E-Commerce. In recent years, with the increasing use of the internet, organizations are shifting from traditional native applications to web based services. This shift has been accompanied by the meteoric rise of web technologies for developing online interfaces for corporate services and research alike. Furthermore, the rise of E-commerce has boosted the need for web application developers in order to develop and maintain their portals.
The curriculum under Information Technology department covers subjects such as Internet Programming, Java Programming, ERP along with electives such as Advanced Internet Programming. A total of 243 students have chosen to opt in for this domain, making it the single largest category under the IT department.

While the syllabus covers topics such as basic HTML, CSS, JavaScript and PHP, it leaves out essential web development frameworks and libraries. As recent trends indicate, JavaScript based frameworks such as React, Node, Angular, among others are becoming increasingly popular tools in full stack development.

II. BACKGROUND

For the purpose of discussion, the growth and evolution of the IT industry can be viewed in three broad phases:

Pre-2000 era: The growth of software exporting firms.

For the two decades in this period, the software sector was largely comprised of firms looking to provide software services to global clients. The companies started solving Y2K issues for their customers and further extended their offerings to help companies manage their legacy portfolio of applications and infrastructure. The first wave of the global Internet and dot-com era created intercontinental Internet infrastructure. Indian companies were able to leverage this infrastructure to deliver software development- related services to global enterprises remotely.

Realizing the potential and the availability of talent, some multinational corporations established their own offshore development centers in India. Companies involved in the software aspects of hardware—for example, design of tools or VLSI (very large-scale integration)/system design—also took root, diversifying their services portfolio.

Circa 2000–2010: The rise of Indian software multinationals and R&D centers.

With experience in dealing with complex IT systems and confidence in working with international customers, several companies became multinationals with offices and centers across countries. They offered a wider range of services like executing large and complex projects involving integration, complete end-to-end solutions including management of IT infrastructure, running the services, providing IT strategy, and other related services.

Global multinational companies also realized India's potential in software services and started increasing their direct presence in India by setting up IT, business process management (BPM), and R&D centers. To date, 1,250 companies from around the world have set up their own centers in India across almost all key industry verticals. Software/Internet, telecom, semiconductor, automotive, and industrial are the top industries present, with R&D being a strong focal point. Enterprises across industries such as banking, retail, and healthcare also started driving digital engineering work from their India development centers.

Today, several centers have matured to deliver end-to- end products from India. These centers also act as the gateway to Asia, helping with product localization and creation of new products for these markets. Even next- generation companies have started setting up centers in India. Uber set up an engineering center in 2017, and OVH—a unicorn

from France that provides cloud services—set up an R&D center in the country last year.

Over 400,000 engineers work in global R&D centers in India. Bangalore, Pune, Hyderabad, National Capital Region (Delhi, Noida, Gurgaon), and Chennai are key locations for such centers, amplifying the possibility of ecosystem wide learning, relearning, innovation, and partnership.

Circa 2011 to present: Vibrant and innovation- driven multi-dimensional sector.

The Indian software ecosystem has now evolved into an extremely dynamic and varied sector that is building and managing the most complex IT systems for global enterprises. The combination of available talent, lower rates of brain drain to the U.S., the presence of large technology companies' R&D centers, and the presence of global venture capitalists has helped accelerate the growth of the start-up ecosystem. India, today, has over 7,000 start-ups (started less than five years ago), and over 1,200 technology start-ups were established in just the last year.

There are largely two types of technology start-ups. The first are consumer-led and largely focused on the India market. Initially these were replicas of U.S. companies, but soon morphed with unique innovations for the India market. For example, the cash on delivery model in e- commerce was pioneered in India and is now used globally. The second set of start-ups are focused on serving the U.S. and European markets.

In the last few years, 18 start-ups touched US$1 billion in market capitalization. Walmart bought India's largest e-commerce company, Flipkart, which is only about 11 years old, at a valuation of US$21 billion. OYO Rooms, a technology-enabled franchise model hotel chain, was started by a 20-year-old, and now has the largest number of rooms under management in India, overtaking both traditional Indian and global hotel chains.

Start-ups are driving innovation at an accelerated pace. To maintain the warp speed of innovation, large companies are building partnerships with the start-ups and are actively looking at acquisitions, both for talent and intellectual property.

For the purpose of discussion, the growth and evolution of the IT industry in India can be viewed as having occurred in different stages of development. According to an IBEF report on the evolution of the Indian IT sector, the process of evolution can be viewed in five stages, as shown in Fig. 1 [6].

According to a NASSCOM report titled “Industry Performance: 2018-19 and what lies ahead”, the past year was defined by technological trends such as Digital Acceleration, which led to a 33 billion USD increase in digital revenue with a 30% year-on-year growth. The same report stated that over 7200 new tech start-ups were launched, which resulted in 8 unicorns over the past year. Furthermore, a 6.6 billion USD investment in E-commerce firms that cater to the demands of 120 million customers lead to an additional boost of 43 billion USD to the digital revenue channels. The government provided extensive support to sustain this technological growth by announcing a nationwide AI for

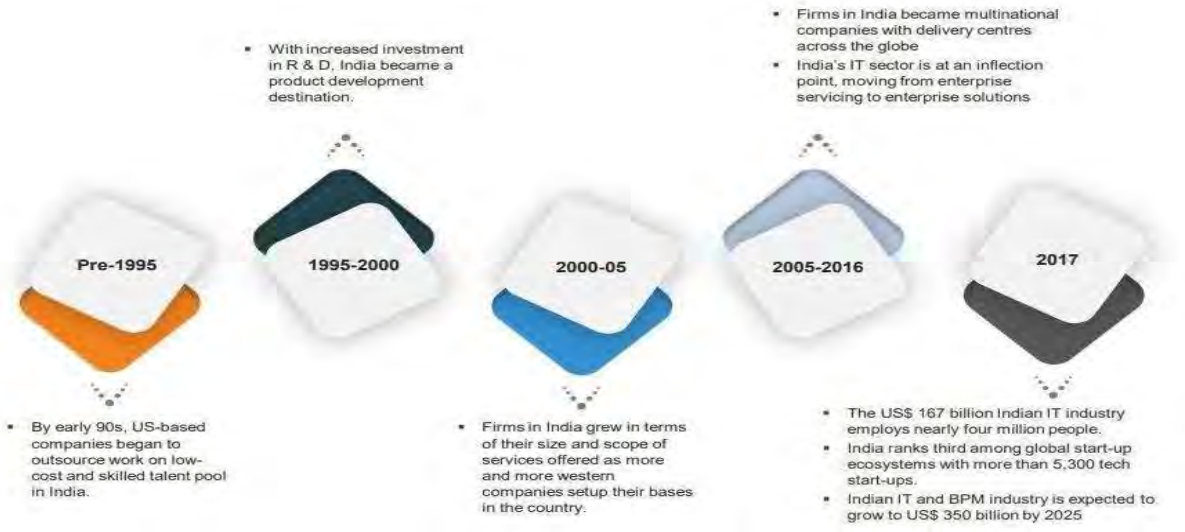

Fig. 1 Evolution of IT industry

all initiative. As a direct result of this move, 400 automation and artificial intelligence start-ups saw light in the past year [7] [8].

NASSCOM also defined evolving digital metrics for the measurement of the growth of evolving technologies and for the recognition of upcoming trends [9]. They are:

Customer Satisfaction: Measuring customer satisfaction emerges as a key metric for Digital growth
o Metrics: CSAT Scores
Investments in Digital: Investing into building capabilities on Digital platforms and services.
o Metrics: Investment in CoEs, Domain
Talent, IP
IP Monetization / Patents Filed: Increased focus on creating products / platforms on new age technologies
o Metrics: No. of Products / Platforms created, Patents filed
Digital Revenues / Margins: Measure and disclose Digital revenues
o Metrics: Growth in Digital revenue
Client Mining: Actively mining targeted clients to drive Digital revenue (E.g. Targeting clients based on spending propensity & industry).
o Metrics: Large deal tracking, Digital Share of the deal
Driving Automation Internally: Deploying automation to boost productivity.
o Metric: Bots deployed
Digital Skilling: Re-skilling existing employees and disclosing percentage of digitally skilled employees.
o Metric: Digital Workforce

According to official sources, the fastest growing trends in the technological industry in India are Artificial Intelligence and Internet of Things. This is supported by the data for the number of patents filed in India, between 2015 to 2018. The greatest number of patents were filed under the domain of AI, with a total of 330 patents filed under it. AI was followed by Cybersecurity, with a total of 193 patents registered. The third domain under which most patents were filed was IOT, with 107, and finally, 88 patents were filed in India for Cloud Computing.

Furthermore, the Indian Brand Equity Foundation released a report [6] that highlighted notable trends in the IT industry, identifying them as follows –

Global delivery model: Indian software product industry is expected to reach the mark of US$ 100 billion by 2025. Indian companies have set up over 1,000 global delivery centres in about 80 countries over the world

Leading sourcing destination: India is a prominent sourcing destination across the world, accounting for approximately 55 per cent market share in the global services sourcing business, as of FY18. India acquired a share of around 38 per cent in the overall Business Process Management (BPM) sourcing market.

Rise of Onshoring: Fall in automation costs and rise of digital has led to higher onshoring by the industry. Onshore revenue of Indian IT industry has grown from around 48 per cent in 2011-12 to 55.2 per cent for the quarter ended June 2018.

New technologies: Disruptive technologies, such as cloud computing, social media and data analytics, are offering new avenues of growth across verticals for IT companies. The SMAC (social, mobility, analytics, cloud) market is expected to grow to US$ 225 billion by 2020

Rural Development: The National Optical Fibre Network (NOFN) is being laid down in phases to connect all the 250,000 gram panchayats in the country.

Changing business dynamics: India's IT market is experiencing a significant shift from a few large- size deals to multiple small-size ones. The number of start-ups in technology is expected to reach 50000, adding to around 2 per cent of GDP

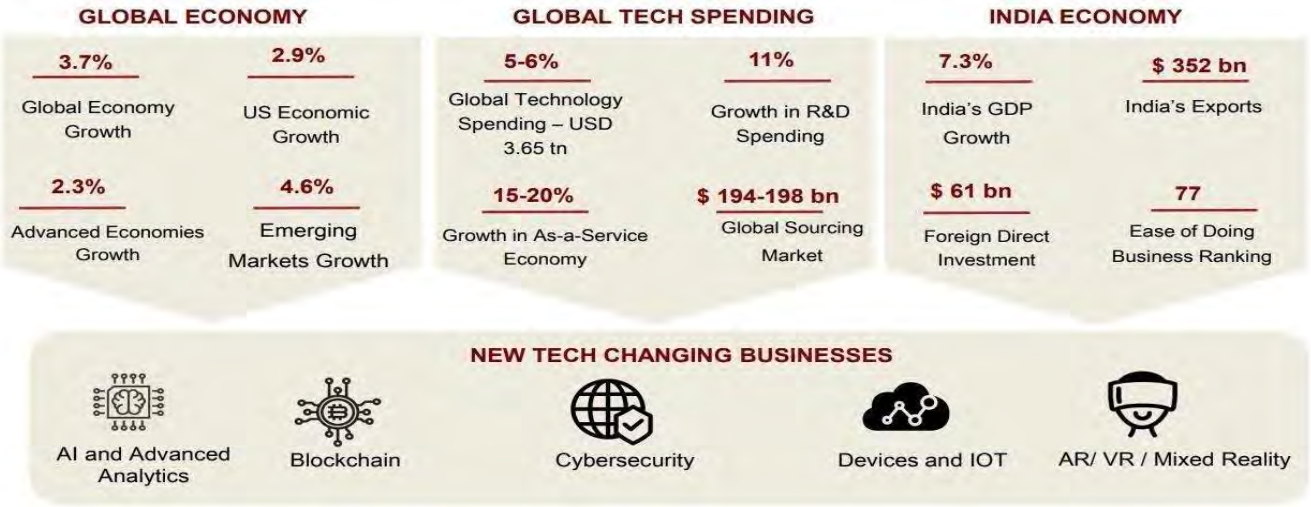

Fig. 2 Review of the last Financial Year in the Indian IT Industry

III. DOMAIN TRENDS

A. Software Programming and Development

The decade from 1990-2000 saw the rise of networking-based applications - the Internet. This led to a very rapid surge in demand. The ascent of the Internet led to a very rapid surge in the need for international information display/e-mail systems on the World Wide Web. Developers were required to deal with representations, maps, photos, other image formats, some animations like never before, with only a few known methods to optimize image display/storage (using thumbnail image). With the rising demand for software in many smaller organizations, a need for low-cost and economical software solutions was created in the early 2000s.

The demand was met by the growth of simpler, accelerated methodologies that developed running software, from requirements to deployment, agile & more accessible. The decade saw evolution of rapid- prototyping to an entire lightweight methodology, such as Extreme Programming (XP), which attempted to facilitate many areas of software engineering, including requirements gathering and reliability testing for the growing, vast number of small software systems. Software engineering is a budding and developing discipline. As per trends, the Software Engineering and Project Management evolved along these years will be relevant for the next decade as well. We see the trend of different programming languages and frameworks popping with each having their own speciality.

The present IT curriculum helps the student by providing training in Java, Python, Web Programming, Software Engineering and Project Management, Software Process Automation, Software Testing and Quality, UI/UX Design and Game Programming. Here DevOps, Functional Programming are few of the new disciplines that have emerged and hence been accordingly introduced in the curriculum [10].

B. Artificial Intelligence and Machine Learning

Significant advances in all areas of AI were made during 1990s, with important demonstrations in intelligent tutoring, machine learning, multi-agent planning, case-based reasoning, scheduling, data mining, uncertain reasoning, natural language understanding and translation, virtual reality, vision, and games. The early 21st century saw a boom in intelligent systems and robotics. The century witnessed the introduction of Interactive robot pets, humanoid robots. Humanoid robot capabilities were made to be able to walk as fast as a human. Search Engines saw breakthrough results with the use of Recommendation technology and Natural Language Processing. AI was introduced in understanding biological intelligence, even driving autonomous cars.

The decade from 2010 introduced virtual assistants - Siri, Google, Cortana, Alexa. Chatbots became an integral part of lives and data became the new oil. From
2010, the AI/ML/DL domain began to see applications in all aspects of life - healthcare, agriculture, transport & logistics, manufacturing, Auto & Aero and Utilities. The domain of AI has given rise to a new set of talents that are able to work with Data science toolkits (R, NumPy, Pandas, Scala-ML), Open source (Docker, Kubernetes, Helm, Linux, Horizon, etc.), AI/ML techniques and algorithms. These are technologies which promise to stay relevant for the next decade. Accordingly, college has introduced the relevant disciplines in the form of compulsory or elective subjects. They include Applied Mathematics, Python and Advanced Python, Computer Graphics and Virtual Reality, Data Mining and Business Intelligence, Big Data Analytics [11].

Fig. 3 Trends in Software Programming and Development

Fig. 4 Trends in AI/ML

Fig. 3, Fig. 4, Fig. 5, Fig. 6 and Fig. 7 signify
* Numbers represent search interest relative to the highest point on the chart for the given region and time. A value of 100 is the peak popularity for the term. A value of 50 means that the term is half as popular. A score of 0 means that there was not enough data for this term. [18]

C. Database Technology

The rise of the Internet applications led to the exponential growth of the database industry. Naive desktop users began to use client-server database systems to access computer systems that contained legacy data. The use of CGI, GCC, MySQL, Apache, and other systems brought open source

solutions to the Internet. This marked the dawn of Online Transaction Processing and Online Analytical Processing Technologies. The Data Warehousing Technology rose in demand. Despite the Internet industry experiencing a decline in the early 2000s, database applications continue to grow. Microsoft, IBM and Oracle tapped in this market trend becoming the current leading database companies.

Databases are now used to enhance our daily life. Cloud storage services, weather forecasting are applications of advanced data management technologies. The current relational databases include giants such as Oracle, MySQL, and DB2. We see a trend that focuses on making newer, potent technologies available to everyone. Database technologies alternative to RDBMS like Hadoop and NoSQL have developed. Database domain goes hand-in-hand and serves as an important prerequisite for Web as well as AI/ML domains. Data scientists expect the leading cloud database platforms to address the broader range of workloads and provide capabilities that these alternative database models have enabled.

Thus, Database modelling seems to be relevant in further coming years being a very specialized field of study. The students are taught Data Structures and Algorithms, Database Management System, SQL/PLSQL, Distributed System, Cloud Computing & Services, NoSQL, Storage Area Networks, Management Information System. While most of the concepts remain constant due to the legacy nature of the discipline, we see the inclusion of new NoSQL Technology in the IT curriculum which is seen as the rising trend in the database industry for the decade [12].

D. Information and Communication Technology

The world wide web became accessible to everyone in 1991. This led to a huge transformation in how people interact with each other and their surroundings. The internet facilitated the creation of information superhighway. The domain of ICT was powered by disciplines of Database, Web Technology and Software Engineering. Cell phones became as common as the computers in the early 2000s and the number of cell phone users grew from 12.5 million to 1.5 billion while the number of internet users grew from 2.8 million to 631 million in just a decade.

Over 2 billion people used the internet by 2012 which is twice the number using it in 2007. Cloud computing became mainstream by 2010. Half of the world's population was connected by 2016. The decade from 2010 witnessed an exponential growth IOT based devices. Daily objects started to include some form of micro computing. This also meant that these devices had all the security faults of computer systems as well.

Thus, the discipline of Cryptography and Network Security gained a small momentum which further developed into high demand jobs. Smartphones became more feature rich and more accessible. The Apple iPhone and Google's Android operating system pushed the smartphone into the mass market. Evolution of wireless technology from 2G to 5G brought faster data transfer speeds than other networks. Voice over Internet protocol (VoIP), sites like Facebook and Twitter allow users to communicate with networks of people.

The field of ICT currently has IOT as its most promising domain. The discipline of IOT being empowered by AI/ML and database has created a new discipline of Edge Technology. This new technology has created a variety of technical expertise in demand like Wireless, LTE, Bluetooth & Wi-Fi, 2G/3G/4G/5G –connectivity, protocols, security, Network infrastructure, Management, Architecture, Data Protocol (TCP/IP, SSL/TLS, DNS). The IT curriculum has adapted the required technology by providing courses on Digital Circuit Design, Principles of Communication, Computer Architecture, Computer Networks, Cryptography and Network Security, Distributed Systems, Cloud Computing Services, Microprocessor, Microcontrollers and Embedded Systems. The Curriculum has also newly included Internet of Things as a discipline for students to be able to adhere with changing industry practices [3] [5] [13].

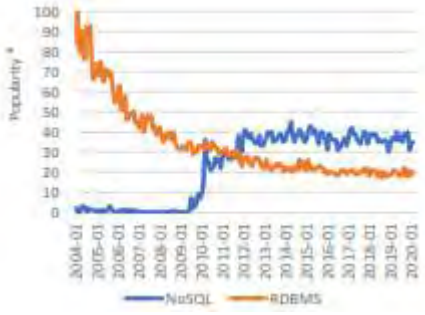

Fig. 5 Trends in Database Technology

magenta and other MVC Frameworks which are industry standards. All these subjects can be included in the curriculum to align it with the industry practices [14] [15] [16].

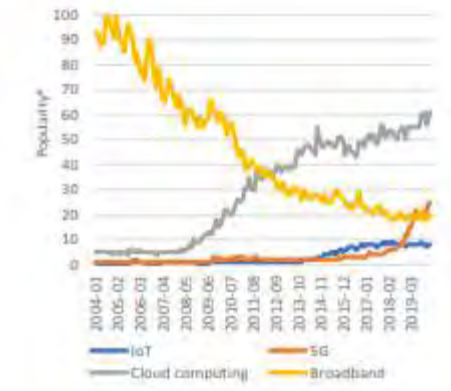

Fig. 6 Trends in ICT

E. Web Technology and E- Commerce

The decade of the 90s witnessed the rise of the Internet. The first web browser-Worldwide Web and search engine-Archie was created. HTML, flash, JavaScript became the go to scripting languages and are still at the top. This decade was a decade of experimentation and finding new applications of networking through the internet. In the later decade, W3C released new standards for HTML (HTML5) and CSS (CSS3). Development in Database technologies enabled new API Technology which help develop application interfaces for mobile technology.

The rise of handheld devices and smartphones gave rise to a new industry of Mobile App Development, Mobile- Friendly UI Design. Advancements were made in UI design with the introduction of MotionUI. Boom of ecommerce websites mandated online presence of a business since it started bringing the major business opportunity. Now, web technology includes AMP which is designed to enhance the overall performance of web content and ads while improving website speed and user experience, Progressive Web Apps , RAIL Concept, Motion UI, Browser Extensions , VR And AR, Single Page Applications, Internet Of Things, Blockchain Technology, better libraries and frameworks, Search Engine Optimization, Rich Internet Applications.

The IT Curriculum meets the industry requirements by including disciplines of Web Programming, ADO.NET, Advanced Internet Programming, Web Commerce, UI/UX Design. The curriculum has now adapted to newer technologies and methodologies of Blockchain as well Ethical Hacking and Cyber Security. On the other hand, the curriculum also lacks training on advanced frameworks like Laravel, Django,

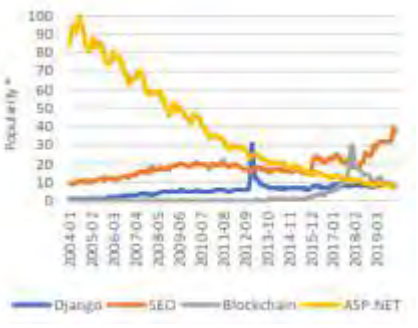

Fig. 7 Trends in Web Technology

IV. CURRICULUM DESIGN

The Second Year (S.E.) curriculum includes Program Specific core subjects such as Data Structures and Algorithms, Computer Organization and Architecture, Digital Circuit Design, Database Management Systems, Java Programming, Python Programming, Advanced Python Programming, Computer Networks and SQL/PLSQL along with laboratory sessions and project based learning sessions which would introduce to them the core areas of the particular course giving them in- depth knowledge and form the basic foundation in them.

The fifth semester offers Domain Specific "Industry Electives" such as Software Architecture, Soft Computing, Distributed Systems and Basics of Machine Learning, along with core subjects including Operating Systems, Cryptography and Network Security, Automata Theory and Web Programming, which satisfy the current Industry demands and requirements. The student's knowledge enhances and makes them abreast with the current technology.

The syllabus scheme provides credits for online courses from Semester VI onwards. This is to motivate the students to enhance their knowledge and encourage Self-Learning amongst students. Furthermore, the sixth semester has in its curriculum subjects such as ML and AI, Software Engineering and Project Management along with electives such as DevOps, Advanced Data Structures, Cloud Computing and Services, Data Mining and Business Intelligence, IOT, Advanced Internet Programming, NoSQL, Image Processing among other, in order to better familiarize students with industry-level knowledge of the technologies under implementation and to train them towards becoming more versatile.The Final Year, Bachelor of Engineering (B.E.) curriculum allows students to choose their own subjects by taking up professional electives and open electives from a comprehensive list of options that include Blockchain, Ethical Hacking, Big Data Analytics, Web Commerce, Cybersecurity and Law, Data Science, UI/UX Design, Game Development, MIS and Research Methodology. This scheme is aligned towards Generalized Knowledge which is an important component of crystallized intelligence. It would help students grow both on personal as well as academic level and develop the openness to experience and analyse situations for better solutions.

Throughout the curriculum, the students are not limited to studying the core subjects prescribed by the University. They are offered a number of Professional as well as Open electives which they can opt from as per their inclination. The students are also awarded credits for complete online courses in various domains with an aim to inculcate a habit of self-learning among the students.

Each semester is divided in two teaching schemes, namely – Program Specific and Holistic Student Development. The Program specific teaching scheme focuses on covering the core as well as domain specific electives in order to ensure that the students have a strong academic foundation. The Holistic Student Development scheme offers Professional skills, Project based learning and activity-based learning. Professional skills ensure that students are taught tools and

frameworks currently used in the industry in order to keep them up to date with industry requirements. The Project based learning provides them an environment to work in a team and learn various aspects of working collaboratively and enhance their team building skills. The Activity based learning provides them an avenue to get practical hands on experience of the skills learned throughout the coursework.

Overall, the curriculum has been designed after a thorough inspection of the trends in the IT sector over the past three decades and by analysing them to identify the direction in which the IT industry is headed over the coming years. This revised curriculum takes into consideration the changing needs of the IT industry and is so designed to provide students with a strong platform to hone their fundamentals and inculcate them with critical skills that will help them succeed as professionals. At the same time, by promoting research- based and project-based learning, the students are

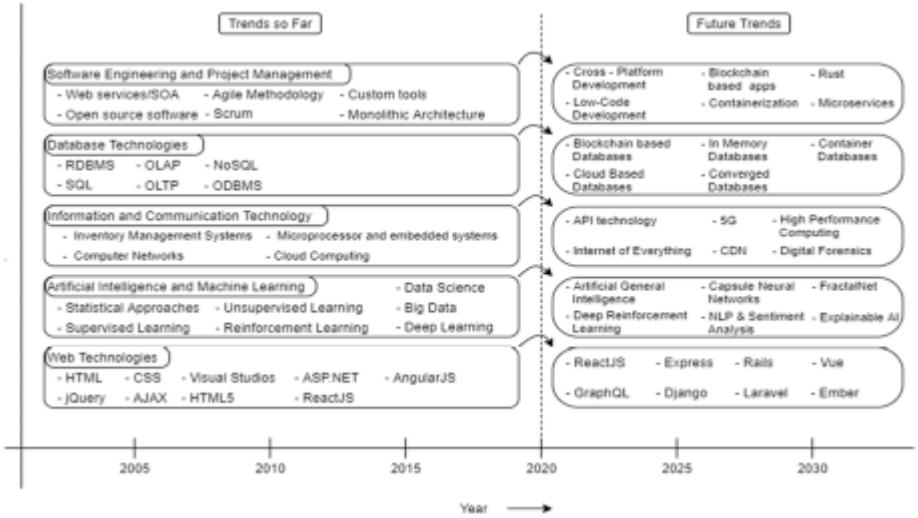

Fig. 8 Industry Trends

Fig. 9 Curricular Aspects of Academic Program

enabled to adapt to any changes by reskilling themselves as per the need of the industry.

V. FUTURE SCOPE

The theoretical instructions and concepts are introduced to students in proper depth. However, there is still lacking in the practical training provided.

One of the observed shortcomings in Programming laboratory sessions is that the practical sessions are geared towards strengthening the students' syntactical understanding of the language and not on actual practical implementations such as problem solving.

While the software engineering curriculum is up to date, modern concepts such as Git and tools such as GitHub which are widely used in industry should be introduced to students as a part of the practical sessions.

The lack of lab sessions for elective subjects such as Advanced Data Structures and Algorithms leaves the need for practical understanding of concepts. Introducing more rigorous lab sessions can help familiarize students with writing code as well as solving the type of problems that are presented to them in interviews.

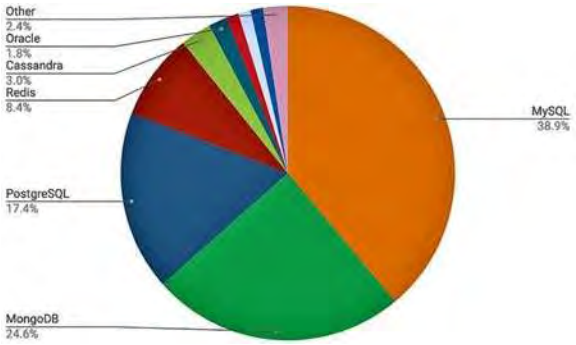

Fig. 10 Popularity of databases in use

As seen from the Fig. 10 above [17], it is clear that there is a demand in the IT industry for database engineers with knowledge of NoSQL databases such as MongoDB. The curriculum would do well to provide a strong introduction to NoSQL and Hybrid Databases, along with a more thorough explanation of data warehousing concepts.

As databases are migrating to the cloud, it is also of essence to include in the syllabus cloud computing concepts at a practical level. While the subject remains a part of the syllabus, it only does so in a theoretical capacity. Including practical applications such as cloud application development, docker, Kubernetes, etc. would enable students to get a hands-on understanding of classroom concepts.

Splitting the Internet Programming curriculum over two semesters in order to accommodate frameworks such as React, Node, Angular, etc., which are widely used in industry, as a part of the syllabus would help the department train students better. The curriculum should also include training in frameworks such as Django, Spring MVC, Ruby on Rails, etc. Given the depth and the breadth of the domain, the most viable path going forward is to allow students to choose a domain to specialize in within the department and provide extensive training in the domain to those that have opted in.

The institute has adopted a credit-based grading system. A more flexible course structure that would allow students to pursue more courses in the domains that interest them, while earning credits for the same should be implemented in order to promote specializations. The practical examinations, too, which rely heavily on oral examinations, should be replaced with project-based scoring, which will ensure student engagement throughout the semester while introducing them to new concepts in the respective subjects. While the department has largely adopted this system, the implementation relies on practical write-ups and vivas as rubrics for student scores. The credit-based system should be rigorously adopted at a practical level, wherein credits are awarded by their performance in the lab, with unique, original work as the output.

Judicial System Using Blockchain

Vinay Agarwal, Prartish Bhansali, Mahir Bhatt
Thakur College of Engineering and Technology Mumbai, India
agarwalvinay180@gmail.com, bhansalipratish287@gmail.com, mahirbhatt9@gmail.com

Abstract— **Blockchain is an incredible invention, the brainchild of an individual known by the pen name, Satoshi Nakamoto. But since then, it has evolved into a technology which holds a vision greater and better than the greatest of creations in the field of technology. A Blockchain is an incorruptible and non- tamper able public digital ledger of data collected through a network. It is how this information is recorded that provides Blockchain its ground-breaking potential. Thus, Blockchain technology provides integrity, authentication, confidentiality and security to everyone on the chain.**

The Blockchain network has no central authority or governance which is the very definition of a decentralized system. Since it is a distributed and an immutable ledger, the information in it is open for everyone to view. The legal industry has ample of features togain from the Blockchain by integrating their existing software with Blockchain.

One of the main issues of judicial systems today is the management and handling of the evidences. From the time of collection by the court it undergoes a series of ownership and scrutinizing and may lead to manipulations that may be deceitful. Also, the current process is entirely paper based processes and acting on single database system which makes it a single- server model. All the data being stored on to a single server makes the system vulnerable on being prone to attacks and can lead to permanent data loss and not to mention making the process slow. For that purpose, this project deals with successfully embedding Blockchain into the judicial systems for making it even faster, secure and making the people possessing the evidence accountable for their deeds which ultimately leads to provide equal justice to all. Our prototype is entirely developed on the Ethereum private network

I. INTRODUCTION

The world is experiencing a great pace of globalization and digitalization. An exponentially increasing number of transactions are being carried out online between entities across the world. If the awareness and implementation of the Blockchain technology becomes a world-wide reality, in a not so distant future, most goods, labour and capital will be allocated through decentralized global platforms and thus make the large amount of systems non-tamper able and error free.

The Blockchain is a digital ledger that logs transactions like a book-keeper that can be programmed to record not just financial transactions but virtually everything with a value. This ledger system is of great use to our proposed system, since all the transactions will be logged in the chain, we as a user can make a proper history of the task, which is the most crucial element of our system.

The legal system is currently paper-based that may result in loss of evidences, duplication, errors, which makes the entire process time consuming and may lead to injustice on the path of an innocent. Blockchain could shape law as much as law shapes them. Smart contracts are automatically executed as they are programmed, but it cannot analyse subjective judgments or include elements from outside the Blockchain. Existing dispute resolution technologies are too slow, too unreliable and too expensive for a decentralized global economy operating in real time. A reliable, transpare-
-nt and decentralized and accountable dispute resolutionmechanism that renders ultimate judgments about the enforceability of smart contracts, key mantra for the Blockchain era.

The sole purpose of our system is to transform the way in which the judicial entities store the data and the evidences, in order to make the system transparent and accountable and tamper-proof.

Accountability: None is held responsible for delay in current Indian Judicial System. Even though court officials might be justified in being overburdened, but finally it's the common man getting pissed off.

Provenance: Provenance of data is lacking currently in Indian Judicial System. Originals can be easily forged and hence, questionable.

A. Summary:

II. HISTORY

Transparency: Despite having privileges of certified copy for legal documents, Indian Judicial System lacks transparency mostly due to malpractices conducted by court officials.Judicial System is an important part of democracy and plays

a crucial role in how democracy works. In current Indian judicial system, there are two ways that a common man can approach court viz. via advocates or through court officials as represented in figure 1.

Fig. 1. *General Process to Approach Judicial System.*

In both the cases, legal procedure is an expensive affair. Common public has no or very limited knowledge about legal proceedings. They completely rely on advocates or court officials for any legal proceedings. There might be various reasons for same such as no legal knowledge, illiteracy, too busy or no interest to gain knowledge regarding legal process and so on. This blind trust on intermediaries might result in expensive dealings or in extreme case, cheating.

Current Challenges:

Below listed are the prominent challenges faced by current
Indian Judicial System:
Data Integration: Currently judicial officials have data records of only respective zones. Integration of criminal records across country will have better opportunity to track criminals and their past records to restrict unfortunate events in future.
Scalability: Current judicial system is not scalable enough to maintain record of cases across state.

B. Background:

In the recent years, with the emergence of the concept of Blockchain and its early use of secure and peer to peer transfer of money in terms of crypto currencies has been one of the widely witnessed phenomena globally. Ethereum was setup based on the Blockchain technology which made it efficient and secure for developing decentralized applications by setting up a private network on determining the consensus. There are about 3 crore cases currently pending in Indian courts, including 42.5 lakh cases in high courts and 2.6 crore cases in lower courts. Even if 100 cases are disposed of every hour, it would take more than 35 years to catch up. For this purpose, this project deals with creating a smart contract that will overcome the drawbacks of the current judicial system using Ethereum networks for fast judgments, reducing the paper work and bringing transparency in the overall system.*C. Problem Definition:*

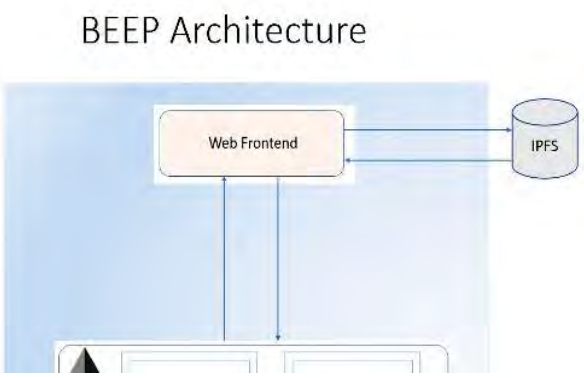
In the current law and order, the system is purely paper based processes. This might result in the loss of evidence, duplication, tampering, and errors and may lead to injustice on the path of an innocent. Using traditional database system can definitely pose a problem in future as it can be hacked, also it would not be possible to access the data when the server is down. Single point of failure can lead to permanent data loss which can be fatal for data critical tasks. The existing system has no facility to provide versioning of the evidences and is not immune to evidence tampering.

D. Proposed Aspects of the Project:

The proposed system will consist of a private Ethereum network connected to different nodes. The data will be stored on a decentralized file storage system (Interplanetary File System) and the hash of the evidence will be stored on the chain. It consists of python flask as a micro-framework. It will allow the user to create and upload the evidence and also transfer its ownership to another user in the network. The user will be the able to see the timeline of the evidence's custody in the update chain of custody module. These evidences will be stored in the IPFS and the hash associated with the evidences will be stored in the private Ethereum Blockchain. The evidences can be retrieved using the hash from get evidence module.

Ethereum private network is to be set up as fully public and uncontrolled network might cause delay in committing transactions. By setting up private network it makes it simple and fast for the users to create evidence and upload them with minimal gas consumption and also causes no delay. The smart contracts are written in solidity language. The interface is designed using Flask which is python- based framework. Python flask used for designing the frontend can be used for storing files and retrieving hash of the files uploaded in IPFS and that hash is uploaded in the network by using web3.py

III. SYSTEM ANALYSIS

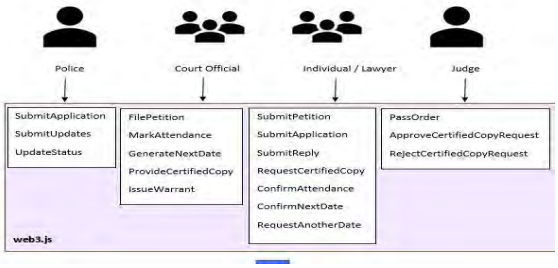


The user once registered in the network, will be able to perform various functions related to evidence. On performing any function, the transaction will be initiated and the mining of the transaction into the block will confirm the transaction. The evidence submitted or changed will be sent to IPFS, on sending the data, a hash will be generated. This ipfs hash will be stored in the blockchain with the wallet address that is logged in to the system.

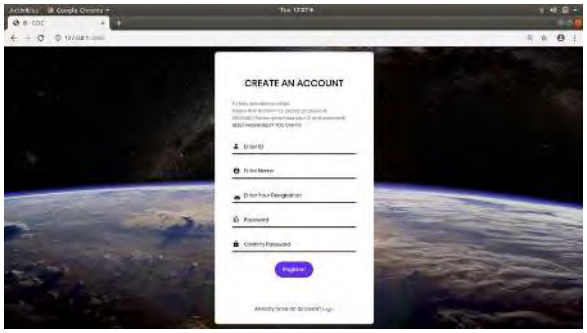
A. Methodology Used:

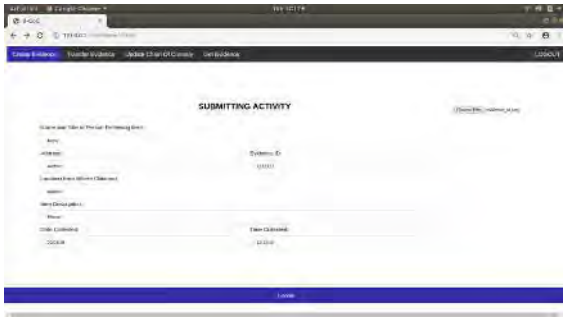
The proposed system will consist of a private Ethereum network connected to different nodes. The data will be stored on a decentralized file storage system (Interplanetary File System) and the hash of the evidence will be stored on the chain. It consists of python flask as a micro-framework. It will allow the user to create and upload the evidence and also transfer its ownership to another user in the network. The user will be the able to see the timeline of the evidence's custody in the update chain of custody module. These evidences will be stored in the IPFS and the hash associated with the evidences will be stored in the private Ethereum Blockchain. The evidences can be retrieved using the hash from get evidence module.

B. Algorithm:



C. User Interface Design(Snapshot):





IV. CONCLUSION

There are a lot of cases in our country for which justice is delayed. Judiciary is one of the strongest pillar in a democratic country. Our system is capable of reducing this delay to a considerable level as our current system is being exploited by many advocates and court officials. Current Indian Judicial System lacks accountability and transparency which will be provided by our system. Our system comprises of immutability for tamper-resistant legal record storage and management. Once uploaded into the network no one can modify, delete that evidence and once a new entry is added one cannot deny the existing ones. .

Our system has eliminated the paper based processes which will not lead to loss of evidences, duplication, tampering and errors. Our system will also assure that evidence once uploaded in private network will not be tampered or deleted. Our system makes the evidence traceable and secure. Our system will benefit the society at large level. Just as Bitcoin brought "banking for the unbanked", our system has the potential to bring "justness for the unjustness" using blockchain.

V. ACKNOWLEDGMENT

The success and final outcome of this project required guidance and assistance from many people and we are extremely privileged and honoured to have completed the project successfully.

We sincerely thank our Principal, Dr B. K. Mishra and HOD, Mr. Rajesh Bansode for always encouraging us to do our best. We are thankful to our guide Dr. Deven Shah who has supported and constantly supervised us throughout this project and helped us in completing this project and provided us with his unfathomable knowledge that was really beneficial to us.

We are thankful and fortunate enough to get constant

encouragement, support and guidance from all the Teaching staffs of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their orderly support.

We would like to express our gratitude towards our parents for their humble co-operation and encouragement which has helped us in completion of this wonderful project.

Theft detection using facial recognition via single-pixel detection with optical data security

Aman Nailwal, Umang Mishra, Mr.Vikas Kaul, Gopal Ojha
Information Technology
Thakur College of Engineering and Technology
Mumbai, India
amannailwal1@gmail.com, umangdmishra1@gmail.com, kaul.vikas@thaureducation.org, ojhagopal.98@gmail.com

Abstract— **An anti-theft system is any device or method used to prevent the unauthorized appropriation of items considered valuable. Surveillance video is used for watching known threats in real time. Video Surveillance is used to observe unusual activity going on to prevent crime."Theft detection using facial recognition via single-pixel detection with optical data security" is an Artificial Intelligence based surveillance and theft detection system which uses Al tools such as Machine Learning, Image Processing, facial recognition, etc without any human interaction involved such as security guards. The system works by placing a smart-phone in a private place as a security camera, the smart phone will be powered on and providing surveillance to the users which they can use via their android smart-phone. The system is loaded with pictures of genuine users who are not thieves, and when an unauthorized user (thief) tries to take away some belongings from there, the theft detection system immediately captures his picture and immediately notifies the user on their android smart-phone app. Hence the user is alerted and the identity of the thief is revealed and it is much easier to catch him then. Since this system does not involve any human interaction, hence it is highly cost efficient and prevents any possible human error. The system is an application that can run on Android operating systems which will do facial recognition via single pixel detection and will also provide optical data security. Basic GUI of the app is prepared using android studio to open front and rear camera of the smart phone to click pictures, and store it in mysql database these images are safe which are known to the user.**

Keywords—Android application, Facial recognition, Optical data security, pixel detection, AI based surveillance, smart phone, Theft detection.

I. INTRODUCTION

People around the world and specially in a country like India people are in a constant tautness of losing their Valuables to a potential theft. So addressing this issue we have come up with a system called as "Theft detection using facial recognition via single-pixel detection with optical data security"."Theft detection using facial recognition via single-pixel detection with optical data security" is an Artificial Intelligence based surveillance and theft detection system which uses Al tools such as Machine Learning, Image Processing, etc to solve one of the major problems of our country – Theft, without any human interaction involved such as security guards. The proposed system uses advance machine learning and image processing algorithms to detect theft and uses encryption to provide optical data security.

Video-based facial recognition is a promising technology that allows covert and unobtrusive monitoring of individuals[1]. Generally, video sequences are a collection of sequential static frames, thereby allowing the use of still-image-based techniques. However, in video-based techniques, one can utilize the temporal continuity of the image sequences to enhance robustness of the recognition process[2]. Single-pixel correlated imaging, widely known as ghost imaging, has been one of the most interesting topics in many application fields due to its remarkable characteristics. In single-pixel correlated imaging, the sample can be reconstructed by scanning the camera at reference beam arm, in which the sample is not located [2].

II. II.LITERATURE SURVEY

In paper [1] Single-pixel imaging via phase extraction is presented for optical security and flexibility enhancement. A series of random intensity patterns are pre-generated as principal security keys, and are sequentially encoded into phase-only masks. It can be advanced by using single-pixel correlated imaging as a quantum or classical technology with potential for significantly enriching the security field.

In paper [2] enhanced authentication method is used that uses video-based facial recognition technology to monitor the user during the entire session in which the person is using the system. Demonstration system uses facial recognition technology to periodically verify the identity of the user. If the authenticated user's face disappears, the system automatically performs a log-off or screen-lock operation. Uncontrolled face recognition from video can be done using newly developed algorithms to improve the facial presence monitoring system.

In paper [3] uses deep motion features as well as deep still-image features, following the success of two-stream convolutional networks, each of which are trained separately
for spatial and temporal streams. It is a Method for exploiting motion information in pedestrian detection with deep learning. The algorithms can be made more efficient so as to differ between human, still objects and animals effectively.

In paper [4] detection of events related to groups of people which are merge, split, walk, run, local dispersion, and evacuation by analysing the instantaneous optical flow vectors and comparing the learned models. It bypasses time-consuming methods such as background subtraction

and person detection and rather resorts to global motion information obtained from optical flow vectors to model the motion magnitude and velocity at each spatial location of the scene.

III. BACKGROUND

Artificial intelligence is a broad field which contains various subfields like image processing ,machine learning, deep learning, data science, NLP, etc. We planned to use the latest technologies and expertise using facial recognition with single pixel detection and optical data security in the best way to make a project that would try to solve one of the biggest security problems of the society and that is theft.

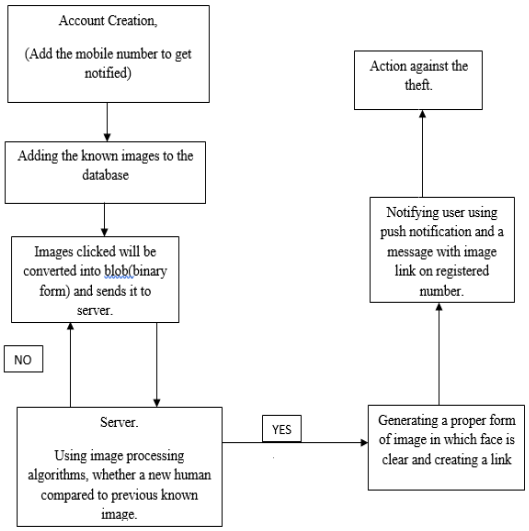
A study on image preprocessing algorithms has been carried out to improve the accuracy performance. It focused on the areas that affect the accuracy of facial recognition, which include geometric correction, face alignment, masking and photometric normalization. Single-pixel correlated imaging via phase extraction has been presented for optical security and flexibility enhancement. A series of random intensity patterns are pre-generated as principal security keys, and are sequentially encoded into phase-only masks.

IV. PROBLEM DEFINITION

We see a lot of theft going around the country like theft in the houses, apartments, jewelry shops, ATM machines, during train journey, etc. We need a system which will be smart and efficient so that the theft taking place around the country can be minimized to a great extent. The proposed system can detect theft and alert the user using advance machine learning and image processing algorithms through smart phone. Facial recognition through single pixel detection is used here with optical data security to provide data confidentiality.

V. METHODOLOGY

Traditionally, an authenticated user has to sit and look for any theft just like an video surveillance on any industry, also one of the upgraded application is in which an external security camera is placed to catch threat without any human interaction alerts the user about the threat there and thereby, whereas our system is just an application based on android operating system below is the detailed proposed architecture shown below.



VI. RESULTS & DISCUSSION

The app uses the camera of the phone to continuously take pictures of the person in front of it and processes it using image processing algorithms,it matches the picture with the already uploaded pictures of the family members and if image matches nothing happens but if it does not matches then an alert is sent to the user that a theft is being carried out. Basic GUI of the app is prepared using android studio to open front and rear camera of the smart phone to click pictures**,** and store it in mysql database these images are safe which are known to the user.We are using machine learning algorithm to generate a unique key for matching, image stored are in BLOB form which helps to protection against eavesdropping.

Facial detection is used to capture every pixels without any distortion in rgb values and image captured. Size of the image depends upon the pixels intensity and how many megapixel of camera is used hence to overcome it we will provide cloud api to enable unlimited cloud storage facility for seamless image processing, matching images, sending or receiving commands. Single-pixel imaging has a potential to prevent some attacks when the keys can be continuously modified. However, conventional single-pixel correlated imaging systems are usually established based on direct use or simple modulation of phase-only masks, and system flexibility is limited. It is also desirable that the indirect space for phase can be large to make single-pixel correlated imaging system difficult for unauthorized receivers. In this paper, single-pixel imaging via phase extraction is presented for optical security and flexibility enhancement. A series of random intensity patterns are pre-generated as principal security keys and are sequentially encoded into phase-only masks. Since different optical sensing infrastructures can be arbitrarily designed, respectively, for the extraction of

phase-only masks and object encoding, high flexibility and high security with a largely indirect (or virtual) space for phase are achieved in the proposed system.

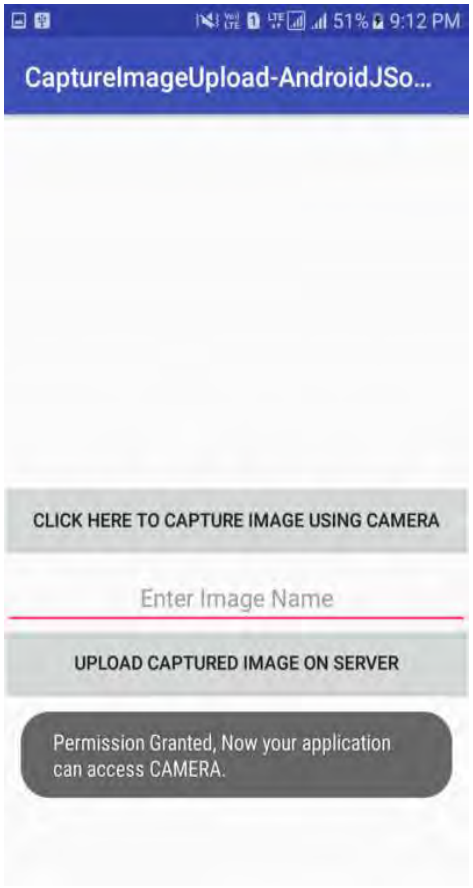


Fig:- 2 GUI to upload images on server.

Fig:- 3 GUI to activate Camera.

Fig:- 4 GUI to choose screen color and camera.

VII. CONCLUSION

This system will provide a completely automated theft detection and surveillance system by simply setting up a smartphone camera in their homes/offices/hotels etc. It will provide image recognition with optical data security. The app uses the camera of the phone to continuously take pictures of the person in front of it and processes it using image processing algorithms, it matches the picture with the already uploaded pictures of the family members and if image matches nothing happens but if it does not matches then an alert is sent to the user that a theft is being carried out.

Currently the application presents a GUI to add known images in the database either captured with camera or from an external storage, every image is converted into BLOB form. Lastly single-pixel detection is used to get the image in correct form with proper mathematical values which helps to generate unique key for matching it with known images, single-pixel imaging has a potential to prevent some attacks when the keys can be continuously modified. However, conventional single-pixel correlated imaging systems are usually established based on direct use or simple modulation of phase-only masks, and system flexibility is limited. It is also desirable that the indirect space for phase can be large to make single-pixel correlated imaging system difficult for unauthorized

receivers. In this paper, single-pixel imaging via phase extraction is presented for optical security and flexibility enhancement.

VIII. FUTURE SCOPE

Our current system is capable of identifying possible thefts along with capturing the criminal's face and reporting the owners. However the system can be further upgraded in the future to also report the incident to

the nearest police station and to get instant help from the police to catch the thief, we hope this move will highly discourage theft activities and will help the police catch the thieves swiftly at the time of crime itself. The system can be made more secure using better encryption techniques.

Abstract— **Security is that the major issue in today's world as several digital services, like Medical, Military, and house imaging systems need reliable security in storage and transmission of digital pictures. The speedy progress of net within the digital world these days, the protection of digital pictures has become additional and more vital to meet such security and privacy desires in numerous applications, secret writing of pictures is extremely vital to attenuate malicious attacks from unauthorized parties. This proposed system is meant to the people that would like privacy for his or her confidential pictures. We will see however antecedently planned strategies like encryption customary (DES), Triple encryption customary (Triple-DES), and International encryption algorithmic rule (IDEA) are applied in image protection domain and the way new ideas of Chaos-based encryption techniques are superior to ancient strategies. Our proposed system provides an answer to existing system by extending its facilities. The planned study aims to explore the likelihood of victimization chaotic or chaos-based secret writing techniques to guard essential pictures and provides high level of security in economical and reliable means.**

Keywords—Security, Attacks, Digital Image Encryption, Chaos-based encryption

I. INTRODUCTION

The development of the area Science and Technology has recently attracted a growing interest from researchers and industrial communities, in the main thanks to sizable amount of doable applications capable to take advantage of remotely perceived information and satellite pictures. Advances in area science, information analysis, and communication technologies gift new opportunities for users to extend productivity, cut back prices, facilitate innovation and make virtual cooperative environments for addressing the new challenges.

The speedy progress of web within the digital world nowadays, the protection of digital pictures has become additional and more necessary .The commonness of mixed media framework innovation in our general public has elevated advanced pictures to assume an extra essential job that requests a critical security of users‟ protection. To fulfill such security and protection needs in various applications, mystery composing of pictures is incredibly important to lessen pernicious assaults from unapproved parties. Digital image encryption is one of the safest methods of securing digital images when transmitted over unse cure channels from unauthorized copying.Sadly, acco rding to [1][2][3] several famous methods of encrypt ion like DES, RSA, AES and others function only we ll for plaintext but not for digitalimages. In most natur al digital images, the values of the neighboring pixels are closely corelated.

This unusual feature will lead to tremendous changes in each pixel of the plain image will not significantly reduce the quality of the cipher image which will mak e the content of the cipher image still easily recogniza ble by humans.

One way to solve these problems is to use chaotic sys tem (i.e. chaotic logistic map) in a cipher since, accor ding to [4][5], chaos is very sensitive to a small chan ge in the initial value and will generate the same effec t as diffusion and uncertainty.

II. MOTIVATION

The total software development life cycle (SDLC) inv olves multiple actors throughout the typical applicatio n creation

and maintenance approach.In terms of features, expen se, schedule, quality, efficiency, and other administrat ive overheads such as vendor integration, this approac h is often granulated by strategies, systems, processes , staff, and resources that

Impact the final product.Throughout the project lifecy cle, the SDLC operations and production engineer's work together from design through to the developmen t process to assist in the entire production process.

Security is been our most important aspect has most of the people are going online so for their protection we needed to do something.

III. BACKGROUND

There are many data hiding techniques some turn the data into non-understandable format, whereas some hide the existence of secret data. Few of the data hiding mechanisms are Cryptography, Steganography and Digital Signature.

1. Cryptography

The Cryptography involves 2 major processes – cryptography and coding. The method of conversion of plain text to cipher text is understood as cryptography whereas the process of conversion of cipher text back to plain text is known as coding.

In cryptography, users (sender and also the receiver) select associate formula to be adopted. This formula is then accustomed first encipher the key knowledge at the sender's finish so followed by the recipient to rewrite the encrypted data so as to reveal the initial secret message. For example: Ceaser Cipher formula.

2. Steganography

Steganography is that the art of activity information in such the way that the existence of the key data is understood solely the concerned parties.

In steganography, data is hidden during a medium referred to as cowl medium in such the way that nobody with the exception of the sender and therefore supposed recipient are aware of it. So, it doesn't attract unwanted attention of the attackers.

3. Digital Signature

A propelled imprint is a logical arrangement for displaying the realness of an automated message or record. A generous automated mark gives a recipient inspiration to acknowledge that the message was made by a known sender, with the end goal that the sender can't deny having sent the message and that the message was not changed in travel. Computerized marks are normally utilized for programming dissemination, budgetary exchanges, and in different situations where it is imperative to recognize phony or altering. Two principle properties are required. Initially, the credibility of a mark created from a fixed message and fixed private key can be checked by utilizing the relating open key. Also, it ought to be computationally in practical to create a substantial mark for a gathering without realizing that gathering's private key. An advanced mark is a verification instrument that empowers the maker of message to append a code that go about as a mark. It is shaped by taking the hash of message and encoding the message with maker's private key. A digital signature scheme typically consists of three algorithms:

1. A key age calculation that chooses a private key consistently at arbitrary from a lot of conceivable private keys. The calculation yields the private key and a comparing open key.
2. A marking calculation that, given a message and a private key, delivers a mark.
3. A signature checking calculation that, given a message, open key and a mark, either acknowledges or dismisses the message's case to validness.

IV. PROBLEM DEFINITION

Data sharing is regularly established on CD/DVD-ROM printed duplicate or on shared framework condition (Internet, LAN, WAN, etc), so there exists common security threat of unapproved access or usage of the thing. To fulfill such security and insurance needs in various applications, encryption of such data is fundamental to constrain attacks from unapproved parties and to protect unstable data.

Stage 1: Image gets gathered from our framework with appropriate configuration for encryption

Stage 2: The picture is then stacked in the product which will get scrambled utilizing the encryption calculation

Stage 3: The encoded picture is then send over system which gets by the client to get decoded utilizing the key gave to him.

V. OBJECTIVE

Despite the fact that there are many picture encryption strategies none of them are reasonable for the systems administration frameworks. So the primary extent of our venture was to give security to the pictures in the systems administration systems. Our venture gives safe methods for intends to move pictures between the systems administration frameworks privately.

This undertaking is planned to the individuals who need security for their classified picture It was generally reasonable in the systems administration frameworks, so it was increasingly qualified in Space Science look into focuses.

VI. LITERATURE SURVEY

We have undergone certain research papers based on the Image Encryption Algorithm and found out certain methodology and key findings. During the process, we have also identified certain research gaps which we can overcome while implementing our project

Venkata Krishna Pavan Kalubandi, Hemanth Vaddi Vishnu, Ramineni,Agilaeeswari Loganathan:

A Novel Image Encryption Algorithm using AES and Visual Cryptography

The cryptographic methodology proposed in this paper has been tested on different types of input images with change in size of the image and keys of AES encryptionThe confidentiality of shares is also tested by changing the key shares before reaching to the destination.

This scheme can possibly be modified to use color image in place of binary image for the key and then generate the shares using Visual Cryptography.

Bhaskar Mondal a, Tarni Mandal:

A light weight secure image encryption scheme based on chaos & DNA computing

The proposed algorithms use logistic map and DNA sequencing and is used in the substitution phase of the encryption process which makes it light weight and resistant against statistical attacks. Permutation is also done on a plain image which gives better performance and quality.

The scheme is proposed for gray label images but the scheme may be extended for color images and text data.

Riah Ukur Ginting,Rocky Yefrenes Dillak:

Digital Color Image Encryption Using RC4 Stream Cipher and Chaotic Logistic Map

Experimental results show that our method can be used as an alternative method to encrypt digital images because this method: (i) can encrypt image in such way so that cipher-image cannot be visually identified by human, (ii) eliminates statistical relation between plain-image and cipher-image.

Since in this algorithm the key stream doesn't rely on plain text in general .Due to its simplicity, vernam stream cipher is widely used as it's depends on variable key-size.

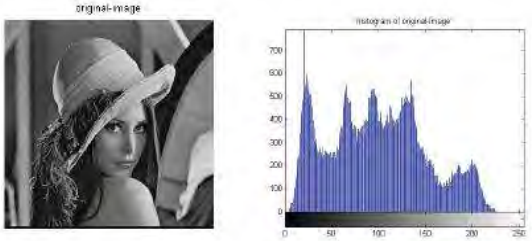
Kamlesh Gupta, Sanjay Silakari, Ranu Gupta , Suhel A. Khan:
An Ethical way for Image Encryption using ECC

The resulting system gives comparatively small block size, high speed and high security. The synthesized texture by an Mrf using the authorized key derived from elliptic curve cryptography is presumably difficult to be revealed.
The proposed system is bounded with an using Mrf texture model to cover a secret message to achieve information concealment before doing a conventional RSA data encryption.

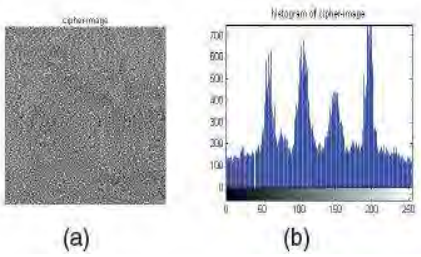
Minal Govind Avasare,Vishakha Vivek Kelkar:
Image Encryption using Chaos Theory
Relations between chaos and encryption are: a. Output has a distribution similar, b. Output changes caused by input , c. System for generating pseudorandom signal.
By doing PSNR and computational time analysis we get that above algorithm are weaker than chaos based techniques.

VII. ANALYSIS

Experimental analysis:
This is the software which has brought security in the image
Form and provide the ability to encrypt it using



Original image to histogram image



Chiper image

Security analysis:
The hidden keys should be immune to a good encrypt ion scheme, and the key space should be large enough to make Bruteforce attacks infeasible.The keyimage and initial valus of chaotic map are used in our encryption algo rithm as hidden keys.The main space is wide enough t o withstand
Bruteforce attacks of all kinds. The experimental resu lts also indicate that our scheme is very sensitive to th e mismatch of the main secrets.

Cipher	Key length	Key space
Vigenère	128	2^{128}
RC4	256	2^{256}
Salsa20	256	2^{320}
DES	56	256
3DES	168	2^{168}
AES	128	2^{128}
ECC	2*64	2^{128}
Chaotic map[49]	3*50	2^{150}

Fig; Analysis of different algorithms key space.

VIII. METHODOLOGY

In our Image Encryption tool, we have a login page in which users will login with their password. After sign in on the tool, login details are checked and if correct we insert the image on the tool on which the encryption mechanism is applied and then image is saved .After that the key is generated and the encrypted image is send across to the network to the receiver. After receiving the image at the receiver's end, the image is decrypted by using the key which was generated during encryption and then the original image is obtained.

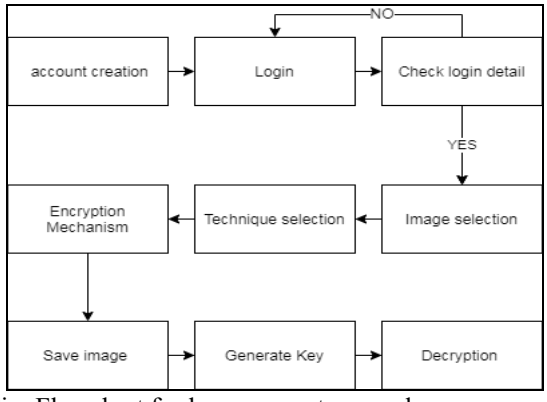


Fig: Flowchart for how our system works.

IX. RCHITECTURE

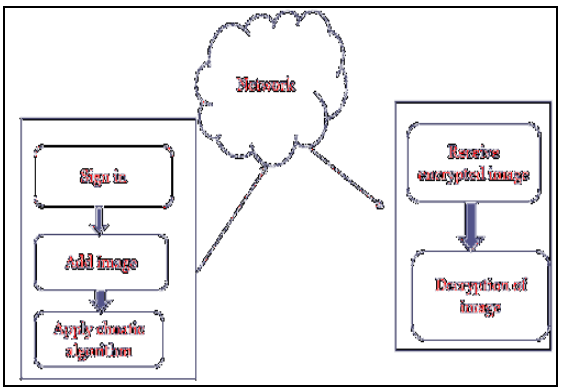

Fig. User interface contains the sign in module which consist of adding an image and applying chaotic algorithm. The encrypted image get transferred over the network to the receiver. The receiver then try to decrypt the encrypted image by using the subsequent key

Concerning the administrator the user can have memb ership. The system generates member ids dynamicall y when presenting user details. Through getting your member I d the user can have transactions. The user a ttaches the encryption file, and encrypts it for sensitiv e images.

Users of the system:

Administrator:

Administrator has all the access rights to this site. Admin will display all of the files, and the encryption and decryption process status. He will have network power over whether to approve the request for image receipt from the server. He will provide all of the image encryption and decryption benefits.

Users:

Users are the people who use this program to protect sensitive photos. This program may have different set of users. The users just load an image to encrypt and encrypt it and enter the destination systems IP address to transfer the image and he can view the status of the network for the sent image.

Guest:

Only the functionalities in the portal can be accessed by guest or new user, and they have no access rights unless approved.

X. FUTURE SCOPE

This venture speaks to a starter investigation of various components utilized for picture security featuring far reaching relative diagram of existing customary picture encryption methods like DES, Triple-DES and IDEA calculations. Some present commotion based picture encryption plans have also been immediately assessed by mulling over and inspecting various computations properties, for instance, encryption speed, comparability to picture association and weight rules, and continuous execution, etc. Presently a day‟s tumult based encryption system is getting increasingly more fame worldwide to manage interactive media informational collections particularly for pictures and is prescribed by numerous specialists. The equivalent methodology of uproar based picture encryption is needed to be applied on satellite imageries since disturbance based strategies have various genuine associations with achieve high security level in gainful and reliable manner, like affectability, ergodicity, intervention, and no normal or returning circles for huge stretches with high spread and chaos. The outline of the planed future work is the accompanying: Continue to think about other proposed encryption methods, hypotheses and calculations, for example, tumult based or disorderly cryptosystem, number hypothesis, AES, DES, RSA and so forth., should be comprehended. Research and analyze the security and heartiness of some disarray based and conventional encryption plans for huge informational indexes for example gigantic satellite pictures. Inside and out examination general frailty properties of satellite symbolism and remotely detected information, and attempt to propose some relating countermeasures, moreover, structure some new plans that have great security properties and can meet the genuine application prerequisites simultaneously.

XI. CONCLUSION

Advances in space science, information appraisal, and correspondence advances present new open passages for clients to expand profit, lessen cost, engage improvement and make virtual system masterminded conditions for watching out for new difficulties. In such procedures information sharing is all around built up on CD/DVD-ROM printed adjustment or on shared system condition (Internet, LAN, WAN, and so on) , so there exists regular security danger of unapproved access or utilization of the thing. To satisfy such security and confirmation needs in different applications, encryption of such information is fundamental to oblige malignant ambushes from unapproved parties and to shield delicate information. From the assessment of the above conventional and dissipate based picture encryption systems; it is ended clear that standard picture encryption methods DES, Triple-DES and IDEA have two or three impediments, for example, these figuring's have high security level under CBC mode yet requires enormous information size, long computational time and high getting ready power.

XII. ACKNOWLEDGEMENT

The quality and ultimate outcome of this paper involved a great deal of support and expertise from many people and

we are incredibly privileged to have successfully completed the paper. We take this opportunity to thank everybody

for their support. We sincerely thank our principal Dr. B. K. Mishra, vice Principal, Dr. Deven Shah, Mentor Dean Dr. Kamal Shah and HOD Dr. Rajesh Bansode for always guiding us to paths that were right for us. We are grateful to our guide Mr. Rahul Neve who supported and constantly monitored this work and helped us in not only completing this project but also

providing us with basic knowledge with their practical aspect that really proved beneficial to us. We are forever thankful and fortunate enough to receive constant encouragement, support and guidance from all IT department faculties that helped us finalize our paper work successfully. We would also like to extend our sincere gratitude to all the laboratory support staff for their timely support. We would like to convey our heartfelt thanks to our parents for their kind cooperation and encouragement without which none of this was possible.

hashabhishekjain@gmail.com, jineshkhatiya@gmail.com, vedantmandre29498@gmail.com, Vhatkarsangeeta@gmail.com

Abstract—**Damage caused by phishing attacks that target personal user information is increasing. Phishing involves sending an email to a user or inducing a phishing page to steal a user's personal information. This type of attack can be detected by blacklist-based detection techniques; however, these methods have some disadvantages and the numbers of victims have therefore continued to increase. In this paper, we propose a heuristic-based phishing detection technique that uses uniform resource locator (URL) features. We identified features that phishing site URLs contain. The proposed method employs those features for phishing detection. The technique was evaluated with a dataset of 3,000 phishing site URLs and 3,000 legitimate site URLs. The results demonstrate that the proposed technique can detect more than 98.23% of phishing sites.**

Keywords—phishing sites, URL-based features, heuristic, machine learning

I. INTRODUCTION

With the recent growth of the Internet environment and diversification of available web services, web attacks have increased in quantity and advanced in quality. Phishing is a type of social engineering attack that targets a user's sensitive information through a phony website that appears similar to a legitimate site, or by sending a phishing email [1]. According to research of the Anti Phishing Working Group (APWG), 85,062 phishing sites were globally detected in the second quarter of 2010; by the second quarter of 2014, 128,978 were detected. These figures mark an increase of 1.5 times the value that count of occurred phishing attack in one quarter [2,3]. In addition, annual damage caused by phishing was measured at $5.9 billion. Thus, phishing is a worldwide malicious activity that continues to increase.

In response to this increase in phishing attacks, phishing detection techniques have been the focus of considerable research. Typical phishing detection techniques include the blacklist-based detection method and the heuristic-based technique. The blacklist-based technique maintains a uniform resource locator (URL) list of sites that are classified as phishing sites; if a page requested by a user is present in that list, the connection is blocked [4]. This technique is commonly used and has a low false-positive rate; however, its accuracy is determined by the quality of the list that is maintained. Consequently, it has the disadvantage of being unable to detect temporary phishing sites [5].

Abhishek Jain, Jinesh Khatiya,
Vedant Mandre
Mumbai University

** This research was supported by Thakur College of Engineering and Technology **

The heuristic-based detection technique analyzes and extracts phishing site features and detects phishing sites using that information [6]. In this paper, we propose a new heuristic-based phishing detection technique that resolves the limitation of the blacklist-based technique. We implemented the proposed technique and conducted an experimental performance evaluation. The proposed technique extracts features in URLs of user-requested pages and applies those features to determine whether a requested site is a phishing site. This technique can detect phishing sites that cannot be detected by blacklist-based techniques; therefore, it can help reduce damage caused by phishing attacks.

II. RELATED WORKS

Phishing is an attempt to steal a user's personal information typically through a fraudulent email or website [1]. We conducted a study on phishing sites, which are either fake sites that are designed to appear similar to legitimate sites or sites that simply have phishing-related behaviors. Almost all phishing sites include the functionality in which users enter sensitive information, such as their personal identification, password, and/or account number. These sites can include links to connect to other phishing sites and malicious code that contaminates a user's computer.

Phishing detection techniques can be generally divided into blacklist-based and heuristic-based approaches. The blacklist-based approach maintains a database list of addresses (URLs) of sites that are classified as malicious. If a user requests a site that is included in this list, the connection is blocked [4]. The blacklist-based approach has the advantages of easy implementation and a low false- positive rate; however, it cannot detect phishing sites that are not listed in the database, including temporarily sites [5].

The heuristic-based approach analyzes phishing site features and generates a classifier using those features [6]. When a user requests a web page, the classifier determines whether that page is a phishing

site. This approach can detect new phishing sites and temporary phishing sites because it extracts features from the requested web page. Nevertheless, it has the disadvantage of being difficult to implement; moreover, generating a classifier is time- intensive. Thus, the two approaches have both advantages and disadvantages. Therefore, these approaches are selectively employed in the proposed technique depending on the application.

III. PROPOSED APPROACH

A. URL Structure

A URL is a protocol that is used to indicate the location of data on a network. The URL is composed of the protocol,

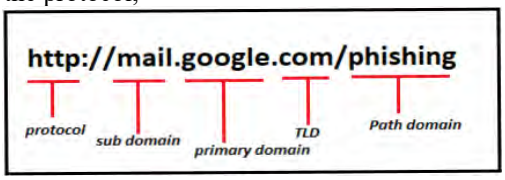

Figure 1. URL Structure.

subdomain, primary domain, top-level domain (TLD), and path domain. [6]. In this study, the subdomain, primary domain, and TLD are collectively referred to as the domain. Fig. 1 depicts the individual components of a URL.

The protocol refers to a communication protocol for exchanging information between information devices; e.g., HTTP, FTP, HTTPS, etc. Protocols are of various types and are used in accordance with the desired communication method.

The subdomain is an ancillary domain given to the domain and has various types depending on the services provided by the domain page. The domain is the name given to the real Internet Protocol (IP) address through the Domain Name System (DNS). The primary domain is the most important part of a domain. The TLD is the domain in the highest position in the domain name hierarchy architecture; e.g., .com, .net, .kr, .jp, etc. [7]. We define features of each component of the URL; these features are used for phishing site detection.

B. URL Features

Table 1 shows 26 URL-based features that are used in the proposed detection technique.

- Features 1 to 6 relate to Google Suggestion. They return a suggested word when a user enters a single term. We analyze the results of Google Suggestion when entering the URLs of phishing sites and legitimate sites. If a search term is similar to a suggested result, input URL is doubtful because that site may be emulating an existing site. We use Levenshtein distance between the two terms—the Google Suggestion result and the search term—as a feature for detecting phishing sites [6,8]. In addition, if a suggested result is the same as that of a domain that is present in the trustworthy whitelist, that search term site may be emulating a legitimate site [8]. For this reason, we can detect phishing sites using this feature.

- Features 7 to 9 can be extracted through page ranking. The page rank is a numerical value that is calculated by the number of visitors and degree of popularity. Phishing sites have a very low page rank value or no value because phishing sites are not often visited by many people and they exist for a short time [9]. Therefore, if a domain page rank value is very low, it can be regarded as a phishing site.

- Features 10 to 14, and 16, 17, 19, and 20, are associated with suspicious URL patterns and characters. Characters such as _@‘ and _//‘ rarely appear in a URL. Moreover, URLs of legitimate sites typically have one TLD. Therefore, patterns of many TLDs in a URL signify a fraudulent site [10]. Therefore, in the above cases, we classify these sites as phishing sites.

- Features 21 to 26 are characterized by URL property values. Because temporary phishing sites, as mentioned, often do not contain the required property values [11], property values can be used as features for identifying phishing sites.

Thus, many URL features exist that have been employed in several studies on phishing detection. In the present research, we incorporate features used in previous studies and define two new features for identifying existing phishing sites.

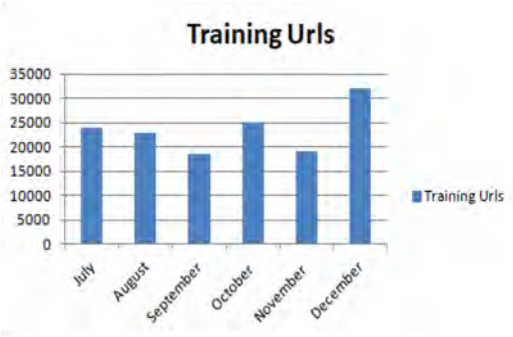

Figure2. Representation of total urls tested in a month

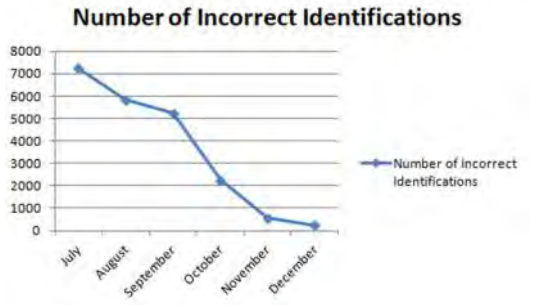

Figure3. Representation of total number of urls that are incorrectly

identified as phished website.

- Feature 15 is defined for identifying newly created phishing sites with the proposed technique. Currently, to prevent a user from recognizing that a site is not legitimate, phishing sites typically hide the primary domain; the URLs of these phishing sites have unusually long subdomains. Therefore, we added a feature that calculates the subdomain length of a URL to determine if it is a phishing site. This feature can be additionally used to identify phishing sites that target vulnerabilities of smartphones, which have small displays that make it difficult to see the full URL.
- Feature 18 is another new feature that reflects current phishing trends. This feature includes eight words that are predefined as phishing terms. It is verified if a requested page's URL contains these phishing terms [12][1]. This feature worked well in previous studies; however, we determined that changes have occurred since the studies were conducted. Thus, through experiments, we identified eight new phishing terms[2] and we employ them in our phishing detection technique.

As noted above, our proposed method employs new features that have not been previously used in studies. IN addition, it advances features from previous works to provide better phishing detection performance.

C. Architecture

The given below figure illustrates the proposed phishing detection process, which includes two phases: training and detection.

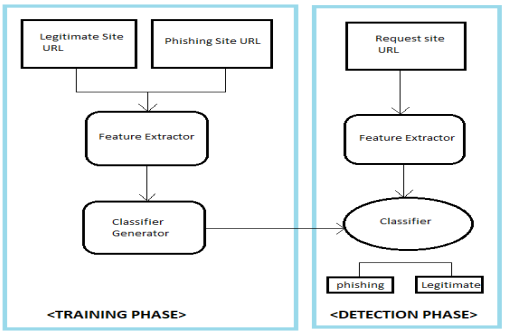

Figure 4. Process of proposed detection method.

In the training phase, a classifier is generated using URLs of phishing sites and legitimate sites collected in

advance. The collected URLs are transmitted to the feature extractor, which extracts feature values through the predefined URL-based features. The extracted features are stored as input and passed to the classifier generator, which generates a classifier by using the input features and the machine learning algorithm.

In the detection phase, the classifier determines whether a requested site is a phishing site. When a page request occurs, the URL of the requested site is transmitted to the feature extractor, which extracts the feature values through the predefined URL-based features. Those feature values are inputted to the classifier. The classifier determines whether a new site is a phishing site based on learned information. It then alerts the page-requesting user about the classification result.

D. Survey

To determine a classifier with the best performance for using URL-based features, we employed several machine learning algorithms: support vector machine (SVM), naive Bayes, decision tree, k-nearest neighbor (KNN), random tree, and random forest.

- SVM is a classification method that was introduced in 1992 by Boser, Gyon, and Vapnik [13]. It is a statistical learning algorithm that classifies samples using a subset of the training samples, called support vectors. SVM is built on the structural risk minimization principle for seeking a decision surface that can separate data points into two classes with a minimal margin between them [14]. The advantage of SVM is its capability of learning in spare high-dimensional spaces with very few training samples.
- Decision tree is a classification method that was introduced in 1992 by Quinlan [15]. It

creates a tree form for classifying samples. Each internal node of the tree corresponds to a feature, and the edges from the node separate the data based on the value of the feature [15]. Decision tree includes a decision area and leaf node. The decision area checks the condition of the samples and separates them into each leaf node or the next decision area. The decision tree is very fast and easy to implement; however, it has the risk of overfitting.

- Naive Bayes is a classifier that can achieve relatively good performance on classification tasks. It is based on the elementary Bayes‘ theorem. It is one of most successful learning algorithms for text categorization [16]. On account of the conditional model‘s feature, naive Bayes is effectively trained in supervised learning. It provides the advantage of learning essential parameters using small training samples.
- KNN is a non-parametric classification algorithm [17]. It has been successfully applied to various information-retrieval problems. It classifies the input data using k training data that is similar to the input data. KNN uses Euclidean distance to calculate the similarity between the input and training samples. Its performance is determined bythe choice of k; nevertheless, choosing a suitable k
value is not easy.
- Random tree is a tree-based classification method that was introduced by Breiman and Cutle [18]. A tree is drawn at random from a set of possible trees.
―At random‖ means that each tree in the set of trees has an equal chance of being sampled [18]. The random tree classifier takes as input a features vector and classifies it with each tree. The output is determined by the majority ―vote. This algorithm can handle both classification and regression.
- Random forest is a classification method that combines many tree predictors; each tree depends on the values of a random vector that is independently sampled [19]. All trees in the forest have the same distribution. This algorithm can handle a large number of variables in the dataset; however, it lacks reproducibility because the process of forest building is random [20].

IV. EVALUATION

To conduct classifier training and evaluation through an experimental dataset, we collected the URLs of phishing and legitimate sites. We gathered 3,000 phishing site URLs from PhishTank and 3,000 legitimate site URLs from DMOZ. The evaluation was conducted using k-fold cross validation. K-fold cross validation divides the input data into k; k – 1 datasets are used for training, and the remaining one is used for validation. This process is performed k times, such as the number in the divided dataset, because all datasets can be used for training and validation. This method is typically used to evaluate the accuracy of the classifier with a small dataset. In this study, we used ten-fold cross validation to evaluate our detection technique. We performed the testing with the WEKA open-source machine learning tool, and we analyzed the performance of each of the machine learning algorithms noted in Section 3. The accuracy was calculated as TP (true positive), TN (true negative), FP (false positive), and FN (false negative). We compared the performance of each classifier using the calculated accuracy. Fig. 3 depicts the TP, TN, FP, and FN matrix.

Figure 5. TP, TN, FP, FN matrix

TP is the ratio of the prediction that a determined phishing site is indeed a phishing site, and FN is the ratio of the prediction that a determined phishing site is actually a legitimate site. In addition, FP is the ratio of the prediction that a truly legitimate site is a phishing site, and TN is the ratio of prediction that a determined legitimate site is indeed a legitimate site. Table 2 shows the TP, TN, FP, FN ratios of each machine learning algorithm.

As a result of the experiments, we obtained TP, TN, FP, and FN ratios to calculate three measurements that we used to compare the performance of each algorithm. The first

measurement was for the specificity of the true negative rate. The second was the sensitivity of the true positive rate. The third was the accuracy of the total ratio of the prediction that a determined phishing site is actually a phishing site, and that a determined legitimate site is indeed legitimate.

TABLE I. TF, TN, FP, AND FN OF MACHINE LEARNING ALGORITHMS

Algorithm	Measurements			
	TP	TN	FP	FN
SVM	97.00%	94.90%	5.10%	3.00%
Decision Tree	96.90%	96.90%	3.10%	3.10%
Naive Bayes	90.90%	95.10%	4.90%	9.10%
KNN (k = 1)	96.30%	96.00%	4.00%	3.70%
Random Tree	96.10%	96.00%	4.00%	3.90%
Random Forest	98.10%	98.40%	1.60%	1.90%

In measuring the classifier performance, (1)

was the equation of specificity, (2) was the equation of sensitivity, and (3) was the equation of accuracy.

		Prediction	
		Positive	Negative
Actual	True	*True Positive*	*False Negative*
	False	*False Positive*	*True Negative*

$$\text{Specificity} = \frac{TP}{TP+FP} \quad (1)$$

$$\text{Sensitivity} = \frac{FP}{FP+FN} \quad (2)$$

$$\text{Accuracy} = \frac{TP+TN+FP+FN}{TP+TN} \quad (3)$$

We additionally used the specificity, sensitivity, and accuracy as measurements of the classifier performance measurement. Table 3 shows the specificity, sensitivity, and accuracy of each machine learning algorithm that we used in training.

TABLE II.EXPERIMENTAL RESULTS OF ALGORITHMS

Algorithm	**Measurements**		
	Specificity	**Sensitivity**	**Accuracy**
SVM	96.93%	95.00%	95.95%
Decision Tree	96.90%	96.90%	96.88%
Naive Bayes	91.26%	94.88%	93.01%
KNN (k = 1)	96.28%	96.01%	96.18%
Random Tree	96.09%	96.00%	96.03%
Random Forest	98.10%	98.30%	98.23%

As a result of the experiment, we determined that the best machine learning algorithm, random forest, used URL features. This classifier detected more than 98.23% of phishing sites. The high accuracy shown in Table 3 and low false-positive rate shown in Table 2 meant that the proposed phishing detection technique can effectively classify sites as either being phishing or legitimate..

V. CONCLUSION

In this paper, we proposed a heuristic-based phishing detection technique that employs URL-based features. The method combines URL-based features used in previous studies with new features by analyzing phishing site URLs. Additionally, we generated classifiers through several machine learning algorithms and determined that the best classifier was random forest. It showed a high accuracy of 98.23% and a low false-positive rate. The proposed technique can provide security for personal information and reduce damage caused by phishing attacks because it can detect new and temporary phishing sites that evade existing phishing detection techniques, such as the blacklist-based technique.

In future work, we intend to address the time-intensive disadvantage of the heuristic-based technique. With a large number of features, it is time-consuming for the heuristic- based approach to generate classifiers and perform classification. Therefore, we will apply algorithms to reduce the number of features and thereby improve performance. In addition, we will examine a new phishing detection technique that uses not only URL-based features, but also HTML and JavaScript features of web pages to improve performance

Abstract-:

The Internet of things is the combination of devices, apps, sensors and network connectivity that enhances these entities to gather and exchange data Technology that enhances these features is already available but is not accessible and affordable by most of the people in developing countries such as India.

The project aims at creating an intelligent but lightweight healthcare assistant. This application will be able to help healthcare and other hospital staff work efficiently. The system monitors patient's health standing, such as heart rate, and temperature. In case, the worth for any of those parameters exceeds predetermined essential values, the position parameters, from the hooked up WIFI module, square measure transmitted to predefined net Application web site. The data is been sensed and encrypted using the AES algorithm and transmitted to the server over the wifi module. This helps to maintain the security of the data which is been fetched and updated continuously to the web application. The project relies on open-source software, such as C Sharp (C#), ASP. Net, Visual Studio, Microsoft SQL Server. The functionality provided by these software's is enough to construct a product capable of usage for healthcare applications. For IoT hardware components such as Heartbeat Sensor, Body Temperature Sensor, Arduino, WIFI Module (ESP8266) (For Data Transmission), which can be readily available in the market. These technologies are used to build a secure data transmission for health care. The result of Secure Data Transmission for Health Care is of extreme use to patients and doctors as well. The patient's family member can check the patient's health status anytime from the comfort of their homes and visit hospitals only when they need to.

Keywords: -IOT, AES Encryption, Sensors, Security, Wifi Module

I. INTRODUCTION

Cost reduction pressures and the need for shortened in-patient stays are promoting the use of IoT Secure Data Transmission for Health Care in hospitals. Their contribution to better process management, superior flexibility and increased efficiency within hospitals is further underlining the appeal of wireless networking options for systems. Improved home care facilities and regular health updates to clinicians reduce the chances of redundant or inappropriate care. [1] It improves patient care and safety by reduction in overall costs for care. Internet of Things (IoT), gather and share information directly from patients and it also make possible to collect, record and analyze new Data Stream faster and more Accurately.

[2] As the technology for collecting, analyzing and transmitting data in the IoT continues to mature, with the help of sensors, actuators, and computing devices. [3] This provides data communication capabilities and security using the encryption algorithm which makes the sensed data safe from any type of attack. These are linked to networks for data transportation. This connected healthcare environment promotes the quick flow of information and enables easy access to diseases such as hypertension, diabetics and cardiac diseases which needs continuous monitoring. [4] This Internet of Things (IoT) is increasingly recognized by the researchers and analysts as one of the most sophisticated technologies for health monitoring and it is safety for people and it also tackled by all. [5] The ability of the devices to gather data on their own removes the limitations of human intervention and it reveals the data-automatically and send it to the doctor whenever they needed. The automation reduces the risk of error. [6]

I. OBJECTIVE AND SCOPE OF THE PROJECT

We will have an application server which will work on any platform supporting multiple departments and its sections present in-hospital major essential areas where all the emergency is required.

A. Objectives:-

1. This project aims at the planning and implementation of a coffee value; however, economic and versatile heartbeat watching and alert system exploitation IoT technology.[3]
2. It is designed in such a way that the heartbeat/pulse rate and body temperature are sensed and measured by the sensors which are being encrypted using the encryption algorithm and sends the signals to the control unit.[1]
3. Proper processing and determination of the heartbeat rate which is displayed on a Website, it then.

B Scope: -

1. The Secure Data Transmission for Health Care is widely used in the healthcare system to sense the patient's heartbeat and body temperature value and to continuously update the data value on the website using the WIFI Module.[1]
2. Storing the patient's information over the cloud, which could be easily updated and accessible by the patient's family members.[6]
3. Here AES and DES encryption algorithm is been used for secure data transmission.[3]

Keywords: - Emergency, Alert, Email, Website, Threshold

II. LITERATURE SURVEY

Analysis of the current market scenario and technological capabilities is essential to the building of a project. Here we analyzed various prevalent research papers pertaining to our project as a part of the literature survey. The project
Aims at creating an intelligent but lightweight healthcare assistant. This application will be able to help healthcare and other hospital staff work efficiently.[3]
Our literature survey was focused on the capabilities of
The choices we made for the core part of the project, namely Internet of Things (IoT) and the use of wearable technology for data collection.[2]Sensing Processing Unit 3.Cloud Server Analyses

III. PROBLEM DEFINITION

The Internet of Things (IoT) is a device which gathers and share information directly with transmitter and receiver, this enables the doctor to collect record and analyze new data streams faster and more accurate. The heart rate and body temperature are sensed and transmitted to the cloud server using the wifi module for monitoring purpose and it is been continuously been sensed and updated on the web application. The data which is been
is encrypted using the AES algorithm for data security

IV.PROPOSED METHODOLOGY

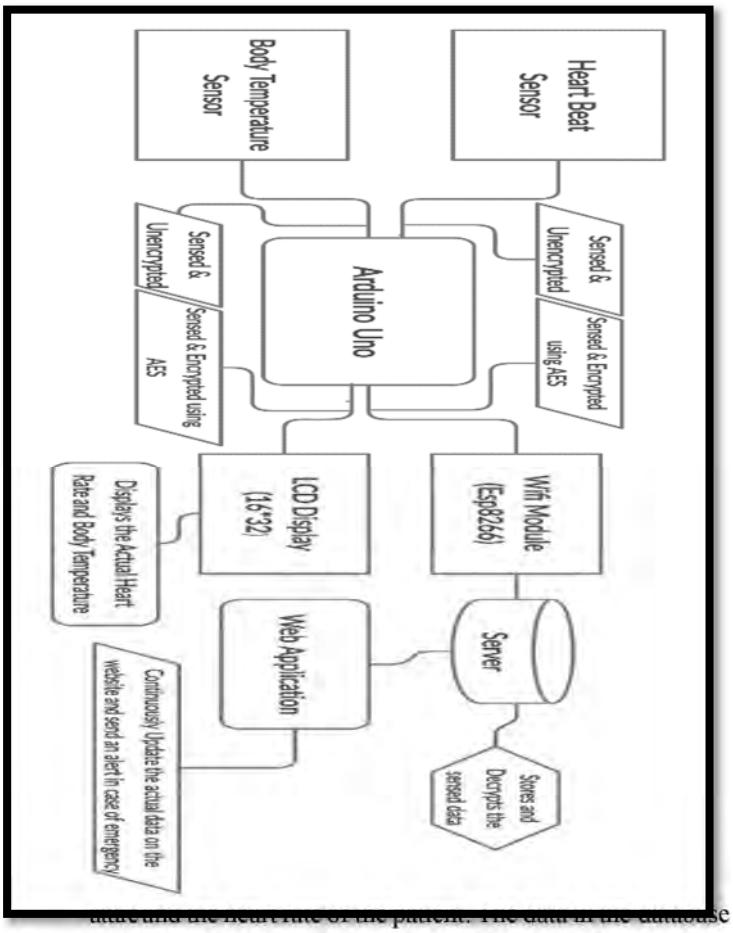

Fig 2: - Block Diagram for secure data transmission of health care

will help us to analyses whether the patient is in good condition or not and we will get to know each and every detailed information of the patient in a secured way through the secure data transmission. The website will give the notification to the patient's family members and the doctors to keep them updated regularly without getting into any tble.

A. Block Diagram

The Temperature and Pulse sensors are connected to the Arduino Temperature sensor gives the readings of room temperature and Humidity of the Patients Healthcare room through GPIO pins. Pulse Sensor gives the pulse rate readings of the heart of the patient. The code which we will implement will capture the data in encrypted format and push online to the server database.[2] There would be a web-based application where we will retrieve this sensed data and process it to show the temper

A. HEARTBEAT SENSOR

Heartbeat device is intended to provide a digital output of heartbeat once a finger is placed on that. Once the center beat detector is functioning, the beat light-emitting diode flashes in unison with every heartbeat. This digital output may be connected to the microcontroller on to live the Beats per Minute (BPM) rate. It works on the principle of sunshine modulation by blood flow through finger at every pulse.[5]

B. BODY TEMPERATURE SENSOR

The Dellas temperature generates a better output voltage than thermocouples and should not need that the output voltage is amplified; Psychological factors conjointly influence body temperature: an excited person typically has an elevated associate temperature. Traditional soma temperature, conjointly called physiological state or euthermia, is that the global temperature varies found in humans. The usual soma temperature varies usually declared as thirty-six .5–37.5 °C (97.7–99.5°F). It could be a preciseness IC temperature device with its output proportional to the temperature (in C). The electronic device equipment is sealed, and so it's not subjected to reaction and alternative processes. With this, the temperature may be measured additional accurately than with a semiconductor. It conjointly possesses low self- heating and doesn't cause quite zero.1 of temperature rise in

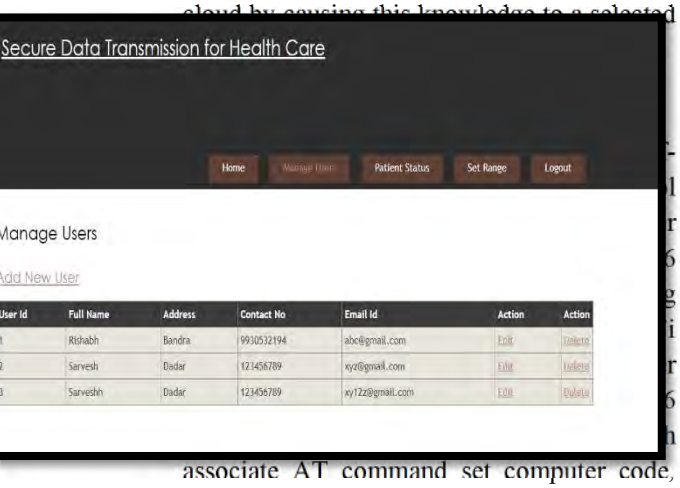
B. HEARTBEAT SENSOR

Heartbeat device is intended to provide a

D. ARDUINO

Arduino refers to associate ASCII text file physics platform or board and also the code want to program it. The Arduino UNO board unendingly reads input from these three

senses. Then it sends this knowledge to the



associate AT command set computer code, meaning, you'll merely hook this up to your Arduino device and acquire concerning the maximum amount Wi-Fi-ability as a Wi-Fi. The ESP8266 could be a cheap Wi-Fi chip with full TCP/IP stack and MCU (Micro Controller Unit) capability made by Shanghai-based Chinese manufacturer.[3]

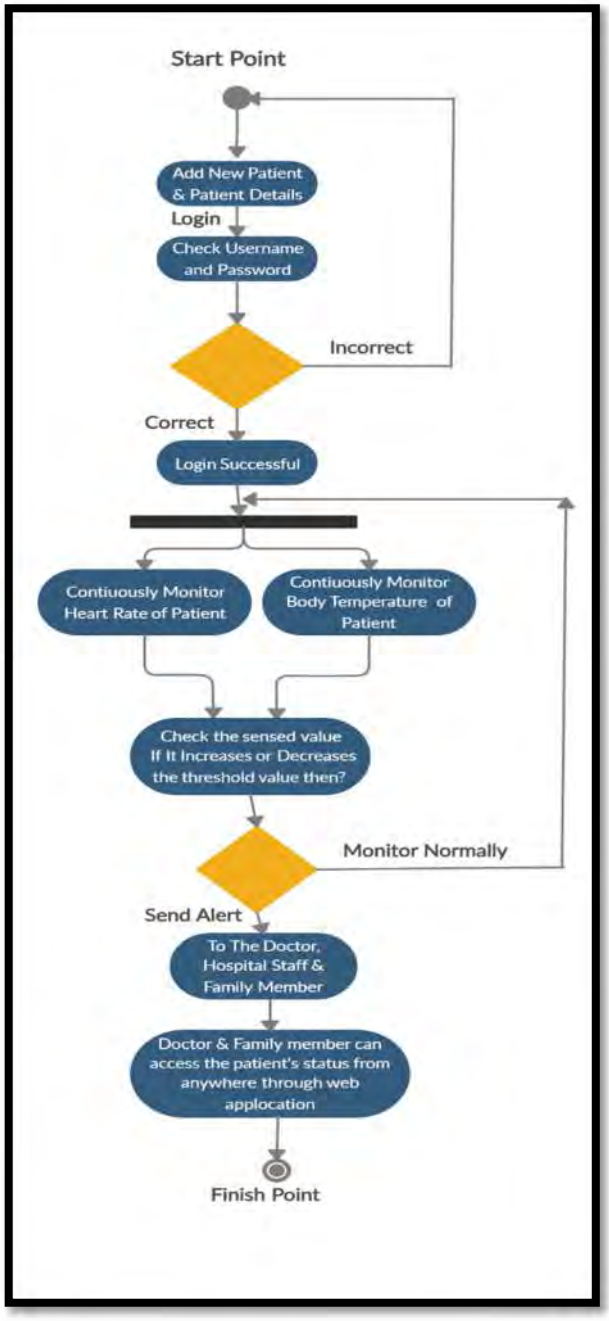
Here we have connected the temperature sensor and the pulse sensor to the

Arduino through which the detected data of

V. ACTUAL RESULTS

the patient is going to get secured through the AES encryption technique and ESP8266 is the Wi-Fi module in order to transfer the data wirelessly over the internet to the server. In case, the worth for any of those parameters exceeds predetermined essential values, the position parameters, from the hooked up WIFI module, square measure transmitted to predefined net Application web site. The data is been sensed and encrypted using the AES algorithm and transmitted to the server over the wifi module. This helps to maintain the security of the
data which is been fetched and updated continuously to the web application.[4]

F. Activity Diagram



A. Outputs

Fig 4: -- To Add New User

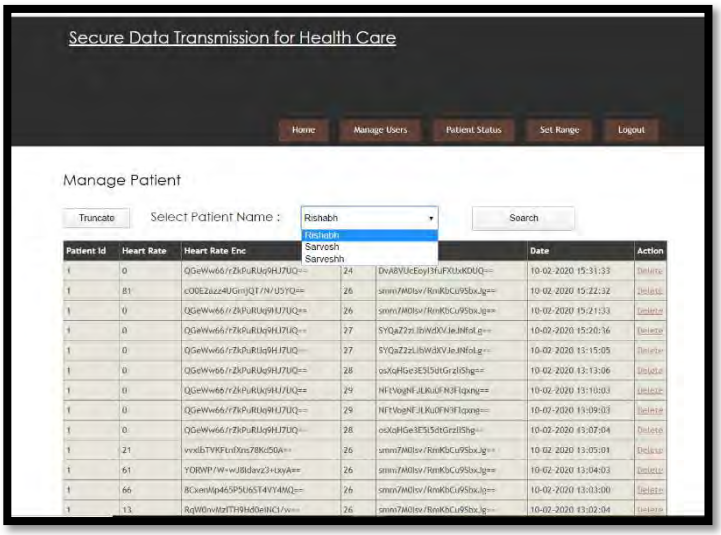


Fig 5: -- To Manage the Patients Heart Rate and Body Temp

Fig 6: -To set the threshold value according to the patient diseases.

The Pulse rate and Temperature Sensor detects the level of the humidity and temperature of patient's healthcare room and pulse rate sensor measure the level of pulses in the patient body. The result would be displayed on the webpage. This helps the concerned authority to carry on a require action.[1]

B. Outcomes

The following are the outcomes were observed as a result of implementing the product:

- Data transmitted securely through the AES encryption algorithm.
- Temperature and Pulse rate of the patient been detected.
- Transmit the information wirelessly to Webpage.
- The data can be accessed anytime and from anywhere.
- The real-time data transmission and access.
- Instant Alert to the end use.

C. Discussion of the Results

The physiological monitoring system provides different monitor units for different clinical purposes. This system architecture increases the flexibility of this system. Moreover, this system based on the Wi-Fi network is highly flexible and can be easily connected. Besides, according to the fast development of wireless technologies and the increasing communication bandwidth, we can expect that more wireless services will be provided and can be readily incorporated into the telemedicine services in the future.[5]

Keywords: - Accessed, Wirelessly, Real-Time, Flexible, Telemedicine

VI. CONCLUSIONS

This technique presents a system to upgrade existing health monitoring systems in the hospitals by providing monitoring capability and thus a better cure. This system is based upon wireless technology i.e. Cloud Computing providing low cost-effective solution. As it is wireless device, the cost of cables is reduced here. This intelligent monitoring system provides long term monitoring capability useful for the staff in the hospitals and reduces their workload. By our project we were able to measure human body temperature as well as heart rate and monitored in a remote pc or in a web application over the internet.[2] The Secure Data Transmission for Healthcare is of extreme use to patients and doctors as well. The patient can check their health status anytime from the comfort of their homes and visit hospitals only when they really need to. This can be done by using our system whose result are brought online and can be seen from anywhere around the world. Since it is a

prototype model, our system shows the almost real time values of various health parameters and emulates how the same can be implemented in the real world. The doctors can also use the log of the patient body condition to study and determine the effect of medicine or other such things.[3]

Instant availability of the patient's information is the main aim of the project. Heart beat can be sensed by using heart beat sensor which is then given to a signal conditioning circuit. This indeed is an easy, practical, inexpensive and yet very effective way for transmitting vital information to the healthcare staff and healthcare providers. The system monitors patient's health status, heart rate, and temperature. In case, the value for any of these parameters exceeds preset critical values, the position parameters, from the attached WIFI module, are transmitted to predefined Web Application Site. [6]

Keywords: - Cloud, Cost-Effective, Application Site, Secure, Transmission

VII. FUTURE SCOPE

The system can be further improved further by adding artificial intelligence system components to facilitate the doctors and the patients. The data, consisting medical history of many patients' parameters and corresponding results, can be explored using data mining, in search of consistent patterns and systematic relationships in the disease. [3] For instance, if a patient's health parameters are changing in the same pattern as those of a previous patient in the database, the consequences can also be estimated. If the similar patterns are found repeatedly, it would be easier for the doctors and medical researchers to find a remedy for the problem.[6]

RPM (Remote Patient Monitoring) device can be used

Remote patient monitoring (RPM) is a technology to enable monitoring of patients outside of conventional clinical settings (e.g. in the home), which may increase access to care and decrease healthcare delivery costs.[2]

It can be used in an RFID (Radio Frequency Identification) card.

Where the data can be stored on cloud. By just tapping the card we could retrieve the patient's past information. This system, which can be created by integrating a probable patient information system and proposed RFID application, is seen as a proper solution in cases when doctors want to have fast and automatic access to patient information and in

Particular when patients are not able to establish healthy communication.[1]

Abstract—**In recent times the concept of smart cities has gained great popularity. Thanks to the evolution of Internet of things the idea of smart city now seems to be achievable. Consistent efforts are being made in the field of loT in order to maximize the productivity and reliability of urban infrastructure. Problems such as, traffic congestion, limited car parking facilities and road safety are being addressed by IoT. Car parking is a major issue in modern congested cities of today. There simply are too many vehicles on the road and not enough parking space. This has led to the need for efficient parking management systems Smart parking enables better and real time monitoring and managing of available parking space resulting in significant revenue generation, better urban environment and reduces fuel consumption. Present days getting a parking space in urban areas is very difficult in peak ours due to lack of parking spaces. Due to this driver stuck in traffic or looking for parking paces around the location makes traffic congestion. This causes waste of money and time. So if we have parking space information, we can plan for advance booking based on acquirement, for that we developed a prototype of cars parking management system using Internet of things. Our system proposes an loT based Smart city car Parking System on Streets which enables the user to park his vehicles in a systematic way and it reduces congestion in parking area.[3]**

I. INTRODUCTION

nternet and its applications have become an integral part of today's human lifestyle. It has become an essential tool in every aspect. Due to the tremendous demand and necessity,
researchers went beyond connecting just computers into the
web. These researches led to the birth of a sensational gizmo, Internet of Things (IoT). Communication over the internet has grown from user-user interaction to device – device interactions these days. The Sensor Network Lab concepts were proposed years back but still, it's in the initial stage of commercial deployment. Home automation industry and Transportation industries are seeing rapid growth with Sensor Network Lab. Since most of the process is done through the internet we must have an active high-speed internet connection. The technology can be simply explained as a connection between humans' computers-things. All the equipment's we use in our day to day life can be controlled and monitored using the Sensor Network Lab. A majority of the process is done with the help of sensors in Network Lab. Sensors are deployed everywhere and these sensors convert raw physical data into digital signals and transmit them to its control center. By this way, we can monitor environmental changes remotely from any part of the world via the internet. This systems architecture would be based on the context of operations and processes in real-time scenarios. The Smart Parking Lot system works in a similar manner, with the use of a number of Ultrasonic sensors connected with a Node MCU (ESP8266) for transmission of collected data to the cloud and then to the user interface, which in our case is a website linked to cloud, using java script. The occupancy status of the parking slot is displayed on the GUI using HTML and CSS. The proposed system eliminates congestions usually faced at parking lots.[5]

II. BACKGROUND

The conventional as well as current parking systems as seen in various public places like malls, theatres, stadiums etc. have various drawbacks. The main is issue in these systems is finding or locating a parking spot that is vacant. To find a parking spot, one has to drive all around the parking lot which

can range from a few 100 sq. meters to a multi-tiered parking lot. This approach of finding a vacant parking space is extremely time consuming and inefficient. 3 Conventional parking could soon be a thing of the past. There are just too many advantages to an automatic parking system! The population is growing, and cities are running out of space. This is where the automatic parking system comes in. It doesn't only save space, but also time and money. Let's start with the disadvantages about conventional parking: The search for a parking space. Sometimes you have to drive around for ages. That's why good parking guidance system and digital signage are very helpful.

III. IMPORTANCE OF PROJECT

The various benefits and importance of attesting smart parking systems in large cities such as Mumbai are as follows:-

1. Since the entire parking system is automated, this will cut down the need of employees to manage the area, thus

cutting down the costs as well as eliminating the need of manpower.

2. Users can remotely get an overview of the parking space before actually being physically present at the area

3. Users can drive directly to the parking spot that is vacant thus eliminating congestion for the other drivers.

IV. LITERATURE SURVEY

1. "Webserver Based Smart Monitoring System Using ESP8266 Node MCU Module" BY: Dlnya Abdulahad Aziz, International Journal of Scientific and Engineering Research, ISSN 2229-5518, June 2018

The term internet of things (IOT) is considered as an important and popular technology aspect nowadays. Life style controllability based on (IOT) became considerably simpler and easier especially in the communicating approaches among the smart devices. The methodology of (IOT) allows accessing and controlling the devices anywhere and anytime. The tendency of this aspect is to communicate among various devices with respect to ESP8266 Node MCU module. The devices even can be controlled with respect to the employed ESP stations. The adeptness of data transfer among the proposed remote locations depends mainly on the behavior of the system while the security and the applicability of the system are considered more efficient. This work shares the information of air quality, Temperature and Humidity in three food stores at three remote locations with each other based on ESP module through web server.

In addition, two control actions are taken automatically in accordance with temperature and air purity output results. First, the air cooler is turned ON to cool the foods in the stores and second the air puller is turned ON to pull the contamination out of the proposed locations. Furthermore, these control actions even can be applied manually by web server administrative person. Finally, the ESP based system is classified as inexpensive project comparing to GSM module.

2. "IoT Based Smart Parking " BY: Dr. Rishi Anand, Abhirup Khanna, International Conference of Internet Of Things and Applications, IEEE 978-1-5090-0044, January 2016

In recent times the concept of smart cities have gained grate popularity. Thanks to the evolution of Internet of things the idea of smart city now seems to be achievable. Consistent efforts are being made in the field of IoT in order to maximize the productivity and reliability of urban infrastructure. Problems such as, traffic congestion, limited car parking facilities and road safety are being addressed by IoT. In this paper, we present an IoT based cloud integrated smart parking system. The proposed Smart Parking system consists of an on-site deployment of an IoT module that is used to monitor and signalize the state of availability of each single parking space. A mobile application is also provided that allows an end user to check the availability of parking space and book a parking slot accordingly. The paper also describes a high-level view of the system architecture. Towards the end, the paper discusses the working of the system in form of a use case that proves the correctness of the proposed model.

3. "Traditional Infrastructure vs Firebase Infrastructure" BY: Sonam Khedkar, Swapnil Thube, IJSRD - International Journal for Scientific Research & Development, ISSN: 2321-0613, 2017

The purpose of this study is to introduce everyone with the amazing features of Firebase that can be useful to rocket boost an Application. Traditionally to get best out of an app we need a huge, expensive, bulky methods or code to be used or implemented, long process of testing which consist of a server and large amount of complex codes, third party API's and even dedicated teams. This takes customer and developer quite far from their destiny of having an application which would be reliable, bug-free and sustainable in long run. Google's Firebase Provides such an extraordinary aid to developers/ customers which can't be possible to think of, from traditional infrastructure. This article focuses on digging into an Amazing product named Google's Firebase and its various features such as Cloud Messaging,

Authentication, Storage, Real-time Database and few more.

V. MOTIVATION

In huge metropolitan cities, the population being large enough to cause congestion at any place, parking spaces to those cities get adversely affected by the large number of vehicles that are present in that city. The main is issue in these systems is finding or locating a parking spot that is vacant. The primary motivation behind this proposed system is:-

1. The conventional as well as current parking systems as seen in various public places like malls, theatres, stadiums etc. have various drawbacks. To find a parking spot, one has to drive all around the parking lot which can range from a few

100 sq. meters to a multi-tiered parking lot. This approach of finding a vacant parking space is extremely time consuming and inefficient.

2. Conventional parking could soon be a thing of the past. There are just too many advantages to an automatic parking system! The population is growing, and cities are running out of space. This is where the automatic parking system comes in. It doesn't only save space, but also time and money

VI. OBJECTIVES AND SCOPE OF PROJECT

A. OBJECTIVES

1. User-friendly GUI to display the vacant parking spots.
2. Eliminating traffic conditions or mega-block at parking lots in some cases.
3. A smart parking system designed at a very low cost than the already existing systems.
4. Easy access to parking systems all around the city..

B. SCOPE

1. At the entry of the parking lot, a Smart Ticket can be generated to be given to the driver which would record for how much time the car was parked.
2. A secure payment gateway present at the exit of the parking lot can be introduced to help with the parking fee.
3. Moreover, a driver can get a recommendation for the nearest vacant parking space based on his or her location when the user logs in on the platform.

VII. PROBLEM DEFINITION

A. CURRENT SITUATION

In the modern society, there is an ever-increasing number of vehicles. This is leading to problems such as large urban parking lots becoming inefficient, increasing difficulty to find open spaces in busy parking lots, as well as the increasing need to devote larger areas of land for additional parking spaces. One may ask, why these problems are significant.[4]

B. PROBLEM STATEMENT

The three main problems that the increasing number of vehicles and the decreasing efficiency of modern busy parking lots are:

1. Valuable time wasted from inconvenient and inefficient parking lots on average, 3.5 - 12 minutes spent waiting for a spot in urban parking lots.

2. More fuel consumed while idling or driving around parking lots, leading to more CO2 emissions
   - Average distance travelled looking for a spot = 1.2km.
   - Average CO2 produced per car per day = 0.14 kg CO2.
   - 14kg for 1000 cars per day and 5110kg per year just for 1000 cars.
3. Potential accidents caused by abundance of moving vehicles in disorganized parking lots
   - 413 accidents occurred in public parking lots in Canada last year
   - There were 788 parked car collisions, 5 being fatal
   - 2/3 of traffic accidents in parking lots involve only 1 moving vehicle 12
     1/3 of these accidents involved 2 moving vehicles
   - Parking System Issue

Phase 1 (planning):
Perform literature survey and find all the research gaps. Phase

Phase 2 (analysis):
Prepare a report or synopsis to set a path that is to be followed after understanding the requirements and making the synopsis the development is to be started.

Phase 3 (design):

In development, the first step is to plan on how the project is to be done, the second step is to set the Ultrasonic sensors and node MCU and make the connections using wires.

Phase 4 (code , implementation):
After all the phases are completed properly, the actual development is to be started. We have created a code and is applied with the help of WiFi.

Phase 5 (testing, deployment):
The code has been rechecked and the needed connections has been made after testing and approval, apply the proposed

system.

C. FEATURES

1. Fully automated
2. User-friendly and interactive GUI.
3. Quick acquisition of vacant parking slots.
4. Minimal or no congestion caused at parking lots.
5. Cheap sensors, providing the same functionalities as a costlier sensor, thus cutting down development costs Vector Art

VIII. METHODOLOGY

A. SYSTEM ARCHITECTURE

The basic hardware components used in developing the system are Ultrasonic Sensors and NodeMCU while at the backend are present Google powered- Firebase and also Arduino IDE. When a car enters into the range of the ultrasonic sensors, the parking spot is shown vacant on the GUI.

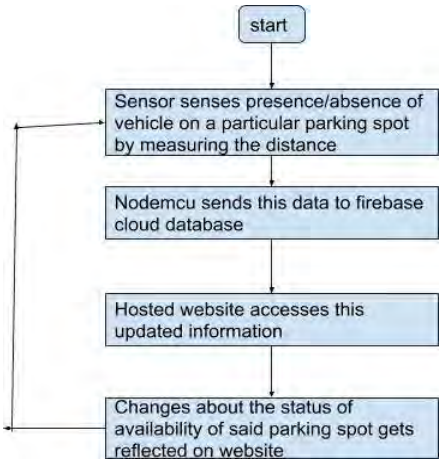

Fig 1: System Architecture (Flowchart)

B. SYSTEM PROCESS FLOW

Once the ultrasonic sensor detects the presence of a vehicle in it's vicinity, it transmits a signal to the Firebase at the backend through means of the NodeMCU (ESP8266) which is a Wi-fi module. The signal sent to the Firebase hereby communicates that the parking spot is occupied by a vehicle. This data of vacancy is displayed on the User interface which is present at the entrance of the parking lot. The data is displayed with the help of retrieving data from the Firebase using JavaScript. The user can thus have an overview of the free spaces in the parking lot.

IX. ANALYSIS AND PLANNING

A. PLANNING:

This step involves finalizing the software platforms to be used and the hardware components that will be required in the circuits.

B. DESIGNING:

In this step , the database design and the circuit connection will be finalized. Here the main architecture of the entire proposed system will also be determined.

C. BUILDING:

Here, the source code for the node MCU board as will be used to carry out basic tasks like reading data that is coming from the ultrasonic sensor and connecting to the Wi-Fi network.

D. TESTING:

After making all the connections and flashing the main source code into the node MCU , the testing phase can start where the entire system will be handling different test cases. Based on the test results

, required changes will be done in the connections or the source code. The process of testing will repeat until expected results are achieved.

E. DEPLOYMENT:

After successful test results the system can be deployed by connecting the front end site to the cloud database. The circuit will be installed at the parking spot and the users will be able to view the status of the parking lot in real time.

X. FEASIBILITY STUDY

A. TECHNICAL FEASIBILITY

This assessment focuses on the technical aspects of the project that will determine the feasibility of this proposed system. The hardware side of the project uses the extremely popular node mcu board and the ultrasonic sensor; both of which are readily available in the market. On the software side, the technologies used for cloud storage is Firebase. Firebase is Google's solution for cloud computing and it is a reliable open

source platform.

B. ECONOMIC FEASIBILITY

The proposed system's cost can vary according to the size of the parking lot. A single circuit consists of two primary components: the nodemcu board which costs around Rs.250-300 and the ultrasonic sensor which costs around Rs.50-75. Thus the final circuit will cost approximately in the range of Rs.300-375 for each parking spot, which is a cheap one time installation costs. As far as the software side is concerned, all the platforms used are free of cost.

C. OPERATIONAL FEASIBILITY

The final circuit will be placed on the ground or just below it in a small hole the size of a hockey puck and at a depth of 5-10 cms. The entire circuit will communicate with the WiFi system of the mall or the parking lot to send the data to the server. This system is fully modular as the circuits connect directly to the Router and do not depend on each other. The proposed solution is also scalable because adding a new parking spot to the system is just as easy as installing the a new circuit at that location and adding the same spot to the GUI.

XI. COMPONENTS

A. HARDWARE COMPONENTS

1 Node MCU:

Node MCU is an open source firmware developed for ESP8266 Wi-Fi chip. By exploring functionality with ESP8266 chip, Node MCU firmware comes with ESP8266 Development board/kit i.e. Node MCU Development board. Since Node MCU is open source platform, their hardware design is open for edit/modify/build. Node MCU Dev Kit/board consist of ESP8266 Wi-Fi enabled chip. The ESP8266 is a low-cost

Wi-Fi chip developed by Espressif Systems with TCP/IP protocol. [1]

2 Ultrasonic sensor:

Ultrasonic sensor is a device that can measure the distance of an object by using sound waves. It measures distance by sending out a sound wave at a specific frequency and waits for that sound wave to bounce back. By recording the time taken between the sound wave being generated and the sound wave bouncing back, it is possible to calculate the distance between the sensor and the object.

B. SOFTWARE PLATFORMS

1 Firebase:

Firebase provides a real-time database and backend as a service. The service provides application developers an API that allows application data to be synchronized across clients and stored on Firebase's cloud. The company provides client libraries that enable integration with Android, iOS, JavaScript,Java, Objective-C, Swift and Node.js applications. The database is also accessible through a REST API and bindings for several JavaScript frameworks such as AngularJS, React, Ember.js and Backbone.js. The REST API uses the Server-Sent Events protocol, which is an API for creating HTTP connections for receiving push notifications from a server. [3]

2 Arduino IDE:

The open-source Arduino Software (IDE) makes it easy to write code and upload it to the board. It runs on Windows, Mac OS X, and Linux. The environment is written in Java and based on Processing and other open-source software. This software can be used with any Arduino or Node MCU board.

XII. EXPECTED RESULTS

A. OUTPUTS

Successfully implemented the Smart Parking System in an economical way. The ultrasonic sensor measures the distance between the sensor itself and the vehicle parked above it. The vacancy data is sent to the Firebase through the NodeMCU and then onto the web application for the user to view.

Phase 1: Analysis

- Creating the synopsis, literature survey and feasibility study for proposed solution which will act as an input to the design phase.

Phase 2: Planning

- Proposing Statement of work, scope definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done

Phase 3: Designing

- Proposing design architecture of Smart Parking System for implementing the surveyed case studies and synopsis.

B. *OUTCOMES*

The following are the outcomes were observed as a result of implementing the product:

- Transmission of data wirelessly from the NodeMCU to the Firebase at the back end.
- Status of the real-time occupancy is presented to the users on the web application which can be accessed even when the user is not present at the parking premises

C. *FUTURE SCOPE*

The main objective of the proposed system has been fulfilled, yet, there are many more things that could be integrated with the already existing system to make it more responsive and smart. The following features could be integrated in the future:-

- An App based application could be designed instead of the existing website
- Geo-location of the parking lots can be provided to the users to help them find the nearest parking lots instead of parking on the streets. This can be implemented using the Google maps API at an initial level.
- A secure payment gateway can be developed at the exit on basis of the period of time the user had parked his/her vehicle in the premises. The time can be recorded by providing a randomly generated key with the timestamp printed on a parking slip provided at the entrance which has to be scanned at the exit for commencing payment.[6]

XIII. CONCLUSION

A In this project we can herby conclude that we can make the best out of ultrasonic sensor and node mcu , that is using it for monitoring tight parking spaces in a busy metropolitan city like Mumbai and it can be used all throughout the world for better space allocation and avoiding stockpiling and traffic of cars. This mainly focuses on the best allocation and indicates a user of this service whether the space is occupied or not and does inform on a prior basis about the required space. It will be able to re direct the user based on the availability of the parking space. The basic Idea is that the sensor detects if there is a vehicle parked on a given area and the sends the information across using Wifi technology and informs the system about the space. This helps to avoid nuisance and keeps the disturbances at lows. Thus this technology in tern helps the users to get through their busy day at a faster pace by allocation of spaces for their vehicles at any given instances. The technology is much cheaper and easier to use than the existing systems that exit today. They are much more expensive and need a learning curve for someone to understand the working and people are required for maintenance. This solves all the problems of a parking allocation and provides the ease of use to every user, efficiently.

Anti-Phishing Mailbox

Vivek Singh, Vinay Singh, Shivam Vishwakarma, Rahul Neve
Thakur College of Engineering and technology, Mumbai, India
viveksingh3421@gmail.com, vinaysingh1093@gmail.com, shivamvishwakarma84@gmail.com, rahul.neve@gmail.com

Abstract- **Phishing has created a serious threat towards internet security. Phish e-mails are used chiefly to deceive confidential information of individual and organizations. Phishing e-mails entice naïve users and organizations to reveal confidential information such as, personal details, passwords, account numbers, credit card pins, etc. Phisher spread spoofed e-mails as coming from legitimate sources, phishers gain access to such sensitive information that eventually results in identity and financial losses. In this research paper, exhaustive study is done on anti-phishing mechanism from year 2002 to 2014. A comparative analysis report of anti-phishing detection, prevention and protection mechanisms from last decade is listed. This comparative analysis reports the anti-phishing mechanism run on server side or client side and which vulnerable area is covered by it. The vulnerable area is divided into three categories on the basis of email structure.**

The number of vulnerabilities covered by existing anti-phishing mechanisms are listed to identify the focus or unfocused vulnerability. . This research paper could be said as tutorial of an existing anti-phishing research work from decade. The current work examines the effectiveness of the tools and techniques against email phishing. It aims to determine pitfalls and vulnerability of anti-phishing tools and techniques against email phishing.

Keywords- Anti-phishing, Mail-Security, Phishing.

I. INTRODUCTION

Phishing is defined as the fraudulent acquisition of confidential data by the intended recipients and the misuse of such data. The phishing attack is often done by email. An example of Phishing; as if e-mail appear to be from known web sites, from a user's bank, credit card company, e-mail, or Internet service provider. Generally, personal information such as credit card number or password is asked to update accounts. These emails contain a URL link that directs users to another website. This site is actually a fake or modified website. When users go to this site, they are asked to enter personal information to be forwarded to the phishing attacker [1, 2].

Phishing is often used to learn someone's password or credit card information. With the help of e-mail prepared as if coming from a bank or official institution, computer users are directed to fake sites. In general, the information that is stolen by a phishing attack is as follows:

- User account number
- User passwords and user name
- Credit card information
- Internet banking

The Anti-Phishing Simulator, which is designed to prevent serious threats like this, catches malicious e-mails arriving at e-mail addresses integrated into the system. This system also provides URL based control. The system evaluates the keywords included in the existing database and thus determines the contents of the mail [3, 4].

Phishing Attack- Phishing sends a fraudulent transmitter that appears to come from a real source. It is usually done by e-mail. The aim is to steal sensitive data such as credit card and login information or to install malicious software on the victim's machine. Phishing is a common type of cyber-attack that everyone must learn to protect themselves. Phishing is start with a fake e-mail or other type of transmission designed to attract a victim. In this type of attack, the message appears to come from a trusted source. If the attacker is deceiving the victim, it is mostly encouraged to provide confidential information in a fraud web site. Sometimes malware is downloaded to the target computer. Attackers provide financial gain by having their victim's credit card information or other personal data. Sometimes, phishing e-mails are sent to retrieve login details or other details of employees to use for an advanced attack against a specific company. Cyber-attacks, such as Advanced Permanent Threats (APT) and ransom software, usually start with phishing.

In a phishing attack, attackers can use social engineering and other public information resources, including social networks like LinkedIn, Facebook and Twitter, to gather background information about the victim's personal and work history, interests and activities. With this pre-discovery, attackers can identify potential victims' names, job titles and email addresses, information about the names of key employees in their colleagues and organizations. This information can then be used to prepare a reliable e-mail. These attacks, including attacks by advanced persistent threat groups, usually start with an e-mail containing a malicious link or attachment. In this type of attack, the most popular vulnerability or clickable phishing environments have been identified as the most popular Facebook feeds. When phishing attacks are created, they are often used for unrealistic news, such as those created around major events, holidays and anniversaries. Usually a victim receives a message that appears to have been sent by a known person or organization. The attack is carried out via a malicious file injection that includes phishing software or through links to malicious websites. In either case, the goal is to direct the user to a malicious website to install malicious software on the device or to trick them into disclosing personal and financial information, such as victims, passwords, account IDs, or credit card

details. A successful phishing message is usually shown from a well-known company; it is difficult to tell from the original messages: in 978-1-5386-3449-3/18/$31.00 ©2018 IEEE phishing e-mails, company logos and other descriptive graphics and data collected from the company. As with other link manipulation techniques, the use of subdomains and misspelled URLs (often spelling mistakes) is common. Phishing attackers use JavaScript to place a legitimate URL of the URL onto the browser's address bar. The URL generated by navigating through an embedded link can also be modified using JavaScript. Defense against phishing attacks should begin with training and informing users to identify phishing messages; but there are other strategies that can reduce successful attacks. For example; a network gateway e-mail filter can capture many targeted phishing e-mails and reduce the number of phishing e-mails reaching users' inboxes [3]. Figure 1 illustrates the process of performing phishing attacks.

II. BACKGROUND

Late years have seen, phished messages as a top-notch device for trickiness of online clients into uncovering delicate data. Right off the bat phishers assemble data by 'social building' (making laws or utilizing different techniques to impact popular feeling and take care of social issues or improve social conditions). They at that point make phished messages and devour them through various specialist organizations like Gmail, Yahoo, Rediff mail, hot mail, and so on. On a very basic level, a phished email is a copy of a general, real email from a confided in source (individual or association). A phished email can be, (a) Textual, offering unique plans at worthwhile rates, fortunate victor rewards, and so forth to draw individual data; (b) Embedded with a url diverting the online client to counterfeit pages, requesting that the beneficiaries do likewise as in point (a); (c) Rooted with a pernicious connections, i.e., tainted PDFs or MS Office reports, et al that, after being downloaded, increase undignified access to private data

III. IMPORTANCE OF THE PROJECT

Phishing sends a fraudulent transmitter that appears to come from a real source. It is usually done by e-mail. The aim is to steal sensitive data such as credit card and login information or to install malicious software on the victim's machine. Phishing is a common type of cyber-attack that everyone must learn to protect themselves. Phishing is start with a fake e-mail or other type of transmission designed to attract a victim. In this type of attack, the message appears to come from a trusted source. If the attacker is deceiving the victim t is mostly encouraged to provide confidential information ii a fraud web site. Sometimes malware is downloaded to the target computer. Attackers provide financial gain by having their victim's credit card information or other personal data. Sometimes, phishing e-mails are sent to retrieve login details or other details of employees to use for an advanced attack against a specific company. Cyber-attacks such as Advanced Permanent Threats (APT) and ransom software, usually start with phishing

IV. OBJECTIVES AND SCOPE OF THE PROJECT

This project aims throwing light on the various dimensions of email phishing. Through this exhaustive study and analysis, it is identified that the researchers were focused mostly on page content vulnerabilities which was mostly used to trick naïve users. Domain vulnerabilities and code scripting vulnerabilities are prone to bigger scams and uses advanced technology to trick naïve as well as proficient users. It has been noticed that lot of work done with regard to reducing phishing, considerable work is being done to provide a safe and secure email and internet service, the same can also be said to be true for the other the fence but still is required to stop from root. This research paper gives a background and a deep literature study on anti-phishing Shweta Shank war et al, International Journal of Advanced Research in Computer Researchers are here recommended to patch all the dimensions of phishing. However, with consistently improving technology and the research that goes into it, the phishing detection and removal techniques might lead to a future where phishing has ceased to exist.

V. SUMMARY

Anti-Phishing mailbox aims to control the security of information and to prevent Infringements, to check whether spam is available from the current database, to enable the use to create his own spam list, and to check whether the incoming mail has dangerous content. The inclusion of the mail account to be protected in the system with this module, the user will also control and communicate without having to open the mail. Figure shows a screenshot of the spam mails detected in the mail system. With this module, it is possible to determine the classification results of keywords and passages in the

database by Link Guard algorithm. The panel where the URLs in the mail are checked and the fake URL is detected.

VI. DESIGN AND IMPLEMENTATION:

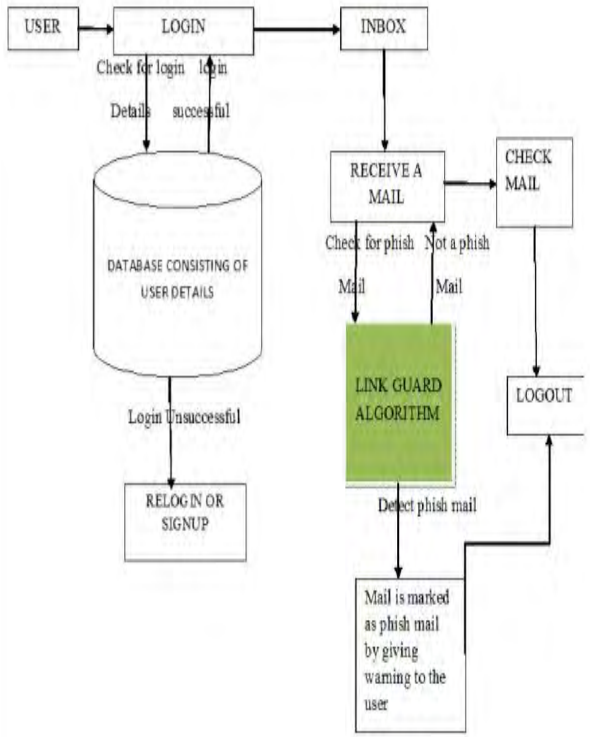

Figure: Block diagram

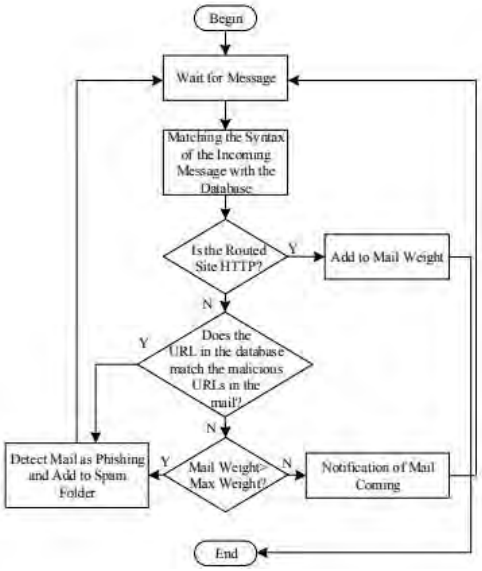
Flowchart

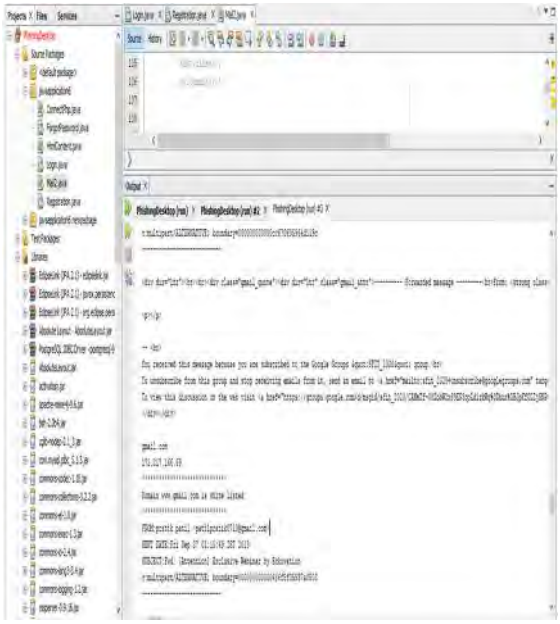


GUI:

Figure: Login Page

Figure: Registration

VII. RESULT:



Software – Net Beans IDE is a free, open source, integrated development environment (IDE) that enables you to develop desktop, mobile and web applications. The IDE supports application development in various languages, including Java, HTML5, PHP and C++. The IDE provides integrated support for the complete development cycle, from project creation through debugging, profiling and deployment. The IDE runs on Windows, Linux, Mac OS X, and other UNIX-based systems. The IDE provides comprehensive support for JDK 7 technologies and the most recent Java enhancements. It is the first IDE that provides support for JDK 7, Java EE 7, and Java 2. The IDE fully supports Java EE using the latest standards for Java, XML, Web services, and SQL and fully supports the Glassfish Server, the reference implementation of Java EE.

PHP started out as a small open source project that evolved as more and more people found out how useful it was. Rasmus Lerdorf unleashed the first version of PHP way back in 1994.

- PHP is a recursive acronym for "PHP: Hypertext Preprocessor".
- PHP is a server side scripting language that is embedded in HTML. It is used to manage dynamic content, databases, session tracking, even build entire e-commerce sites.
- It is integrated with a number of popular databases, including MySQL, PostgreSQL, Oracle, Sybase, Informix, and Microsoft SQL Server.
- PHP is pleasingly zippy in its execution, especially when compiled as an Apache module on the Unix side. The MySQL server, once started, executes even very complex queries with huge result sets in record-setting time.
- PHP supports a large number of major protocols such as POP3, IMAP, and LDAP. PHP4 added support for Java and distributed object architectures (COM and CORBA), making n-tier development a possibility for the first time.
- PHP is forgiving: PHP language tries to be as forgiving as possible.
- PHP Syntax is C-Like.

VIII. Outcomes

The Anti phishing mailbox detects all the phishing mails and blacklist all and allow all type mails which is white listed because of this Mailbox the user can only access the mails which is necessary and feasible. Email is one of the most significant specialized strategies. Expanded spam messages cause traffic blockage, diminished profitability, phishing and this is a significant issue as far as the universe of data. The quantity of spam messages is expanding each year. Consequently, spam email separating is a significant, important and testing issue. Because of the quick spread of phishing assaults, various methods for assurance have been created. Genuine and counterfeit website pages are some of the time very hard to tell from the way that phony pages are the equivalent as far as structure. The steady development of email clients has brought about undesirable messages getting so boundless. Existing server and customer side hostile to spam channels are

being utilized to recognize various highlights of spam messages. Be that as it may, some viable stunts have been created with the expansion of spam senders' spam content as advanced pictures, pdf and word; this augmentation has rendered it insufficient for current systems dependent on examining computerized message in the body zones of the email. A large portion of the work methodology proposed in the examination gives an against spam separating approach dependent on information mining procedures that characterizes spam and phishing messages. The viability of these methodologies is assessed on the expansive body of the basic content informational collection and the content implanted picture informational collection.

"Hostile to Phishing Simulator" gathers phishing and spam messages at a typical point. Messages in the spam box, it enables you to control the "spam box" at whatever point you need. The individuals who are in fact qualified by the "URL Control" highlight will have the option to look at the connection address via the post office in more detail. Later on, it is planned to dissect mail content all the more completely with fundamental content mining by expanding the spam watchword database considerably more. It is additionally meant to get increasingly exact outcomes and characterization with fake neural systems.

IX. Conclusion

Phishing is the try to accumulate touchy facts such as usernames, passwords, and credit score card information (and occasionally, circuitously, cash), often for malicious motives, through masquerading as a honest entity in an digital communication. Now days it has emerge as very serious. There are many techniques to solve those problems. But humans may also don't aware of the seriousness of phishing. Periodical updating of anti-phishing gear or software's in their personal structures may useful to relaxed their personal data and credentials. This examine may additionally give the attention about the phishing issues and answers. Anti-Phishing mailbox aims to control the security of information and to prevent Infringements, to check whether spam is Available from the current database to create his own spam list, and to check whether the incoming mail has dangerous content. The inclusion of the mail account to be protected in the system with this module, the user will also control and communicate without having to open the mail.

Smart Blood Storage Monitoring and Management System using IoT

Tanisha Gupta, Janhavi Patil, Sidddhant Manjrekar, AbdulRehman Shaikh
Information Technology Thakur college of Engineering & Technology Mumbai ,India
tanishag78@gmail.com, janhavip61198@gmail.com, siddhantmanjrekar042@gmail.com, abdulshaikh2504@gmail.com

Abstract - **The unit which administers and manages the requisition and distribution of the blood is named as a blood bank. The main objectives of the blood banks are providing blood to the patients with minimal blood transfusion error. The blood is very important medical supplies so it should be managed well. As the blood bank management consists of a number of manual steps, therefore it will become difficult for the blood banks to provide a high level of accuracy, reliability, automation in blood storage and transfusion process. The system proposed is divided into three segments, the first segment consists Temperature sensor, IR sensor nodes which is installed in rack of blood bank, and the GSM Module for sending request of blood to the donors and blood banks all these are interfaced with Arduino Mega. Second segment consists of wi-fi module for data transfer to the server and third segment is displaying the status of available blood stock. All the real time status relates to the available blood stock of the blood bank is are displayed on web page, so that the blood seeker can get the blood from their nearest blood bank.**

I. INTRODUCTION

The process of managing the blood bag that is received from the blood donation events needs a proper and systematic management that is done by the blood banks. As the blood is related to someone's life so the bags of must be handled with care and treated thoroughly. The blood consists of different blood constituents and every constituent of blood is having a specific function. Statistics say that in our India every two seconds someone needs a blood transfusion. The Blood transfusions are used for trauma victims - due to accidents and burns - heart surgery, organ transplants, women with complications during childbirth, newborns and premature babies, and patients receiving treatment for leukaemia, cancer or other diseases, such as sickle cell disease and thalassemia [6].The different blood constituent is applied to the patient for different type's disease given in table1.

India today faces a blood shortage of 10% relative to its blood requirements. It means that we require covering a shortfall of over 12 lakhs of blood units. Given that the eligible donor population of our India is more than 512 million, this deficit is surprising. Every day more than 1200 road crashes occurring in our India, 60 million trauma induced surgeries are performed in the country every year. Near about 230 million major operations, 331 million cancer-related procedures like chemotherapy and 10 million pregnancy complications all these require the blood transfusion [9]. Besides all this, the patients which are for sickle cell anaemia, thalassemia and haemophilia require large quantities of blood daily. Another reason for the shortage of the blood supply is the ban on payment to blood donors that was enacted in 1995. Previously near about onethird of the blood supply was from paid donors. But with the ban, both private and government hospitals have faced a larger shortage in the blood supply.

Table -1: Different Blood Constituents with their uses for different diseases and there functions

Blood Constituents	**Functions**	**Diseases**
Plasma	Medium in which the blood cells are transported around the body	Burn patients, Shock, Bleeding disorders
Red blood cells	Carries oxygen	Surgery, Any blood loss , Blood disorders such as sickle cell
White blood cells	Part of the immune System	Infectious disease and foreign invaders
Platelets	To facilitate blood clotting	Cancer treatments, Organ transplants ,lower platelet counts, suffering from leukemia

The current system that is using by the blood bank is manual system. With the manual system, there are problems in managing the records related with blood stock. There is no centralized database of volunteer donors. So, it becomes really tedious for a person to search blood in case of emergency. Without an automated management system, there are also problems in keeping track of the actual amount of each and every blood type in the blood bank. In addition, there is also no alert available when the blood quantity is below its par level or it become zero. Healthcare as a sector is a definite beneficiary of the increasing adoption of technologies such as the Internet of Things. One of the areas where IoT can be used is blood bank management. In our country thousands of litters of blood get wasted every day due to less than adequate management practices, thousands of litres of this precious resource get wasted every day across the country. Such a wastage is occurring during a day and age when healthcare providers are battling an acute shortage of blood units for various medical

procedures. Given this backdrop, the significance of deploying technologies that encourage efficient management of blood banks cannot be understated. The purpose of the blood bank management system is to simplify and automate the process of searching for blood in case of emergency and maintain the records of blood stocks in the bank.

II. METHODOLOGY

The proposed system is an embedded system which will closely monitor the available status of the blood and temperature of the refrigerator which is present inside the blood bank. The proposed system includes service domain and administration domain. Service domain has blood bank that has sensing unit installed to it which has array IR sensor, temperature sensor, Arduino mega as a gateway with Wi-Fi module using wireless protocol for wireless communication between blood bank and cloud, RTC for real-time operation.

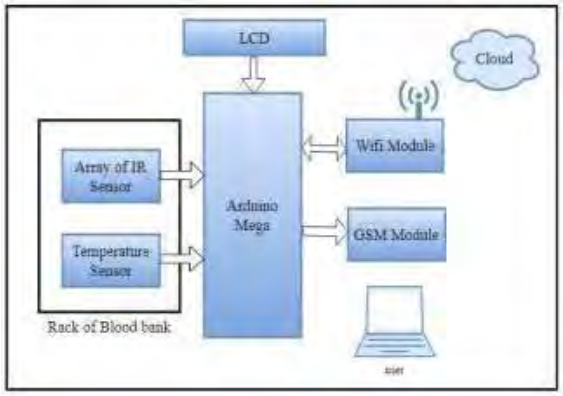

Figure -2: Block diagram of IoT Based blood bank system

In Administration domain information transferred from the blood bank is analyzed and processed. It includes webpage hosted on a server, for analysis and processing of the received data from the blood bank, depending on which corresponding notifications are displayed. It uses HTTP protocol for secure communication between server and blood bank in an application layer of IoT. For the more efficient operation, the called blood bank locations are located using maps. The two domain of proposed system is given below.

2.1 Service domain:

The service domain consists the hardware part of the system. It includes IR sensors, Temperature sensor, Arduino Mega, LCD, GSM module and ESP Module. The IR sensors are used for providing information of the available bloodstock, if the blood bottle is placed at rack then the LED rays of IR sensor gets reflect back then signal from IR to Arduino has been send. If the bottle is not placed in such condition the Rays not gets reflect back and its show the bottle is not present. For displaying the temperature of the refrigerator the temperature sensor is used which is display on the LCD. If the bloodstock is not available in such condition the Request message for donating blood is sent to the blood donor as well as one request message is sent to the nearest blood blank to provide the blood if they have availability of specific blood group of blood. All the data related to available bloodstock is displayed on the website using ESP module.

2.2 Administration domain:

In this domain, the Blood bank information, Blood status information, location of blood bank, the data received is collected. To achieve this web hosting is used where server is used. Server manages database for the information received from service domain i.e. values for each sensor for blood unit of each blood bank.

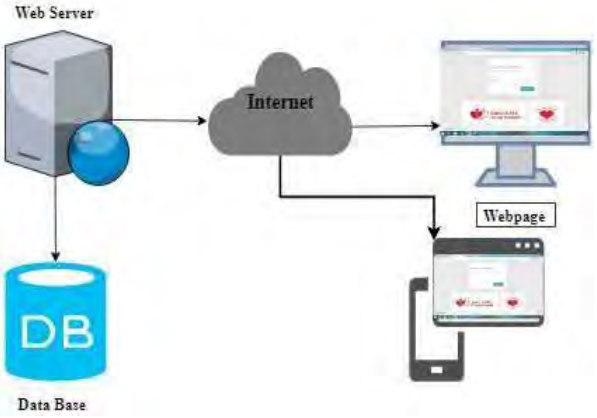

Figure -2.2: Administrator Domain for Smart Blood Bank System

It consists the IoT part, as ESP module sends the information of available blood is sent to the cloud. The cloud is connected to the website so the website will show all available bloodstock on 24*7 basis. So initially user has to select their region from options of the website the according to that the website will display all the blood bank of that region. And that blood bank provides real-time available bloodstock on the webpage. Also, the direction of that specific blood bank is provided on the google map for that one tab is provide as locate on the map.

III. RESULTS

Blood bank centers and various organizations needs to register on website of blood bank. So that each blood bank is getting connected with the cloud so that data of available blood stock of every data registered blood bank is displayed on the webpage. Also the log related with blood stock also available on the webpage so that it become easy to cross check the data of the blood stock.

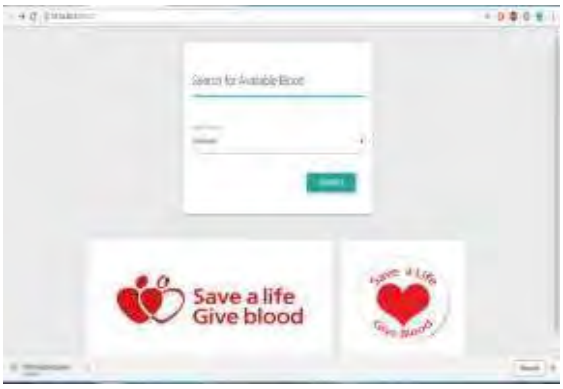

Figure - 3.1: Homepage of website

The results of the system going to be displayed on the webpage hosted over server i.e. the real time data frames sent in bytes by service domain module with the HTTP protocol to server. By using the domain name or IP address of the webpage in browser the real time data is seen on the computer or mobile that is connected to internet. Initially from homepage blood seeker has to choose the specific district of Maharashtra state, then after choosing the specific district of Maharashtra the page will show the status of available blood stock in each blood bank of specific region.

The webpage display real time information of available blood stock over. This saves time and is useful for minimizing the route in turn saving the time and fuel. The Screen shot of websites home page is shown above in figure 3.1.

After choosing the district the webpage directed to the next webpage, which is displaying available blood stock in the all blood banks. The Figure. 3.2 Shows the search result of Amravati District, it is showing four blood bank status located at the Amravati region. It is displaying status of four blood group as A, B, AB and O. Also the route of the Blood bank also provided on the webpage.

Figure -3.2: Search Result of Website

After finding availability of the blood the users need location of blood bank. So the webpage providing google map facility so that the user will finding the exact location of blood bank and also user will gets the exact distance of that blood bank so it will become easy to choose blood bank which is placed at the minimum distance from them. The Figure. 3.3 Shows Map it locate the blood bank, so any blood seeker can get the route of the blood bank. The direction toward any nearest blood can be obtained from the Google map.

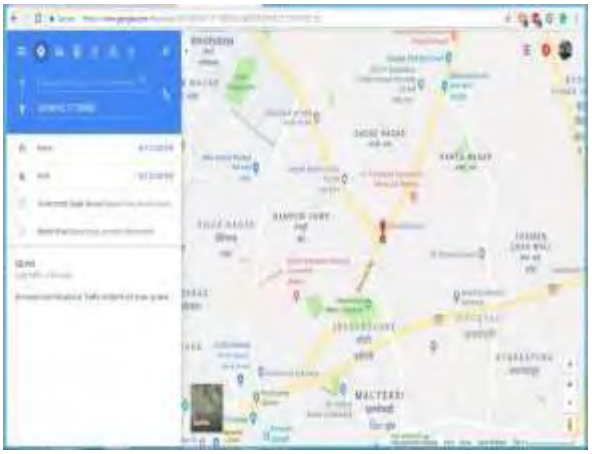

Figure -3.3: Location provided on Google Map

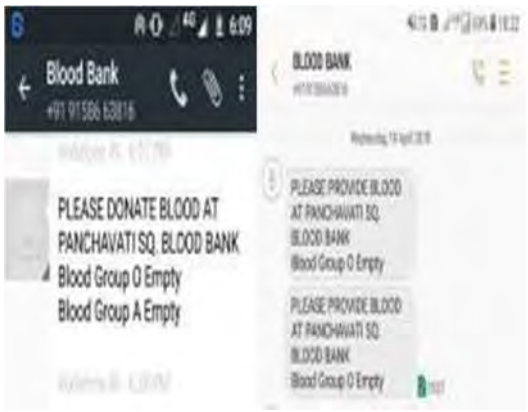
The System sends a short message to staff of other blood bank and blood donor's mobile phone when system senses the blood stock is below than the acceptable limits. When any blood stock reaches to zero in that case two different requests are send form the respective blood bank to full filling the blood stock. One request is send to the nearest blood bank and other request is send to the blood donor shown in figure 3.4



(a) **(b)**

Figure -3.4: (a) Screen shot of blood request Received by Blood Donor
(b) Screen shot of Blood Request Received by Nearest Blood Bank

Also the log file of the available blood stock is also obtained from the website of blood bank so that is will become easy for the blood bank employee to cross the data of the blood stock. And they can easily download that log file from the webpage itself shown in figure 3.5. It shows data of all the four blood banks.

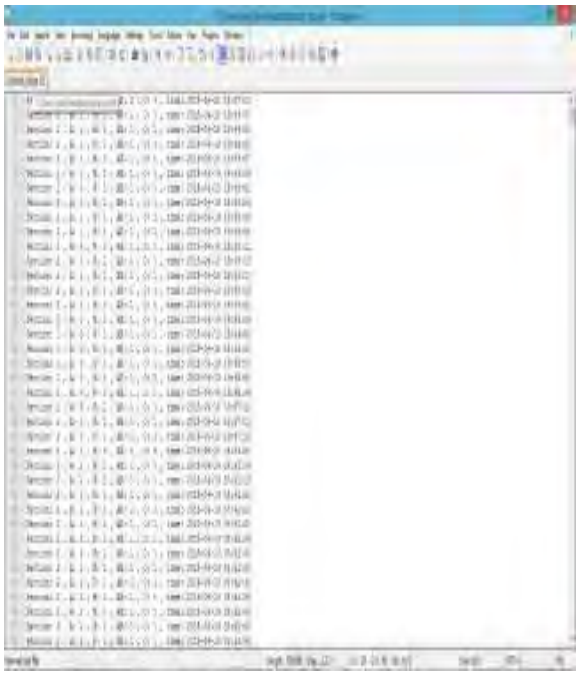


Figure -3.5: Log file of available blood stock

IV. CONCLUSION

Growing population has increased the need for the blood supply for various diseases. In every two seconds, some person required blood transfusion and currently India facing problem of the blood shortage. To address the problem an effective system is designed using the Internet of things. The system provides a methodology to fulfil the requirement of blood to the patients/victims without rushing to the blood bank to know the availability of the blood. An IR Sensors are connected to the Arduino board which continuously monitors the status of the available bloodstock. The output data provided by the Arduino is displayed on the webpage using the wifi module so anyone accesses the website and obtained the information of available bloodstock in real time. It will reduce the manpower required at the blood bank to update the online data also reduces the efforts of blood seeker of searching bloodstock at each blood bank. When bloodstock reaches to zero system helps to send a request message to the donor and nearest blood bank. By using IoT the real-time available bloodstock is displaying on the website it minimizes the efforts of blood seeker.

V. FUTURE IMPLEMENTATION

There are three different topics related to the Internet of Things concept that has major future scope in terms of improvement and research: efficiency, scalability and quality of service. The developed system is prototype version which provides the information about the available bloodstock. It consists of an array of IR sensors that covers the minimal area. To cover large blood packet the IR sensors can be replaced by the load cell. It will cover the large blood packet and help efficiently to provide information on bloodstock on a real-time basis. Also, one alert system using RFID Tag with smart temperature sensor can be also added to the system for indicating the expired blood packet and its temperature.

In the future, this work can be extended in the context of total blood banks of a country. Big Data analysis can be done on the gathered data from Region. So that the specific domain names can also be allocated to the blood bank site. Also on the website of blood bank, the login id and passwords can be provided to the blood seekers so that they can be made the online request for the blood units.

IOT Based Green House Monitoring and Control System

(TCET-IT, Student) Mumbai, India.
yashsinghania15@gmail.com, ayushsharma0009@gmail.com, muskantiwari0697@gmail.com, purvisankhe@gmail.com

Abstract— **In the ongoing time, with the fast flood of development in territories of computerization and digitalization, our lives are improving as nearly everything is experiencing motorization which is supplanting the crude manual, escalated work frameworks. Today, as Internet has become an indispensable vital piece of our everyday lives, all the electronic gadgets likewise should be expedited the system. This is the primary point of Internet of Things (IoT), which is one of the new up and coming advancements that aides in setting up association, control, and the executives of independent insightful articles which are associated with Internet by means of various capacities and conventions.**

In our task the fundamental goal is to concentrate on consolidating IoT innovation in the field of farming, explicitly in the nursery framework. Utilizing a few electronic segments, for example, NodeMCU, Arduino, and various sensors associated over the web, the nursery parameters will be observed and controlled with the assistance of various electronic gadgets like advanced mobile phone, PC and so forth.

This proposed model of a Smart Greenhouse, encourages the nursery laborers to do the work in a nursery consequently without utilizing a lot of labor. Nursery, a shut situation shields the estates from cruel climate conditions and creature, bother assaults. The water system of savvy nursery is finished by the utilization of motorized dribble water system, which works on the parameter of soil dampness determined as ideal to the plants. In view of parameters from soil wellbeing card and information nitrate sensor legitimate measure of minerals can be applied by utilizing dribble water system procedures. Appropriate water the executives tanks are developed and they are loaded up with water subsequent to estimating the ebb and flow water level utilizing a ultrasonic sensor. Plants are given the fitting measure of light when it gets darker utilizing movable drove lights. The temperature and stickiness sensor are utilized to screen them.

We propose observing and controlling the nursery parts with the assistance of IOT. The ebb and flow model water tank for water system, water tank is definitely not an attainable arrangement our model uses dribble water system. The greater part of the current nurseries have inappropriate ventilation with absence of moistness control. We have proposed portable folds which work for controlling the moistness and temperature of the nursery.

I. OVERVIEW INTRODUCTION

Despite the fact that India gets bounty measure of precipitation and has various enormous waterway frameworks, yet 33% of the all out land for horticulture is joined by means of trench water system framework. Rest larger part of the segment depends on rainstorm or cylinder wells for the development of estate. There are places having overabundance water yet face issues of land saltiness, as a result of over water system and water-logging. The Greenhouse, being a shut casing structure defends the plants from overwhelming climate conditions, for example, sea tempests, Ultraviolet radiations, hailstorms, and bug and irritation assaults. Here, the water system of farming field is done with the assistance of a mechanized trickle water system process, which works as per the edge soil dampness that is being set so that an ideal measure of water is given to the plants all the time. In light of the information from soil wellbeing card, fitting measure of supplements, water and different imperatives might be provided by utilizing dribble water system methods. The plants are given the essential light wavelength through shining LED during the evening time. Inside the nursery, air stickiness and temperature are observed by the mugginess and temperature sensors separately, and can be controlled with the assistance of versatile rooftop folds which work consequently as it arrives at the limit temperature and moistness.

II. BACKGROUND

In India, farming is as yet completed in the customary manner and falls behind in using the cutting edge advances accessible to humankind. This model means to improve the previous agrarian practices by consolidating brilliant present day advancements for proficient and better creation of nursery. The undertaking gives a model of a shrewd nursery, which will help the ranchers in completing the homestead work consequently, in an unmanned way.

At present, there are various nursery models which work in a computerized way, yet a large portion of them need minor parameters, which affect the generation of nursery. With the assistance of the proposed model, these weaknesses can be proficiently survived, in this way improving the generation of the nursery. Our venture means to connect every one of these holes which will help in effective and less time of client being utilized in performing excess errands. At present, with the headway of innovation there have been a ton of enhancements in the nursery, yet at the same time there's plentiful space for further improvement to expand the productivity and generation pace of the nursery. There are nurseries which have dribble water system framework introduced in them, sensors that solitary gather information yet are not customized to play out any trigger-component based activities, so we expect to beat these deficiencies with the assistance of our proposed model. Generation rate is reasonable in the current nursery frameworks and can be helped with a lot of proficiency. Additionally, a large number of the nurseries have been subject to labor or human help with a few or the other way,

which can be changed into a totally robotized process by every minute of every day Real-time checking of the green house.

III. IMPORTANCE OF THE PROJECT

India being an agro-based nation, horticulture is as yet being completed in a conventional way, and along these lines falls behind in the joining of present day strategies and innovations. About 57% populace in India has been effectively occupied with farming and related exercises, which make for about 15% of the nation's GDP. Subsequently, it is significant in the present time for the included partners to abandon the old ordinary acts of farming and excel by modernizing the rural procedure with the assistance of better and proficient more up to date advances. The monetary commitment of rural exercises to the GDP of India is immovably diminishing with the nation's wide-extending development in economy, albeit an enormous number of individuals are still tirelessly occupied with the horticultural part.

IV. OBJECTIVES AND SCOPE OF THE PROJECT

The nursery ought to have the option to make various smaller scale atmospheres with exactness that favors custom condition for an assortment of plants. The nursery ought to have the option to monitor assets there by reducing expenses of the estate procedure and could prompt various development cycles in a limited capacity to focus time, expanding the efficiency and income for the customer.

- The robotized nursery in this venture is intended for residential utilize yet can likewise be scaled to be actualized for greater ranch. This venture centers around one plant as it were. Nonetheless, this reference can be changed into some other plant.
- The nursery can make a microclimate appropriate for the development of the plant, which was accomplished by controlling the variables, for example, mugginess, temperature, dampness, light source.

Other scopes of this project are:

- The robotized nursery in this venture is intended for residential utilize yet can likewise be scaled to be actualized for greater ranch. This venture centers around one plant as it were. Nonetheless, this reference can be changed into some other plant.
- The nursery can make a microclimate appropriate for the development of the plant, which was accomplished by controlling the variables, for example, mugginess, temperature, dampness, light source.

Summary

All the previously mentioned parts of present agrarian practices ought to be improved to get better return. Henceforth, we move towards a savvy nursery model where the plant is given a domain for its ideal development. Because of the shut structure of nursery, creepy crawlies and vermin can't enter inside, along these lines disposing of the necessity of bug sprays and pesticides. Sparkling LED lights are turned on at whatever point light force is low for photosynthesis, this guarantees quicker pace of development.

Our proposed model altogether improves Greenhouse efficiency which is fundamental for expanding gainfulness. Nursery profitability has been expanded by comprehension and anticipating crop/plant execution in an assortment of natural conditions which can be created by our proposed model. Existing nursery framework use a great deal of labor in controlling and checking the green house our proposed model has IoT computerization and gives constant information of the nursery condition for observing and control.

Flowchart

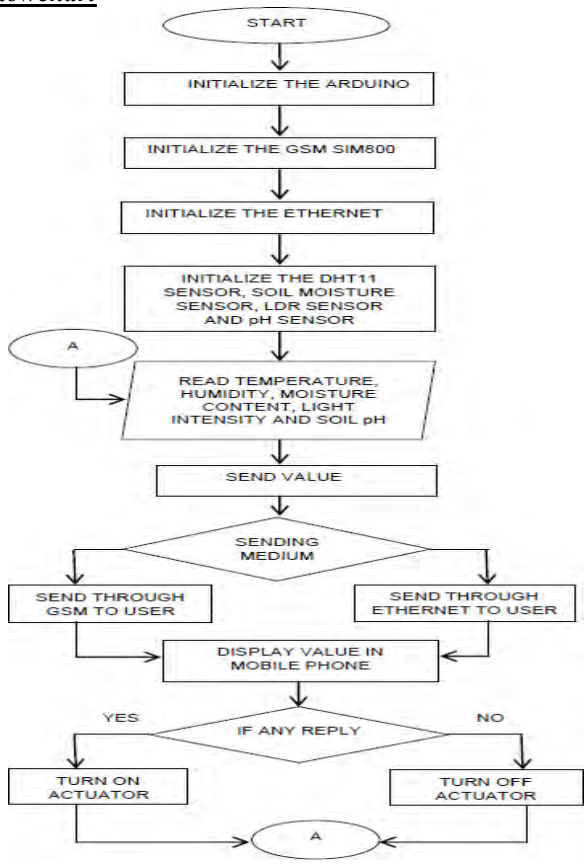

Figure No 3: Flowchart

V. RESULTS & DISCUSSION

IOT based systems are now a part of a variety of specializations from Agriculture monitoring to the Home Automation smart systems, which can be accessed from any part of the world, making it easy even for Farmers, doctors, working professionals to access the resources whenever

they require.
This is merely the beginning. Not long from today, IOT will be used to advance our understanding of wireless network through analysis of highly dense networks and huge datasets, help us invent new solutions and make smart systems more thorough and personal. IOT based Greenhouse systems can revolutionize agriculture sector and allow new paradigms in planning of architecture. Machines will run our homes more efficiently, make businesses more productive and help predict risks to society.

Actual Results

We were able to build a system for monitoring and controlling of the greenhouse system .Besides this, we were also able to add some basic features such as transferring that data to the device and showing the plants humidity ,temperature ,moisture on the device. The device which is required can be a monitor or mobile device which can be connected to Node MCU and can easily get the output.

Outputs: We were able to build a system for monitoring and controlling of the greenhouse system .Besides this, we were also able to add some basic features such as transferring that data to the device and showing the plants humidity ,temperature ,moisture on the device. The device which is required can be a monitor or mobile device which can be connected to Node MCU and can easily get the output.

Outcomes: The nursery ought to have the option to make numerous smaller scale atmospheres with exactness that favors custom condition for an assortment of plants. The nursery will be come up short evidence since every one of the parts will have the option to work autonomously so there is no single purpose of disappointment. The nursery ought to have the option to save assets in this way reducing expenses of the manor procedure and could prompt numerous development cycles in a limited capacity to focus time, expanding the efficiency and income for the customer.

Discussion:

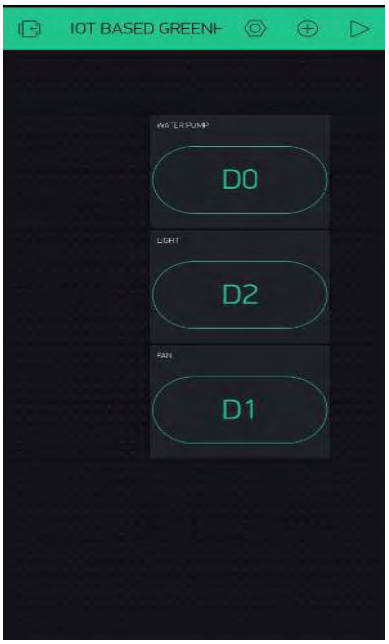
IOT based systems are now a part of a variety of specializations from Agriculture monitoring to the Home Automation smart systems, which can be accessed from any part of the world, making it easy even for Farmers, doctors, working professionals to access the resources whenever they require.
This is merely the beginning. Not long from today, IOT will be used to advance our understanding of wireless network through analysis of highly dense networks and huge datasets, help us invent new solutions and make smart systems more thorough and personal. IOT based Greenhouse systems can revolutionize agriculture sector and allow new paradigms in planning of architecture. Machines will run our homes more efficiently, make businesses more productive and help predict risks to society.

Future Scope

Intelligent agriculture is developing rapidly in recent years and it raises more attentions in both industrial and academic societies. This thesis take a full consideration of cost, practicability and other factors, combining the IOT with fuzzy control method ,using GPRS to remote control, designing an smart greenhouse monitoring system with better performance, simple structure and easy extensibility. There is also controlling action taken automatically that is greenhouse windows/ doors roll on/off based on the soil moisture levels. Thus, the system will help the farmers to avoid physical visit to the field, and increase the yield with the maintenance of précised parameters such as CO2, soil moisture, temperature, and light in the greenhouse with the help of IOT. The project is carried out with the help of IOT kit and internet connection.

Deployment

Deployment can be a major challenge in software which involves machine learning. Huge amounts of processing is required just to get it up and running. Data generated in the process is humongous as well. The ML model will be deployed using Google firebase or spring. The cloud platform will provide a base for future developments where flexibility, portability and reliability is required. The GUI by itself is not very difficult to deploy. We have multiple ways of offering interfaces, such as web interfaces and command line interfaces. It will expand to a desktop GUI in the future as well. The web interface will be deployed using Heroku or AWS, depending on the relative cost of hosting. The command line can be used as a windows executable file. Users can simply download it and run it natively on their windows PC



VI. CONCLUSION

We utilize the actuators (engines/moving parts) too, in this manner giving observing and information investigation as well as exact control for the brilliant nursery.

The results are analyzed for the greenhouse parameters such as CO2, soil moisture, temperature, and light for bell pepper plant with the help of graphical representation based on the practical values taken by the IoT kit. The comparative result shows the effectiveness of the proposed work.

IOT Based Grain Moisture Monitoring

Anshu Singh, Hetal Amrutia, Manish Singh, Yash Shukla

Information Technology Thakur College of Engineering and Technology Mumbai, India

s.anshu4855@gmail.com, hetal.amrutia@thakureducation.org, ms292735@gmail.com, vashshukla048@gmail.com

Abstract— **Moisture is one of the important parameter which is always considered when deciding the quality and price of grain, at the stage of harvesting, storage, processing and marketing. Grain having excess moisture content, if stored for long duration, will spoil due to insect/fungus infestation. The types of moisture meters available in the market are with the lookup tables which cause inconvenience when carrying out measurements. These previously existing moisture meters are inaccurate sometimes due to their way of measuring the moisture of the grains with respect to a constant room temperature and the user also has to check the lookup table for checking the moisture index which is way too hectic for the user. So to overcome this problem we have developed IOT based Grain Moisture Meter which due to its novel design gives moisture (%) on an android application and also on a web application. The moisture meter will provide an analysis report of the grain storage.**

I. INTRODUCTION

Accurate measurement of grain moisture content is important during harvesting, drying, storage and processing operations. The accuracy of the moisture meters in measuring the moisture content of the grains is very important to ensure fair trade between farmers and buyers. Electrical moisture meters cannot measure the moisture content of a commodity accurately due to a variety of reasons. The parameters of measurements of these moisture meters are affected not only by the moisture content but also by the sample size, shape, temperature and physical and chemical constitution of the commodity.

It is therefore essential to test and calibrate the relationship between electrical reading and the actual moisture content, determined by standard oven method. An air oven method was adopted as the standard method in moisture determination of grains and seeds (ASAE, 2003) and method outlined by the International Organization for Standard (ISO) (Anon 2001) have been used to standardize simplified oven methods that are regarded as practical working methods. During procurement there is now available an inexpensive method of sufficient accuracy used generally by farmers for determining grain or/and forage moisture content. In most cases, the farmer relies upon his experience to estimate the moisture content. For grain, this might entail biting, rattling, feeling, and observation but officially there is always need for rapid moisture measurement and so the electrical instruments have been developed. As long as the grain moisture-sample level is not too high, such instruments have been relatively satisfactory. At moisture content above 20-25%, however the consistency and reliability of measurement with existing moisture meter begins to deteriorate. Over the past 50 years, numerous instruments have been developed for measuring grain moisture content by electrical means. Instruments that sensed the dielectric properties then became more popular because dry outer layer of the kernels did not degrade their reliability as much. The dielectric properties of grains were also studied in connection with radiofrequency dielectric heating for grain drying. These electric properties of grain have long been utilized by electric and electronic grain moisture meters, which sense the electric conductivity or dielectric properties of grain and are calibrated to read moisture content.

The knowledge about electric properties of grain is also useful in designing of equipment for electro treatment of grain, i.e., dielectric drying, electrostatic cleaning and sorting, desensitization, and also electrical stimulation (Datta et al, 1995). Consequently, there is a need for development of instruments with better accuracy, consistency and reliability for rapidly measuring the moisture content of high moisture grain.

II. LITERATURE SURVEY

A. Research Gap

Focuses more on micro organisms, Insects and Rodents rather than humidity and temperature control. Uses canola/rapeseed storage time chart that predicts grain quality only for 5 months. No focus on air conditioners/room chillers in room to maintain the cooling temperature for grains stored in warehouse. Uses capacitance principal which is the one of the oldest methods. Every time the user will need to check the display to get the moisture level. Not giving 100% accurate output and the developed system is working satisfactorily. This paper only tell about wheat grain and no other grains in the market. Uses only direct method to prevent moisture content of wheat and having approx. estimation of moisture. It does not show how the grains can be protected from high temperature and humidity in the warehouse. It only tells that how wheat moisture can be maintained after harvesting. This paper tells more about measurement of water in the grains, sand rather than showing humidity affecting it. Samples with very high moisture content (say 60% and above) the insertion loss is too great to be measured correctly. This method has the drawback, though, that a single measurement can take up considerable time. Suggested to use hermetic bags instead of non-hermetic bags which is expensive and challenging. The PHL meter, John Deere meter and GAC 2100 meter was suggested to use instead of oven dry method which is mostly used nowadays. Conducted measurement on maize grain and had to check the moisture every month manually. For

measuring the grains different meters are used from which the work is done manually which is time consuming and hectic for humans to do the work. Price of moisture meters is expensive and for unique grains different meters are required such as:

- Resistance type Indosaw (2000)
- Resistance type osaw (40471)
- Capacitance type Indosaw (DM-06)

III. OBJECTIVE AND SCOPE OF THE PROJECT

1. When Quality grain production:

Crop quality is determined by soil nutrition, crop management, crop handling, and weather. The two main obstacles to producing high quality organic grain are insufficient soil nitrogen and the farmer's lack of knowledge and experience. Many new organic farmers have just moved to the country, and bought depleted or marginal land. Their poor soil and lack of experience lead to a poor quality crop. Sometimes farmers are 'organic by neglect' in that they don't use any inputs -- neither the prohibited pesticides and synthetic fertilizers, nor useful organic amendments. In contrast, successful organic farmers are 'organic by design'.

To produce high quality food and be 'organic by design', walk the fields and pay attention to details. Learn to recognize weeds, crop quality and changes in the soil. Take the effort to learn about the farm, and to develop a good understanding of soil, plants and animals. Learn from experience, from talking to other farmers, reading books and going to workshops. A commitment to quality improvement and an investment of time and dedication will lead to better crops.

Being 'organic by design' requires good planning and problem prevention. Plan your crop rotation three years ahead, but check the growing conditions and adapt the rotation as needed. Off-farm inputs are used if needed, including soil amendments. A wise selection of high-quality tools is purchased for the farm.

2. Grain storage management:

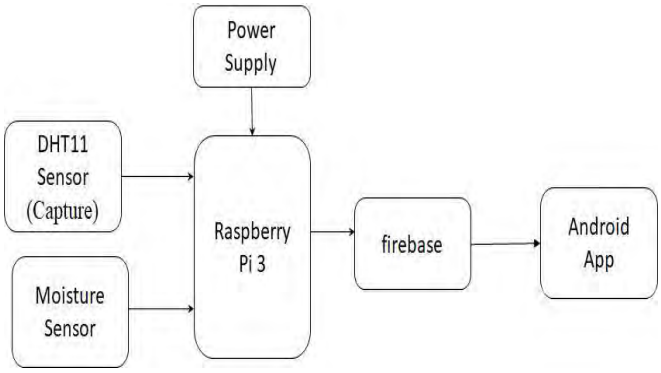
As our project is going to give the moisture, room temperature and humidity in the warehouse due to which the warehouse manager will get to know whether if the room temperature or moisture increases or decreases then what measure is to be taken. Accordingly the warehouse manager will shift the crops or will keep the doors open to maintain the room temperature or increase or decrease the moisture of the grains so that the quality of the grain remains the same it does not gets degraded. It would help the warehouse manager to manage and store the grains accordingly in the suitable condition.

3. Analytics of grain moisture:

The moisture, room temperature and humidity of the warehouse or the place where grains are stored this data can be stored to the database which would help the farmers to get a high-quality grain production.

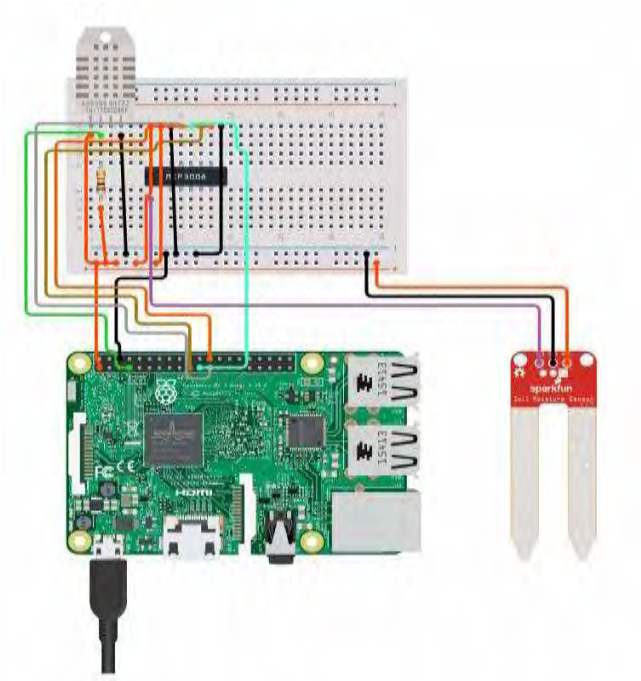
IV. PROPOSED METHODOLOGY

A. Block Diagram:



The dht 11 and moisture sensors are connected to the raspberry pi 3 B+. DHT 11 sensor gives the readings of room temperature and Humidity of the Warehouse through GPIO pins. Moisture Sensor gives the moisture readings of the grains in a sack. The code which we will implement will capture the data in json format and push online to the firebase database. There would be a android application where we will retrieve this Json data and process it to show the quality of the grain and the condition of the grain. The data in the firebase will help us to analyze whether the crop is in good condition or not and we will get to know in which period that is in which season the farmer has got the quality production of food grains. The android app will give the notification to the farmer to the farmers that if the quality is degraded then what is the solution. The app will also help in inventory management that is how many sacks of grains were sold and how many sacks were of which quality.

B. Circuit Diagram

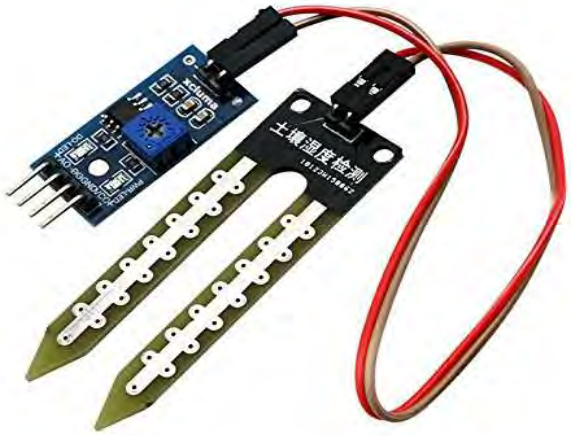


Here we have connected the soil moisture sensor to the raspberry pi using MCP3008 which is an analog to digital converter as the raspberry pi does not consist of a analog pins. Dht 11 is directly connected to raspberry pi at GPIO pin 27. MCP3008 gets the analog signals from the Moisture sensor and converts them into digital signals and passes it to raspberry pi.

All sensors used in our system are RoHS certified, according to which the sensors are made up of environment friendly materials. The sensors used are:

a. DHT11:
In our proposed system this sensor is playing an important role to get the current room temperature, which will help to know whether the grains are stored in the favorable weather conditions. The dht 11 provides the data in digital form so it is easy to connect to our system on chip (Raspberry Pi 3B+). The information is retrieved from sensor via using Adafruit_GPIO.SPI in Python, this library helps to retrieve and process the data. This sensor also gives the humidity of the warehouse. After getting data from the sensor it is stored in the json file, easy to access and light weight database.

b. Moisture Sensor:
This sensor is the backbone of the system it helps to retrieve the actual moisture of the grains which are in the grains. The sensor provides data in the analog form which is not compatible to our system on chip as the raspberry pi consists of all digital pin. To make our sensor compatible i.e. to get the data in digital form we are using Analog to Digital Convertor MCP3008. The MCP3008 helps to convert the analog data into digital data which helps our SOC to read the data easily. To get this data and process it accurately we use spidev library provided by the sensor manufacturer itself. After getting data from the sensor it is stored in the json file, easy to access and light weight database. The stored data can be accessed via a web portal. The web portal also provides the live graph of the moisture sensed via sensors.



c. MCP3008:
It is a analog to digital convertor which helps to get the analog data of moisture sensor to the raspberry pi in digital form.

V. ACTUAL RESULTS

a. Outputs (Output of the project only)

Successfully implemented the Moisture meter for grains.

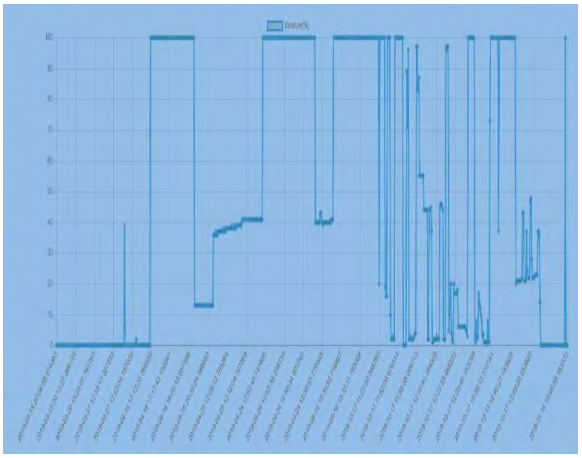
The DHT11 Sensor detects the level of the humidity and temperature of warehouse and moisture sensor measure the level of grains moisture and alerts the system, of the increase in the level. The result would be displayed on the webpage. This helps the concerned authority to carry on a require action.

b. Outcomes

The following are the outcomes were observed as a result of implementing the product:

- Temperature and Humidity level detection of warehouse.
- Moisture level of grain dictated in real time wirelessly.
- Transmit the information wirelessly to



Webpage.

- The data can be accessed anytime and from anywhere.
- The real-time data transmission and access.
- Avoids the Grain Wastage.

c. Discussion of the results

This IoT based wireless grain moisture and warehouse temperature detection system, which is very useful for Warehouse and even the rural areas as equally. In the Warehouse lack of the grain moisture level management has been leading to wastage of grains. In order to eradicate this kind of wastage of grain, this system is developed. Hence the monitoring will widely help them take the necessary precautions and prevent the grain from degrading in warehouse. IT has been observed that tons of grain get degraded/destroyed because of increase/decrease of moisture level in warehouse. The system is designed to solve this issue and will provide complete details of the grain moisture in the warehouse. The concerned authority can access the information from anywhere and anytime to get the details. Accordingly, they can take the decision on this immediately. In addition to the added advantages of being able to monitor the grain moisture and warehouse temperature wirelessly, a feature has been incorporated where the all detail about grain can be access through Android Application. This particular feature further enhances the capability that this particular product or project brings to the table. This adds to the existing feature of being able to monitor, but when the

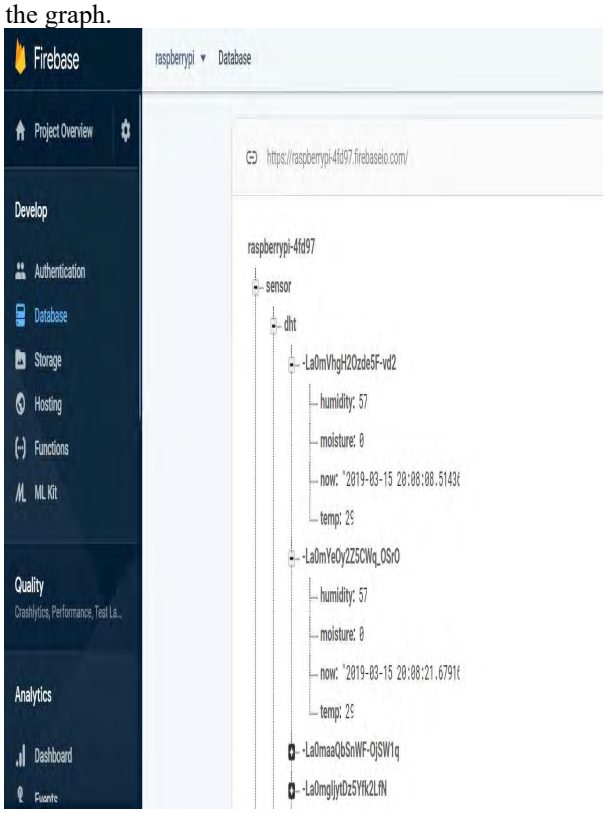
authorities are away, it gives them an added option of continuous monitoring.

d. Database Outcome:

Here in our system we have used the google firebase database. Google Realtime Firebase database stores the live data. It stores the data in JSON format; which is a light weight file and can be accessed easily. JSON data can be converted to multiple file formats according to the usage and convert that JSON data to csv file format

which is used by python to provide analytics report or the graph.



VI. FUTURE SCOPE

In future we will be adding inventory management module which will be helping them to know how many sacks of grains were sold to whom and at what time. The warehouse manager could also see the monthly or yearly billing of the grains which were sold, which will be helpful to calculate and order grains from the farmers at value price.

VII. CONCLUSION

Apparently, a systematic study has never been conducted over a wide range of moisture in grains by conditioning or drying to the range of different grain moisture meters and various characteristics of grain that contribute to variability in dielectric properties. In addition, there should be more study conducted on the how the physical properties of grains moisture content during procurement, storage and processing. The best dielectric properties and best frequency ranges should be selected while designing the instrument for quick moisture determination. The proper selection and use of circuits are as important as to design the sample holder capacity for different commodities. The other important requirements for grain moisture measuring instrument include the ease of use, accuracy, consistency, precision, reliability and light weight so that one can easily carry the instrument from heap to heap during procurement season. Developed a moisture meter for grains which is capable of sensing room temperature and humidity of warehouse as well as moisture of the food grains. Collecting data and research can be done from this proposed system and can protect the grains from getting rancid or spoiled.

Abstract- — **In Internet of Things (IoT),lot of information is being shared between the devices like smart houses,self driving cars etc. But the information is not protected as the Hackers can hack our system and also steal or change our information. In such circumstance there is a need for protecting the data using cryptographic algorithms. With the boom of Internet of Things, the embedded devices are being able to connect to the internet and intercommunicate with each other. Internets of Things find many applications in various fields but the emergence of IoT have put the embedded device communication and interaction at risk. There are various security conditions that need to be satisfied to be able to securely connect the embedded device to the internet. The information is not protected as the Hackers can hack our system and also steal or change our information. In such circumstance there is a need for protecting the data using cryptographic algorithms. In this Paper a strong Encryption Cipher Called PRESENT which is an Ultra-Lightweight Symmetric Block Cipher is discussed as an application of PRESENT cipher,Text message encryption is considered. Elliptic Curve Diffie Hellman (EC-DH) Algorithm has emerged as an attractive and effective public key cryptosystem. Elliptic curves are widely used in various key exchange techniques that include the Diffie-Hellman Key agreement scheme. The proposed work also involves analysis of power, performance, area, and their comparisons thereof. The comparison is based on metrics obtained, after implementing the algorithms in synopsys using 90 nm UMC Faraday library. The ECDH algorithm is found to be better than others as far as power and area are concerned. The results of IOT failures can be severe, therefore the study and research in security issues in the IOT is of extreme significance. The main objective of IOT security is to preserve privacy, confidentiality, ensure the security of the users, data and devices of IOT .Thus research in IOT ecosystem has recently been gaining much momentum .Traditionally the data was compromised during the time of transmission, facing problems like confidentiality, Integrity etc. As a traditional approach, only present algorithm was used which is a light weight algorithm**

I. OVERVIEW INTRODUCTION

The Internet of Things (IoT) brings a new set of security concerns. Unlike VPN encryption, which safeguards networks through an encrypted and anonymous tunnel, IoT devices must be inbuilt with their own strong security and encryption standards. VPN allocates an isolates space on the network. However inside VPN space, all of the network nodes can be accessed by any participant. When IoT devices are out there, a VPN has many open doors Securing the Internet of Things is critical not only for the integrity of data streams and software within each of the IoT application, but it is also for the integrity of the enterprise resources tied into those applications. IoT security is a complex problem, which requires a systematic approach for understanding possible threats and corresponding mitigation methods. In Internet of Things (IoT),lot of information is being shared between the devices like smart houses,self driving cars etc. But the information is not protected as the Hackers can hack our system and also steal or change our information.In such circumstance there is a need for protecting the data using cryptographic algorithms. In this Paper a strong Encryption Cipher Called PRESENT which is an Ultra-Lightweight Symmetric Block Cipher is discussed as an application of PRESENT cipher,Text message encryption is considered. In today's technology, there is an increasing number of electronics applications require secure communication for example the IoT devices. Elliptic Curve Diffie Hellman(EC-DH) Algorithm has emerged as an attractive and effective public-key cryptosystem. Elliptic curves algorithm are widely used in various key exchange techniques that include the Diffie-Hellman Key agreement scheme. When contrasted with conventional cryptosystems like RSA,ECC offers equivalent security with smaller key sizes, which results in lower power consumption, speedier calculations, and also lower memory and transmission capacity (bandwidth) reserve.What we are doing is that we are implementing present lightweight algorithm along with Deffie Hellman elliptical curve algorithm, which will provide more security to transfer the data.

Phase 1: deals with the deep study of the existing systems,by analysing the previously available research papers and technology.
Phase 2:The result of the literature survey and analysis based on various algorithms using previously available data on IoT security.
Phase 3:The parameters that are major reasons for the data security and attacks are detected and analysed to produce the design of the system.
Phase 4:implementation of the design using technologies planned in the above phases.
Phase 5: Testing and implementation of the software using the tools and the technology.

II. BACKGROUND

The main objective of this project is to develop a secure path of transmission of data between two devices that will secure the connection and the data which is been sent to the other iot devices, so that no other device can interfere in the transmission. This will be done by using the encryption and the decryption methods to ensure

confidentiality, integrity and availability of data. The algorithm used for encryption is Present algorithm and for decryption is Diffie Hellman elliptical curve..

Importance of the project

To Secure Device Hardware Accessibility :

Software security has proven inadequate to thwart the known threats. A networked device which lacks adequate hardware security can be easily hacked by an end-user. So, can you overcome this security flaw and secure your IoT devices against end-users? By encrypting and protecting configuration bit streams.

To Secure Port Communication :

Communication to and from the device needs to be secured using encrypted communication. One way to ensure this is avoiding the use of insecure encryption algorithm. Using weak encryption algorithms creates a false sense of security. We always think that our encrypted data will never be decrypted and stay hidden as long as we want. However, that will only be if you use solid encryption algorithms or follow secure encryption processes.

To Use Encryptions:

Encryption can help to prevent unauthorized access to data and devices. Also part of a complete security management process, encryption uses standard cryptographic algorithms to secure data at rest and in transit between IoT edge devices and back-end systems. This helps maintain data integrity and prevent data sniffing by hackers.

User Authentication:

All communication with your IoT devices should be authenticated using strong passwords, authentication protocols or time-based authentication tokens.

To Ensure Protection Against Phishing and Malwares :

Antivirus software which are useful can provide a critical layer of protection against attacks. They limit communication to only to the known, trusted hosts, blocking hackers before they can launch an attack.

Employ Middleware Hardware Physical Security:

A category of software, Middleware Hardware Physical Security provides a variety of platform and applications which are designed to integrate multiple unconnected security applications and devices and control them through one comprehensive user interface. By controlling access to hardware and software, physical security eliminates the possibility of any other device or user to damage or steal devices or data. Moreover, it limits physical interaction with equipment and implements systems to ensure that equipment is safe from environmental threats and to promote physical security.

Objectives and Scope of the project

III. OBJECTIVE

- Ensuring security of personal data on public databases: Interviews with our respondents suggested that there was a lot of concern with respect to two important issues. The first issue is unnecessary storage of private data on public forums. Many of the IoT devices and applications constantly stream data to other devices and servers. And this data never gets deleted. Rather it is an aggregated and used for trend analysis or evaluation of browsing histories. Second issue is indefinite availability of search histories.

- Maximize data integrity: Data integrity emerges as a fundamental issue in IoT. This is because there is a constant transmission of data from one device to the other. And there is an increased change of unauthorized changes and the accuracy of the data that is received. It is therefore paramount that technologies that enhance integrity be integrated into IoT. One of the respondents in our study noted:

- Maximize security awareness of IoT: While security awareness has always been a vital issue to consider, its importance is elevated in an IoT environment. This objective dealswith the increasing awareness of IoT and educating the consumers on IoT security. In a survey conducted by AT&T, it has been concluded that only 10 percent of respondents are fully confident with that their devices are fully secure. About 68 percent of respondents say that their companies are planning to invest IOT security in 2016.Many organizations deploy IOT devices, but in some of them the IOT devices are deployed without proper security measures.

- Enhanced protection of personal information on devices: This objective emphases the importance of placing reasonable limits on the collection and retention of data by IoT. When a large amount of data is stored, it is more likely at the risk of being hacked by the intruders, thus increasing the potential harm to the personal information on the devices. Scope: To be able to securely send the data hashing can also be used .

- MD5 is a hashing algorithm which outputs a message digest which is of fixed length derived from an input of arbitrary length.

- The designed algorithm will have various features that can be used to satisfy the security concern in IoT. The proposed research about present algorithm will allow the use of MD5 for securing the embedded device from attacks when connected to the internet to become a part of the Internet of Things.

Feasibility study

Economic

The project relies on open source software, such as Python, MATLAB. The functionality provided by these software's is enough to construct a product and capable of making project.

Technical

The capabilities required for the project are fairly in the feasible range. Most of the planned feature hinge around linking Databases. A GUI is required, which will be done with the pyGUI framework. The GUI will be kept simple and minimalist. We also have a feature for users to set personal data, preferences.

Operational

On an operational level, the software will need to run intensive processing tasks while it's in its learning phase. The software will be deployed to the IoT devices which eill help in encrypting and decrypting the data which is been send from the devices. It will need internet to operate.

Legal

Since the project deals with a sensitive topic with potential for major harm, it will carry a disclaimer for improper usage. The software is not meant to be use for any illegal activity. However, the potential for misuse, whether intentional or not, still exists.

IV. METHODOLOGY

- From Literature survey, we understood how the data is attacked in IOT device transfer and also how it can be prevented.
- From Gap analysis, we understood that the prevention techniques of data been accessed by other devices during transmission but all this techniques are not fully supported and they sometimes cannot be trusted.
- From problem definition, we understood that as of now there is no permanent solution for prevention of data been accessed by other user.
- From proposed solution, we decided to build an application that will stop the other device to gain access to the transmission device so that no data is leaked.
- From result, we understood how our system will analyze the data, encrypt the data, use public and private key for encryption and decryption and simultaneously get the data in the normal form at the other end.

Product Backlog or Sprint backlog

The backlog of the project is given as follows:

1. All the coding will be done in Python and C.

2. Simulation will be used to show the real time application of project.

3. There will a shared secret key exchange between sender and reciever using ellptic curve diffie Hellman key exchange algorithm

4. Then the input from the sender will be encrypted using the shared secret key and present algorithm and send to the receiver through the channel.

5.The encrypted data will be received by the receiver and decoded using the decoder and the shared secret key.

6. Design
   - Creating simulation environment
   - GUI building
   - Modeling
   - Feasibility analysis

Project Planning

IT projects require resources in terms of money, time, human resources, infrastructure and technology, both hardware and software. Resources are not just a mean, but also an approximation of constraints. Project planning is essential to managing the scope, schedule and budget of the project. For this, we used tools such as Matlab,Turbo C,Sublime text ,python ide, MS PowerPoint, online MS project as well as various modeling tools.

We divided our project into various phases and sub-phases, and allocated date ranges from a week to 3 weeks to every sub-phase. This was done using the timeline chart feature of online MS project. We then used a Gantt chart to model schedule dependencies and fine tune the scheduling. The Gantt chart was created using the Gantt chart feature available in MS Excel. Using these two, we further planned our sub-phases.
The modeling included charts and diagrams such as UML diagram, GUI modeling, dependencies and other diagrams. These were done using free tools like draw.io. Drawing these models helped to incisively assess our requirements and features.we analyzed various prevalent research papers pertaining to our project as a part of the literature survey. The project aims at researching about the encryption algorithm in IoT network. Tapplication will be able to help organizations secure their SQL database.

Our literature survey was focused on the capabilities of the choices we made for the core part of the project. We have divided the project into 2 phases.

- Phase I – Phase 1 will focus on forming a base for the project. With thorough planning, analysis and design, we will ensure that the actual implementation is smoother.
- Phase II – Phase II will focus on fine tuning the project and ensuring that the intended features will work as we wanted them to.

Scheduling

V. RESULTS & DISCUSSION

Actual Results

A system is proposed for secure communication betwseen two devices over the internet by using the encryption and decryption.
Using present algorithm we will protect the data of the user and confidential data in IoT devices the data will be encrypted using public key encryption.

a. Outputs:

Sprint 1: Literature survey and deep study of previously available system provided the outcome as the requirements of this project

Sprint 2: Documentation and formulation of the design.The ultimate design of the system is the overall output.

Sprint 3: The design is being implemented with GUI and the hardware

b. Outcomes:

The outcome of the above sprints are, sprint 1 provided the key findings and research gaps that can become requirements for the projects. Sprint 2 contributed by finalization of the system and services to be provided by the project. Sprint 2 also provided the design of the overall system. Sprint 3 provides output as 50% implementation of the system.

Outcomes:

This algorithm will provide security to IOT devices by using deffie hellman elliptical curve algorithm for key exchange and present algorithm for encryption and decryption.
Using present algorithm we will protect the data of the user and confidentiality of data in IOT devices will be encrypted using public key cryptosystem.

Future Scope

For future research, the implementation of the algorithm on hardware and software in various computation and network environment is under consideration. We will also use the advance hashing techniques like MD5 hashing algorithm which outputs a message digest which is of fixed length derived from an input of arbitrary length Moreover, the algorithm can be optimized in order to enhance the performance according to different hardware platforms. The scalability of algorithm can be exploited for better security and performance by changing the number of rounds or the architecture to support different key length.

Testing

Once the program code is designed and implemented, some testing technique will be used to ensure the program function correctly.

Unit Testing
Individual modules will be tested. The project is made up of smaller parts that can tested individually against the specification and design to confirm their correct operation.

Integration Testing
Several units will be tested together to see how they interact and to confirm whether their overall function is performed correctly. This testing will apply to each of the main section of code; the use interface, data processing, etc.

System Testing
The entire system is tested against the specification to check it meets the project's requirements.

.

VI. Deployment

Deployment can be a major challenge in software which involves networking.
The GUI by itself is not very difficult to deploy. We have multiple ways of offering interfaces, such as web interfaces and command line interfaces. It will expand to a desktop GUI in the future as well.
The web interface will be deployed using heroku or AWS, depending on the relative cost of hosting.
The command line can be used as a windows executable file. Users can simply download it and run it natively on their windows PCs.

VII. Conclusion

The internet of things is growing exponentially. It has spread from the power grid to smart refrigerators at home and at industrial levels by monitoring production line efficiency. The devices that connect to the internet must be encrypted because of the personal and business intelligence data they transmit. IoT users and security managers need to be attentive to security and to the ways encryption can both power and protect the next generation of secure networks and devices. The best protection available right now is encryption. The security requirements are similar to those of earlier generations of networked devices, embedded devices or security tokenization but need to be combined together strategically to match each specific use case. The security design of an IoT node can greatly benefit from the experiences gathered in the fields of platform, network security, and highly sensitive applications such as payment or financial transaction, government related application, content protection. The solution must be adapted to each specific use case

Abstract:- **With globalisation and the thirst for connectivity across society, the demand placed on wireless infrastructure and the associated resource is growing exponentially. Very soon this resource will reach saturation point, due to the finite bandwidth available in the Radio Frequency (RF) spectrum. A method of countering the impending saturation needs to be found. That method can be Visible Light Communication (VLC).**

Light Fidelity (Li-Fi) is a research field within VLC that utilises the visible light band within the electromagnetic wave spectrum. This band is 10,000 times larger than the RF band and cannot be 'leased' or saturated with users. Light waves can be modulated to carry an enormous amount of simultaneous data, at speeds faster than current consumer equipment can handle. This Dissertation describes in detail the research, construction and testing of a Li-Fi prototype using Arduino. The prototype is compact, low cost, uses accessible components and provides a solid foundation for other students to follow on with further work in this field. The prototype successfully demonstrates the principle of Visible Light Communication and shows the viability of using Python for coding, SPI for data transfer and lists suitable electronic components to process bit-wise data signals. The prototype shows that while it is possible to use addressable LED's as the transmitting element, the Dissertation concludes that they are not suitable outside of a heavily constrained environment.

Keywords— Arduino; processing; Arduino software; LED; LDR; visible light communication; file transfer.

I. INTRODUCTION

We now live in a world that is infinitely connected through a multitude of invisible, networked pathways. They stretch and travel across houses, towns, countries and continents. We are a truly global society that now has an insatiable appetite for connection, information and convenience.

This intrinsic appetite has fuel led the proliferation of connection technology from crude military beginnings at DARPA (Dennis et al. 1988), through excruciatingly slow networks of public computers and onto networks increasing in speed and computational power, now without the use of cables.

Almost exponentially the world has developed and embraced technology that now allows us to carry super-advanced, micro-computers in our pockets. The majority of these devices are connected wirelessly to internet service providers, who in turn connect to the World Wide Web. With a swipe of our finger we can find out the weather at that exact moment in Nairobi, St Petersburg and Honolulu. A supplementary or superseding method of communication needs to be developed to combat the inevitable RF band saturation. There is such a method and it utilises a relatively untapped source of waves, with an extremely large bandwidth. This method uses the visible light spectrum band, which is shown (not to scale) in Figure 1 below.

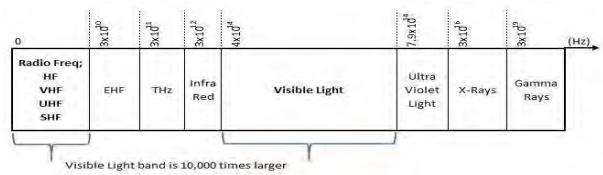

Figure 1 - Radio Frequency vs. Visible Light Frequency Bands. Courtesy of author.

Electromagnetic spectrum of RF and Visible Light are disproportionately assigned in current communication methods. Not only is there larger space to grow into, it is 'greener', the band cannot be regulated, leased or saturated, it does not create electromagnetic interference with other devices and modulation of data can occur at frequencies that the human eye cannot detect (Stefan & Haas 2014). There is even research underway by Rajagpol et al. (2012) where data streaming is being conducted at light levels such that the light appears to be off according to the human eye. This could account for daytime or purposefully dark environments where people may use their devices.

II. LITERATURE SURVEY

This literature review covers the published research relating to video or data transfer via VLC (Light Fidelity), in particular utilising Raspberry Pi or similar low-cost, consumer accessible microprocessor modules. It covers key project concepts such as any potential transmission and receiver circuit configurations, signal management, encoding and decoding of the data into a bit-stream and vice versa, and modulation techniques. VLC is a field of research that has recently taken on greater importance within our lives. Take for example, the industrial pursuit for releasing to the public, society's first truly operational 'driverless vehicle'. The foundation of this technological product is built on the foundation of VLC (coupled with radar and machine vision). The concept of transmitting data via light waves is evolving into a subject that can yield solutions across our lives, including RF band congestion and quenching the global thirst for faster and more complex data transmission.

While Dr Harald Hass demonstrated video data transmission during his TEDGlobal talk Wireless Data from Every Light Bulb (2011), the technological complexities involved in that demonstration were out of reach of anyone other than PhD level academics. Dr Haas is by far the leading worldwide exponent in the field and outside of his academic research at the University of Edinburgh, he has started his own company called pureLiFi (pureLiFi 2014). This company takes the scientific advances they test in the laboratory and turn them into

consumer orientated modules. At present they have a 10Mbps half-duplex system (Li-Flame) that works at a distance of up to 3m (pureLiFi 2014). Although this system focuses on bi-directional internet access, any development of this platform is limited to commercial partnerships with the parent company or through PhD pathways at the university. The Li-Flame system also requires additional roof modules to be mounted next to the LED lights and preclude it from being integrated into many publicly accessible applications. This is largely due to the vandalism exponent and the 'irregular' intrusion into a 'headspace' envelope. For these reasons a recessed or concealed system is mandatory for commercial acceptance.

III. METHODOLOGY

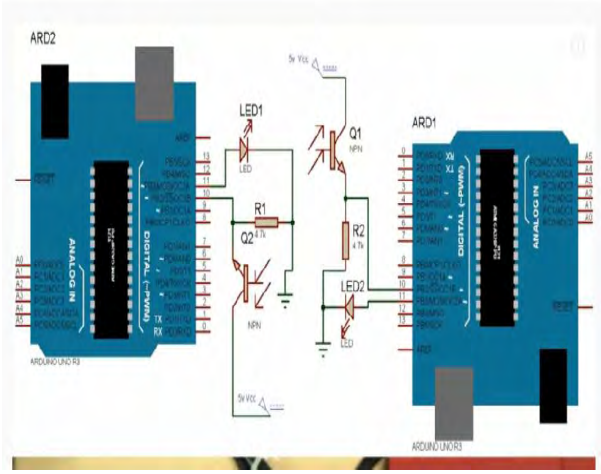

Fig.3.1 Block Diagram

This project was purely one of research and experimental work. The project was executed as a progressive development of concept following a body of research and expansion of ideas to achieve the aim. The steps generally followed a typical Project lifecycle model from the Project Management Book of Knowledge (Stackpole, 2010).

- Project Initialisation – research proposal, literature review, design information
- Project Start Up – procurement, production readiness
- Project Production Phase – build the prototype
- Project Execution – get the prototype working, test and develop
- Project Closure – write up dissertation, demobilisation

Initialisation The Project Initialisation Phase was a combination of producing a preliminary report, deeper research into prototype specifics and formalisation of the project scope and outcomes. This phase was purely research driven and the investigation carried out defined the general shape of the project. Significant information was gathered during this phase and a thorough search helped to prevent errors or miscalculations during construction. The outputs of the Initialisation Phase were;

- A mental roadmap of the Project direction, with alternative routes in reserve,
- A list of required resources, and
- Set-up of a Project Diary to track daily progress and the reasons behind the various decisions made throughout the Project.

Start-Up The Project Start-Up phase took the outputs from the Initialisation Phase and built on them to begin the procurement of Project resources, allocation of Project space, Project management systems and to mark the start of the physical work phase of the Project. This phase moved the Project from an idea, theory and research based Project to one that was tangible. Outputs of the Start-Up Phase were;

- An allocated workspace to construct the prototype,
- Focussed research to a preliminary modulation technique,
- Understood how to drive the LED's from a 3.3V Ardunio uno output signal to a LED i/p signal
- All necessary software downloaded and installed, and

Production The Production Phase marked the start of the actual building of the prototype. This was undoubtedly one of the most exciting aspects of the project and brought with it the start of the major challenge to get it working. The outputs of the Production Phase were;

- Build and develop the LED driver circuit to deliver the required voltage to modulate the LED's, and
- To completely construct all power supplies, equipment and components.

Execution This phase contained the largest amount of work, frustration, technical demand, support and investigation. The primary focus was to get it working and then to look for optimisation and improvement, time permitting. The planned sequence of work was;

1. Connected power supply and signal management circuits to drive LED's on,
2. Confirmed that photodiodes could receive the LED's being manually switched on and off,
3. Used the Arduino uno transmission module (TX) to create a simple square wave to send to the uno receiver module (RX) and achieve basic communication, displayed on a screen or other output device,
4. Increased data speed (via small steps) and maintained expected outputs,
5. Attempted to send a file across free space, maintaining the quality of the original. The outputs of the Execution Phase were;

- A Project Diary that recorded the path followed throughout the Project to provide a resource to build the Dissertation from,
- A working Prototype that could send files across free space using Visible Light Communication technology, and
- A final configuration (including software + code used) of the system.

Project Closure The Closure Phase intends to wrap up the Project and finalise all aspects ready for academic

submission. Closure includes decommissioning the prototype system, returning borrowed or loaned equipment and writing up the results. Should the Project provide suitable material, a publishable paper could be written to give information to the wider engineering community. The outputs of the Project Closure phase are;

- An academic Dissertation submitted to USQ for ENG4112,
- Decommissioning of the prototype, and
- A final parts list and configuration document to share with industry.

IV. PROJECT PROTOTYPE

Prototype Development

This chapter describes in detail the steps that were taken to arrive at a working prototype. It covers all of the technical information, principles and operation pertaining to the prototype.

Project System Diagram

The system can be broken down into two sub-systems; the Transmitter (TX) and the Receiver (RX). Each one is made up of smaller functions such as the LED electrical control circuit and board, the photodiode electrical control and board, the software in the TX and RX modules, the peripherals (keyboard, monitor, mouse etc.) and support software (e.g. MobaXterm). The Figure below illustrates how the prototype is made up from a system point of view and shows the interaction between the varying components.

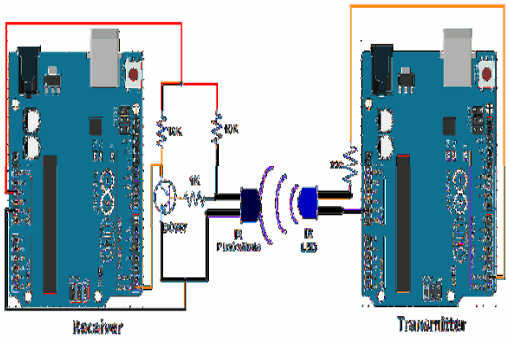

Fig.4.1 Project System Diagram

Graphical Representation

Led light is use to transfer data on basis of capacity of light to data transfer of particular led lights which is shown as follows:

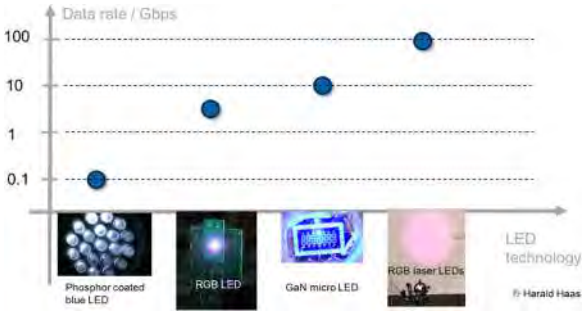

Fig.4.2 LED vs Data Rate

GUI

The system having two parts which is composed of transmitter and receiver the same thing is developed by using python code as shown follow:

Transmission Frame composed of text enter area and button to send and listbox which is used to show transmitted data to user.

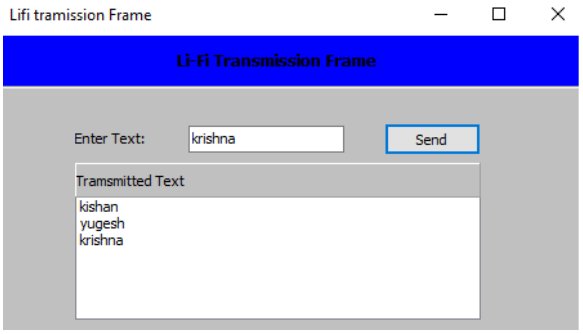

Fig.4.3.1 Transmission Frame

Receiver Frame composed of listbox which is used to show the received data.

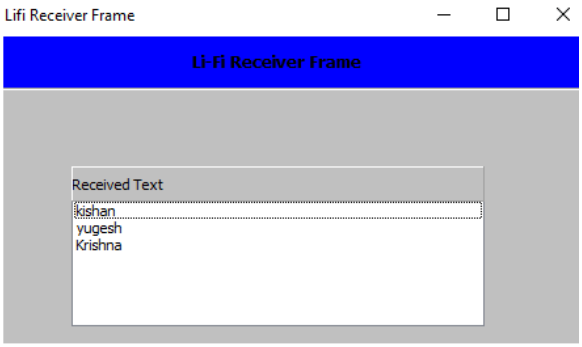

Fig.4.3.2 Receiver Frame

Port which is used for connection and baud rate is low the error rate is low.

V. FUTURE SCOPE

This Technology can be improved further and can be used to transmit the data to the mobile phones and computers that does not use radio waves for the transmission, home automation, monitoring activities and Li-Fi hotspots which can transmit the data in the order of GBPS.

VI. CONCLUSION

Therefore, by using this system, we can obtain a better speeds than Wi-Fi and normal connecting cables which are commonly used for the file transfer. The Radio band crisis problem can also be solved by employing the further existing system with this technology. As internet is not required for any of its software the bandwidth is also conserved hence reducing the network complexity. By further development of this technology can transfer the Files ranging GB's within few seconds.

VII. RESULTS

Fig.7.1 Output

1.At low baud rate the error rate is low e.g At baudrate=1200 | error <1% ,however as we increase the baudrate the error rate increases i.e At baudrate=9600 | errorr>15%.

2.With expensive LED like APA102 Dotstar with Luminous flux = 18 Lm and frequency upto 20kHz the data rate can be improved to 50kbps.

3.With Normal LED data rate upto 4-5 kbps is achievable.

4.With high performance photo receptor like HAMAMATSU S5971 Photodiode with 1Mhz frequency is acheiveable.

5.Using phototransistor (L14F1) & RS-232 protocol we are succesfully able to send text message from one PC to another PC at a rate of few kbps.

6.Though image type file is not supported in RS 232 protocol but we can still send the binary code and then at the software side process and convert it back to image.

7.To send a file of size 5kB it takes around 1-2 secs and for image of size 50kB it can take 10-12 secs.

Fingerprint Security on cloud using IOT

Niket Singh, Utsav Singh, Tanya Sinha, Neha Patwari
Information Technology, Thakur College Of Engineering and Technology, Mumbai, India
niket11097@gmail.com, singh.utsav100@gmail.com, tanyasinha017@gmail.com, neha.patwari83@gmail.com

Abstract- **The Internet of Things (IoT) is a system which consist of interrelated computing devices, mechanical and digital machines that are provided with unique identifiers (UIDs) and has the capacity to transfer data over a network without requiring human-to-human or human to-computer interaction. IoT security is the technology area concerned with safeguarding connected devices and networks in the internet of things (IoT). IoT involves adding internet connectivity to a system of interrelated computing devices, mechanical and digital machines. Each thing is provided with a unique identifier and the ability to automatically transfer important data over a network. The activities like storing the data securely and processing the data take place in the cloud rather than on the device itself, this has significant implications for IoT. Many IoT systems makes use of large numbers of sensors to collect data and then make high quality intelligent decisions. Current approaches of authentication is based on mainly password and pin based authentication. Here we have planned to implement a biometric based authentication system which would be based on fingerprint biometrics. It would be implemented using a fingerprint sensor and raspberry pi 3. The fingerprint credentials collected using the sensor would be stored in cloud such as Google, AWS, etc or even our own cloud server. As we know that major drawback of cloud is its security issue. The stored fingerprint credentials could be attacked by the intruder and can be explored further for illegal and unauthorized activities, this project stores fingerprint over the virtual cloud and provides high security to the fingerprint. The fingerprint is collected from raspberry pi 3 and stored over the virtual cloud created and the security is given using the AES or RSA algorithm. So we are focusing on providing security to the data stored over the cloud. The conventional cloud security (public cloud) has weak security as it is made feasible to large number of users.**

Keywords: Encryption, IoT, Cloud Security

I. INTRODUCTION

The reach of internet has extended itself to many applications and such usage is now clocking at intense level. To put this into perspective, a live example is Banking where lockers and confidential data are stored using the physiological characteristics. Biometric authentication is one of the popular technologies.[1] This biometric identification includes fingerprint, iris and face recognition etc. The usage of Raspberry Pi and its connectivity with cloud is now becoming a new trend. In addition to this feature we would provide security to the data on cloud using a security algorithm. As the storage on local disks is unreliable in some cases, cloud-based storage is attracting everyone to store data on cloud which can be accessible from everywhere.[3] The number of individuals storing their data on cloud is increasing day by day, so the security level needs to be upgraded because when particular data is uploaded to the cloud the information is transparent to two parties, one is cloud services and the other is cloud administrator. Everyone uses their own encryption mechanisms and keys. By this many people think that their data is secured, but no there is a chance to know the respective key of an individual.

II. BACKGROUND

Blowfish algorithm is used for encryption process for securing information. It is used for image encryption. Blowfish is a symmetric block cipher that has been utilized generally these days. On the off chance that a client needs to store his/her information in the cloud through Cloud Service Provider (CSP) the client presents their prerequisites and picks best-indicated administrations offered by the provider.[5] At the point when the information is moved to the picked CSP occurs and in future at any point if the user uploads any information in the cloud, the information will initially be encrypted using the AES algorithm and after that sent to the provider. The information is transferred on the cloud after its encryption, any demand to peruse the information will happen after it is decrypted on the client's end and after that the plain content information can be perused by the client. This incorporates a wide range of information. This encryption is straightforward to the application and can be coordinated rapidly and effectively with no progressions to the application. Since it might bargain the key additionally, the key is never put away alongside the encoded information.[1] A physical key administration server can be introduced in the client's premises so as to store the keys. This encryption assurances to secure information and keys that they stay under client's control and will never be exposed in storage or in transit. DIFFIE-HELLMAN for key exchange. It is a selected algorithm for changing cryptographic keys. It is a standout amongst the maximum activate sensible models of key trade within the area of cryptography.[4] The Diffie– Hellman key trade system grants social affairs that have no earlier studying of each different to together set up a shared mystery key over a questionable correspondences channel. This key would then have the capacity to be used to scramble subsequent trades using a symmetric key figure. The arrangement was first dispersed by Whitfield Diffie and Martin Hellman in 1976, regardless of the way that it had been freely built up several years sooner inside GCHQ, the British signs knowledge office, by James H. Ellis, Clifford Cocks, and Malcolm J. Williamson, notwithstanding, was kept

classified.[citation needed] In 2002, Hellman proposed the estimation be called Diffie– Hellman– Merkle enter the exchange affirmation of Markel's duty to the advancement of open key cryptography.

III. IMPORTANCE OF THE PROJECT

Biometric security measures exist at various points in the data pathway that makes up the IoT. From securing a device with a fingerprint sensor to utilizing a smartcard to verify your identity, these security points help create a seamless experience and allow data to flow freely and quickly between points. That data arriving untampered is important. This allows for quick and efficient connections to be made, and keeps the data used to make those connections as secure as possible during the transfer and delivery processes. As the number of connected devices continues to grow, the need for failsafe security becomes more important and will continue to stay in the forefront of security expert and developers minds. It provides real time reports. It provides interoperability with other applications, which is quite affordable, easy to install and had no maintenance cost. It is independent of any password, pin or RFID card.

IV. OBJECTIVES AND SCOPE OF THE PROJECT

1) To provide a system that gives security to biometric of user.
2) To successfully implement the security encryption technique over the cloud.
3) To develop the project such that it can be easily integrated with the new technologies.
This is an encryption system that stores the biometrics (fingerprint) over the cloud. It is more cheaper than compared to other similar system. It uses the Diffie-Hellman algorithm to encrypt the images stored which is a strong algorithm for commercial purpose.

V. SUMMARY

Here we analyzed various familiar research papers relating our undertaking as a part of the literature survey. The venture goals at growing an more secured cloud the usage of the powerful safety algorithm. This utility will be capable of help the safety and other developers' paintings efficaciously. Our literature survey became focused on the abilities of the selections we made for the middle part of the undertaking, particularly key encryption set of rules and the cloud generation that provides protection to records We have divided the challenge into 2 stages, which are in addition divided into five and a couple of sub-stages every. The trouble definitions for each section and sub-segment are as follows. 13 Phase I – Phase I will recognition on forming a base for the project. With thorough making plans, evaluation and design, we can make sure that the real implementation is smoother. Phase II – Phase II will consciousness on satisfactory tuning the task and ensuring that the supposed functions will work as we desired them to. Due to these 2 being freely available, the mission may be very low value and for that reason viable from an financial standpoint. The expected general cost is hence 300 rupees. As such, we do no longer need any outside investment. The skills required for the venture are fairly within the feasible variety. Most of the planned feature hinge around processing datasets. A cloud server is required to be able to be performed on AWS platform. The server might be kept simple and minimalist. We even have a function for users to set private records, preferences. On an operational stage, the software will want to run extensive processing duties even as it's in its getting to know phase. This utility may have many advantageous packages on society. It will permit customers to manipulate their healthcare desires in a reasonably-priced and clean manner. Since the venture deals with a touchy subject matter with potential for foremost damage, it will convey a disclaimer for mistaken utilization. The software isn't always intended to be an alternative to doctors or hospital supplied healthcare. Users must ideally best use it to supplement expert healthcare. However, the potential for misuse, whether intentional or no longer, nonetheless exists. The technique that we chose for our task is Agile. Agile lets in us to be flexible, manage converting requirements, manage the ever-increasing scope as well as get customer perspective. Agile has cognizance on client delight, which is a crucial factor of any healthcare software. Agile software program development is a technique for software program tasks below whose framework venture necessities and answers evolve via the collaborative attempt of self-organizing and go-purposeful groups and their consumer and meant customers. Users showed interest in Fingerprint safety over cloud the usage of IoT, in addition to a software which could do it for a reasonable price. Besides this, we researched pursuits of clients in wearable technologies. Technologies like KYC have already made a touch within the security marketplace.

VI. DESIGN AND IMPLEMENTATION :

Algorithm to be used: Diffie-Hellman: The Diffie-Hellman algorithm is being used to establish a shared secret that can be used for secret communications while exchanging data over a public network using the elliptic curve to generate points and get the secret key using the parameters. Step by Step Explanation:
Flowchart

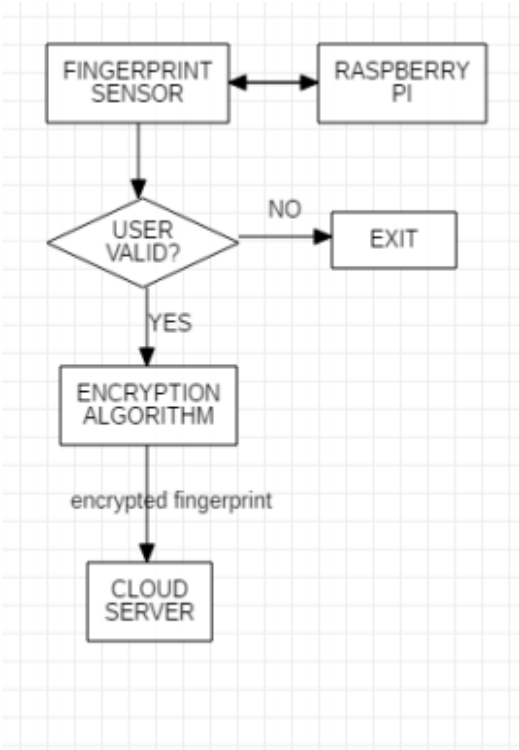

Figure: Flow Chart

Block Diagram

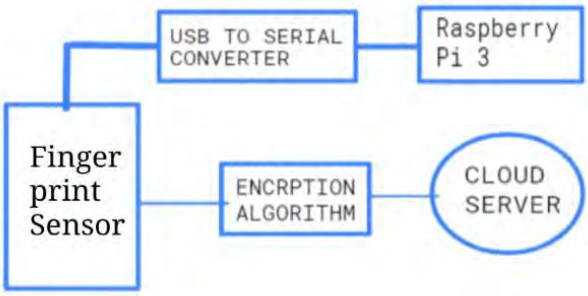

Figure: Block Diagram

Algorithm used

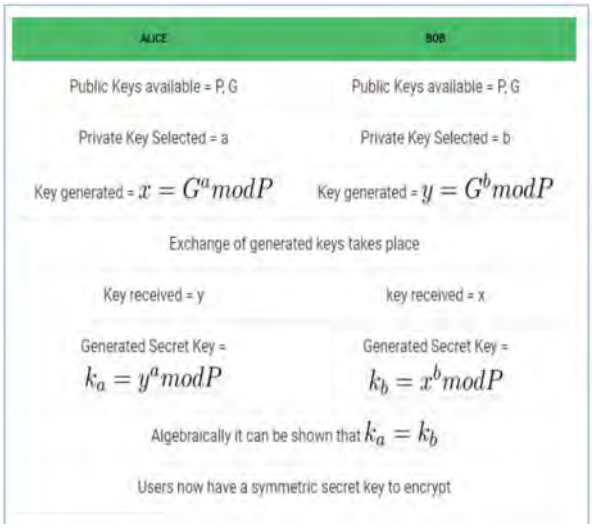

Figure: Algorithm used

Components:

Hardware:

A. Fingerprint Module

The captured fingerprint traits are sent to the Raspberry Pi has enhancement and fingerprint verification for capturing fingerprints. Figure 3 Block diagram of fingerprint based digital transaction system. The main stages of this algorithm include normalization, ridge orientation estimation, ridge frequency estimation and filtering. The first step in this approach involves the normalization of the fingerprint image so that it has a pre-specified mean and variance. An orientation image is then calculated, which is a matrix of direction vectors representing the ridge orientation at each location in the image.[2] The next step in the image enhancement process is the estimation of the ridge frequency image. The frequency image defines the local frequency of the ridges contained in the fingerprint. The next step in the enhancement process is to construct the final filtered image using the pixel values from the prefiltered images.[1] Lastly, local adaptive 50 thresholding is applied to the directionally filtered image, which produces the final enhanced binary image. After a fingerprint image has been enhanced, the next step is to extract the minutiae from the enhanced image. Following the extraction of minutiae, a final image post processing stage is performed to eliminate false minutiae.

B. Raspberry Pi

Raspberry Pi has authenticated the user (by using right thumb) by using fingerprint matching algorithm and displays the user details on the screen. Next to perform the digital transactions, Raspberry Pi has generated the random finger using novel infinity noise algorithm. Then Raspberry Pi verify the injected random finger and perform the operations like balance enquiry, money transfer, money withdraw and deposit the money. If the finger hasn't match the system asks right thumb for authentication and system start the procedure from beginning. Now the security of our money is literally in our hands or rather on our fingertips.[3] Enter the password to open digital bank account with the help of a keypad. Immediately the bank account will be opened. After the work has been completed if key is pressed

again with help of touch pad the account will be closed again or it close automatically after 3 minutes if the user not processing any data. If an unauthorized person tries to scan his fingerprint image then an indication will be given by a buzzer which is interfaced to the controller and also if wrong password is entered by the user again indication will be given by the buzzer.

C. USB to Serial convertor:

A USB to serial adapter, also referred to as a USB serial converter or RS232 adapter is a small electronic device which can convert a USB signal to serial RS232 data signals. RS232 is the type of signal which is in many older PCs and is referred to as a serial COM port.

A USB to serial adapter typically converts between USB and either RS232, RS485, RS422 or TCP signals, however some USB to serial adapters have other special conversion features such as custom baud rates, high-speed or other. Even the USB to serial adapter RS232 standard is an older communication protocol it is still used by many modern serial RS232 devices in both business and consumer markets and is also often used for personal and office serial devices. [3] More recently most new computers do not have a built-in COM port so a USB serial adapter is often used for connecting many types of serial devices to a computer. A standard USB to serial adapter is a very useful device for connecting equipment such as printers, scanners, scales and GPS devices, but also most business and consumer equipment can be connected to a computer by using an industrial grade adapter.

Software:

A. 000Webhost:

000webhost is one of the very few web hosts which give you the ability to host your website while paying nothing. This may sound like a hoax or a fraud but 000webhost has been in the paid hosting business for around 4 years and they are providing free hosting since 2 years. 000webhost is a great place to start experimentations or hosting relatively unimportant websites. The free hosting which is provided by 000webhost does have some drawbacks which can be instantaneously removed by upgrading your account. 000webhost or $0.00 webhost as they liked to be called have a very reliable performance history and they also guarantee 99% uptime.

B. Python IDE:

Python is a high-level, interpreted, interactive and object-oriented scripting language. Python is designed to be highly readable. It uses English keywords frequently where as other languages use punctuation, and it has fewer syntactical constructions than other languages.

Python is a MUST for students and working professionals to become a great Software Engineer specially when they are working in Web Development Domain.

Advantages of learning Python:

- Python is Interpreted − Python is processed at runtime by the interpreter. You do not need to compile your program before executing it. This is similar to PERL and PHP.
- Python is Interactive − You can actually sit at a Python prompt and interact with the interpreter directly to write your programs.
- Python is Object-Oriented − Python supports Object-Oriented style or technique of programming that encapsulates code within objects.
- Python is a Beginner's Language − Python is a great language for the beginner-level programmers and supports the development of a wide range of applications from simple text processing to WWW browsers to games.

VII. RESULTS AND DISCUSSION

a. Outcomes:

1) The project made is compatible with any environment with little atomization.
2) The project will carry out process as programmed for the security purposes.

b. Discussion of the results:

Finally this project will store the biometric (fingerprint) of the user and provide it security using the key encryption algorithm. The fingerprint is captured using the fingerprint sensor which is connected to raspberry pi 3B model. This data will be encrypted using Diffe-Hellman algorithm to encrypt the fingerprint. This system uses the
Linux as the environment for the raspberry pi and python for programming. The cloud server is made using the programming language and then the security algorithm is applied to it. This system makes a secure environment for the storage over the cloud which in current scenario is not given attention.

VIII. CONCLUSION

The proposed Project has high quality value in terms of research point. The presented model is low-cost IoT

based Biometric verification system with the use of Raspberry pi. The proposed system is efficient / secure and can be used for security and access control mechanisms and can be implied in any areas where authentication is must essential. However, we will able to achieve greater and Extra versatility, which was probable the motive that the algorithm changed into no longer that accurate inside the first region. Fingerprint security using IoT provides a solution for the security concerns of cloud services and tries to overcome that problem. IoT system faces more security concerns than normal IT system. IoT system contains new communication technologies and resource constrained devices. There is also different attack methods involved in IoT system than that of normal information system. Security on IoT system can be deployed by presenting a security framework according to the security need of IoT system. Security framework helps in understanding and minimizing security threats and issues of IoT system. Certified authorities can provide trust system for mutual authentication between multiple end points. By using digital certificates, keys and security credentials, authenticated and encrypted communication can be made possible. Our future work will address a special issue of back up connection in IoT system along with implementation details.

Tiny Encryption Algorithm for IOT Data Security

Mr. Ashutosh Pandey, Ms. Sneha Thakur, Mr. Dushyant Trivedi
Thakur College Of Engineering. & Technology
Mumbai, India
pandeyashutosh2498@gmail.com, snehathakur0578@gmail.com, dushyant.trivedi99@gmail.com

Abstract— **In wireless technology we have created an exponential rise in the number of connected devices leading to the internet of things (IoT) revolution. Large amounts of data are captured, processed and transmitted through the network by these embedded devices (An embedded device is an object that contains a special-purpose computing system. The system, connected to the internet which is completely enclosed by the object, may or may not be able to connect to the Internet).**
In Iot networks Security of the transmitted data is a major concern. Encryption algorithm such as:DES/3DES or TripleDES, TEA(Tiny Encryption Algorithm), Blowfish, AES, Two fish, IDEA, MD5, SHA 1, HMAC, etc. The lower memory utilization and ease of implementation on both hardware and software scales in TEA is the most attractive among all. The usage of the same key through all rounds of encryption, produces a reduced security evident from the avalanche effect of the algorithm is the major issue in TEA. Also,at the time of encryption and decryption the text is high, leading to lower efficiency in IoT networks with embedded devices. This project uses the symmetric encryption algorithm (TEA) which is proposed in order to minimize the memory footprint, processing time and maximize the speed, increasing the performance of the system. The project is targeted for the embedded system or Smart mobile phone which concerns more over speed & space. The basic operations from mixed algebraic groups and a large number of rounds to attain security with severity the plaintext is encrypted and decrypted. It has sixty- four (64) Feistel rounds are used in the TEA encryption as well as decryption process. The outcomes is to design a possible implementation on embedded devices through which cloud services will store the data passed by the devices. These projects can be possibly taken further from embedded devices to Smartphone devices.

I.INTRODUCTION

The Internet of Things (IoT) is turning out to be an emerging discussion in the field of research and practical implementation in the recent years. IoT is a model that includes ordinary entities with the capability to sense and communicate with fellow devices using Internet [1]. As the broadband Internet is now generally accessible and its cost of connectivity is also reduced, more gadgets and sensors are getting connected to it [2]. Such conditions are providing suitable ground for the growth of IoT. There is great deal of complexities around the IoT, since we wish to approach every object from anywhere in the world [3]. The sophisticated chips and sensors are embedded in the physical things that surround us, each transmitting valuable data. The process of sharing such large amount of data begins with the devices themselves which must securely communicate with the IoT platform. This platform integrates the data from many devices and apply analytics to share the most valuable data with the applications. The IoT is taking the conventional internet, sensor network and mobile network to another level as every thing will be connected to the internet. A matter of concern that must be kept under consideration is to ensure the issues related to confidentiality, data integrity and authenticity that will emerge on account of security and privacy [4].

A. Applications of IoT:

With the passage of time, more and more devices are getting connected to the Internet. The houses are soon to be equipped with smart locks [5], the personal computer, laptops, tablets, smart phones, smart TVs, video game consoles even the refrigerators and air conditioners have the capability to communicate over Internet. This trend is extending outwards and it is estimated that by the year 2020 there will be over 50 billion objects connected to the Internet [6]. This estimates that for each person on earth there will be 6.6 objects online. The earth will be blanketed with millions of sensors gathering information from physical objects and will upload it to the Internet. It is suggested that application of IoT is yet in the early stage but is beginning to evolve rapidly [7], [8]. An overview of IoT in building automation system is given in [9]. It is suggested in [10] that various industries have a growing interest towards use of IoT. Various applications of IoT in health care industries are

discussed in [11], [12] and the improvement opportunities in health care brought in by IoT will be enormous [13].

It has been predicted that IoT will contribute in the making the mining production safer [14] and the forecasting of disaster will be made possible. It is expected that IoT will transform the automobile services and transportation systems [15]. As more physical objects will be equipped with sensors and RFID tags transportation companies will be able to track and monitor the object movement from origin to destination [16], thus IoT shows promising behavior in the logistics industry as well.

With so many applications eying to adapt the technology with the intentions to contribute in the growth of economy health care facility, transportation and a better life style for the public, IoT must offer adequate security to their data to encourage the adaptation process.

B. Security Challenges in IoT:

To adopt the IoT technology it is necessary to build the confidence among the users about its security and privacy that it will not cause any serious threat to their data integrity, confidentiality and authority. Intrinsically IoT is vulnerable to various types of security threats, if necessary security measures are not taken there will be a threat of information leakage or could prove a damage to economy [17], [18]. Such threats may be considered as one of the major hindrance in IoT [19], [20].

IoT is extremely open to attacks [21], [22], for the reasons that there is a fair chance of physical attack on its components as they remain unsupervised for long time. Secondly, due to the wireless communication medium, the eavesdropping is extremely simple. Lastly the constituents of IoT bear low com- petency in terms of energy with which they are operated and also in terms of computational capability. The implementation of conventional computationally expensive security algorithms will result in the hindrance on the performance of the energy constrained devices.

It is predicted that substantial amount of data is expected to be generated while IoT is used for monitoring purposes and it is vital to preserve unification of data [23]. Precisely, data integrity and authentication are the matters of concern.

From a high level perspective, IoT is composed of three components namely, Hardware, Middleware and Presentation [1]. Hardware consists of sensors and actuators, the Middle- ware provides storage and computing tools and the presenta- tion provides the interpretation tools accessible on different platforms. It is not feasible to process the data collected from billions of sensors, context-aware Middleware solutions are proposed to help a sensor decide the most important data for processing [24]. Inherently the architecture of IoT does not offer sufficient margin to accomplish the necessary actions involved in the process of authentication and data integrity. The devices in the IoT such as RFID are questionable to achieve the fundamental requirements of authentication process that in- cludes constant communication with the servers and exchange messages with nodes.

In secure systems the confidentiality of the data is main- tained and it is made sure that during the process of message exchange the data retains its originality and no alteration is unseen by the system. The IoT is composed of many small devices such as RFIDs which remain unattended for extended times, it is easier for the adversary to access the data stored in the memory [25]. To provide the immunity against Sybil attacks in RFID tags, received signal strength indication (RSSI) based methodologies are used in [26], [27], [28] and [29].

Many solutions have been proposed for the wireless sensor networks which consider the sensor as a part of Internet connected via nodes [30]. However, in IoT the sensor nodes themselves are considered as the Internet nodes making the authentication process even more significant. The integrity of the data also becomes vital and requires special attention towards retaining its reliability.

C. Motivation And Organization of Paper:

Recently a study by HP reveals that 70% of the devices in IoT are vulnerable to attacks [31]. An attack can be performed by sensing the communication between two nodes which is known as a man-in-the-middle attack. No reliable solution has been proposed to cater such attacks. Encryption however could lead to minimize the amount of damage done to the data integrity. To assure data unification while it is stored on the middle ware and also during the transmission it is necessary to have a security mechanism. Various cryptographic algorithms have been developed that addresses the said matter, but their utilization in IoT is questionable as the hardware we deal in the IoT are not suitable for the implementation of computationally expensive encryption algorithms. A trade-off must be done to fulfil the requirement of security with low computational cost.

In this paper, we proposed a lightweight cryptographic algorithm for IoT named as Secure IoT (SIT). The proposed algorithm is designed for IoT to deal with the security and resource utilization challenges mentioned

in section I-B. The rest of the paper is organized as follows, in section II, a short literature review is provided for the past and contemporary lightweight cryptographic algorithms, in section III, the detail architecture and functioning of the proposed algorithm is pre- sented. Evaluation of SIT and experimental setup is discussed in section V. Conclusion of the paper is presented in section VII.

II.CRYPTOGRAPHIC ALGORITHMS FOR IOT:

The need for the lightweight cryptography have been widely discussed [32], [33], [34], also the shortcomings of the IoT in terms of constrained devices are highlighted. There in fact exist some lightweight cryptography algorithms that does not always exploit security-efficiency trade-offs. Amongst the block cipher, stream cipher and hash functions, the block ciphers have shown considerably better performances.

A new block cipher named mCrypton is proposed [35]. The cipher comes with the options of 64 bits, 96 bits and 128 bits key size. The architecture of this algorithm is followed by Crypton [36] however functions of each component is simplified to enhance its performance for the constrained hardware. In [37] the successor of Hummingbird-1 [38] is proposed as Hummingbird-2(HB-2). With 128 bits of key and a 64 bit initialization vector Hummingbird-2 is tested to stay unaffected by all of the previously known attacks. However the cryptanalysis of HB-2 [39] highlights the weaknesses of the algorithm and that the initial key can be recovered. [40] studied different legacy encryption algorithms including RC4, IDEA and RC5 and measured their energy consumption. They computed the computational cost of the RC4 , IDEA and RC5 ciphers on different platforms. However, various existing algorithms were omitted during the study.

TEA , Skipjack and RC5 algorithms have been implemented on Mica2 hardware platform . To measure the energy consumption and memory utilization of the ciphers Mica2 was configured in single mote. Several block ciphers in- cluding AES , XXTEA , Skipjack and RC5 have been implemented, the energy consumption and execution time is measured. The results show that in the AES algorithm the size of the key has great impact on the phases of encryption, Decryption and key setup i-e the longer key size results in extended execution process. RC5 offers diversified parameters i-e size of the key, number of rounds and word size can be altered. Authors have performed variety of combinations to find out that it took longer time to execute if the word size is increased. Since key setup phase is not involved in XXTEA and Skipjack, they drew less energy but their security strength is not as much as AES and RC5. proposed lightweight block cipher Simon and Speck to show optimal results in hardware and software respectively. Both ciphers offer a range of key size and width, but atleast 22 numbers of round require to perform sufficient encryption. Although the Simon is based on low multiplication complexity but the total number of required mathematical operation is quite high.

III.PROPOSEd SYSTEM

The architecture of the proposed algorithm provides a simple structure suitable for implementing in IoT environment. Some well known block cipher including AES (Rijndael) , 3-Way , Grasshopper , PRESENT , SAFER, SHARK , and Square use SubstitutionPermutation (SP) network. Several alternating rounds of substitution and transposition satisfies the Shannon's confusion and diffusion properties that ensues that the cipher text is changed in a pseudo random manner. Other popular ciphers including SF, Blowfish, Camelia and DES , use the feistel architecture. One of the major advantage of using feistel architecture is that the encryption and decryption operations are almost same. The proposed algorithm is a hybrid approach based on feistel and SP networks. Thus making use of the properties of both approaches to develop a lightweight al- gorithm that presents substantial security in IoT environment while keeping the computational complexity at moderate level.

Another vital process in symmetric key algorithms is the generation of key. The key generation process involves complex mathematical operations. In WSN environment these operations can be performed wholly on decoder ,on the contrary in IoT the node themselves happens to serve as the Internet node, therefore, computations involved in the process of key generation must also be reduced to the extent that it ensures necessary security. In the sub-sections the process of key expansion and encryption are discussed in detail. Some notations used in the explanation are shown in Table I

TABLE I: Notations

Notation	Function
⊥	XOR
J	XNOR
++, ‖	Concatenation

KEY EXPANSION

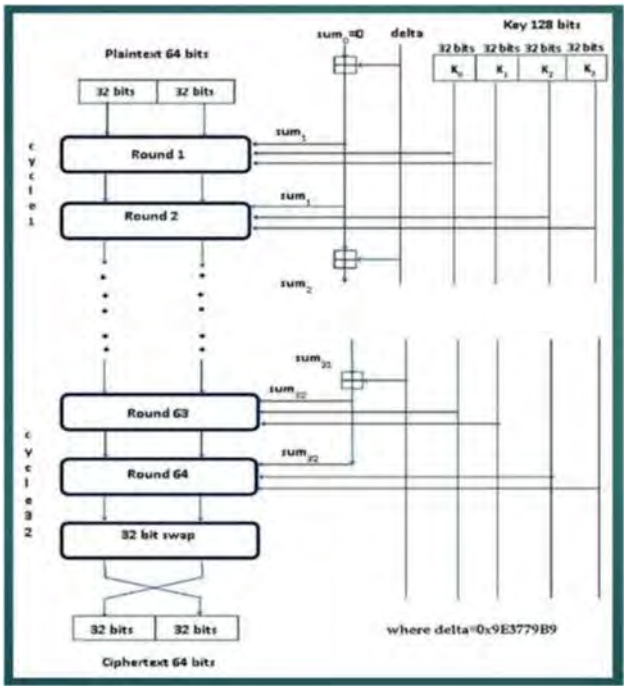

Fig. 1: Key Expansion

The most fundamental component in the processes of encryption and decryption is the key. It is this key on which entire security of the data is dependent, should this key be known to an attacker, the secrecy of the data is lost. Therefore necessary measures must be taken into account to make the revelation of the key as difficult as possible. The feistel based encryption algorithms are composed of several rounds, each round requiring a separate key. The encryption/decryption of the proposed algorithm is composed of five rounds, therefore, we require five unique keys for the said purpose. To do so, we introduce a key expansion block which is described in this section.

To maintain the security against exhaustive search attack the length of the true key kt must be large so that it becomes beyond the capability of the enemy to perform $2kt^{-1}$ encryp- tions for key searching attacks. The proposed algorithm is a 64- bit block cipher, which means it requires 64-bit key to encrypt 64-bits of data. A cipher key (Kc) of 64-bits is taken as an input from the user. This key shall serve as the input to the key expansion block. The block upon performing substantial operations to create confusion and diffusion in the input key will generate five unique keys. These keys shall be used in the encryption/decryption process and are strong enough to remain indistinct during attack. The architecture of the key expansion block is shown in Fig. 1. The block uses an f -function which is influenced by tweaked Khazad block cipher . Khazad is not a feistel cipher and it follows wide trial strategy. The wide trial strategy is composed of several linear and non-linear transformations that ensures the dependency of output bits on input bits in a complex manner. Detailed explanation of the components of key expansion are discussed below:

In the first step the 64-bit cipher key (Kc) is divided into the segments of 4-bits.

The f -function operates on 16-bits data. Therefore four f -function blocks are used. These 16-bits for each f - function are obtained after performing an initial substitu- tion of segments of cipher key (Kc) as shown in equation

IV.ENCRYPTION & DECRYPTION

A. TEA Encryption Function

```
void encrypt(unsigned long k[], unsigned long text[])
{
unsigned long y = text[0], z = text[1];

unsigned long delta = 0x9e3779b9, sum = 0; int n;

for (n= 0; n < 32; n++) {

sum += delta;

y += ((z << 4) + k[0]) ^ (z+sum) ^ ((z >> 5) + k[1]);

z += ((y << 4) + k[2]) ^ (y+sum) ^ ((y >> 5) + k[3]);

}
```

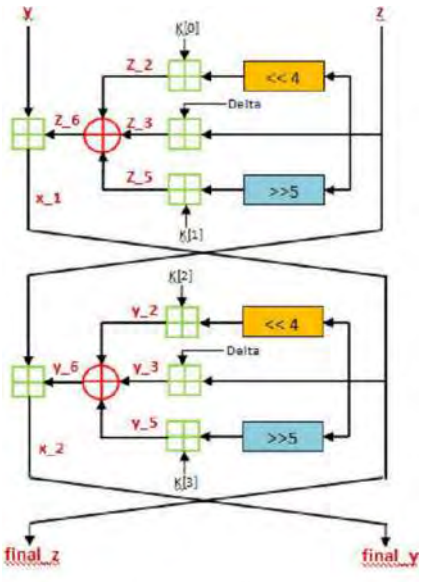

Fig. 1: Encryption Function

B. TEA decryption function

```
void decrypt(unsigned long k[], unsigned long text[])
{
unsigned long y = text[0], z = text[1];
unsigned long delta = 0x9e3779b9, sum = delta << 5;
int n;
for (n= 0; n < 32; n++) {
z -= ((y << 4) + k[2]) ^ (y + sum) ^ ((y >> 5) + k[3]);
y -= ((z << 4) + k[0]) ^ (z + sum) ^ ((z >> 5) + k[1]);
sum -= delta;  }
                text[0] = y; text[1] = z;  }
```

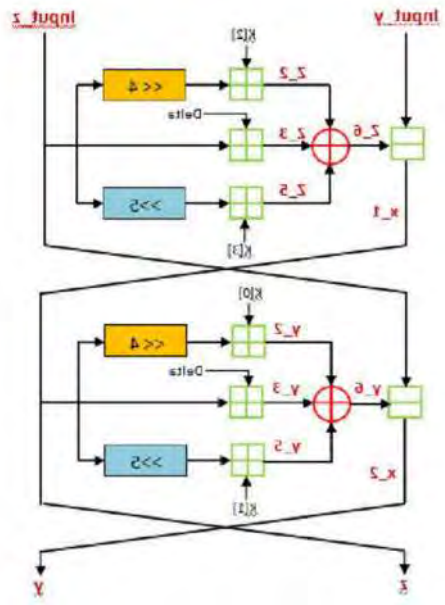

Fig. 1: Decryption Function

V.CONCLUSION

In the near future Internet of Things will be an essential element of our daily lives. Numerous energy constrained devices and sensors will continuously be communicating with each other the security of which must not be compromised. The implementation gives desired results which makes the algorithm accepted in IoT applications. In the near future we are interested in the detail performance evaluation and cryptanalysis of this algorithm on different hardware and software platforms for possible attacks.

Abstract – **Internet of Things has been more deeply embedded in our day-to-day lives at home and work. In the recent decades, Urbanization has increased tremendously. At the same time there is an increase in quantity of Garbage. Waste management has been one of the most important issues to be considered. So, it is necessarily having control on overflowing garbage as well as introducing or building a system which will overcome issue of overflowing garbage using Internet of Things (IOT). One of the major problems faced by most of the countries is the issue of increasing garbage which gets difficult to monitor giving rise to overflowing Dustbins; this is one of the motivations for this research, to deploy computing techniques in creating a barrier to wastage in order to help the environment. Smart Dustbin and Garbage Monitoring system is an innovative system which will inform the users about the level of garbage present in the Dustbin and will prevent it from overflowing. It also automatically detects the user and opens the lid. To demonstrate this the system makes use of Dustbin, where there are two ultrasonic sensors where the first ultrasonic sensor is placed at the top of Dustbin Facing Downward to detect the Garbage level and compare it with the Dustbin's Depth and other one is placed at front of dustbin and it detects the user and automatically opens the lid. The system makes use of Arduino Uno, Servomotor for automation, Bluetooth Module for sending data about the level of garbage present in dustbin to cell phone and a buzzer. The garbage level is highlighted as distance from the bottom in centimeters to show the level of garbage present in the container with the help of a display to the user. The buzzer starts ringing when the set limit of the garbage is crossed. Thus, this system helps to prevent the overflowing bins by informing about the garbage levels of the Dustbin.**

Keywords: Bluetooth Module, Arduino Uno, Garbage Monitoring.

I .INTRODUCTION

India is getting buried beneath hills of rubbish as the nation has been producing more than 1.50 lakh metric ton (MT) of strong squander each day. More awful - around
90 per cent (1,35,000 MT per day) of the overall sum is collected waste[1]. Nearly 15,000 MT of trash stay uncovered each day, coming about in nearly 55 lakh MT of strong squander arranged in open ranges each year, which leads to "serious" contamination level. Of the whole collected squander, as it were 20 per cent (27,000 MT per day) is handled and the remaining 80 per cent (1,08,000 MT per day) is dumped in landfill destination Dustbins (or Trash cans, Waste Cans) are little plastic (or metal) holders that are utilized to store junk (or squander) on a brief premise. They are regularly utilized in homes, workplaces, roads, parks etc. to gather the waste. In some places, littering could be a genuine offense and thus Open Waste Containers are the as it were way to arrange little waste. Usually, it may be a common hone to utilize isolated containers for collecting damp or dry, recyclable or non-recyclable waste. In this extend, we have outlined a straightforward framework called Shrewd Dustbin and rubbish monitoring framework utilizing Arduino, Ultrasonic Sensor, Bluetooth module and Servo Engine, where the top of the dustbin will naturally open itself upon discovery of human hand and screens the level of rubbish within the dustbin and in case the dustbin is full buzzer begins buzzing and notice is appeared in versatile.[2]

II . PROBLEM DEFINITION

This extend combats the issue of flooding strong squander containers which contaminate the surroundings. The level of trash show in any container is decided by the ultrasonic distance measuring sensor. When the trash level in any waste container surpasses a pre-defined level, then the microcontroller send a caution message to the e-monitoring station, and, the workstation at that point allots the closest waste collecting truck to gather the trash from such bins, which have sent an alarm message. It advises when the holder is at full capacity and when it must be purged, hence permitting the sanitation masters to work more efficiently and cut pointless costs.[4]

III. SYSTEM ARCHITECTURE

The IOT Garbage Monitoring System framework may be a exceptionally innovative system which is able offer assistance to keep the cities clean. This system screens the rubbish containers and educates around the level of rubbish collected within the rubbish containers through a web page. For this the framework employments ultrasonic sensors placed over the canisters to identify the trash level and compare it with the trash canisters profundity. The framework makes utilize of Arduino family microcontroller, LCD screen, Wi-Fi modem for sending information and a buzzer. The framework is powered by a 12V transformer. The LCD screen is utilized to display the status of the level of garbage collected in the bins. [1]

Whereas a web page is built to appear the status to the usermonitoring it. The internet page gives a graphical see of the garbage canisters and highlights the rubbish collected in color in arrange to appear the level of rubbish collected. The LCD screen appears the status of the trash level. The framework puts on the buzzer when the level of waste collected crosses the set restrain. Hence this framework makes a difference to keep the. City clean by educating approximately the rubbish levels of the canisters by giving

graphical picture of the canisters through a web page. The ESP8266 Wi-Fi Module may be a self-contained SOC with coordinates TCP/IP convention stack that can allow any microcontroller get to your Wi-Fi organize. The ESP8266 is able of either facilitating an application or offloading all Wi-Fi organizing capacities from another application processor. Each Bluetooth module comes preprogramed with an AT command set firmware. The Bluetooth module is an amazingly fetched compelling board with a gigantic, and ever developing localities[3].

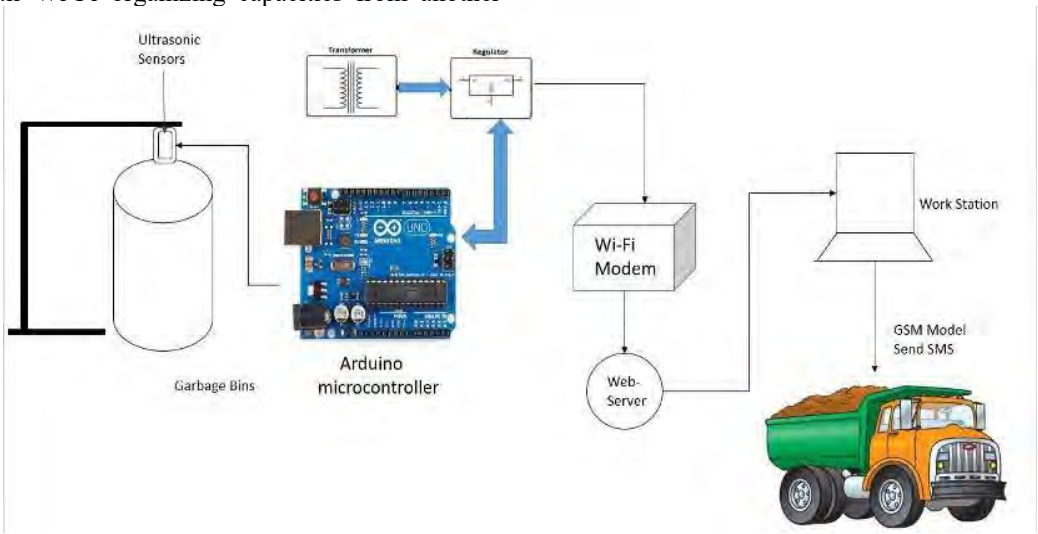

Fig.1: System Architecture

IV. HARDWARE USED:

Microcontroller: It get data from sensor and prepare on it. It compares the gotten information with the limit level set and appropriately yield is created. The microcontrollers are based on a 16/32-bit CPU with real-time imitating and executed follow back, that combine the microcontroller with 32 kB, 64 kB, 128 kB, 256 kB and 512 kB of executing high-speed streak memory.A128-bit wide memory interface and one of a kind quickening agent engineering empower 32-bit code execution at most extreme clock rate.[3]

Power Supply: We utilize 12v control supply in our venture. It is basically utilized to supply DC voltage to the components on board. 3.3V for lpc2138 and 4.2v for Bluetooth module is apply from control supply. 5V is required for transfer connected from control supply.[2]

Ultrasonic Sensor: The Ultrasonic Sensor sends out a high-frequency sound beat and after that times how long it takes for the resound of the sound to reflect back. The sensor has 2 openings on its front. One opening transmits ultrasonic waves, (like a modest speaker), the other gets them, (like a modest amplifier). The speed of sound is around 341 meters (1100 feet) per moment in discuss. The ultrasonic sensor employments this data together with the time distinction between sending and accepting the sound beat to decide the remove to a protest.

HC 05 Bluetooth Module: The HC 05 Bluetooth module is the foremost prevalent module within the Indian market and this module is generally utilized within the inserted ventures. The HC 05 Bluetooth modules are simple to utilize & straightforward, its cost is moo and these sorts of modules are interfaces with the Arduino, Raspberry Pi, and Microcontroller through the serial UART interface. These modules are outlined for the transparent remote association setup and it is exceptionally simple to utilize within the Bluetooth serial harbour protocol. The serial harbour, Bluetooth module is exceedingly qualified Bluetooth with the form of the V2.0+Enhanced Information Rate of 3Mbps. The tweak has totally 2.4 GHz radio handset and baseband. These seriaharbour, Bluetooth modules utilize the CSR Blue core 04-external single chip Bluetooth framework by utilizing the COMS innovation additionally with the Adaptive Frequency Bouncing Highlight. The impression of this Bluetooth module is as little as 12.7mmx27mm. Consequently it'll offer assistance within the by and large plan and advancement cycle.[5]

Servo Motor: A servo engine is an electrical gadget which can thrust or turn a question with incredible exactness. In the event that you need to turn and question at a few particular points or remove, at that point you utilize servo engine. It is fair made up of basic engine which run through servoinstrument. On the off chance that engine is utilized is DC fuelled at that point it is called DC servo engine, and in case it is AC fuelled engine at that point it is called AC servo motor. Able to get an awfully tall torque servo engine in a little and light weight bundles. Doe to these highlights they are being utilized in numerous applications like toy car, RC helicopters and planes, Mechanical autonomy, Machine etc.

Buzzer: We utilize a buzzer that's a critical component of our surveillance framework. Within the occasion a trespasser bypasses the manual security, our observation framework will not miss the trespasser. When identified close the restricted area, an alert is raised with the assistance

of the buzzer, which can alarm the security individuals and drive the trespasser to run away. We make utilize of a piezo buzzer, which is promptly accessible and cost-effective. A piezo buzzer is built of a piezo-electric fabric. The working of the piezo buzzer is based on the converse of the guideline of piezo power. The rule of piezo power states that at whatever point mechanical weight is connected on piezo electric fabric, it produces power. And piezo buzzers take after the inverse rule, which states that when a voltage is connected on a piezo electric component, it misshapes back and forward (a alter in measurement takes put) and produces an capable of being heard sound.

V. METHODOLOGY:

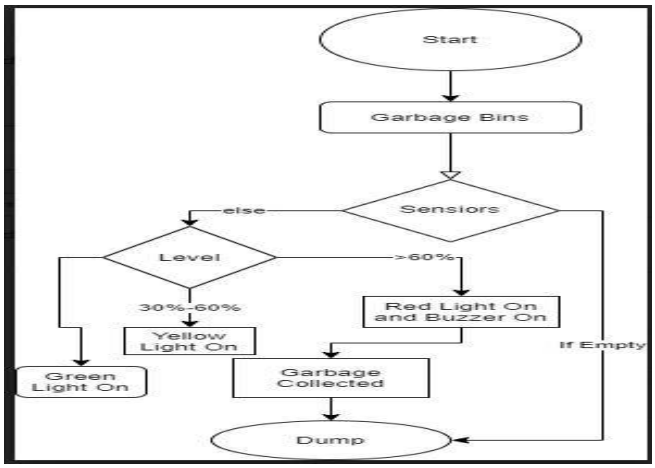

Fig.2: Flow Chart (Garbage Moniitoring)

ADVANTAGES:

Monitors the trash canisters and advises approximately the level of rubbish collected within the

the extraordinary conditions either full or empty. Some impediments of this observing framework are as follows:

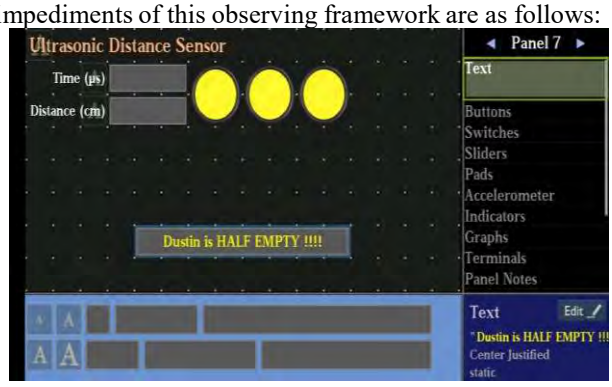

Fig.4: Bluetooth App Interface (Half Empty State)

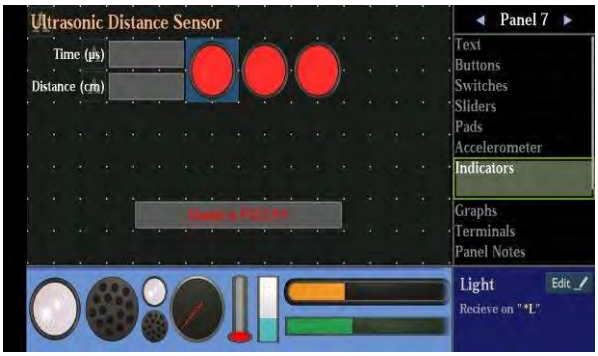

Fig.5: Bluetooth App Interface (Overflowing State)

VII. CONCLUSION

In this extend, a coordinates framework of Bluetooth, modem, IoT, Ultrasonic Sensor is presented for proficient and financial trash collection. The created framework gives made strides database for waste collection time and squander sum at each area. We dissected the arrangements as of now accessible for the execution of IoT. By actualizing this venture we'll maintain a strategic distance from over streaming of trash from the holder in private range which is previously either stacked physically or with the assistance of loaders in conventional trucks. It can consequently screen the trash level & send the information to collection truck. The innovations which are utilized within the proposed framework are great sufficient to guarantee the common sense and culminate for strong rubbish collection handle observing and administration for green environment.

anjali301199@gmail.com, jhanehatcet@gmail.com, tanyaravikantgupta@gmail.com

Abstract— **IoT, i.e. Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology. New medical technologies have arisen as a result of ageing population and an increasingly greedy demand for better healthcare. Some are focused on prevention, others in care. The system built here focuses on collecting electrical activity from the heart with a simple electrical circuit embedded in an Arduino microcontroller, with the aim of early detection of heart disease.An efficient and inexpensive approach was suggested, and the system performed hundreds of trials. These showed a high detection rate of R, S, and T-peaks (~100 percent, 78, 3 percent, and 72, 5 percent, respectively) with a specific measure of heart rate.**

Despite the good results achieved, this tool should not, for no w, be used for purposes other than monitoring. After studying the literature survey it was planned to overcome the research gaps and the system was tested using the test cases and then the outputs were generated. The output of the ECG were been shown according to different test cases and thus the Electrocardiograph become more responsive then those currently in use.

Keywords – Electrocardiograph(ECG); Internet of things(IoT); ADC Conversion; Arduino; Microcontroller

I. INTRODUCTION

Big efforts to provide good healthcare at affordable prices have become a central issue in the last decades. Along with wide technological developments, it has been possible to create more efficient devices and with new available features. Wearables are a category of devices that have grown exponentially in recent years, as battery life issues get overpassed. This electrocardiograph connects Arduino's features to an analog circuit and acquires, amplifies and filters a very low chest signal. A series of algorithms were then proposed to detect arrhythmias, cardiac muscle necrosis, hypertrophic ventricles, variations in cardiac rhythms depending on the position (down, sitting or standing) of the person. Then, a series of tests were conducted to determine the accuracy and reliability of the measurements obtained.

Despite having only been able to test our system in healthy people (thus, no pathological recordings were obtained), specific and representative results among all candidates were obtained. Given the results obtained against the simplicity of the circuit, it is predicted that significant changes will be made in a reduced time scale. Heart failure is generally a result of heart mechanical disturbances, but not electrical anomalies, and is not associated with specific patterns of the ECG. Nonetheless, some ECG results are encountered in cases of heart failure due to enlargement of the cardiac chamber and other related changes. Left atrial enlargement is known to cause characteristic changes in the P wave which sometimes show parallel path to the clinical condition. This objectively checks the ECG requirements for atrial enlargement. R wave height also showed first increase and then decrease in cases of cardiac enlargement, which was improved in a relatively short time period. Tissue edema was thought to be the main reason for the initial increase and the distance to the later decrease between the recording electrode and the heart, though other factors may contribute and change the findings.

Small disruptions in the conduction due to myocardial stretching and other causes may also lead to changes in the QRS complex. Examination of RR cycles provides a further possibility to describe heart failure. In cases of heart failure, a decrease in variability of the RR intervals and in high frequency components was recorded on frequency spectrum.

ECG is boon which helps to save many lives. The project focus on building an IoT based Portable Electrocardiograph using arduino as platform. Before the project starts there is the first chapter which speaks about the background of the project, why it is required and also it adds about the need and motivation for the project which is the recent incidents happened related also creating a great loss of life and and adds the scope of the project.Thus, the project was a great success with all the use cases and fulfilling all the phases of a project development and deployment.

II. LITERATURE SURVEY

A literature review collects scholarly publications, books, dissertations, conference proceedings, and other tools related to a particular issue, study area, or theory, and provides context for a dissertation through the analysis of past research. Research tells a story, and existing literature helps us figure out where we are in the story at the moment.

Continuing the story with new research and new perspectives is up to those writing a dissertation, but they must first be familiar with the story before they can move forward. The first piece of paper on A WEARABLE ECG MONITORING SYSTEM, based on IoT-CLOUD by the authors Zhe Yang ,Qihao Zhou , Lei Lei , Kan Zheng in December 2016. They invented and introduced a wearable monitoring system for electrocardiographs in this paper. The ECG data collected from the human body will be transmitted directly to the IoT cloud using Wi-Fi, without a mobile terminal being required. The outcome of this paper was to eliminate the need of mobile applications, the web-based GUI provides a versatile means independent of any mobile OS platform for users to access to the ECG data.

The second paper was written on A SURVEY ON HEALTH CARE APPLICATION Program IOT by the authors Sasippriya Saminathan, K.Geetha in 2017. In this

paper Body wireless sensor Network (BWSN) is used to transmit the patients' health parameters collected to the physicians and caregivers via Raspberry Pi microcontroller wirelessly . Being a long range wireless technology, the patient's health emergency situation is easily identified and prompt action leads to the patient's life as saved. This paper focuses on an all-encompassing health care monitoring system in real time using IoT and cloud computing service which are more beneficial for elders and chronic diseases' patients.

The third paper was written on An IoT-based low cost ECG Remote Patient Monitoring System by the authors Devendra R Sanghavi, S V. Athawale in 2018. In some nations, due to different obstacles people still do not have access to quality health facilities. The physical distance between the patient and the clinic is one of the main reasons for this. This paper explores the use of IoT in the area of health care and suggests a framework for tracking the ECG of distant patients. This system consists of Raspberry Pi, Arduino Uno, ECG Monitor and IoT Cloud for storing and plotting ECG data in real time. From this system it is seen that, the ECG monitoring system based on IoT is low cost and efficient for remote patient.

The next paper was written on Electrocardiography Circuit Design in 2013 by Nathan M Kesto . This application note will attempt to provide the reader with information on ECG signals as well the methods and design techniques used to construct an ECG demonstration board. It will focus on amplifiers for small ECG signals as well as on some of the different ways to reduce the various noises in the system; this includes explaining the Right Leg Drive circuit.

A Paper on a real-time ECG monitoring system based on IoT using Cypress WICED in 2017 by Uttam U. Deshpande, Milan A. Kulkarni. Monitoring of ECG based on Cypress Wireless Internet Connectivity for Embedded Devices (WICED). The ECG data was obtained via a wearable monitoring node and transmitted directly via Wi-Fi to the IoT cloud. The ECG signal gets distorted from sources such as ambient electrical interference, measurement (or electrode contact) noise, electromyogram noise (muscle contraction), movement artifacts, instrument noise (such as ADC conversion artifacts).

III. PHASES OF PROJECT

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting clear idea of the project title and doing research on it .So that we will get our definition and after that we will first create the Literature Survey of the project and do the whole documentation. Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project.

Designing: Then we will draw the circuit diagram of the device and according to that, will list down all the requirements needed for the construction for the prototype of our project.

Implementation: After acquiring the requirements we first developed the connections of the hardware components(Arduino,Tiga-Mega Gold Electro deetc.)and then added the coding part later with help of Arduino data cable to the Arduino.

Phase 2: Testing andDeployment.

Testing:After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again.

IV. PROJECT PLANNING (RESOURCES, TOOLS USED, ETC)

Hardware Tools :

Quantity	Hardware Components
1	ARDUINO MEGA 2560, rev3, CODE:A000067
3	Tiga-Med ECG Solid Gel Electrodes 45 mm by EKG Einmalelektroden Schaumstoff
1	ECG Module AD8232
10	Connecting Wires

Software Tools:

1. Arduino IDE

Components:

Arduino uno

The Arduino Uno is an open-source microcontroller board based on the Microchip ATmega328P microcontroller developed by Arduino.cc. The board is fitted with digital and analog input / output (I / O) pin sets that can be interfaced with different boards of expansion (shields) and other circuits.The board has 14 Digital pins, 6 Analog pins, and can be programmed with the Arduino IDE (Integrated Development Environment) via a Type B USB cable. It can be powered by a USB cable or an external 9-volt battery, although it supports voltages from 7 to 20 volts.

Fig 3.1:Arduino Uno

Tiga Mega Gold Electrode

Tiga Mega Gold Electrode Spinal cord injuries are among the most traumatic situations, having relevant repercussions on an individual's occupation performance. Although the most significant effect is the loss of function, neuropathic pain can determine a person's inability to return to day-to-day activities. Hence, the development of new technologies with significant impact on the process of rehabilitation of spinal cord injury is important.

Fig 3.2 Tiga Mega Gold Electrode

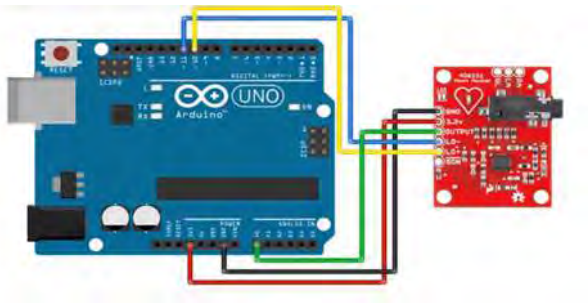
ECG Module

The AD8232 is a sleek little chip used to monitor the heart's electrical activity.

V. Design and Implementation

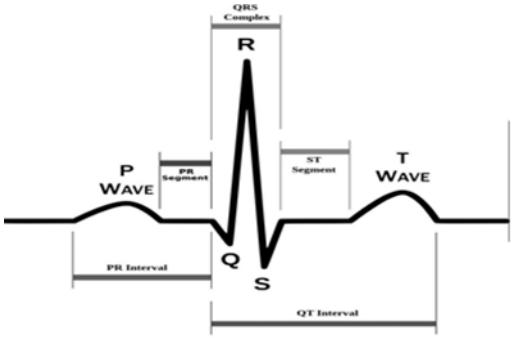
- Connected 3 electrodes to the body(1 on left arm,1 on right arm,1 on right leg).
- Connect the connector wires onto the electrodes.(Yellow to the left arm, Red to the right arm and Green to the right leg).
- Connect the AD8232 to the Arduino using jumper wires.
- Connect the Arduino to laptop and with the help of Arduino IDE upload the code to the Arduino.
- Once uploaded, check the serial plotter to see your heartbeat.

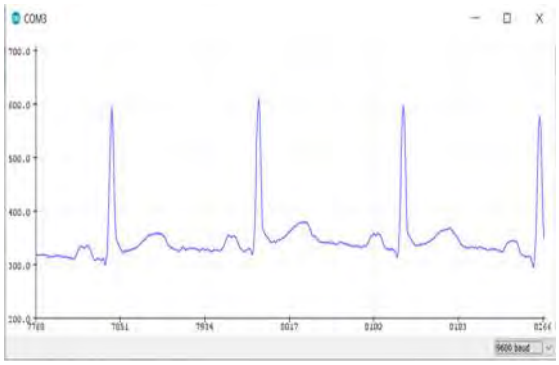
Circuit Diagram:



VI. Results

The normal one cycle ECG pulse output figure from a heart beat. From the figure one cycle consists of wave P, wave QRS up to wave T. P wave offers gain knowledge about the time of the impulse propagation to both atria. Then proceed with a flat pattern called PR segment arising from the transmission of the electrical impulse from atria to ventricles.And proceed with the complex QRS wave which can be seen in the figure above. The complex of Q, R and S consists of three small waves, i.e. a low Q wave, a high R wave and a weak S wave. The QRS network provides information on fibrillation and arrhythmias, and monitoring heart attacks can be helpful.





And then the ST phase, it follows the S wave and may point to the incidence of ischemia even with the T wave. This reflects the time during which ventricles contract, which is the final stage of the cardiac cycle. The T wave helps one to have cardiac hypertrophy information, heart attack and ischemia information. Certain parameters, such as the QT interval, also allow the characterisation of different additional pathologies. The ECG signal finally ended with a slight peak, U wave. Keep still while calculating. Normal movement of the muscle still produces the electric pulse and you really want to get rid of it. Place the pad near soft tissue, as electric pulse due to its poor conductivity can hardly pass through the skeleton.

VII. IMPROVEMENTS IN RESEARCH GAPS(FINDINGS)

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

- When an irregular pattern is shown by the ECG system, multiple unrelated reasons can occur including a standard version. To sort things out, a doctor needs to do more thorough examinations, including other tests (e.g. echocardiogram).
- The biggest concern with ECG is probably false negatives. The EKG may be completely normal for some heart patients but their symptoms should be expressed in the ECG. The reasoning behind that is not well understood. A good reading of the ECG does not exclude the underlying heart disease and other symptoms, such as chest pain, need to be considered and further examination may be needed.
- Not all heart problems present on an ECG.Vulnerable plaque (a type of atheroma) is a prime example. Vulnerable plaque is a rapidly growing deposition or degenerative accumulation of plaques containing lipids on the innermost layer of an artery wall .Since artery walls usually expand in response to expanding plaques, they do not affect blood flow and can't be detected even in an ECG check for heart stress.But fragile plaque is a significant cause of heart attacks

VIII. FUTURE SCOPE

The future scope for Portable Electrocardiograph are:

1.Using IOT Technology (Through SMS Warning and Mail), data can be uploaded or sent directly to doctors so that everybody will be registered.

2. Measurement of the electrodes can be more precise by using more.

3. It can be used by normal humans as it is portable.

IX. CONCLUSION

A Portable Electrocardiograph was designed and developed. We were able to monitor the heartbeat of human . We obtained a good-looking signal with a very simple circuit embedded in a highly portable system. Staying still during measurement may give you accurate results. Placing the **Tiga Mega Gold Electrode pads** near soft tissue can provide accurate results since electric pulse hardly travel through skeleton due to its poor conductivity. Future studies related to ECG monitoring are still needed in the future. It is believed that long-term and user-friendly ECG monitoring can greatly help mollify existing healthcare problems to a convinced matter.

Automatic Medicine Reminder

Nevil Kaspale, Shubham Maheshwari, Rajeshkumar Jha
Thakur College of Engineering and Technology
Mumbai, India
tcet@thakureducation.org

Abstract--**The idea of a digital world where different types of sensors and common processing among them to slice information is widely used in many industries nowadays. There are a lot of products which are developed using these ideas. Healthcare industry is the one where there are a lot of improvements already taking place. Medicines play a major role in every individual for the prevention and cure for most diseases. Many harmful diseases can be solved through proper medication time. There are a lot of people who take their medicine regularly. Our Project's main aim is to make a Smart Medicine Reminder system using NodeMCU for users who take medicines regularly for longer periods as one often tends to forget one or the other dosage. It is very important for such users to take the medication as per scheduled by the doctor for their care. Also, for the patients who are suffering from the permanent diseases like diabetes, blood pressure, breathing problem, heart problems etc. forgets to take the pill on proper time. Similar kinds of problems are also observed in hospitals where nurses monitor the patients and its quite difficult for them to keep the track of the medicines of each and every individual. In this Project, a medicine reminder system is designed which reminds the user to take the medicine once or twice or thrice a day. The time slots can be selected using push buttons. Also, it shows current Date and time. The medication reminder can also be integrated with Patient monitoring System.**

Keywords – NodeMCU; Automatic Reminder; RTC Module; Blynk;Arduino;

I. INTRODUCTION

In our modern, day-to-day busy lives, the number of people consuming medicine has increased drastically. The reason behind this is diseases are increasing in large amount this was not the case few years back. Poor medicine adherence despite everything is a significant urgent looking by a large portion of industrialized nations prompting declining illness seriousness and expanded expense related with higher hospital admission rates[4]. To overcome our illnesses and live a better life we need to take medicines regularly. One should be in counsel of the Doctor who instructs us to take wanted pills in wanted manner with the goal that

patients face issues like overlooking pills to take at ideal time and furthermore when Doctor changes the medicine of medication patients need to recall the new schedule of medication[5]. Forgetting pills at right time, taking wrong medicines and also accidentally taking expired medicine is a major problem faced by many people and this leads to them suffering from an unhealthy life. Our project is to make a NodeMCU based smart medicine reminder which uses real time clock and gives an audio-visual alert for the given medicine type.

II. BACKGROUND

There are many people who constantly need help be it the elder ones or our family members who needs some special needs. With aging, people experience poor eyesight and poor memory. It may happen that some people may forget to take medicine at the correct time and forget the medicine which they have to take. In order to eliminate the factors of always needing observation or taking a risk of missed doses one must find an easy, portable, efficient and smart solution. . In order to make a very useful and smart solution it had to be integrated with smart technologies. While at the same time it had be fit for the elders and their limited knowledge and experience to implement the ease of use. Size and portability were also an important fact that we had to keep in mind. For it to be called smart, it's connected through a wireless network, which enables it to be connected to the internet for the future applications and integration. Through that equivalent system its associated with the cell phone, which with it you can set the planning interim for the portion and furthermore informs you by numerous ways when the portion opportunity arrives. Also, we added a notification system such that it alerts you on your mobile phones via notification and an Email. Since nowadays phones are a very handy product, so it seems best to act as a medicine reminder.

Importance of the project

With increase in the number of people suffering from diseases it is very important for them to take medicines on a regular basis. Smart medicine reminder helps one to take their medicines on time. Medicine reminder is very wide and can be used by patients at home, doctors at hospitals and at many other places. Importance of the medicine reminder using NodeMCU on day-to-day life is as below:

- Audio alert reminds the patient about the medicine.
- SMS alert is also important for the people whose daily life schedule is very busy and to remind them about the medicine, SMS alert is very effective.
- The proposed system is very useful in hospitals where a nurse monitors more than 4- 5 patients about the reminder of medicines.

As a human being almost, everyone has the habit of forgetting things and taking thing very lightly but it can cause a lot of damage sometimes. Considering the scenario where a nurse monitors many patients it may happen that they might forget some medicines for some patient and can cause a severe damage if that patient is in a critical situation and also for the people who are suffering from the permanent diseases like diabetes, cancer etc. It's very important for them to take medicines on a daily basis to treat the symptoms of the disease. It's even more important for the older people suffering from

these diseases to take medicines on a regular basis. With the world moving towards digitization and using smart products it became a very challenging aspect to solve the above-mentioned problems and it gave the motivation to help something for the society and we decided to develop a simple cost effective and smart medicine reminder using NodeMCU.

Objectives and scope of the project

This aim of this project is to build a smart medicine reminder for the people who tend to forget to take the medicines on time. When the pill time has been set, the system will remind patients to take pills utilizing audio and visual alerts. This model can aid elders to take their medication[6]. The proposed system can be extended to patient monitor system and can be used for continuously monitoring patients. Moreover, it can be used by hospitals to reduce human efforts.

The proposed system is designed for, but not restricted to, helping old people in taking care of themselves in taking their medication at the correct time and in the correct amount[6]. It has been observed that people in general neglect their health and also give preference to the other things than taking their medicines. This is also the reason they forget to take their prescriptions on time. Many health maintenance organizations, health practitioners and medical researchers have realized that increased use of patient reminders can significantly increase the treatment of chronic illness and delivery of medical services to the patients who need it.

III. LITERATURE SURVEY

In this method, an Android based application is created for the patients. This application will remind their customer to take the required medication at an appropriate time by setting the updates in a compact and systematic manner. These updates can be set in the application in total accordance with the patient's prescription. Urvashi Sharma, Chetna Chauhan, Himani Sharma, Anjali Sharma had proposed a Smart Medicine Reminder using Arduino. ARDUINO module comprises a micro-controller which controls the function of the system and performs all the tasks[1]. No external peripheral devices and memory devices are required. Many systems serving the same purpose are difficult to use, non-mobile, expensive and complex processes. The proposed system overcomes these problems. Priyadarshini, Ramya, Kalaiyarasi, have inquired about a novel approach of micro-controller based Automatic Medication Reminder (AMR) structure for patients. In this approach gear worked using microcontroller is used for the patients. This application will give a refresh using ringer and LCD will demonstrate the name of pharmaceutical. This structure is insignificant as it relies upon microcontroller which is difficult to embed.

Aditya Vijay and Durgesh Kumar have proposed a system built on customer server correspondence where Client specified information will be stored at server end in a MySQL database and USB link is used to refresh information into the Arduino[2]. The device alerts via an alarm beep and a message on the LCS successfully. But this framework is hard to utilize, non-portable, costly and complex.

Tahseen Fatima, Pallavi B V, Dr. Baswaraj Gadgay's proposed device consists of a small box divided into seven compartments for storing pills for a week, each compartment is sub divided into 3 sections[3]. An Arduino mega 2560 is used, which processes the activities and accordingly displays the pill details and time of intake on the LCD attached to the box and a GSM module which sends message to the family physician or members in case the pill is taken or not taken and also sends message about patient health condition. The device helps in keeping track of regular medicine taking activities and reduces manual supervision and human effort.

Sanjay Bhati, Harshid Soni, Vijayrajsinh Zala, Parth Vyas, Mr. Yash Sharma have proposed a Smart Reminder Box in which present time will be saved in RTC module and notification time will be saved in EEPROM[5]. At the time of taking medicine system generate Notification sound and display the Bright light in certain pill boxes. It can sense if the patient had taken out pills from the box or not. This system is useful for especially those people who are taking pills regularly, prescription of medicine is very long and hard to remember for those users. The proposed system is also reusable by exchanging those other medicine box that has only alerting system and are non-usable or affordability compare to our product.

IV. PLANNING AND RESOURCES

Project planning (Resources, Tools used, etc.)

Hardware Tools:

1. NodeMCU
2. RTC Module
3. Breadboard Connecting wires

Software Tools:

1. Blynk
2. Arduino IDE

NodeMCU

NodeMCU is an open source Lua based firmware for the ESP8266 WIFI SOC from Espressif and uses an on-module flash-based SPIFFS file system. NodeMCU is implemented in C Programming Language and is layered on the Espressif NON-OS SDK. The firmware was initially developed as is a companion project to the popular ESP8266-based NodeMCU development modules, but the project is now community- supported, and the firmware can now be run on any ESP module.

RTC Module

Real Time Clock(RTC) is an Integrated Circuit(IC) which is used as timekeeping device. RTC is an important component of many time critical devices and applications

like Servers, GPS, and Data Loggers etc. The DS3231 is an RTC IC developed by Maxim Integrated. It is a comparatively cheap, and extremely accurate RTC IC with communication over a I2C Interface. An interesting feature of the same is that it comprises an integrated crystal oscillator and a temperature sensor, hence eliminating the need to connect an external crystal.

Blynk:

-Blynk App => allows to you create amazing interfaces for your projects using various widgets we provide.

-Blynk Server => responsible for all the communications between the smartphone and hardware. Blynk Cloud can be used or you can run your private Blynk server locally. It is open source, can easily handle thousands of devices and can even be launched via a Raspberry Pi.

-Blynk Libraries => for all the popular hardware platforms - enable communication with the server and process all the incoming and outgoing commands.

In this after understanding the topic the project feasibility was analysed by performing different types of feasibility studies and by also planning the project tools. Feasibility study will help in better understanding the various feasibilities associated with the project and helping to make the correct decisions and completing the project within the schedule, budget, etc. The tools were specifically identified in this chapter in accordance with which technology can be feasible and how efficiently can the project be implemented. This helps us in understanding the tools and technology that can be used for the project.

IV. PROPOSED SYSTEM

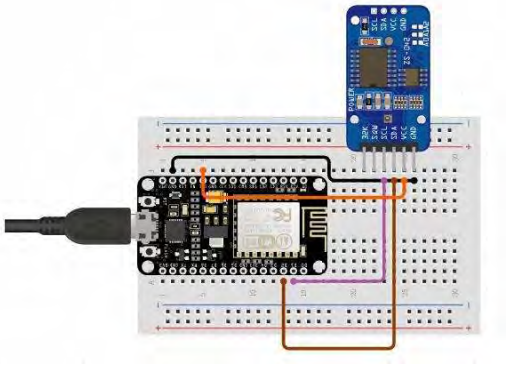

Fig 1 Block diagram

The NodeMCU can be connected to any power supply source. In our case a laptop powered the NodeMCU module. Then we specify a schedule in Arduino IDE and run the program. The RTC or Real Time Clock counts seconds in real time and sends to the NodeMCU. The Blynk App is wirelessly connected to the NodeMCU. Our program is such that if the specified time matches the real time then a notification will be sent to the user in addition with an E-Mail Reminder for the same via the Blynk App.

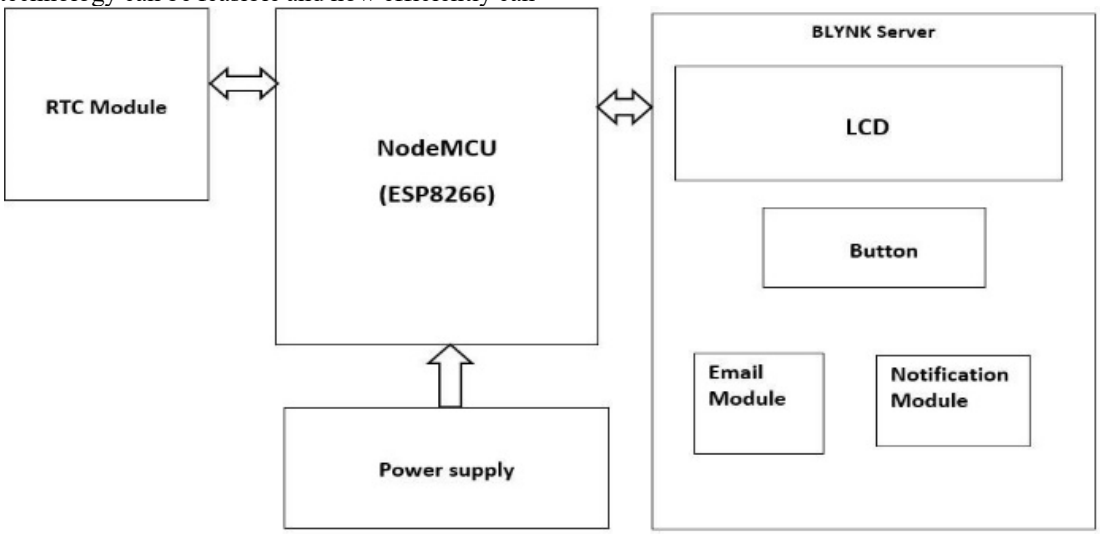

Fig 2 Circuit Diagram

V. RESULT AND DISCUSSION

1. When the time set on the device a notification as well as an email will be sent to the recipient.

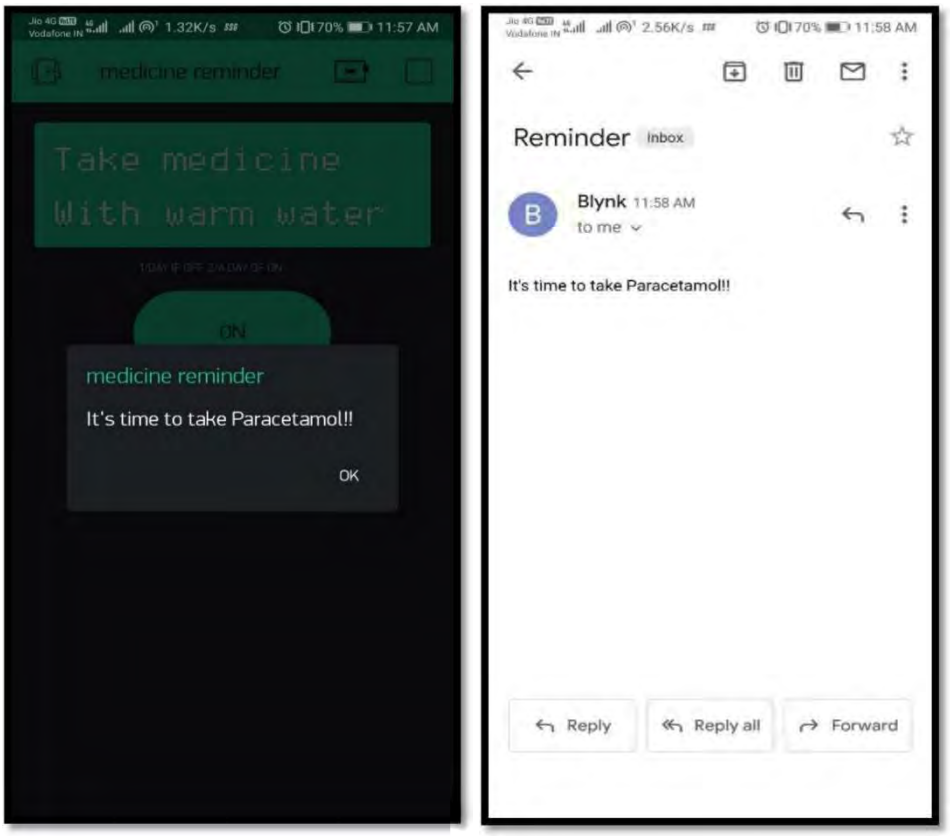

Fig. 3 Mobile and Email Notifications

2. Even if the recipient is offline, they will receive a notification

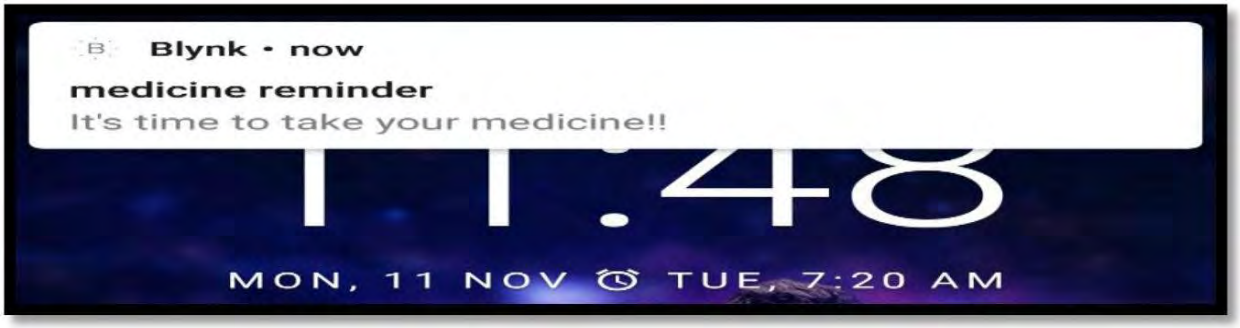

Fig. 4 Mobile Notification

Discussion :

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. As in this system the timing for the reminder was set in the code itself, in the next version the time can be set manually. Also, this system does not allow user to set number of days for which they have to take the medication, we can implement it to make their life easy. A push notification regarding the amount of smoke can also be sent to the owner and their neighbours and contacts. If the amount of smoke is high, a notification can be sent to the concerned nearest emergency contacts, such as the nearest fire station, along with the entire location of smoke site. The biggest concern is the size of this system, we can try to make it small in size so it can be portable and easy to use.

VI. CONCLUSION

There are numerous frameworks which are filling for a similar need. Be that as it may, these frameworks are hard to utilize, non-portable, costly and complex process. The proposed framework defeats these issues. The NodeMCU Based Medicine Reminder is easy to utilize, moderate, better exactness. This framework is useful for each age gathering and can likewise be utilized as a part of healing facility for a gathering of individuals. This framework will decrease the awful impact caused because of wrong admission of medication. In hospitals, a screen can be placed that is connected to the system, outside their ward to notify the nurse to give patients their medicine. Moreover, it can be used by the families that have elderly people that always forget to take their medicines.

Currently, there are many medication reminder system which is operable manually. Due to manual work, the

available system becomes more time consuming. So, in the given work, an attempt has been made to implement fully automatic medication reminder system. The system reminds user about their medicine intake schedules.

VII. ACKNOWLEDGEMENT

The author would like to thank subject lecturers current and previous), curriculum planners and other computer and mathematics school staff members who have previously planned, created and taught this subject at different times

Automated Pet Feeder using Arduino

Shubham Mishra, Lokesh Mishra, Pragya Khandelwal

TCET- Mumbai

shubhi.mishra5555@gmail.com, lokeshmishra2@gmail.com, pragya.khandelwal2@gmail.com

Abstract— **over the years, more and more households are beginning to have pets. Pet feeders came into existence as more and more pet owners found it difficult to cater time to feed their pets. Pet feeders are automated machines that dispense food at preset schedule. They are mainly timed based and dispense a certain amount of food at specific time of the day. The pet feeder is a programmable system which is mainly controlled by a microcontroller. It consists of a LCD screen for input display, buzzer to alert pets for meals, stepper motor to control the speed.**

The work is about pet feeding machine automatically for a daily minimum period of time of eight hours when all people of nuclear family members are busy at work for the survival in the metro cities and other cities. This set up is controlled by the Mobile app automatically. The pets of home can get food after an interval of three hours and the same can be monitored using mobile app and the owner of the pet always ensure about the feeding of the pet especially dogs and cats when they are busy at work. The food for pet has been kept inside a box while leaving home. The food would be served to the pets automatically up to a certain quantity only when the pet comes near to the box when they feel hungry. It is an excellent idea to protect the pets from starving whenever no one is at home and all are busy with their scheduled routine works and job at office or in business.

Keywords – Pet feeder; LCD screen; Mobile Application; Arduino Mega

I. INTRODUCTION

Dog is the most common pet that people owned. Nowadays dog is also one of family member to the owner. So, dog's healthiness is important. Regular feeding is the most important thing, but it also one of the problems in dog's maintenance. Owners often forget to feed their pets because of their work. A dog feeder can be the answer to these problems. For this project we will design and build a prototype of an automated pet feeder which will be suitable for use by cats and small dogs. This product will be called the Smart Pet Feeder. This system will hold enough food for 5 feedings. This device can provide regular feeding without disrupting owner's work. Owners can monitor feeding process with their Android smartphone virtually. Smart Dog Feeder can give authentication with RFID, set feeding time and portion per serving through Android smartphone, send feeding report (eaten or partially eaten), and dog arrival when the feeding time has arrived. Every setting about feeding time, portion, stock and waiting time will be set on Android App. Smart Dog Feeder will save the schedule and set alarm which will interrupt when the feed time has arrived. Food will be served based on user's setting and be measured by load cell. Experiment is done by seeing punctuality, portion congruence, delivery of settings and notification within devices. The result of experiment is Smart Dog Feeder can receive messages from server and do feeding at the right time. The Smart Pet feeder will give pet owners a solution to this problem, thereby improving the lives of both pets and the owners.

"Technology stems from humanity." This sentence is a good description of modern life. The interaction between humans and physical devices and objects in the real world is gaining more attention and requires a natural and intuitive methodology to employ. Cyber physical systems refer to a new generation of systems that integrate computational and physical capabilities and are capable of interacting with humans through many new modalities. Thus, this study examines the ability of computation, communication, and control technologies to improve human interaction with pets.

Different sensors are used for the automatic pet feeder so that it works efficiently. A distance sensor or a proximity sensor will be connected to the Arduino and as the pet is sensed in the vicinity of the pet feeder, the food from the bottle will be poured in the bowl. Whenever the distance sensor senses motion at a particular distance from the pet feeder i.e. as the pet comes closer to the bowl, the food is served. A servo motor will be used for the locking system. It will be similar to the locking system controlled by angle. All these components will together determine an efficiently running automatic pet feeder. The cost of a care taking of a pet has been reduced down due to the launching of such machine in the market. Such idea is being globally getting popular due to Automatic system and mobile app involvement.

Automatic pet feeding system features a machine which can feed pets (e.g. dogs) automatically after frequent intervals in absence of his master. By using machine master don't have to stay with his pet every time to feed it and he gets liberty to do his other works outside without caring about his pet. Dish for feeding pet could be filled in number of ways one is we can set the time and date using Arduino UNO which is displayed on LCD screen fitted on body of pet feeder.

The effectiveness of any application also depends on how the products are detailed and how the components are used. The most important part is of the ultrasonic sensors to detect the presence of the pet because if it fails to work then it is not possible that the model can work. The cost is also low as per our model requirements.

II. SUBJECT HISTORICAL DATA

In this section, we present the previous research done by the people by reading their papers published. Also, the problem definition, features of the project and methodology is explained and learned in detail.

A. Literature Survey

Mritun Jay, Subhash Chandra Tiwari, Sahil Manoj Hawal in their journal "International Journal of Innovative Research in Science ,Engineering and Technology(2018)" states that it was based on Arduino. They have used various sensors for various purposes. They have provided real time notification, feedback on web-server in which customer can see what is happening in their home. Rachel Heil, Kristine McCarthy in their book "WENTWORTH INSTITUTE OF TECHNOLOGY(2008)" states that the proposed system makes sure that each pet has access to a healthy amount of food throughout the day, regardless of the owner's schedule and each pet eats only its own food .

B. Problem Definition

Dog's care should be enjoyable not burdensome and so the goal of this project is to assist owner with pet care by providing an automatic pet feeder IOT based system. The purpose of the project helps the owner of the pet feeding their pet on time even when they are not at home. Other than that, it also can help the owner know the diet of their pet. Knowing the diet of the pet is very important for the owner to make sure that the pet is in good health. This system assists pet owner to feed the pet. The system act in two ways, one is feeding the pet and sends the feeding information to owner. Sick pets require special diets and large amounts of time and money and is difficult to make sure the correct pet is receiving medication or special food. No product on the market to addresses this issue which made us develop this automated feeding system which makes it easier for the owner.

C. Features of the Project

The proposed system is an automated Pet feeding system, consists of sensors. Server controls and monitors the various sensors, and can be easily configured to handle more hardware interface module (sensors).. Wi-Fi technology is selected to be the network infrastructure that connects server and the sensors. Wi-Fi is chosen to improve system security (by using secure Wi-Fi connection), and to increase system mobility and scalability.

The features of our project can be highlighted in following points:

- •Simplified automation.
- •Minimal controls
- •Cost efficient
- •Can be upgraded if needed

D. Methodology Used

In today's world everyone has shortage of time and in this era of technology there should be a mobile app that could be used to control the home appliances with the help of speech recognition.

This project will use the system which will be powered with Wi-Fi, making interconnectivity between the devices and creating an internet of things. In this project the Arduino Mega 2560 and the Arduino Wi-Fi shield have been used to implement the smart pet feeder.

- •In this proposed project a mobile app is used which includes all the features of controlling the feeding system with the help of interconnectivity of devices.
- •The mobile app contains all the commands like turn off, turn on, set timer etc.
- •The user is authenticated using a unique authentication token generated by the server, which is then hardcoded into the microcontroller.
- •After successful authentication the user will be able to control all the appliances with the mobile app.
- •No longer need to worry about their pets during business trips or vacations.
- •No longer need to purchase multiple feeder for multiple pets.

III. ANALYSIS AND PLANNING

Analysis is an important part of any project to know calculate the wrongs and rights of the project i.e. the economic study tells us the capital used, the planning tells us about the time taken, resources used gives us all idea about how well the project is being going on.

A. Fesiability Study

Analysis is an important part of any project to know calculate the wrongs and rights of the project i.e. the economic study tells us the capital used, the planning tells us about the time taken, resources used gives us all idea about how well the project is being going on.

1. Economic Feasibility:

This project is based on Android App and few electronic components like Arduino mega 2560 ,relay switches etc. which are affordable, making it economically feasible to implement.

2. Technical Feasibility:

This project is based on wireless technology and embedded system which is reasonably in phase with currently used technology. Therefore, it is very much favored by the technology.

3. Operational Feasibility:

This software will have very easy to use, user friendly interface so it will be pretty much operable by anyone having little experience of using an Android Device. It could be helpful for physically disabled person too, controlling home appliances with the click of a button. So, it is operationally feasible.

B. Assumption Risk:

a) Assumption:

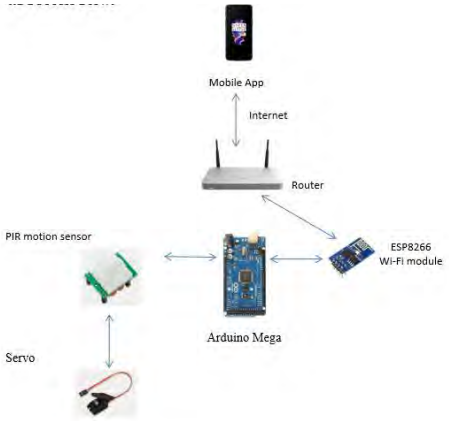
- Management will ensure that project team members are available as needed to complete project task and objectives.
- The team members will participate in the timely execution of the Project Plan (i.e., timely approval cycles and meetings when required.)

b) Risks:

- Accurate identification of the system requirements, interpretation and design depend on the patience and commitment of the team members in focus.

IV. DESIGN REQUIREMENTS

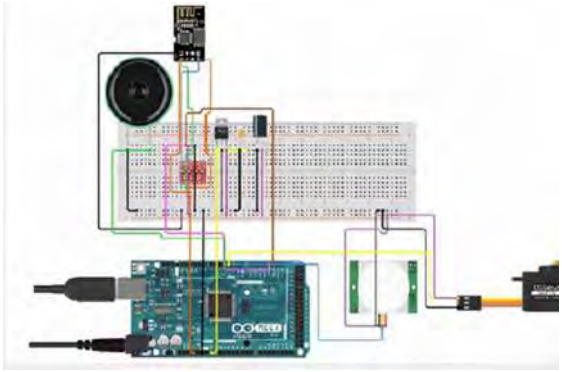
C. Process Flow



This is the process flow of the project.

D. Block Diagram

The following is the Breadboard implementation of the project which can also be converted to a PCB in order to make the assembly smaller.



V. RESULT

Results show that everything worked as anticipated, although some high pings in the network may cause minor occasional lag in the connection and data exchange, however, there was no major lag detected affecting the model control and testing. The lag maybe a casual effect of using 3G connection, however, most Pet Feeder systems employ DSL or Broadband connection, resulting in acceptable performance. Eventually, expected results were met. Automatic Pet Feeding System was planned to ensure the time to time feeding of pet in absence of its master so that master can do his other tasks without worrying about feeding. Automatic Pet Feeding System has attractive design and aesthetic model. Arduino and IoT add Automation in the system. The report showcased the basic design of the system to be made. And also the Arduino circuit to control the functions of the system. Automatic Pet Feeder works efficiently and fulfils the objective of feeding pet in absence of its master. It works for on house hold 230V AC supply. The servomotor rotates the Auger and food gets delivered into plate as programmed in the Arduino. On the backend, there is Arduino mega 2560 which has been programmed to control the status of GPIO pins and thereby controlling the appliances.

VI. CONCLUSION

This project brought together several components and ideas to achieve a common goal that is design an automated pet feeder using Arduino mega. The key components of the project include a distance sensor to detect or identify the presence of the pet i.e. whether the pet is near the bowl or not and a servo motor which will be programmed to serve the food as soon as the pet comes closer. It relieves the owner from having to feed his pet multiple times a day. The proposed project senses the presence of the pet using the distance sensor and serves accordingly. The owner does not have to worry about making plans or feeding his pet because of this automated pet feeder. This automatic pet feeder serves as a helping hand as it works efficiently in the absence of the owner.

VII. FUTURE SCOPE

IoT is a platform which can embed both software and hardware. It is obvious from that IoT is an efficient way to access data. As suggested, SOAP based mechanism with web services is an ideal choice for managing diversified devices and appliances in home environment. Various sensors are used to monitor various activities of the pet say, an IR sensor is used to monitor if food is available in plate or not. The design can be made more factories feasible and aesthetic. The auger can be made by 3D printing which can be created as the auger is the moving part. The APF could be made more advanced by installing cameras and audio box as it would make possible to interact with pet through smart phones as well as keep observation on it. APF is indeed a helper to the owner for proper care taking of pet and more advancement can be expected in future.

VIII. ACKNOWLEDGEMENT

We sincerely thank our guide Mr. Anil Vasoya for his guidance and support for carrying out our project work. We also thank all the project coordinators for arranging the necessary facilities to carry out the project work.

We thank our Principal, Dr. B.K Mishra, HOD, Mr. Rajesh Bansode and the College Management for their support. We would like to thank all our classmates & faculty members for their inputs and valuable insights.

Smart Noise Detector System

Mr. Mohit Pandey, Mr. Shivam Pathak, Mr. Aakash Peringathara
Information Technology, Thakur College Of Engineering and Technology, Mumbai
mohit.pandey.c.610@gmail.com, shivampathak704@gmail.com, akashjperi4@gmail.com

Abstract—**IoT, i.e. Internet of Things, is currently the foremost trending field within the Branch of knowledge Communication Technology. Pollution is taken into account because the major problem that we all face in our day to day life. This is often a serious problem especially in areas where there are hospitals, schools, baby care centers, etc. With rising pollution near hospitals, schools etc., it's taken a significant toll on students, patients, etc. So a strict action should be taken and control the pollution. Although several decibel-measuring devices are applied to the environment, which indeed must be kept quiet, the decibel-meters can only detect the pollution limited to the closest area around the device. When checked in larger spaces such as a library, problems of inaccurate data will be arised. For such problems mentioned above, maybe we use more decibel-meters around different areas to an improved solution. Such problems need to be solved like averaging the measuring data, inter-connecting the cross-data between the devices with the present decibel-meters within the market. So, the proposed system implements a mobile, small-scale and internet-based sound-detective prototyping by using Internet of Things (IoT) technology to supply an improved solution mentioned above. Proposed approach is to form use of cheaper materials and low-precision sensors and single-chip microcomputer like Arduino with Bluetooth connection ability to develop an ardent sound detection device. The device will be developed under very low-cost with none display thereon, but all sensor data are going to be sent into the android application and be displayed on mobile devices.[1]**

I. INTRODUCTION

More than 72% of Indian population lives in some villages and the rest in towns and concrete agglomerations. In 1991, there were 23 metropolitan cities in India, which increased to 35 in 2001 and 53 in 2011. Thanks to this growing density, noise has gradually and steadily increased and is taken into account among the foremost pervasive and frustrating sources of everyday annoyance. Noise is taken into account as an environmental pollutant due to the danger it poses to health like Cardiovascular and Metabolic disease and also its impact on our well-being and quality of life. Noise management is a vital component within the smart cities vision, is supported by new sensors that are capable of detecting and processing various parameters associated with noise. The net of Things (IOT) enables the connectivity, accessibility and tasking of the sensors to enable the citizens to access real time information on the noise levels. This may help them in planning various activities of their daily routine in a much smarter way. Since noise incorporates a spatial component, GIS (Geographic Information System) can help to provide an appropriate and useful platform for mapping and analyzing noise sources and ultimately help for its management. It's possible to get an accurate map of the acoustic situation and Noise Risk zones (NRZ), with the assistance of advanced interpolation techniques in GIS supported by a limited number of sample points recorded using the microphone of smartphones as a sensor.

Integrating crowd sourcing techniques, it's possible to develop an efficient noise mapping system that may show the dynamically changing noise environment in a very city and thus be successful for certain authorities.[5]

II. SUBJECT HISTORICAL DATA

According to the Ministry of Environment, Forest & global climate change, energy released by any source in a very medium creates vibrations of molecules. The molecules start vibrating within the oscillatory mode and also the energy travels through the medium in kind of vibrations. If the oscillations within the medium are within the range of 20 Hz to twenty KHz it's audible by human ears and categories as sound. Ambient Noise Ambient noise is usually stated as environmental noise. It's the noise that one hears in day to day life and doesn't include workplace noise. The prime sources of noise are traffic, construction sites, industries, road-traffic, rail traffic, and structure, indoor sources such as air coolers, radio, television, air conditioners, and other home appliances. [5]

The Committee on pollution Control constituted by Central Pollution control panel, recommended noise standards for ambient air and for domestic appliances, construction equipment and automobiles as given below.

Table 1: Data of noise limits in different zonal areas

Code	Category of Area /Zone	Limits in dB	
		Day Time (6.00 am to 10.00 pm)	Night Time (10.00 pm to 6.00 am)
A	Industrial area	75	70
B	Commercial area	65	55

A. Subject Learning Outcomes and Contents

The goal of the smart noise detector is to produce a means to detect the noise and notify the needed individuals. It is of great benefit to hospitals, schools, colleges, universities residing in the silence zone. It can assist the government. Officials to require the required action against

the violations of rules in silence zones. Thus, the project is helpful in establishing authority in society.

•We present a sensible noise detector that works over IOT in order that noise is monitored.

• Our project should allow the needed officials to examine the regions violating the laws.

• The project should also display the noise levels over the android smartphones. Once a

Regions cross the brink level, it can be notified on smartphones.Areas around the 100 meters of premises such as courts,
hospitals and educational institutions are silence zones. Declaration of silence zones are done by the necessary authorities. Use of vehicular horns, bursting of crackers and
loudspeakers shall be banned in these zones. Most monitoring stations where high levels of noise were recorded were next to busy and congested roads where vehicles were the most important contributors with constant honking aggravating the matter. The ambient noise levels in residential and commercial areas indicate average day time noise levels within the metros to be more than the national standard of 55dB for the residential and 65dB for the commercial area. Because the data is obtainable on real-time, the governments can devise traffic plans for actual time intervention. [4]

III. SUBJECT DESIGN AND CURRICULUM

The design of this subject is predicated on practical hands-on knowledge of the sphere. The rationale behind this design approach is that at the successful completion of the topic, the coed should be ready to independently perform a digital forensic task. Also, the topic design caters to the requirements of two cohorts, experienced professionals working during this field and therefore the newcomers within the field. For knowledgeable professionals, the topic provides advanced topics like smartphone, web and email forensics. they will hinge on this data to further enhance their technical skills as legal skills. For the beginners, the topic starts with building the muse in digital forensics. The stress then is on the legislation, policies, procedures, technical knowledge, and preparation for reporting on digital forensic investigation cases. There's lots of emphasis on hands-on projects and solving the cases. The main focus is to develop a mindset of how evidence should be acquired and presented within the court of law that's admissible as a bit of digital evidence. For this reason, students are encouraged to create upon computing and technology knowledge, investigative skills, logic, familiarity with the local legislation and lots of passion.

• To suit the notification, the location of the violation can be provided using our project.

B. Subject Requirements

Hardware Requirements:

- **Arduino Uno (Soldered)**

The Arduino Uno is an open-source microcontroller board. It is developed by Arduino.cc. The board is provided with various sets of digital and analog input/output (I/O) pins that will be interfaced to expansion boards (shields) and numerous other circuits .The board has 6 Analog pins, 14
Digital pins and programmable with Arduino IDE (Integrated Development Environment) with USB cable. It is powered by the USB cable or by an external 9-volt battery, though it accepts voltages between 7 and 20 volts. It's also like the Arduino Nano and Leonardo. Commons Attribution Share- Alike 2.5 license offers the imaginative hardware reference design on Arduino website. Layout and production files for a few versions of the hardware are available.

- **Sound Sensor Module**

Generally, this module is employed to detect the intensity of sound. The applications of this module mainly include switch, security, still as monitoring. The accuracy of this sensor is changed for the convenience of usage. This sensor employs a microphone to produce input to the buffer, peak detector and an amplifier. This sensor notices a sound, & processes an output signal to a microcontroller. After that, it executes required processing. The sensor has the ability to detect the noise level decibels within the range of 3 kHz - 6 kHz frequency. In smartphones, there's an android application namely decibel meter accustomed to measure the sound level.

- **HC-05 Bluetooth Module**

HC-05 may be a Bluetooth module which is meant for wireless communication. This module is employed in a master or slave configuration. *Smart Noise Detector System*
Bluetooth serial modules allow all serial enabled devices to speak with one another using Bluetooth.

HC-05 Bluetooth module can communicate with smartphones using a Bluetooth terminal application for sending and receiving data. Various Bluetooth terminal applications for android and windows in respective applications can be found.

- **Android Smartphone**

The android is a robust operating system and it supports a huge number of applications and softwares in Smartphones. These applications are more attractive, advanced and comfortable for the users. The supporting hardware is based on ARM architecture. As android is an open source operating system, it can be used for free by anyone and can easily be developed further.

C. Assessment Items

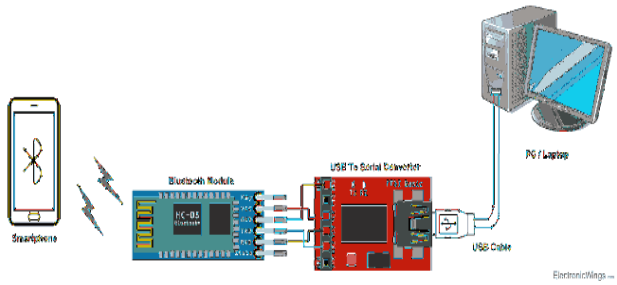

Fig 2: Data sharing

The neighborhoods of hospitals are declared as silence zones in order that patients receiving treatment don't seem to be disturbed. So are areas around schools, colleges, courts and other such places that are required to be noise-free.

According to the standards, the decibel level in silence zones mustn't exceed 50 dB during the day and 40 dB during the night. The noise monitoring network can be further expanded to provide informative noise maps. Using such maps, we can install various barriers such as enforcement of speed limits for heavy vehicles traversing through residential areas, demarcation of no-honking zones and adoption of proper land use plans in trouble spots like hospitals, libraries and various sensitive buildings.

This project was developed to produce a convenient method of detecting noise in silence zones. This project, as far as feasibility is worried, didn't cost an enormous amount because we used Arduino Uno .This project is implemented around a value of Rs.800 for every setup .The materials used are easily available and thus the project is extremely feasible and may be expanded as required.

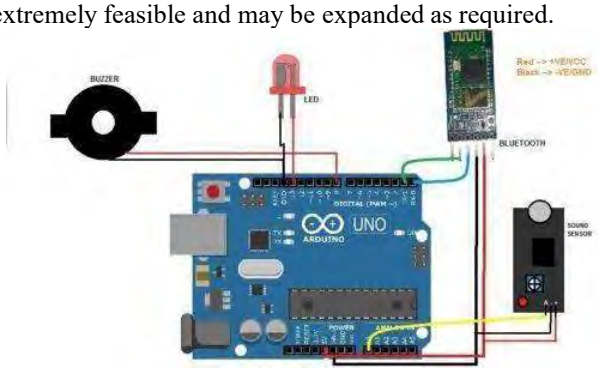

Fig 3: circuit Diagram of system

D. Final Examination

Our system detects the noise within the silence zone using the Sound Sensor. Sound sensor detects noise in decibels. The default intensity is entered within the program in a similar way of decibels. The system is placed in a very very silence zone and when the amplitude crosses the sting level, it's notified on a buzzer and a LED for a certain period of it slow. The system also uses a Bluetooth module to share data to an android device.

Data is shared over Bluetooth to an android application. The android application provides us the selection to modify the threshold and thereby control the amplitude in a very very surrounding. The GPS module is utilized to provide the location of the violation.

Thus, we are able to detect noise successfully in a very very silence zone and control the threshold level using an android application.

For Testing, power the Arduino and open the app tap at the Bluetooth Icon and choose HC 05 from the list to connect your phone to Bluetooth. Now you will see the amplitude value within the text bar. When amplitude reaches the sting value, the LED light and Buzzer will automatically get triggered by Arduino. User can also set a threshold value using the app. To do so, tap on the text box next to the 'send' button and enter the price you'd wish to feature and click on on the 'send' button to line the sting value.

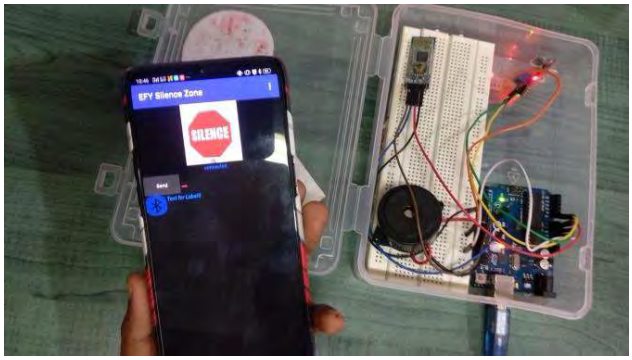

Fig 4: Final Kit of system

IV. CONCLUSION

This project mainly consisted of detection of noise in silence zones. Declaration of silence zones are done by the necessary authorities. Use of vehicular horns, bursting of crackers and loudspeakers shall be banned in these zones. Most monitoring stations where high levels of noise were recorded were next to busy and congested roads where vehicles were the biggest contributors with constant honking aggravating the matter. The ambient noise levels in residential and commercial areas indicate average day time noise levels within the metros to be above the national standard of 55dB for the residential and 65dB for the commercial area.

This project presented a framework using which attendance management is created automated and on-line. Fingerprint Identification System used for student identification is quicker in implementation than the opposite fingerprint identification systems. Biometric

NOISE DETECTOR gives a wonderful assistance to high school management because it complies with authenticated student attendance requirements of universities authorities & enhance the status of a college to face with the only within the peer set as a up to date, progressive and iconic institution giving students, teachers and administrators the way of pride and positivity. For straightforward and easy understanding basic SQL is utilized .The proposed system saves college precious time and value, session on session which could be instead invested in improving the academic systems, student development practices and developing a desirable college culture. It brings in simplicity, consistency and accuracy in College operations and reports which suggests lesser hassles in reconciliation, mistake and error management.

In the future, this project is extended to convey more detailed analysis and solve problems like attendance, maintaining manual record of information, studying the data manually and will help to avoid wasting plenty of time. Also, it's accustomed to predict the outcomes and suggest measures which can be taken to forestall an error and significantly it'll help to chop back labor costs. Regarding our fingerprint identification system, we are planning to introduce more indexing techniques like ridge density tolerance etc. for creating the search faster. Also the keys used are more efficient when complex keys are visiting. We try to reduce matching error rates. The project relies on a static calendar and in future we are determined to create it flexible for dynamic. We are able to show graphical representation of the attendance which may be very easy to interpret.

Voice Controlled Assistant Using Raspberry-Pi

Yash Bhatt, Hetvi Shah, Tanmay Phalke
Tcet, Mumbai
bhattyash031@gmail.com, hetvishah208@gmail.com, tanyphalke1210@gmail.com

Abstract—**As technology is entering a new era of computing that many are calling the Internet of Things (IOT). System to System, System to infrastructure, System to Environment, the Internet of Everything, the Internet of Intelligent Things, Intelligent systems—call it what you want, but it's happening, and its potential is huge. A voice controlled Assistant offers voice commands, voice searching, and voice-activated device control, letting you complete a number of tasks after you've said the "OK Google" or "Hey, Google" wake words. It is developed to give you chatty communications. Here we propose an IOT based Voice Controlled Assistant project using Raspberry Pi3. This Raspberry Pi Voice Controlled assistant project will walk you through your very own Pi-powered voice controlled Assistant. This assistant will actively listen to your commands and respond to your queries, all we need to say is "Ok Google" or Hey Google‖ followed by your query. The System consists of the Raspberry Pi3 Board with Speaker and Mic that are connected to it. The system starts just by saying "OK GOOGLE", followed by the query. The System records the query from the Mic, processes the query and the reply is given from the speaker that is connected to the raspberry pi board.**

Keywords –, voice searching, voice-activated device control , chatty communications, Ok Google.

I. INTRODUCTION

"IF YOU PONDER THAT THE INTERNET HAS CHANGED YOUR LIFE, THINK AGAIN.

The Internet of Things is about to transform it all over again!"

A Voice Controlled Assistant focuses on voice commands, voice searching, and voice- activated device control, letting you complete a number of tasks after you've said the "OK Google" or "Hey Google" hot words. It is designed to give you interactive interactions. Our project Google Assistant Using Raspberry Pi3 mainly focuses on conversation between the human and the

Assistant to get your query solved or to get the information about any smallest thing happening around.

Voice Controlled Assistant Is mainly designed to reduce the human efforts. Instead Of Entering the Browser and typing the query and search for it takes a lot of time. Voice Controlled Assistant Makes It simpler for us. All we need to do is give a command "OK! Google" and ask the query and the assistant will give the desired results within seconds.

All we need to do is setup the whole assistant on raspberry pi. After successful setup of the assistant we need to run various scripts, programs and commands. After successfully completing it Our Pi-powered assistant is ready. All we need to do is say "Ok Google" to make it active followed by your questions like ―How are you or tell the traffic update It will give the answers quickly.

II. PROBLEM DEFINITION

Design a smart IOT assistant that helps us automating things that we do in our day to day life that eliminates input via text and takes ―voice as input which helps us getting things done on the go. To build a system which provides you appropriate knowledge when asked for. To develop an assistant which performs various tasks for you such as playing songs, giving you the traffic update ,telling you the weather or like making a shopping cart for you or playing a joke. It also can interact with the user in various languages. This device has lesser cost than the original GOOGLE HOME and has all of the features of it. It works in two languages English as well as Hindi.

III. BACKGROUND

Voice Controlled Assistant is an Artificial Intelligence (AI) based virtual assistant developed by Google that is mainly available on mobile and smart home devices. Unlike the company's previous Virtual

Assistant. Google Now, the Voice Controlled Assistant can engage in two-way conversations.

Voice Controlled Assistant initially debuted in May 2016 as part of Google's messaging app Allo, and its voice-activated speaker Google Home. After a period of exclusiveness on the Pixel and Pixel XL smartphones, it began to be positioned on other Android devices in February 2017, counting third-party smartphones and Android Wear (now Wear OS), and was introduced as a unique app on the IOS operating platform in May 2017. along side the announcement of a software development kit in April 2017, the Assistant has been, and is being, further stretched to upkeep a large diversity of devices, including cars and third party smart home machines. The functionality of the Voice Controlled Assistant can also be boosted by third- party developers.

Now the Voice Controlled assistant can be integrated with any of the devices or the system. We also have integrated the Google assistant in our project using the raspberry pi.

IV. IMPORTANCE

Google Assistant is focused on reducing human efforts. Google Assistants are widely used on mobile phones, speakers, Television, Cars etc. Our main intention was to develop a Google Assistant On the different system which makes use Of Internet Of Things. We thus developed a Google Assistant on the Raspberry PI using various components. Importance of ―Google Assistant Using Raspberry Pi3‖ are as follows:-

- Create new calendar events on the fly by telling the Assistant "add to my calendar" or "make an appointment" followed by the event's name, date, time, and optionally even location.
- Get a broader overview of your day by activating Assistant and saying "tell me about my day" or even just "good morning."
- Asking Google Assistant to Play a song or even tell you jokes.
- Getting the traffic or the weather updates by just asking a question.

V. OBJECTIVES AND SCOPE

The main objective of developing this project was to build a Pi-powered Voice Controlled Assistant which interacts with people in human language. The user just needs to activate the system by saying ―OK! GOOGLE followed by the query say how are you? And the assistant will take the input and give the output by giving the

Appropriate, answer. Various Objectives fulfilled by the project are:-

User can create new calendar events on the fly by telling the Assistant "add to my calendar" or "make an appointment" followed by the happening's title, date, time, and voluntarily even location. User can get a broader overview of the day by activating Assistant and saying "tell me about my day" or even just "good morning.

User can ask Voice Controlled Assistant to Play a song or even tell you jokes. User can get the traffic or the weather updates by just asking a question. In the future this assistant can be used to develop a Intruder Detection System using Fingerprint Sensor by capturing the fingerprints and allowing only authorized users to enter the system and sending alerts if intruder tries to enter the system. It can also be used For Home Automation which is trending topic in the real world.

VI. PHASES

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting strong knowledge of the project title and doing exploration on it, we will get our description. Preparation: After scrutiny we will first study about it and do some research on the project for our better understanding and also getting a rough depiction about what would be our problem definition for this particular project.

Designing: Then we will build the design of the project and agreeing to that, will list down all the necessities needed for the creation for the prototype of our project. Implementation: After gaining the requirements, we first developed the connections of the hardware components (Raspberry Pi 3, Microphone, Speaker) and then added the coding part.

Phase 2: Testing and Deployment.

Testing: After the model is ready we will first associate the hardware with the allotted code and then we will check if it supports the machine or not. If not we will resolve the issues relating to it and will crisscross again.

Deployment: After completion of integration and testing of project, real time testing and operation of the system will be done.

VII. METHODOLOGY

This proposed method takes an automatic control action upon detection of hot word ―OK GOOGLE!. The assistant will get invoked and start running its function to read the command spoken after detection of the hot word. It then processes the input and then gives the desired output after connecting with the Google servers. Then it gives us back the processed output through the connected Speaker.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

Hardware

- 1 Raspberry Pi 3
- 1 Speaker
- 1 Microphone
- 1 HDMI to VGA converter
- 1 USB cable

Software

- NOOBS OS
- PYTHON 3
- LINUX
- Google SDK

IX. BLOCK DIAGRAM

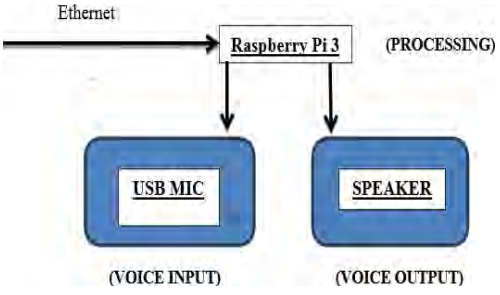

Fig. Block Diagram

The above block diagram represents the actual working of our project. Here the voice input is given to the mic which is processed using the raspberry pi and the reply is given through the speaker in human language.

X. CIRCUIT DIAGRAM

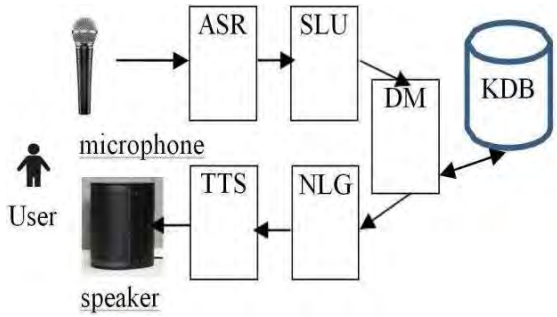

Fig. Circuit Diagram

This circuit diagram represents the internal working of our assistant. It consists of (ASR) Automatic Speech Recognition Part, (SLU) Spoken Language Understanding, Dialog Manager (DM), A Knowledge Database (KDB), A Natural Language Generator (NLG) and a Text To Speech Synthesis (TTS) system which makes the Google assistant fully functional.

XI. OUTPUT

When we say OK Google! The assistant starts running and reads input in the form of voice and does the task according to the input received.

XII. RESULT

When we say OK Google! The assistant starts running and reads input in the form of voice and does the task according to the input received.

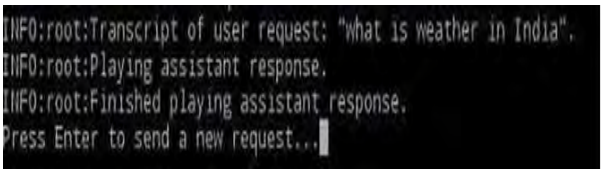

Fig. Voice Controlled Assistant working Kit

XIII. OUTCOMES

Creating the outline, works survey and achievability study for proposed solution which will act as an input to the design phase.

Suggesting Statement of work, scope description and scope border for planning the model from the problem definition to decide what needs to be done and what not to be done.

Phase 1 Implementation:

Implementation of the Raspberry PI model with the help commands running it in the Linux environment.

Phase 2 Testing:

Testing was done with cases like testing mic and speakers , Testing by asking different queries to the assistant .The testing of the model was a success are mentioned in the above figures.

Phase 2 Deployments:

Real time working was done when we asked questions and assistant replied the answers appropriately. Thus the model works efficiently.

XIV. RESEARCH GAPS

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

- Since the Wi-Fi was not working with the Raspberry Pi, the device cannot be connected to the home Wi-Fi right now.
- API such as YouTube and Google Play Music have not been installed currently due to errors in Google SDK.
- The device cannot control other devices connected on the network right now. It needs to be configured in that manner to do so.

XV. SUMMARY

A Voice Controlled Assistant focuses on voice commands, voice searching, and voice-activated device control, letting you complete a number of tasks after you've said the "OK Google" or "Hey Google" keywords. The project focuses on building an IOT based ―Google

Assistant‖ using Raspberry PI3 platform. Before the project starts there is the abstract and the introduction of our project which gives the brief idea about the project. It also consists of the Importance of the project, Objectives and the future scope of the project. Thus, this project was a success with all the use cases and fulfilling all the phases of the project development anddeployment.

XVI. CONCLUSION

We have successfully shown that the implementation of an Assistant by IOT based project is possible. It fulfills the various commands commanded by the user. The Assistant takes the input from the user through the Microphone connected. It gets activated when the user gives the input by saying “OK Google” and according to the given input command, the output is obtained to the user. The weaknesses of the system are that currently it is not able to perform the Google Play API and also does not support Head Listyet.

Saline Monitoring System Using Ardiuno

Pratimesh Majumdar, Shivam Kumbhar, Pratik Kumbhar
TCET, Mumbai
pmajumdar912@gmail.com, shivamkumbhar432@gmail.com, pratikkumbhar121999@gmail.com

Abstract— **IV saline is used to replenish lost fluids, flush wounds, deliver medications, and also in surgery. A constant monitoring of the saline level in the bottle is required because if the saline in the bottle is fully consumed and the bottle is not replaced immediately then the pressure difference between the patient's blood pressure and the empty saline bottle causes an outward rush of blood into the saline. This situation can pose a serious threat to the patient's well-being. In current health care measures whenever a saline is fed to any patient, they need to be continuously administered by a nurse or any caretaker.**

In this paper we have proposed an Internet of Things (IOT) based saline monitoring system. The project is made on Arduino platform and uses infrared sensor to indicate if the saline level falls below a certain level. The working of this model is based on the phenomenon of refraction. When infrared rays pass through different medium refraction occurs which causes a reduce in the voltage received at the receiver. This system notifies the concerned authorities, if such is the case, which is achieved by triggering the buzzer.

It is meant to improve the quality of health-care provided at a time when the work-load on hospitals is ever increasing. Having one less concern allows them to concentrate on different tasks which not only proves beneficial for the patients, but also for the staff. If the saline level falls the staff is alerted, who can then prioritize the timely change of saline IV, thus preventing the above-mentioned concerns as well as lead to the effective utilization of their time. The solution provided can be made at a relatively low cost.

Keywords – Arduino; Saline IV; Hospital; IOT

I. INTRODUCTION

The working condition in hospitals may lead to improper health care monitoring. This might be due to excessive number of patients or the inattentiveness of relatives. If, in such a case, the saline bottle gets empty, the pressure difference between the patient's blood and the empty saline bottle causes a vacuum to be created which causes the blood to be sucked out from the patient's body causing excruciating pain. The only way to solve this is to change the saline IV bottle. In such cases prevention is the only feasible solution. The Saline Monitoring System constantly monitors the saline bottle and helps to detect whether the saline level has fallen below a certain level. This results in the reduction of hemoglobin level of patients and may also lead to shortage of red blood cells (RBCs) in the patient's blood causing tiredness. Therefore, there is a need of developing a saline level monitoring system which will reduce the patient's dependency on the nurses or caretakers to some extent. If it does, the system alerts the concerned work-staff. Thus, they are reminded of this only when their concern is necessary leading better work flow as well as providing a fast and efficient response.

The reverse blood flow might at times be so intense that it infuses into the saline bottle and colors the whole fluid red. Though there is little or no harm to the patient, the increased pressure causes intense pain, alerting and diverting the attention of the attendants and the nursing staff. Thus, it simply induces uneasiness in the patients and increases the work of the staff as they need to clean that up. The proposed system can not only be used for monitoring saline level in hospitals but also can have many different applications.

With the increasing demands in the healthcare sector the quality of care provided has been falling. With the increase in populace and the deterioration of their lifestyle, the number visits to the hospital has considerably increased in the present time.With such high demand many hospitals cannot keep up with their quality of healthcare. Our project is a small step in improving the care provided by such hospitals to the patients as well as reduces the stress of the staff and nurses.

The goal is to design a microcontroller (IoT) based Saline Monitoring System that will continuously monitor to check whether the saline level has fallen below the required minimum level and if yes, activate the alarm to notify the staff.

II. EXISTING APPROACHES

In the current healthcare measures, professional nurses are responsible for managing, monitoring and providing care to patient receiving saline. Roller clamp is used for manually controlling the saline infusion rate at the hospitals. If roller clamp rolls in one way, it compresses the intravenous tube more tightly which make tube more thin and allow saline fluid to flow through at a slower rate.

In the present world, there is no such monitoring system which will reduce the dependency of the patients on the nurses, doctors and would also reduce the need for the nurses to go to patient's bed every time to check saline level status of each patient. Therefore, there is need for development of IoT based saline level monitoring system

III. IMPORTANCE

- The requirement of the saline level detection and its alert system is because of the increase in the negligence of the hospital staff caused by factors such as increased work load, lack of sleep due to overworking or simply forgetting about it.
- Hence, this project is of great importance to manage the staff's time, leading to helping both the patient and the staff. Importance of the Saline Level Detection and its alert system are as below:
- Alert system is primarily designed to alert the staff of a drop in the saline level so they can safely change the saline bottle.

- Correctly maintaining and operating the alert system is effective in improving the work flow.
- Better health care can be provided by giving timely alerts.

IV. FEATURES

The Project consists of the following features:

- Alerting mechanism: In order to alert the staff of the low saline level a buzzer is used.
- The buzzer will ring if the saline level falls below a certain level.
- High sensitivity: The Infrared sensor used is sensitive to the amount of saline present at each point of time in the bottle. As soon as it senses that the saline is below the threshold level it triggers the alerting mechanism.
- Cost effective: The overall cost of the project is low and can thus be easily implemented.
- Simple circuitry: The connections are simple and hence it is easy to develop.

V. PROPOSED METHODOLODY

The proposed method takes automatic action upon detection of saline level through constant measuring of saline level. Initially while the saline bottle is full the voltage at the receiver of the phototransistor is low. This is due to the diffraction of the IR rays through the solution. When the solution falls below the level at which the IR phototransistor is placed the voltage increases as there is no diffraction. This sends a high signal to the microcontroller which triggers the alarm and notifies the ones concerned.

VI. SYSTEM REQIOREMENTS

The Arduino UNO is developed by Arduino.cc and is an open-source microcontroller board based on the Microchip ATmega328P microcontroller. The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits. It has 14 Digital pins, 6 Analog pins, and is programmable with the Arduino IDE (Integrated Development Environment) via a type B USB cable. IR phototransistor and receiver Infrared phototransistor is a special dark lens that reduces sensitivity to visible light. It can only trigger on with infrared light.

Infrared Phototransistor

An Infrared light emitting diode (IR LED) is a special purpose LED emitting infrared rays ranging from 700 nm to 1 mm wavelength. An IR LED is a type of diode or simple semiconductor. Electric current is allowed to flow in only one direction in diodes. As the current flows, electrons fall from one part of the diode into holes on another part. In order to fall into these holes, the electrons must shed energy in the form of photons, which produce light. An IR sensor is a device that detects IR radiation falling on it. Buzzer A buzzer or beeper is an audio signaling device which may be mechanical.

In common parlance a Buzzer is a signaling device that is not a loudspeaker. It can be mechanical, electromechanical, or electronic (a piezo transducer).If the saline level is below the preset threshold the buzzer would start buzzing and alert the nurse or the doctor.

VII. ARCHITECTURE

Fig.1: Block Diagram

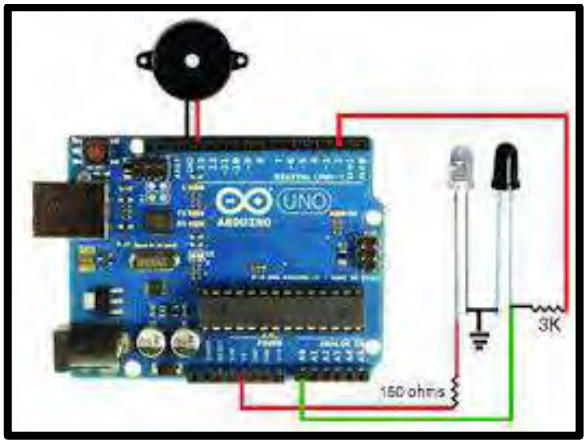

Fig.2: Circuit Diagram

VIII. WORKING

Initially while the saline bottle is full the voltage at the receiver of the phototransistor is low. This is due to the diffraction of the IR rays through the solution. When the solution falls below the level at which the IR phototransistor is placed the voltage increases as there is no diffraction. This sends a high signal to the microcontroller which triggers the alarm and notifies the ones concerned.

When the saline level is above the level at which the IR phototransistors and receivers are placed the voltage is always below 4V which shows that the rays are getting diffracted and thus the buzzer does not get triggered. when saline bottle is full Whenever the saline level falls below the threshold it is detected by the sensor which gives an output around 5V which triggers the buzzer

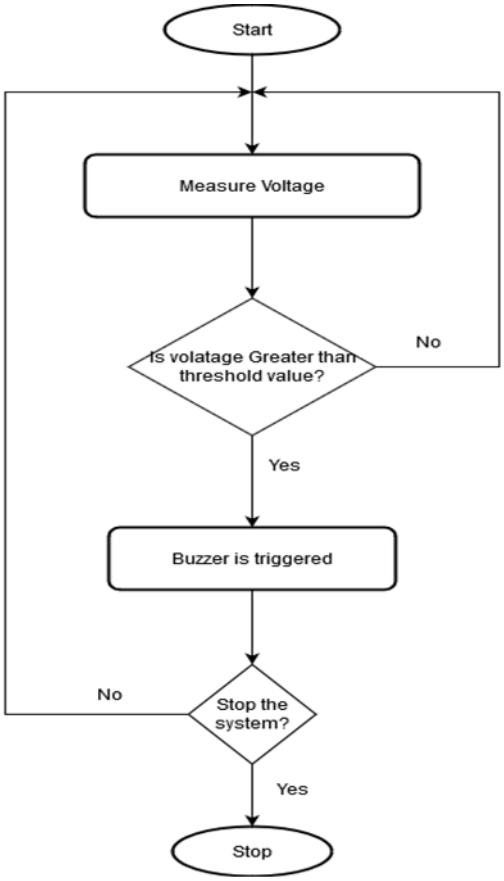

Fig.3: Flowchart of the proposed system

IX. RESULTS

When the saline level is above the level at which the IR phototransistors and receivers are placed the voltage is always below 4V which shows that the rays are getting diffracted and thus the buzzer does not get triggered.

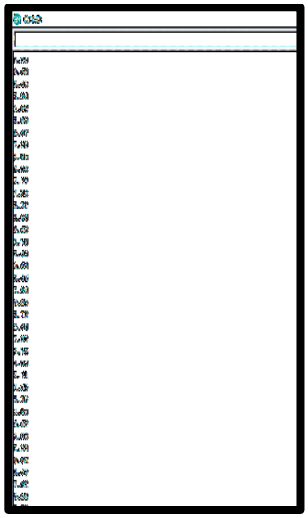

Fig 4: Voltage when saline bottle is full

Whenever the saline level falls below the threshold it is detected by the sensor which gives an output around 5V which triggers the buzzer.

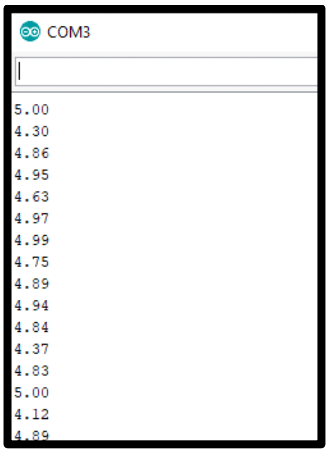

Fig 5: Voltage when saline bottle is empty

X. CONCLUSTION

We have successfully shown that the saline level monitoring system based on IOT is possible and can detect saline level, warn consumer when the saline falls below a certain threshold level. The system can constantly keep track of the saline level ensuring that the alarm is sounded reliably. This system uses the buzzer as a warning device in the event of low saline level. It increases the work efficiency of the staff as well as improves the health care provided.

Abstract—**Garbage may consist of the unwanted material leftover from City, Public area, Society, College, home, etc. This project is related to the "Smart City" and based on the "Internet of Things" (IoT). So, for a smart lifestyle, cleanliness is needed, and cleanliness begins with Garbage Bin. Garbage Monitoring System project helps to eradicate or minimize the garbage disposal problem. Many times, in our city we see that the garbage bins or dustbins placed at public places are overloaded. It creates unhygienic conditions for people as well as ugliness to that place leaving a bad smell. To avoid all such situations, we are getting to implement a project called IoT Based Smart Garbage and Waste Collection Bins. These dustbins are interfaced with a microcontroller-based system having Ultrasonic wireless systems alongside central system showing level and current status of garbage, on an internet browser with HTML page by Wi-Fi and Email will forward Gmail account. Hence the status will be updated on the web page. A major part of our project depends upon the working of the Wi-Fi module; essential for its implementation. The main aim of this project is the enhancement of a smart city vision and reduction of human resources. This proposed system assures the gathering of garbage and waste soon when the waste level reaches its intensity. The system will thus provide correct information, increase the efficiency of the system. This proposed system is more efficient and time-saving as compared to the existing system.**

Keywords –IoT- Internet of things, IR -Infrared sensor, GSM-Global System of Mobile Communications module, etc.

I. INTRODUCTION

Internet and its applications became an integral part of today's human lifestyle. It has become an important tool in every aspect. Due to the tremendous demand and necessity, researchers went beyond connecting just computers into the online. These researches led to the birth of a sensational gizmo, Internet of Things (IoT). Communication over the web has grown from user-user interaction to device – device interactions lately. The Sensor Network Lab concepts were proposed years back but still, it's in the initial stage of commercial deployment. The home automation industry and transportation industries are seeing rapid growth with Sensor Network Lab. Yet not many articles are published during this field of study. This paper aims to structure a state of the art review on Sensor Network Lab. The technology, history, and applications are discussed briefly alongside various statistics. Since most of the process is done through the internet we must have an active highspeed internet connection. The technology is often simply explained as a connection between humans-computers-things. All the equipment we use in our day to day life can be controlled and monitored using the Sensor Network Lab. A majority of the process is done with the help of sensors in Network Lab. Sensors are deployed everywhere and these sensors convert raw physical data into digital signals and transmit them to its centre. In this way, we can monitor environmental changes remotely from any part of the world via the internet. This systems architecture would be based on the context of operations and processes in real-time scenarios. Smart collection bin works similarly with the combination of sensors namely weight sensor and IR sensor that indicates its weight and different levels respectively. The IR sensors will show us the varied levels of garbage within the dustbins and also the load sensor gets activated to send its output ahead when its threshold level is crossed. These details are further given of the microcontroller (ARM LPC2148) and the controller gives the details to the transmitter module (Wi-Fi module). At the receiver section, a mobile handset is required to be connected to the Wi-Fi router, therefore, the details of the rubbish bin are displayed onto the HTML page in the web browser of our mobile handset.

II. BACKGROUND.

Learn cleanliness from the cat is claimed and appreciated in Ethiopian society. The scenario beyond this proverb is that keeping the environment clean is quite important and it is used to emphasize more on giving attention to the cleanliness. Nonetheless, it's not as easy to speak out the proverb to effectively and properly managing the garbage. We frequently observe garbage bins being filled over and extra waste materials being disposed and accumulated around the bin in several cities of Ethiopia. That improperly disposed of garbage will be the dwelling for a various number of dangerous microorganisms, insects, and mosquitoes to breed on. Because of this, the severe and contagiousdisease is stimulated and also bad smell comes out of it and may cause illness to human beings. The municipality of most cities in Ethiopia has strived its best to alleviate this problem by providing several, garbage bins throughout the town. However, it is a manual approach and several trucks from the municipal authority is sent to the waste bins to collect the waste. The wastes are loaded to the truck and conveyed to the pre-specified locations. Because of this, the category of the people involved in collecting and transporting the wastes are usually not responsible enough to do the job well done. Very often the wastes are not collected from every waste bin properly due to municipal authorities did not have information about the garbage bin. The manual waste collection and management approach has problems such as a lack of information about the collecting time and place. Because of this, it is and less effective i.e. trucks go and may get empty garbage bin. Generally, there is a lack of a proper monitoring system to follow all activities related to waste management and lack of smart monitoring of the condition of the bin. This proposed paper shows an effective solution to manage, garbage. This garbage monitor is implemented using sensors, and

Raspberry Pi microcontroller. The details of each dustbin are monitored by the municipal authorities with the help of GUI. The implementation of a garbage monitoring system using sensors, microcontrollers and GSM modules assures the cleaning of dustbins soon when the garbage level reaches its maximum and also notify the people not drop the dust outside the dustbin when they try to drop it out of the bin by sensing their motion. If the dustbin is not cleaned in a specific time, then the record is sent to the higher authorized office who can take appropriate action against the concerned contractor [2]. This system also helps to watch the fake reports and hence can reduce corruption within the overall management system. This reduces the total number of trips of Automated Garbage Monitoring System Using Raspberry Pi.

A. SYSTEM ARCHITECTURE.

Fig. 1 describes the diagram of the monitoring system. It consists of several ultrasonic sensors,
the Raspberry Pi Uno microcontroller, and the GSM module. The ultrasonic sensors are wont to detect the extent of garbage in each bin, and it'll send this information to the Raspberry Pi Uno, which acts as the system controller. In the case where the bins are
already full or almost full, then it'll generate a warning message which can be sent to the municipality via SMS, by using the GSM module. Moreover, this
system is also connected to several LEDs, in green or red colors, in order to alert all the residents regarding the bin status.

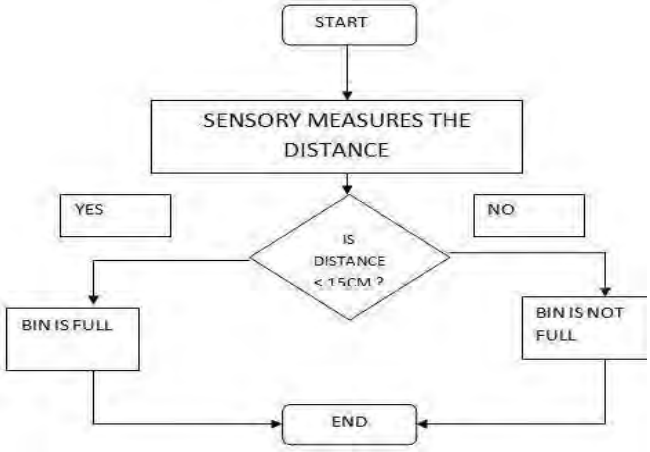

Fig. 1- Methodology.

B. SYSTEM PROCESS FLOW.

At first, the level or the height of the garbage in each bin is measured by using the ultrasonic sensor. This information is then received and processed by the Raspberry Pi Uno. It will determine whether the garbage level has been surpassing the threshold level or not. For this research purpose, there are two threshold levels sets: the first threshold is at 70% of the bin height, and the second threshold is set at 90% of the bin height. If the garbage level in the bin is crossing the first threshold level, then the first warning message is generated and sent to the municipality. Besides, the green LEDs will be turned ON in order to alert all the residents on every floor. Next, if the garbage level in the bin is crossing the second threshold level, then the second warning message is generated and sent to the municipality. In this case, all the residents will be alerted when the red LEDs are turned ON.

C. FEASIBILTY STUDY

1. Technical Feasibility - this assessment focuses on the technical resources available to the organization. It helps organizations determine whether the technical resources meet
capacity and whether the technical team is capable of converting the ideas into working systems. It also involves the evaluation of the hardware, software, and other technical requirements of the proposed system.
2. Economic Feasibility - this assessment typically involves a cost/ benefits analysis of the project, helping organizations determine the viability, cost, and benefits related to a project
before financial resources are allocated. It also is an independent project assessment and enhances project credibility— helping decision-makers determine the positive economic benefits to the organization that the proposed project will provide.
3. Legal Feasibility - this assessment investigates whether any aspect of the proposed project conflicts with legal requirements like zoning laws, data protection acts, or social media laws.
during a specific location. A feasibility study might reveal the organization's ideal location isn't zoned for that sort of business. That organization has just saved considerable time and energy by learning that their project wasn't feasible right from the start.
4. Operational Feasibility - this assessment involves undertaking a study to research and determine whether—and how well—the organization's needs are often met by completing the project. Operational feasibility studies also analyze how a project plan satisfies the wants identified within the requirements analysis phase of system development.
5. Scheduling Feasibility - this assessment is that the most vital for project success; in any case, a project will fail if not completed on time. In scheduling feasibility, a corporation estimates what proportion time the project will fancy complete.

D. SYSTEM DESIGN REQUIREMENT.

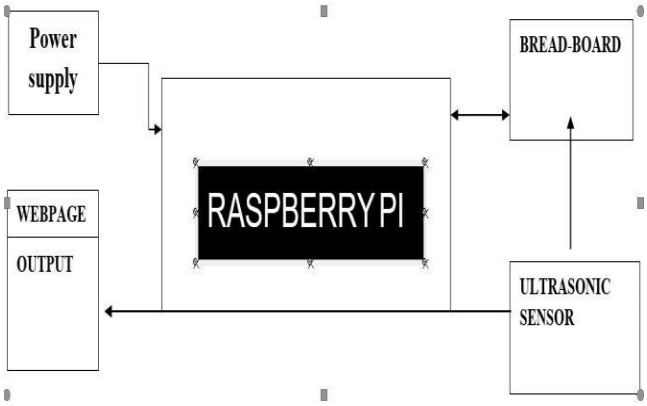

Fig. 2 – Block Diagram.

The power supply is given to the raspberry pi it activates the Raspberry pi. Then make the necessary connections with the jumper wires with the bread board and Raspberry Pi. Connect the ultrasonic sensor with the bread board. When the code runs, the ultrasonic sensor takes the input and the output is displayed on the webpage wirelessly.

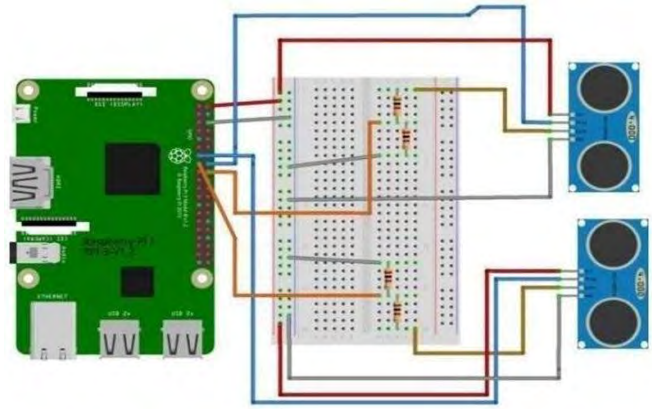

Fig. 3 – Circuit Diagram.

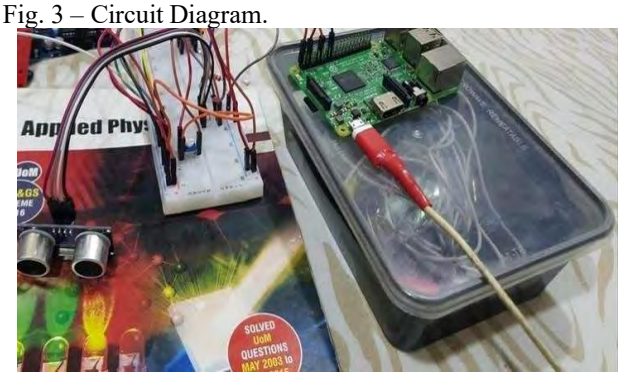

Fig. 4 – GUI Design.

In the above fig, the jumper wires are used to connect the bread-board with the GPIO pins of Raspberry Pi, and resistors are used for proper power supply for the Ultrasonic sensor, which measures the distance.

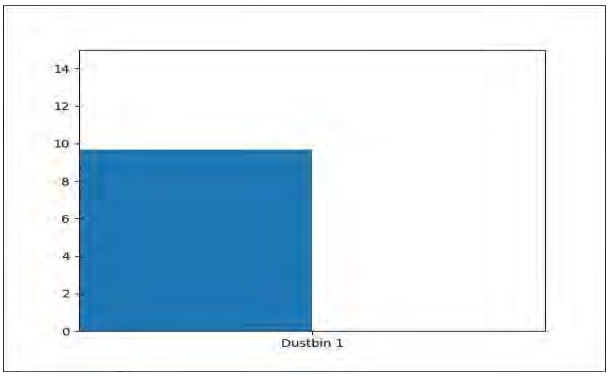
When an object is placed in front of the ultrasonic sensor it takes the input as the distance and displays whether the bin is full or not on the webpage on the laptop.

III. SYSTEM OUTPUT.

A. Outputs (Output of the project only)

Successfully implemented the garbage monitoring system. The Ultrasonic Sensor detects the level of the trash in the bins and alerts the system, of the increase in the level. The result would be displayed on the webpage. This helps the concerned authority to carry on a cleanup drive.

Graph 1: Dustbin is fully empty. Therefore, graph has no blue bar and it is fully white.



Graph 2: Dustbin is partially empty. Therefore blue bar is seen, Blue bar show how much dustbin is full. In below graph it can be seen that dustbin is 8.9 m full.

B. Outcomes

The following are the outcomes were observed as a result of implementing the product:

- Waste Level detection inside the dustbin.
- Transmit the information wirelessly to local authorities.
- The data can be accessed anytime and from anywhere.
- The real-time data transmission and access.
- Avoids the overflows of Dustbins

IV. DISCUSSION OF THE RESULT.

This IoT based waste management is extremely useful for smart cities and even the agricultural areas as equally. Even in the rural areas lack of garbage management has been leading to various diseases that have been taking shape in different aspects. Hence, the monitoring will widely help them take the necessary precautions and build health into rural areas. IT has been observed seen that in cities there are different dustbins located in the different area's and dustbins get overflown many times and the concerned people do not get information about this. The system is designed to solve this issue and will provide complete details of the dustbin located in the different areas throughout the city. The concerned authority can access the

knowledge from anywhere and anytime to urge the small print. Accordingly, they can take the decision on this immediately. In addition to added, advantages of being able to monitor the garbage bin over various areas, a feature has been incorporated where the overflowing bin location, when triggered could send out the information to the concerned authority. This particular feature further enhances the capability that this particular product or project brings to the table

V. FUTURE SCOPE.

The main objective is to take care of the extent of cleanliness within the city and form an environment that is best for a living. By using this technique we will constantly check the extent of the rubbish within the dustbins which are placed in various parts of the town. If a specific dustbin has reached the utmost level then the workers are often informed and that they can immediately take certain actions to empty it as soon as possible. The workers can check the status of those bins anytime on their mobile phones. This will convince be a really useful system if used properly. The system is often used as a benchmark by the people that are willing to require one step further for increasing the cleanliness in their respected areas. An ultrasonic sensor is getting used during this system to see the extent of garbage within the dustbins but in future various other sorts of sensors are often used with the ultrasonic sensor to urge more precise output and to require this technique to a different level. Now, this technique is often utilized in certain areas but as soon because it proves its credibility it is often utilized in all the large areas. As this technique also reduces manual work certain changes are often wiped out the system to require it to a different level and make it more useful for the workers and other people who are using it. In the future, a team is often made which can be responsible for handling and maintaining this technique and also to require care of its maintenances.

VI. CONCLUSION.

This project work is the implementation of smart garbage management system using the ultrasonic sensor, Raspberry Pi and Wi-Fi module. This system assures the cleaning of dustbins soon when the rubbish level reaches its maximum. If the dustbin isn't cleaned in specific time, then the record is shipped to the upper authority who can take appropriate action against the concerned contractor. This system also helps to watch the fake reports and hence can reduce the corruption within the overall management system. This reduces the entire number of trips of garbage pickup vehicle and hence reduces the general expenditure related to the rubbish collection. It ultimately helps to keep cleanliness in society. Therefore, the smart garbage management system makes the rubbish collection more efficient.

Abstract-**In this paper we represent smart glove for deaf and dumb patient. About nine billion people in the world are deaf and dumb. The communication between a deaf and normal visual people. This creates a very little room for them with communication being a fundamental aspect of human life. The blind people can talk freely by means of normal language whereas the deaf-dumb have their own manual-visual language known as sign language. The smart wearable glove will solve many issues related to different fields like healthcare, defense sector, automation, public safety, control systems and many more. Once, it comes in public domain then it will truly change the life of many and will encourage such innovative projects and ideas so that more and more similar product is introduced for the benefit of the society.**

Keywords- Smart Glove; Solutions for Deaf and normal visual people; Gesture Vocalizer App; ConvoHand;

I. INTRODUCTION

The internet of things (IOT) is a computing concept that describes the idea of everyday physical objects being connected to the internet and being able to identify themselves to other devices. The IOT is significant because an object that can represent itself digitally becomes something greater than the object by itself.

General, deaf people have difficulty in communicating with normal people. Even those who do speak aloud typically have a "deaf voice" of which they are self-conscious and that can make them reticent. Hence there is a need of the system which recognizes the different signs and conveys the information to the normal people.

The ConvoHand glove is a normal glove with buttons along the length of each finger and the thumb. Buttons are used instead of flex sensors to make the product cheaper. The button output a stream of data that varies with ASCII code. The output from the button are analog values, converted to digital and processed by using microcontroller and then it will be transmitted through Bluetooth wireless
communication, then it will be received in the receiver section and processed giving the output. The output is been shown in an app called CONVOHAND which is made through MIT App inventor-2, the responses are in text and voice. In this project buttons plays the major role.

Analysis is the third phase in software development lifecycle which aims in finding the requirements for the project which we are going to implement. Analysis means to understand the business needs and processes so that the project we implement becomes efficient. In system analysis we consider what the
system will need to take into consideration all the
points so that the stakeholders will have the right model built That signifies to collect the requirements which reflects the stakeholder's expectations. So, in this phase we spent considerable amount of time talking with the customers and understanding their requirements. In short, we can say that analysis phase means conquering requirements and analyzing them. So, in analyzing requirements we create the deadline and consider various ways to achieve it and hence the requirements are considered formal requirements.

II. OBJECTIVE

The main objective of this project is to help deaf and dumb people by removing communication barrier so that they are not restricted in a small social circle and are able to convey their feelings and emotions . This project also aims to solve the daily challenges faced by the people, who are unable to speak (dumb) or one who has recently undergone an accident and is unable to speak. It can also be used by elderly people, who find difficulty in speaking. Whenever they want. Also it would be helpful in education and health issues related to deaf and dumb people. Assertive technology products for special people to promote building an inclusive society. This work includes a voice based and text based interaction approach.

III. SCOPE

To achieve the objectives, the scope of this project is determined. With this wearable smart glove, dumb people or patient can easily communicate by just tapping the points on the glove by their thumb that results in 4 different commands that are both audible audio and image on any Android smartphone via an app. This can also be used in automation of day to day things like home appliances and many more. This can also be integrated in the field of automation where one can automate things without getting in direct contact of the machines/appliances that are to be automated or controlled.

IV. PROBLEM DEFINATION

Problems faced by the disable person regarding employment can be overcome by our method. So in the implemented work an intelligent microcontroller based system using Flex sensors is developed which is able to convert gesture into voice and text. Help a person to control his home appliances if he could not walk to

switchboard .In today's technology wireless gloves are not yet reliable because to be used as wireless, the gloves should have inbuilt battery and some electronics controller board which makes gloves heavier and may cause irritation. Thus wired equipment's are preferred for patients and partial disable people.

V. OBSERVATION MATRIX A

Observation

In the society, we observe that many problems
occurred while communicating with deaf and dumb people.

- Unable to convey the message
- Takes time to understand
- Time wastage
- Less security
- Less safety

B. Scouted challenges

In current technology we face the many problem.

- More reliable
- Automatic system
- Fast working
- Less time consumes
- Security
- Base planning

C. Top Five problems

There are many problems with these people. Problem like

- people like this can't get the employment.
- At least one person is required to understand the person.
- Delay in understanding may lead to unexpected problems.
- Patient in hospital always requires an assistant.
- People may take the advantage of their disability.

VI. FEATURES OF THE PROJECT

It can solve the daily difficulties suffered by the people, who are cannot speak (dumb) or one who has recently undergone an accident and is not in a condition to speak about this health to the doctor or express his feeling to his family. It can also be used by elderly people, who find difficulty in talking due to their bad heath conditions.

This can also be integrated in the field of automation where one can automate things without getting in direct contact of the machines/appliances that are to be automated or controlled.

It has wide application in defense sector and war equipment, where solider will not put their life in danger and can control the artillery or explosive without coming in direct contact of it from a safe distant zone. This smart glove can also work as a controller for Wheel chair and stuffs that are wheeled and needs to be controlled by gestures in some critical or required situation. So, this glove can easily communicate by just tapping the points on the glove by their thumb that results in twelve different expressions/commands in text, image and audio format on any android smartphone via an app. But, its application possibilities are more in different fields.

VII. SYSTEM REQUIREMENT

A. Software

There are two main software used in developing this
project which are Arduino software and MIT App Inventor. Arduino software used to write the program using C language and Arduino language. It is used to compile and install the program into the microcontroller. It will display the value of button and make the project easier to be tested.

The MIT App Inventor, online app development application software. The application has two parts.

1. Screen Layout.

2. Blocks.

The MIT App Inventor development environment is supported for Mac OS X, GNU/Linux, and Windows operating systems, and several popular Android phone models.

B. Hardware

There are five main hardware in this projects.

1. Arduino UNO
2. Bluetooth module HC-05
3. Jumper wires
4. Glove and Metallic Buttons
5. Soldering Iron

VIII. IMPLEMENTATION FOR METHODOLOGY

A. Flow of the project implementation:

1. Connect the battery to the Arduino Uno.
2. on the Arduino and Bluetooth.
3. Open ConvoHand app and touch any one button make the app active.
4. Let the required person wear the glove and use the glove as it is required.

B. Block Diagram:

The figure 4.2 shows all the connections from the glove and the Bluetooth module HC-05 to the Arduino Uno. The color of the wire shown the figure 4.2 is identical to the wire in the working model.

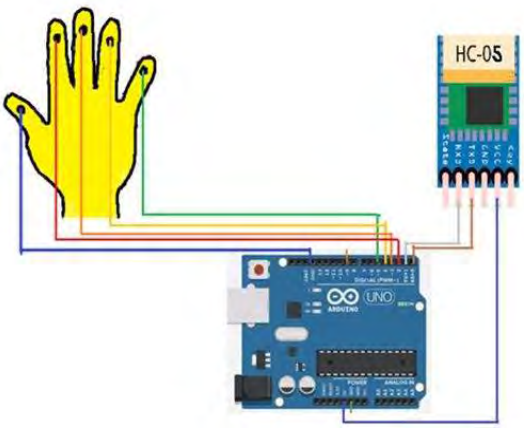

Fig1. Block Diagram of working model

C. Arduino UNO:

Arduino Uno is the main part of this project which it
act as microcontroller. Since the price is very cheap and easy to use, it is very good for the development of new products or interesting projects. Coming with
14 digital pin, 6 analog pin, 16 MHz crystal oscillator and USB connection, it is suitable to be used as a
microcontroller. Based on ATmega328, this microcontroller board can simply connect to computer using USB cable or using adapter to connect with battery to get started.

Fig 2. Arduino UNO

D. Bluetooth Module HC-05:

The Bluetooth module HC-05 is a MASTER/SLAVE
module. By default the factory setting is SLAVE. The Role of the module (Master or Slave) can be configured only by AT COMMANDS. The slave modules cannot initiate a connection to another Bluetooth device, but can accept connections. Master module can initiate a connection to other devices.
The user can use it simply for a serial port
replacement to establish connection between MCU
and GPS, PC to your embedded project, etc.

Fig3. Bluetooth Module HC-05

E. Glove and Metallic Button:

This project has been made by using plastic and rubber glove. We can also use woolen glove as per
convince. Metallic buttons has been attached to this glove in order to make the connection. On the backside of buttons we have solder electrical wires so that message can be passed using electrical medium.

Fig4. Glove and the Metallic buttons

F. Android App -MIT App Inventor:

The MIT App Inventor, an online app development
application where developer cans drag- drops the layout of Android app as the requirement of the developer. The MIT App Inventor project seeks to democratize software development by empowering all people, especially young people, to move from technology consumption to technology creation. The app can be cloned to an Android phone using MIT AI2 Companion that can be downloaded from Android Play Store, showing how exactly it looks on an Android phone. If you don't have an Android phone, you can build your apps using the Android emulator, software that runs on your computer and behaves just like the phone. The MIT App Inventor development environment is supported for Mac OS X, GNU/Linux, and Windows operating systems, and several popular Android phone models. Using MIT App Invertor, developer can make his own Android app using Build option using a QR code using .apk.

Fig5. Android App

G. CONVOHAND APP:

Fig6. Display page of the CONVOHAND App

This is the first page of app. The first line of page include title of the app the second line shows virtual voice which means it will convert the message in voice message for users. A different command has different voice messages.

Fig7. Command 1

This page shows the result of command touched by the user. 8 128 128 128 is the code value with
convert the number from Arduino to app and helps to display the correct message.

Fig8. Command 2

IX. RESULT ANALYSIS

As result of the project we are able to achieve wearable smart glove. Which is not only useful for deaf and dumb but also for people who don't get any employment. This smart glove is connected with android app which can be get transmitted through and android phone. Cost of this glove is very less as compare to other replacement available in market. Rather than using any sensor this glove has been developed with the help of metallic buttons which is very cheap.
Thus, the smart wearable glove will solve many issues related to different fields.
Once, it comes in public domain then it will truly change the life of many and will encourage such
innovative projects and ideas so that more and more similar product are introduced for the benefit of the
society.

Fig9. Result of working model

X. OUTCOMES PHASE 1:

i. Analysis:
Creating the synopsis, literature survey and feasibility
study for proposed solution which will act as an input to the design phase.

ii. Planning:
Proposing Statement of work, scope definition and
scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done.

iii. Designing:
Proposing the design architecture for the prototype.

iv. Implementation:
Implementation of Arduino UNO with the help of
code running in the Arduino
IDE environment.

PHASE 2:

i. Testing:
Testing was done by sending messages multiple
times to the GSM module.The testing of the model successes are mentioned in the above figures.

ii. Deployment:
When a real-time notice is sent to the GSM Module,
it is extracted and sent to Arduino, which is displayed on the LCD Screen. Thus, the model works efficiently.

XI. CONCLUSION

With CONVOHAND: Smart Glove we are able to help disable person in their daily work. As it is difficult to monitor and understand disable person, with ConvoHand he/she can easily communicate with others to express their feelings. This is achieved by making the glove consisting a button on each finger carrying a specific message with could be pressed and displayed on the screen to the concerned person. These messages are going to be displayed via app named "CONVOHAND" which was build on the application known MIT APP INVENTOR. This app has been connected with Arduino by Bluetooth module. This project is really helpful in medical field as well as in the customer care field.

Self-stabilizing spoon for Parkinson's sufferers with pulse sensor

Mukesh Choudhary, Chinmay Dali, Jignesh Dhakad, Sunnykumar Bhagat
TCET, MUMBAI
mukeshchoudhary464@gmail.com, chinmaydali395@gmail.com, jignesh.dhakad@gmail.com, bhagatsunny1998@gmail.com

Abstract— **Parkinson's disease (PD) is a progressive disorder that affects nerve cells in the brain responsible for body movement which accompanied by aberrant behavior in the patients .Other movement disorders include cerebral palsy, ataxia, and Tourette syndrome. Nerve cells, or neurons, are responsible for sending and receiving nerve impulses or messages between the body and the brain. It happens when the patient tries to move or stay still. The symptoms of Parkinson's disease develop gradually. They often start with a slight tremor in one hand and a feeling of stiffness in the body. The tremors first occur in the patient's hands which causes and of all the problems that come along the worst is when they try to eat . The aim of this project is to develop a supporting unit for the patients suffering from Parkinson's disease to help them create a system for stabilizing and leveling handles, designed to help people with hand tremor or limited hand and arm mobility thereby retaining dignity, aplomb, and self-subsistence during their eating process. A prototype of a "self-stabilizing spoon" was constructed to work under real circumstances and intended to be a complement for people who are in need of assistance during their eating process. To make this possible, a sensor with gyroscopes combined with accelerometers was used to identify which direction the device's handle was being tilted, as well as how fast its position was changed. Two servo motors were placed orthogonally to each other to establish a system that operates in 2D[two dimensions]. With this setup, the spoon was intended to maintain its spoon bowl in a horizontal position as they were intended to be.Thereby patient can easily eat their food. Experimental results of the spoon showed interesting results, performance with some unconventional limitations.**

I. INTRODUCTION

Parkinson's Disease is one of the most common neurological disorder and is defined as "a progressive disease of the nervous system marked by tremor (rapid and unintentional movements), muscular rigidity, and slow, imprecise movement, mostly impact middle-aged and elderly people. the world population, over 60 years old, lives with PD . It is a intensifying disorder that is caused by degeneration of nerve cells in the, which controls the movement.Over time, other symptoms develop, and some people will have dementia. Beginning periods of the ailment, the side effects are shaking, unbending nature,trouble with strolling and gradualness of development. The Demeanor and debating issues may likewise happen for this PD.The Parkinson's disease is analyzed by specialist by making inquiries about the indications and they will tests that show how well the patinas nerves are functioning. There are no labs or blood tests for the analysis, at times, specialist may have attempt a medication.The aim of this project is to produce a

stabilizing spoon that will compensate for unintended motions, such as tremors. With a low budget, the goal is to make a highly efficient prototype that consists mainly of a microcontroller and servo motors To make this possible, a sensor with gyroscopes combined with accelerometers was used to identify which direction the device's handle was being tilted, as well as how fast its position was changed. Two servo motors were placed orthogonally to each other to establish a system that operates in 2D[two dimensions].There are several different technological assisting spoons on the market today, but the products are unfortunately quite expensive [liftware.com, 2016]. With results from this project, further research could be able to continue developing cheaper and better stabilizing spoons.

II. PROBLEM DEFINITION

Design a self-adjusting spoon for patients having parkinson;s disease, so that during tremor they are able to eat food without spilling the food.Along with spoon there is a pulse rate sensor that records the pulse rate everytime the spoon is held.

III. BACKGROUND

Pharmacological therapy is an option to mitigate tremors but it has its own aftereffects. There are other prying technologies e existing like "Deep Brain Stimulation" is a process which is neurosurgical which utilizes microelectrodes to electronically stimulate definite areas of the brain. There are other existing technologies like gyroglove directly stabilise the hands of someone suffering from tremors. There are companies such as 'GYENNO' and 'Liftware' who are manufacturing "Smart Spoon" or "self-stabilizing spoon" which stabilizes 85% of tremors, although the majority of users are very happy, some find it difficult to use since their handles are very bulky and putting pressure might damage the product.

IV. IMPORTANCE

The requirement of the self-stabilizing spoon is because of the increase in the number of Parkinson's disease sufferers and as a result they have problem while doing daily activities. With the help of self-stabilizing spoon, the

problem of tremor can be solved up to a great extent. Importance of Self-stabilizing spoon are as follows:-In this project, we aim at designing a handle for the Parkinson patients to eat on their own.The spoon will be light and comfortable enough to be used by the patient.Support system for disabled people so that they won't worry about eating.The spoon is only an attachment to a stabilizing handle, so you have a selection of an everyday spoon, soup spoon and a fork attachment.

V. OBJECTIVES AND SCOPE

The objective of this project is to investigate how an Arduino microcontroller can be implemented to help people with impaired motor skills. Constructing a self-stabilizing spoon for Parkinson's sufferers. Every time when the spoon is used the patients pulse rate is also checked and can be seen anywhere. The spoon has the ability to move and rotate around x-axis and y-axis along with the spoon the pulse rate can be checked and displayed on thingspeak api. Using this spoon, it is helpful to a great extent to patients as well as the doctors.

VI. PHASES

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting strong knowledge of the project title and doing exploration on it, we will get our description. we will first study about it and do some research on the project for our better understanding and also getting a rough depiction about what would be our problem definition for this particular project.

Designing: Then we will build the design of the project and agreeing to that, will list down all the necessities needed for the creation for the prototype of our project. Implementation: After gaining the requirements, we first developed the connections of the hardware components (Arduino, MPU6050, Servo motor) and then added the coding part.

Phase 2: Testing and Deployment.

Testing: After the model is ready we will first associate the hardware with the allotted code and then we will check if it supports the machine or not. If not we will resolve the issues relating to it and will crisscross again.

Deployment: After completion of integration and testing of project, real time testing and operation of the system will be done.

VII. METHODOLOGY

Keeping all the data in the mind, regarding the architecture of the device the placement of our Arduino Uno and the connection of two consecutive servo motors along with each other is such that the horizontal shaft of one is connected with the other shaft causing the spoon to rotate. Both of them are connected to digital pins of Arduino Nano. MPU6050 sensor detect the tremor and roll angle of the vibration of the patient's hand. Simultaneously the pulse rate sensor will also count the pulse rate and display it on the Thingspeak api.

VIII. HARDWARE AND SOFTWARE REQUIREMENTS

Hardware

- 1 Arduino Uno
- 1 MPU6050 gyroscopic sensor
- 2 servo motor
- Nodemcu
- 1 pulse rate sensor

Software

- Arduino IDE
- Thingspeak api

IX. CIRCUIT DIAGRAM

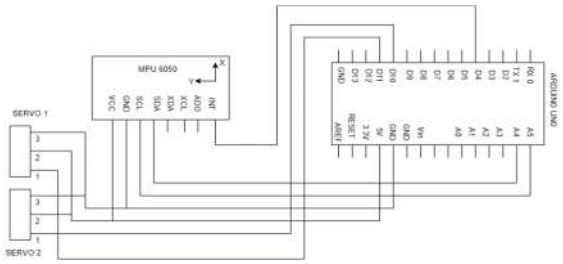

Fig. Circuit Diagram

This circuit diagram represents the connections of Arduino with Mpu6050 and servo motor. The pulse sensor is connected to nodeMCU so that it can send readings to thingspeak api over wifi.

X. OUTPUT

When we move or shake our hand ,the spoon rotates to opposite direction and stabilizes itself, parallelly pulse is checked

XI. RESULT

When activated the spoon is set to 180 degrees to hand level.on hand movement the servo motors adjust in horizontal as well as vertical direction.

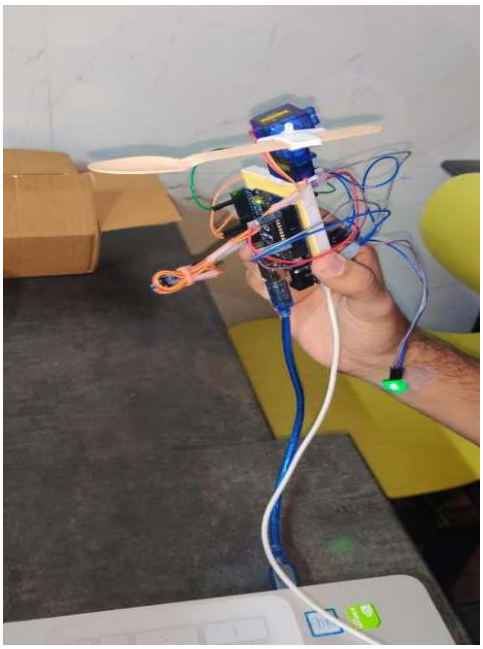

Fig. self-stabilizing spoon Kit

XII. OUTCOMES

Arduino Uno is connected to two servo motors for rotational movement, a MPU 6050 gyroscopic sensor to determine the pitch of the spoon and a spoon. After uploading the code on Arduino Uno, the servo motors adjust itself at a position of 90 degrees. When a movement of hand is encountered by the system, the gyroscopic sensor determines the direction and the angle of movement and sends the data to Arduino uno which in turn sends data to servo motor to react in the opposite direction to the reaction of hand. The spoon is adjusted in such a way that it always faces the upper direction irrespective of the movement. The pulse sensor which is attached to the hand and connected to the NodeMCU, senses the pulse rate and sends the data to the thingspeak api. The system is capable of Performing both tasks at same time.

XIII. RESEARCH GAPS

Every project has some gaps in it. No project is 100% efficient. There are some gaps:

Since our project uses two Arduino boards, one Arduino Uno and one Esp8266 Nodemcu, instead only one board can be used for both spoon and the pulse rate sensor. The code for Arduino can be optimized and high sensitivity and power servo motor can be used In order to React to the motion of hand.

XIV. CONCLUSION

We were able to stabilize the spoon in 3 dimensions. The main objective of the project is for Parkinson's disease which is one of the common neurodegenerative disorder. Due to this disorder the patient suffers from severe tremor related issue. When the person focuses on a particular body part he/she suffers severe tremor in that body part. Due to this the person is not able to hold things, eat properly and therefore suffers a lot of problem.To overcome this problem we designed an Self adjusting Parkinson's spoon for the Parkinson's sufferer while eating which help to control the tremor to a great extent. This device can be used as a rehabilitation or supportive device as it does not completely removes the tremors. Along with spoon the pulse sensor also checks the pulse rate and gives the results on Thingspeak api.

Smart Irrigation System

Vaibhav Tiwari, Saurabh Yadav, Shreya Patil

Thakur College of Engineering and Technology

Mumbai, India

vt65760@gmail.com, sy083844@gmail.com ,shreyapatil1815@gmail.com

Abstract—**Proposed system for Smart Irrigation System, automation of farm irrigation and soil moisture control by Arduino using soil moisture sensor and L293D module. This automatic irrigation system senses what the moisture content of the soil is and it automatically switches the pump on when the power is on. A proper usage of irrigation system is very necessary because there is a shortage of land reserved water due to lack of rain, and the spontaneous use of water, and as a result large amounts of water goes waste. This is exactly the reason why we use this automatic plant watering and soil moisture level detecting and monitoring system. This system is very useful in all climatic conditions. India is an agriculture based country. A vast majority of people in India are completely depended on the agricultural harvesting. Agriculture is a source of employment of a majority of Indians and has great impact on the economy of the country. In dry areas or in areas lacking rainfall, irrigation becomes difficult. So, it needs to be automated for proper watering of crops, to be done by remote handling by the farmer. When the soil goes dry or if the moisture content in the soil is less than that which is advised, the pump will start watering the crops.**

Keywords: Smart Irrigation, Sensors, Bluetooth communication, Android.

I.INTRODUCTION

The main aim of this proposed system was to provide water to the plants or gardening automatically using microcontroller (Arduino Uno). One can automatically water the plants, say, when said person are going out on vacation and there is no possible way to water the plants by physical presence, and we don't want to bother the neighbors. Sometimes the neighbors water the plants excessively and the plants end up dying anyway. There exist devices which are timer based in India which water the soil on set intervals. They fail to sense the soil moisture and the immediate surrounding temperature to recognize if the soil actually needs watering or not. Assimilation is that, the artificial application of water to the land or soil. It is used to support in the developing of agricultural crops, preservation of landscapes, and re vegetation of disturbed soils in dry areas and during periods of scarce rainfall. When a sector comes on, the water flows through the adjacent lines and finally ends up at the irrigation electrode (drip) or mechanical device heads. Several sprinklers have pipe thread creeks on the lowest of them that allows a fitting and also the pipe to be connected to them. The sprinklers are usually attached to the top of the head flush with respect to the ground surface. As this dripping method reduced not only huge water losses but it also became a popular method by reducing the labor cost and increasing the profits and harvests. When the components are activated, all the components will read and give the output signal to the controller, and the information will be displayed to the user (farmer).

II.SCOPE OF THE PROJECT

The Smart Irrigation System has an extensive scope to automate and industrialize the complete irrigation system. The proposed system aims and revolves around building an IoT based Irrigation System using Arduino UNO Module and DHT11 Sensor. It will not only automatically irrigate the water based on the moisture level in the soil but also send the data to Blynk App to keep track of the land condition. The System will consist a water pump which will be used to sprinkle water on the land depending upon the land environmental condition such as Moisture, Temperature, Humidity.

III.PROPOSED SYSTEM

An automatic plant watering system using Arduino microcontroller UNO R3 is programmed such that it gives the interrupt signals to the motor via the motor driver module. The soil sensor is connected and linked to the A0 pin of the Arduino board which senses and makes a note of the moisture content existing in the soil. Whenever the soil moisture content values goes down, the sensor senses the humidity change, giving signal to the microcontroller so that the pump (motor) can be activated. This theory can be used successfully for automatic plant watering system. The circuit includes an Arduino UNO board, a soil moisture sensor, a 5V motor pump, a Motor driver L293D (IC1), motor driver IC to run the water pump. One can control the Arduino board using a 5V-9V plug in adaptor or the best, solar panel. A separate 5V-9v battery for the pump motor is a must.

3.1 FLOWCHART

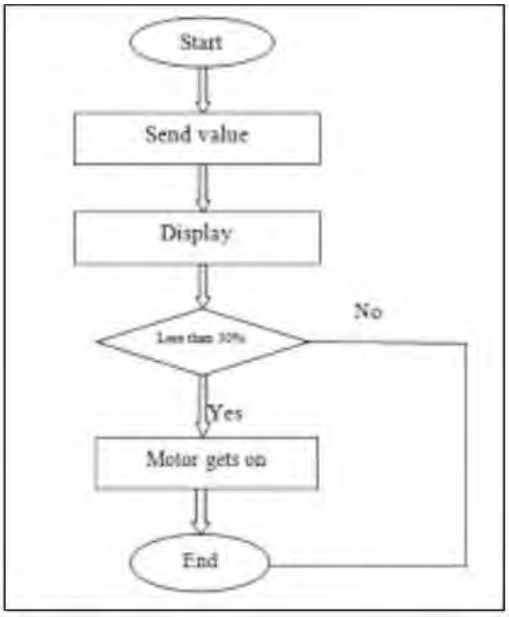

Fig: Flowchart for Smart Irrigation System

3.2 SYSTEM DESIGN

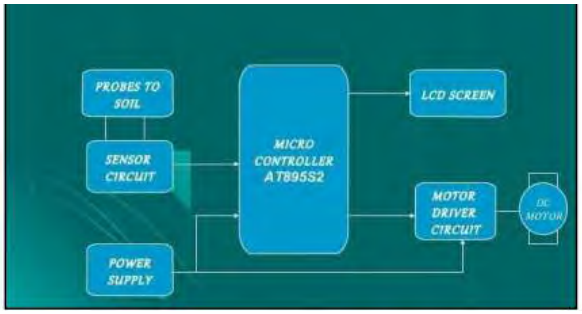

Fig: System Design Diagram for Smart Irrigation System

3.3 WORKING OF THE CIRCUIT

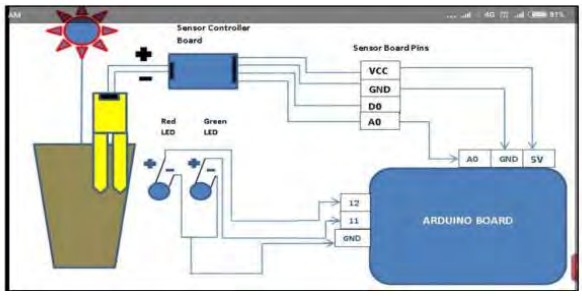

Fig: Working of the Circuit for Smart Irrigation System

IV.COMPONENTS AND DESCRIPTION

i.Arduino Uno –

The Arduino Uno R3 (also called ATmega328) is a dual-inlinepackage (DIP) microcontroller AVR microcontroller. Overall, it has 20 I/O digital pins. Arduino computer programs are easily loaded to full on the Arduino Uno R3.

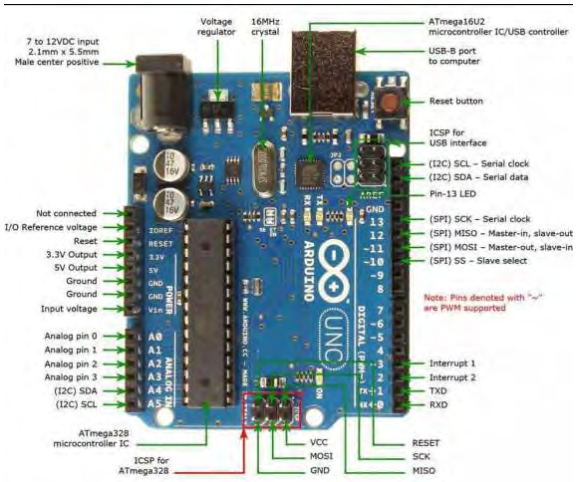

Fig: Arduino Uno

ii.Breadboard –

Initially it was literally a bread board, it was a polished piece of wood used for cutting and slicing bread. In the 1970s the solder less breadboard became available; nowadays the term "breadboard" is commonly used to refer to these.

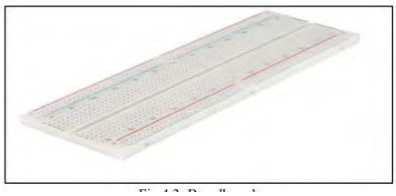

Fig: Breadboard

iii.Jumper Wires-

Jumper wires are merely wires that have connector pins at each end, which allows them to be used to connect two points to each other without the need of soldering. Jumper wires are naturally used with breadboards and other prototyping tools to make it easy to change a circuit as and when needed according to the requirement.

Fig: Jumper Wires

iv.Soil Moisture Sensor-

Soil moisture sensors guesses and gives a rough estimate of the soil water content based on the dielectric constant of the soil. The dielectric constant can be perceived as the soil's capability to transmit electricity. The dielectric constant value of soil rises as the water content level of the soil increases. This reaction is because the dielectric constant value of water is much superior than the other soil apparatuses, including air. Thus, measurement of the dielectric constant gives a probable approximation of

water content. It consists of a pair of electrodes to measure and note the resistance of the soil.

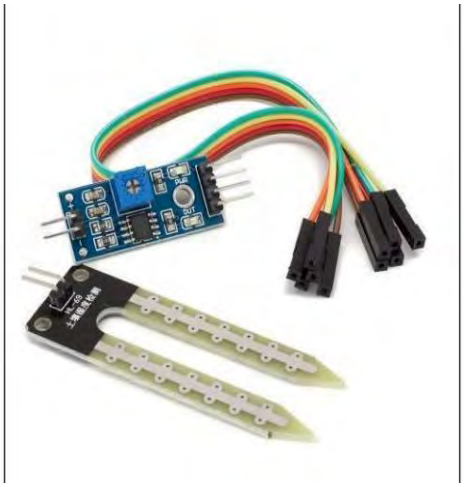

Fig: Soil Moisture Sensor

V.RESULTS AND DISCUSSIONS

a. Project Working:

Fig: Project working

The project working goes as: the soil moisture sensor, senses the moisture level that we have set on the Blynk App, and if the moisture content is less than the set moisture level, then the motor in the water pump will automatically start and start pumping out water through the pump, and it will continue to do so until the said moisture level is required. On the other hand, if the soil moisture sensor picks up a level which exceeds the set level, then the motor in the water pump will not start and there will be no pumping of water, thus not overwatering the plant, leading to its death.

b. Blynk App interfacing:

Fig: Blynk App Interfacing

On the Blynk App, a new project is created and the user can set the limits of the humidity, temperature and moisture. Through this app, it is also possible for the user to remotely water the plants with the mere click of a button and the user doesn't have to necessarily be physically present for watering the plant. Thus giving an ease and comfort.

VI.ANDROID MOBILE APPLICATION

Android is used to develop mobile application for automatic irrigation. Android's user interface is mainly based on direct manipulation using touch gestures that loosely correspond to real-world actions, such as swiping, tapping to manipulate on-screen objects, along with a virtual keyboard for text input. The data of the sensor and onset values are stored in the local memory of the mobile. The user can read and know the sensor data, and can regularize the system into an automatic mode so that the system can automatically switch on the motor depending on the sensor data value and previously set onset value. The user can also set the system to manual mode and he himself has the ability to decide the switching on and off of the motor. And he can get the notifications concerning the water level in tank so that he can take and make alternative decisions when there is shortage of water in tank.

VII.FUTURE SCOPE

The system can be interfaced with cloud, using Raspberry pi 3b or Bolt IoT. Further GSM module can be interfaced with it for SMS features. This worked quite perfectly but some parts of the secondary aim was left considering the fact of us being not expert in programming. The system built works only on one resistance (default) value measured by the sensor thus moistening the field always by the same amount for all the plants. Due to difficulties and complications arising in the programming, different resistance values cannot be set for diverse plants to provide altered level of moisture which can be the future development for the proposed system.

VIII. CONCLUSION

The main objective of this proposed smart irrigation system is to make it more innovative and ground-breaking, user friendly, comprehensible, tangible, time saving and more efficient than the existing systems available. Measuring four parameters such as soil moisture content and the system also includes intruder detecting system. Due to the updates given by the app, the farmer can recognize about crop field nature at any given time, anywhere. The application of agriculture networking technology is in need of the modern agricultural development, and this is the future of agricultural development. After building the agricultural water irrigation system hardware and analyzing and researching the network hierarchy features, functionality and the corresponding software architecture of precision agriculture water irrigation systems, actually applying the internet of things to the highly effective and safe agricultural production has a significant impact on ensuring the efficient use of water resources as well as ensuring the efficiency and stability of the agricultural production. With more advancement in the field of IoT expected in the coming years, these systems can be more efficient, much faster and less costly. In the Future, this system can be made as an intelligent system, where in the system predicts user actions, rainfall pattern, time of harvest, animal intruder in the field and collaborating the information through advanced and cutting-edge technology like IoMT can be implemented and employed, so that the whole agricultural system can be made self-regulating and independent of human operation and in turn quality and huge quantity yield of crops can be obtained.

Text – To – Speech Synthesis (TTS)

Advait Singh, Aditya Singh
TCET MUMBAI
singhadvait16@gmail.com, iamsinghaditya@gmail.com

Abstract – Speech is one of the oldest and most natural means of information exchange between human. Over the years, Attempts have been made to develop vocally interactive computers to realise voice/speech synthesis. Obviously such an interface would yield great benefits. In this case a computer can synthesize text and give out a speech. Text-To-Speech Synthesis is a Technology that provides a means of converting written text from a descriptive form to a spoken language that is easily understandable by the end user (Basically in English Language). It runs on JAVA platform, and the methodology used was Object Oriented Analysis and Development Methodology; while Expert System was incorporated for the internal operations of the program. This design will be geared towards providing a one- way communication interface whereby the computer communicates with the user by reading out textual document for the purpose of quick assimilation and reading development.

Keywords: *Communication, Expert System, FreeTTS, JAVA, Speech, Text-To-Speech*

I. INTRODUCTION

Voice/speech synthesis is a field of computer science that deals with designing computer systems that synthesize written text. It is a technology that allows a computer to convert a written text into
speech via a microphone or telephone. As an emerging technology, not all developers are familiar with speech technology. While the basic functions of both speech synthesis and speech recognition takes only minutes to understand, there are subtle and powerful capabilities provided by computerized speech that developers will want to understand and utilize.
Automatic speech synthesis is one of the fastest developing fields in the framework of speech science and engineering. As the new generation of computing technology, it comes as the next major innovation in
man-machine interaction, after functionality of Speech recognition (TTS), supporting Interactive Voice Response (IVR) systems.
The basic idea of text-to-speech (TTS)
technology is to convert written input to spoken output by generating synthetic speech. There are several ways of performing speech synthesis:
1.Simple voice recording and playing on demand;

2.Splitting of speech into 30-50 phonemes (basic linguistic units) and their re-assembly in a fluent speech pattern; The maximization of these two criteria is the main development goal in the TTS field.3.The use of approximately 400 diaphones (splitting of phrases at the centre of the phonemes and not at the transition).
The most important qualities of modern speech synthesis systems are its naturalness and intelligibility. By naturalness we mean how closely the synthesized speech resembles real human speech. Intelligibility, on the other hand, describes the ease with which the speech is understood. The maximization of these two criteria is the main development goal in the TTS field.

II. OBJECTIVES OF THE STUDY

The general objective of the project is to develop a Text-to-speech synthesizer for the physically impaired and the vocally disturbed individuals using English language. The specific objectives are:
1. To enable the deaf and dumb to communicate and contribute to the growth of an organization through synthesized voice.
2. To enable the blind and elderly people enjoy a User-friendly computer interface.
3. To create modern technology appreciation and awareness by computer operators.
4. To implement an isolated whole word speech synthesizer that is capable of converting text and responding with speech
5. To validate the automatic speech synthesizer developed during the study.

III. SCOPE OF THE STUDY

The study is focused on an ideal combination of a human-like behaviour with computer application to build a one-way interactive medium between the computer and the user. This application was customized using only one (1) word sentence consisting of the numeric digit 0 to 9 that could be used in operating a voice operated telephone system.
Human speech is inherently a multi modal process that involves the analysis of the uttered acoustic signal and includes higher level knowledge sources such as grammar semantics and pragmatics. This project intends to focus only on the acoustic signal processing without the incorporation of a visual input.

IV. SIGNIFICANCE OF THE STUDY

This project has theoretical, practical, and methodological significance:
The speech synthesizer will be very useful to any researcher who may wish to venture into the "Impact of using Computer speech program for brain enhancement and assimilation process in human beings".

This text-to-speech synthesizing system will enable the semi-illiterates assess and read through electronic documents, thus bridging the digital divide. The technology will also find applicability in systems such as banking, telecommunications (Automatic system voice output), transport, Internet portals, accessing PC, emailing, administrative and public services, cultural centres and many others. The system will be very useful to computer manufacturers and software developers as they will have a speech synthesis engine in their applications.

V. TEXT – TO - SPEECH SYNTHESIS DEFINED

A speech synthesis system is by definition a system, which produces synthetic speech. It is implicitly clear, that this involves some sort of input. What is not clear is the type of this input. If the input is plain text, which does not contain additional phonetic and/or phonological information the system may be called a text-to-speech (TTS) system. A schematic of the text-to-speech process is shown in the figure 1 below. As shown, the synthesis starts from text input. Nowadays this may be plain text or marked-up text e.g. HTML or something similar like JSML (Java Synthesis Mark-up Language).

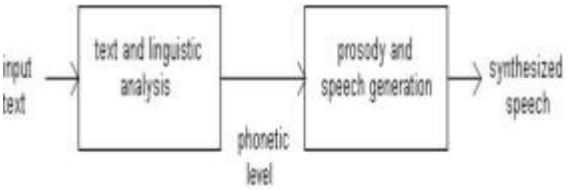

Figure 1: Schematic TTS

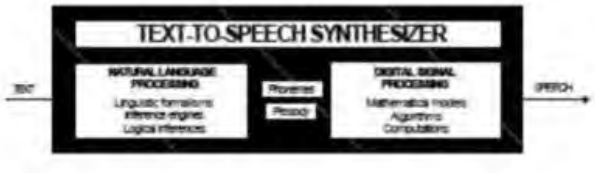

Figure 2: A general functional diagram of a TTS System.

5.1. Representation and Analysis of Speech Signals

Continuous speech is a set of complicated audio signals which makes producing them artificially difficult. Speech signals are usually considered as voiced or unvoiced, but in some cases they are something between these two. Voiced sounds consist of fundamental frequency (F0) and its harmonic components produced by vocal cords (vocal folds). The vocal tract modifies this excitation signal causing formant (pole) and sometimes anti-formant (zero) frequencies (Abedjieva et al., 1993). Each formant frequency has also amplitude and bandwidth and it may be sometimes difficult to define some of these parameters correctly. The fundamental frequency and formant frequencies are probably the most important concepts in speech synthesis and also in speech processing. With purely unvoiced sounds, there is no fundamental frequency in excitation signal and therefore no harmonic structure either and the excitation can be considered as white noise. The airflow is forced through a vocal tract constriction which can occur in several places between glottis and mouth. Some sounds are produced with complete stoppage of airflow followed by a sudden release, producing an impulsive turbulent
excitation often followed by a more protracted turbulent excitation (Allen et al., 1987). Unvoiced sounds are also usually more silent and less steady than voiced ones. Speech signals of the three vowels (/a/ /i/
/u/) are presented in time-frequency domain in Figure 3. The fundamental frequency is about 100 Hz in all cases and the formant frequencies F1, F2, and F3 with vowel /a/ are approximately 600 Hz,
1000 Hz, and 2500 Hz respectively. With vowel /i/ the first three formants are 200 Hz, 2300 Hz, and 3000 Hz, and with /u/ 300 Hz, 600 Hz, and 2300 Hz.

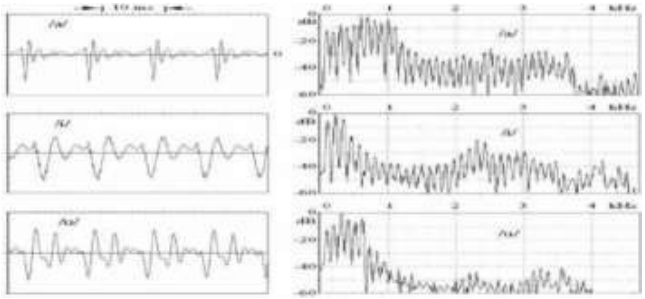

Figure 3: The time-frequency domain presentation of vowels /a/, /i/, and /u/.

VI. APPLICATIONS OF SPEECH SYNTHESIS

The application of synthetic speech is expanding fast whilst the quality of TTS systems is also increasing steadily. Speech synthesis systems are also becoming more affordable for common customers, making these systems suitable for everyday use. For example, better availability of TTS systems may increase employability for people with communication difficulties. Listed below are some of the applications of TTS system:

1. Applications for the Blind.
2. 2. Applications for the Deafened and Vocally Handicapped
3. Educational Applications.
4. 4. Applications for Telecommunications and Multimedia

5. Other Applications and Future Directions (e.g. Human-Machine Interaction)

VII. METHODOLOGY AND SYSTEM ANALYSIS

7.1 Analysis and Problems of Existing Systems

Existing systems algorithm is shown
below in Figure 4. It shows that the system does not have an avenue to annotate text
to the specification of the user rather it
speaks plaintext.
STOP

Figure 4: Algorithm of already existing systems

Due studies revealed the following inadequacies with already existing systems:
1. ***Structure analysis***: punctuation and formatting do not indicate where paragraphs and other structures start and end. For example, the final period in "P.D.P." might be misinterpreted as the end of a sentence.
2. ***Text pre-processing***: The system only produces the text that is fed into it without any pre-processing operation occurring.
3. ***Text-to-phoneme conversion***: existing
synthesizer system can pronounce tens of thousands or even hundreds of thousands of words correctly if the word(s) is/are not found in the data dictionary.

7.2 Expectation of the New System

It is expected that the new system will reduce and improve on the problems encountered in the old system. The system is expected to among other things do the following;
1. The new system has a reasoning process. 2. The new system can do text structuring and annotation.
3. The new system's speech rate can be
adjusted. 4. The Pitch of the voice can be adjusted.
5. You can select between different voices and can even combine or juxtapose them if you want to create a dialogue between them
6. It has a user friendly interface so that people
with less computer knowledge can easily use it
7. It must be compatible with all the vocal
engines 8. It complies with SSML
specification.

VIII. CHOICE OF METHODOLOGY FOR THE NEW SYSTEM

Two methodologies were chosen for the new system: The first methodology is Object Oriented Analysis and Development Methodology (OOADM). OOADM was selected because the system has to be represented to the user in a manner that is user-friendly and understandable by the user. Also since the project is to emulate human behaviour, Expert system had to be used for mapping of Knowledge into a Knowledge base with a reasoning procedure. Expert system was used in the internal operations of the program, following the algorithm of Rule-Based computation. The technique is derived from general principles described by researchers in knowledge engineering techniques (Murray et al., 1991; 1996).
The system is based on processes modelled in cognitive phonetics (Hallahan, 1996; Fagyal, 2001) which accesses several knowledge bases (e.g. Linguistic and phonetic knowledge bases, Knowledge bases about non-linguistic features, a predictive model of perceptual processes, and knowledge base about the environment).

9. Speech Synthesis Module

The TTS system converts an arbitrary ASCII text to speech. The first step involves extracting the phonetic components of the message, and we obtain a string of symbols representing sound- units (phonemes or allophones), boundaries between words, phrases and sentences along with a set of prosody markers (indicating the speed, the intonation etc.). The second step consists of finding the match between the sequence of symbols and appropriate items stored in the phonetic inventory and binding them together to form the acoustic signal for the voice output device.

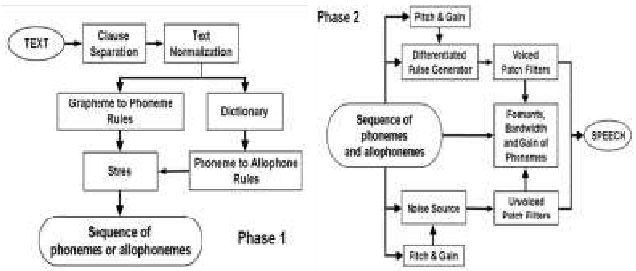

Figure 5: Phases of TTS synthesis process

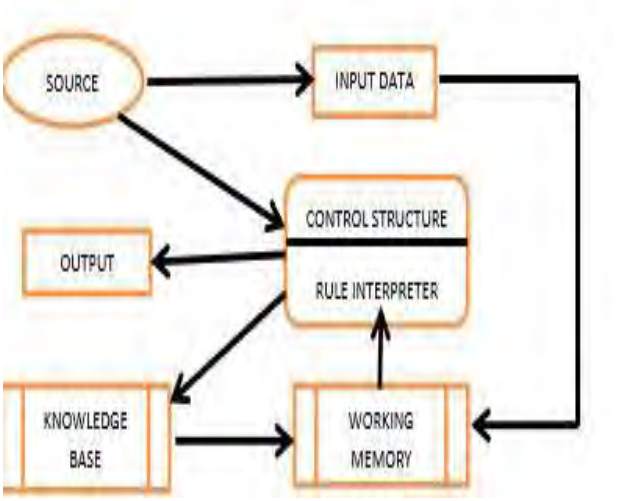
To compute the output, the system consults
1. A database containing the parameter values for the sounds within the word,
2. A knowledge base enumerating the options for synthesizing the sounds.

Incorporating Expert system in the internal programs will enable the new TTS system exhibit these features:
1. The system performs at a level generally recognized as equivalent to that of a human expert
2. The system is highly domain specific.
3. The system can explain its reasoning process
4. If the information with which it is working is probabilistic or
fuzzy, the system can correctly propagate uncertainties and provide a range of alternative solution with associated



likelihood.

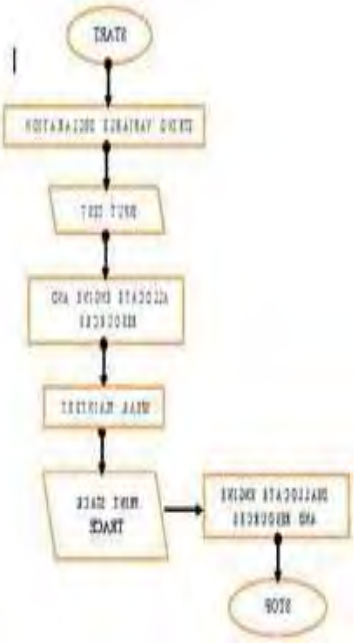


Figure 6: Data flow diagram of the Speech synthesis system Using Gane and Sarson Symbol

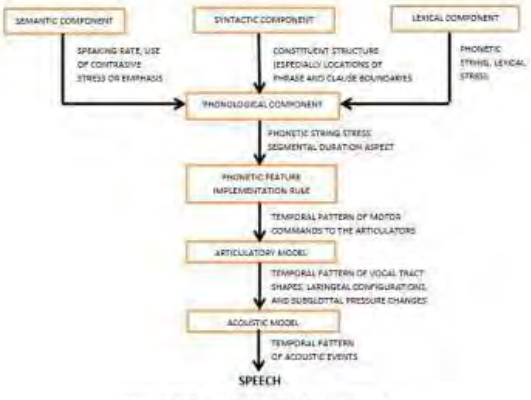

Figure 7: High Level Model of the Proposed System

User Interface (Source): This can be Graphical User Interface (GUI), or the Command Line Interface (CLI).

Knowledge Base (Rule set): FreeTTS module/system/engine. This source of the knowledge includes domain specific facts
and heuristics useful for solving problems in the domain. FreeTTS is an open source speech synthesis system written entirely in the Java programming language. It is
based upon Flite. FreeTTS is an implementation of Sun's Java Speech API.
FreeTTS supports end-of-speech markers. **Control Structures**: This rule interpreter inference engine applies to the knowledge base information for solving the problem. **Short term memory**: The working memory registers the current problem status and history of solution to date.

8.1 Choice of Speech Engine and Programming Language

The speech engine used in this new system was the FreeTTS speech engine. FreeTTS was used because it is programmed using JAVA (the backbone programming language of this designed TTS system). It also supports SAPI (Speech Application Programming Interface) which is in synchronism with the JSAPI (Java Speech Application Programming Interface). JSAPI was also the standardized interface used in the new system.
FreeTTS includes an engine for the vocal synthesis that supports a certain number of voices (male and female) at different frequencies. It is recommended to use JSAPI to interface with FreeTTS because JSAPI interface provides the best methods of controlling and using FreeTTS. FreeTTS engine enable full control about the speech signal. This new designed system provides the possibility to choose a voice between three types of voices: an 8 kHz, diphone male English voice named *kevin*, a 16 kHz diphone male English voice named *kevin16* and a16khz limited domain, male US English voice named *alan*. The user could also set the properties of a chosen voice: the speaking rate, the volume and the pitch.

A determining factor in the choice of programming language is the special connotation (JSML) given to the program. This is a java specification mark-up language used to annotate spoken output
to the preferred construct of the user. In
addition to this, there is the need for a language that supports third party development of program libraries for use
in a particular situation that is not amongst the specification of the original platform. Considering these factors, the best choice of programming language was **JAVA.** Other factors that made JAVA suitable were its dual nature (i.e. implementing 2 methodologies with one language), its ability to Implements proper data hiding technique (Encapsulation), its supports for inner abstract class or object development, and its ability to provide the capability of polymorphism; which is a key property of the program in question.

IX. DESIGN OF THE NEW SYSTEM

Some of the technologies involved in the design of this system includes the following:

Speech Application Programming Interface (SAPI): SAPI is an interface between applications and speech technology engines, both text-to-speech and speech recognition (Amundsen 1996). The interface allows multiple applications to share the available speech resources on a computer without having to program the speech engine itself. SAPI consists of three interfaces; The *voice text* interface which provides methods to start, pause, resume, fast forward, rewind, and stop the TTS engine during speech. The *attribute interface* allows access to control the basic behaviour of the TTS engine. Finally, the *dialog interface* can be used to set and retrieve information regarding the TTS engine. **Java Speech API (JSAPI):** The Java Speech API defines a standard, easy-to-use, cross-platform software interface to state-of-the-art speech technology. Two core speech technologies supported through the Java Speech API are speech recognition and speech synthesis.

Speech recognition provides computers with the ability to listen to spoken language and to determine what has been said. Speech synthesis provides the reverse process of producing synthetic speech from text generated by an application, an applet or a user. It is often referred to as text-to-speech technology.

9.1 Design of Individual Objects of the Program

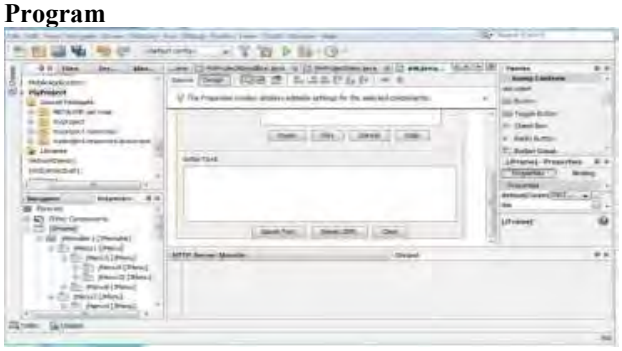

Figure 9: Netbeans Interface and program object manipulation

Figure 11: Overall view of the new system

9.2 Functions of the Abstract Classes

1. Menu Bar: This will have the function of selecting through many variables and File chooser system.
2. Monitor: Monitors the reasoning process by specifying the allocation process and de-allocation state
3. Voice System: This shows the different voice option provided by the system
4. Playable session: This maintains the timing of the speech being given out as output, and produces a speech in synchronism with the rate specified.
5. Playable type: This specifies the type of text to be spoken, whether it is a text file or an annotated JSML file
6. Text-to-Speech activator: This plays the given text and produces an output
7. Player Model: This is a model of all the functioning parts and knowledge base representation in the program
8. Player Panel: This shows the panel and content pane of the basic objects in the program, and specifies where each object is placed in the system
9. Synthesizer Loader: This loads the Synthesizer engine, allocating and de- allocating resources appropriately

X. CONCLUSION AND RECOMMENDATION

Synthesizing text is a high technology advancement and artificial formation of speech given a text to be spoken. With Text-to- Speech synthesis, we can actually mediate and fill in the lacuna provided by not fully exploiting the capabilities of some handicapped individuals. It's never been so easy to use a text-to-speech program, as just one click and your computer will speak any text aloud in a clear, natural sounding voice. Therefore, there is need to use Information Technology to solve the problem for the Before the use of the new system, proper training should be given to the users. This training can come in handy with proper tutor on how to handle JSML language and how to use it to annotate text for the proper output and emphasis.

9.2 Functions of the Abstract Classes

11. Menu Bar: This will have the function of selecting through many variables and File chooser system.
12. Monitor: Monitors the reasoning process by specifying the allocation process and de-allocation state
13. Voice System: This shows the different voice option provided by the system
14. Playable session: This maintains the timing of the speech being given out as output, and produces a speech in synchronism with the rate specified.

15. Playable type: This specifies the
type of text to be spoken, whether it is a text file or an annotated JSML file
16. Text-to-Speech activator: This plays the given text and produces an
output
17. Player Model: This is a model of all the functioning parts and knowledge
base representation in the program
18. Player Panel: This shows the panel and content pane of the basic objects in the program, and specifies where each object is placed in the system
19. Synthesizer Loader: This loads the Synthesizer engine, allocating and de- allocating resources appropriately

Arduino Based Real Time Air Quality Monitoring System

Priyanka Sharma, Riddhi Thanki, Saloni Singh
TE. Information Technology Thakur College of Engineering and Technology Mumbai, India
sharmapriyanka3585@gmail.com, iamriddhithanki@gmail.com, thakursaloni1999@gmail.com

Abstract— **Universal object interaction conceptualizes the idea of remotely connecting and monitoring real world objects (things) through the Internet. The air quality has become major issue from last decade due to the increase of pollutants in the atmosphere. Urbanization has boosted the number of air pollutants in numerous territories. This is damaging human health to a great extent. Thus, we developed an Arduino based system to measure the quality of air in the environment. The system uses MQ135 sensor to displays the real time data of the quality of air on LCD and Blynk mobile application using internet.**

Keywords— Air quality, MQ135 Sensor, Arduino, PPM.

I. INTRODUCTION

Air plays an important role in the ecosystem. Due to increase in the count of industries, vehicle, etc. various harmful gases are emitted in the atmosphere at large. The wellspring of air toxins can be regular or anthropogenic. Gases like Nitrogen Dioxide, Sulphur Dioxide, Carbon Dioxide, Carbon Monoxide and Ozone are the main cause of air pollution. These gases have harsh impact on human health. Air pollution causes various respiratory disorder, minor allergies, cerebral pain, aggravated asthma, eye and nose irritation and many more diseases. As indicated by WHO consistently 9 out of 10 individuals inhale air containing significant level contaminations.[1] Long time presentation to surrounding air results into passing. In view of study 4.2 million individuals bite the dust each year because of introduction to encompassing air contamination. Polluted air not only harms human but crops and animals too. The quality of crops degrades due to harmful gases present in the environment. It has become fundamental need to screen the nature of air in encompassing. Observing of air contamination utilizing conventional strategies is very costly and tedious work. Sensor innovation has risen as a financially savvy, simple and quick technique for checking surrounding air quality. Arduino based air quality observing framework measures the nature of air utilizing Arduino and showcases it as PPM on LCD screen just as on Blynk mobile application through web availability. The ringer goes off if the air quality drops down from indicated PPM esteem. For estimating air quality, we utilized MQ135 sensor as it distinguishes the

majority of the destructive gases and can gauge their sum precisely. Cell phones are most regularly utilized gadget, applications on versatile are anything but difficult to utilize contrasted with web server. Subsequently constant update of nature of air can be observed whenever anyplace. This framework can for the most part be introduced in businesses and houses where destructive gases can be found and can give alert at whatever point as far as possible is crossed.

II. LITERATURE REVIEW

The disadvantages of the traditional system are their huge size, enormous weight and unprecedented cost. These lead to scanty organization of the checking stations.[6] So as to be powerful, the areas of the checking stations need cautious arrangement on the grounds that the air contamination circumstance in urban territories is profoundly identified with human exercises (for example development exercises) and area subordinate (e.g., the traffic stifle focuses have a lot of more awful air quality than normal).Due to this awkward foundation it was hard to control the air contamination or measure the nature of air. Arduino Based Air Pollution Monitoring System screens the Air Quality over a portable application using web and will trigger an alert when the air quality goes down past a particular level, infers when there are total of dangerous gases present perceptible all around like NH3, smoke, benzene, NOx, CO2. The system will show the air quality in PPM on the LCD and on the application which makes it simpler to utilize.
MQ135 sensor is utilized for observing Air Quality as it identifies most unsafe gases and can quantify their sum precisely. Right now, it can screen the contamination level from anyplace utilizing your Cell phones or portable. This framework can be introduced anyplace and can additionally trigger some gadget when contamination goes past some level, buzzer will make individuals aware when air quality gets perilous.

III. PROBLEM DEFINITION

Air contamination is the nearness of contaminants noticeable all around that meddle with human wellbeing andproduce other hurtful condition effects. Due to medical problems brought about via air toxins there is a genuine spotlight on air contamination checking exercises. Clean air is fundamental requirement for each individual. [4] Dirtied air causes numerous medical issues and a few harms. In this way to make any progression in front of controlling the contamination rate it is important to screen the air quality which may assist us with making a correct choice at perfect time. There are different reasons for expanding the contamination, for example, smoke vehicle exhaust, concoction release from ventures, radioactive substance etc. These are principle reason of diminishing the nature of air. The cardinal gases which truly impact the human prosperity are carbon monoxide (CO), hydrogen sulfide, sulfur dioxide (SO2), Nitrogen dioxide (NO2) and the standard duty of these gases are traffic related sullying release.

Tremendous endeavors are required to improve the nature of air in both outside and indoor condition. Observing of condition has been controlled from manual to the programmed control bit by bit. There is different improvement in the instrument of condition checking yet at the same time can't meet the unforgiving condition.

IV. PROPOSED WORK

All the hardware components are connected to each other with the help of jumper wires.[2] Arduino Uno is a microcontroller board dependent on ATmega328P. Arduino is simply connected to the computer via USB cable. Here computer can act as power source or an external power supply is given to the board. As soon as the power supply is provided to the system MQ135 gas sensor collects the data of gases present in the surrounding.MQ135 sensor is able to sense gases like ammonia, oxides of nitrogen, alcohol, benzene, smoke, carbon dioxide. This data from sensor is transferred to Arduino Uno in the form of voltage Level. Further these voltage levels are converted into PPM (parts per million) using a library for MQ135 gas sensor. The safe air quality level is 350 PPM and it should not exceed the limit of 1000PPM. If the value exceeds 1000 PPM it will result into various health issues such as heavy breathing, headaches, sleepiness, etc. When the sensor senses the value above 1000PPM the buzzer will be triggered. LCD screen will continuously display the quality of air in PPM as well as based on the value it will also display message-“Fresh air” if less than 1000PPM,”Bad air” if more than 1000PPM and “Danger” if more than 2000PPM.Parallely using Blynk mobile application the readings of air quality as well as message will be displayed on the respective mobile phone via internet. Here MQ135 sensor gives input to board, LCD and mobile application shows the output of the reading in PPM and buzzer will make people aware when air quality becomes dangerous. The way toward transferring yield on LCD or versatile application is finished with the assistance of Node MCU. It offers access to Wi-Fi or web. It can communicate with any microcontroller and it is the most driving gadgets in the IOT stage. Prior to starting the coding for this venture, we have to initially Calibrate the MQ135 Gas sensor. Here we are utilizing the Library for MQ135. Before this we have to adjust the MQ135 sensor, for aligning the sensor transfer the calibration code and let it run for 12 to 24 hours and afterward get the RZERO value While transferring the ensure that you

are associated with the Wi-Fi of your Node MCU gadget and the it will show yield on application.

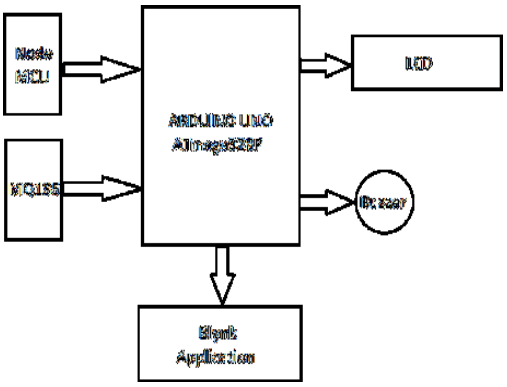

Figure 1. Block Diagram

V. METHODOLOGY

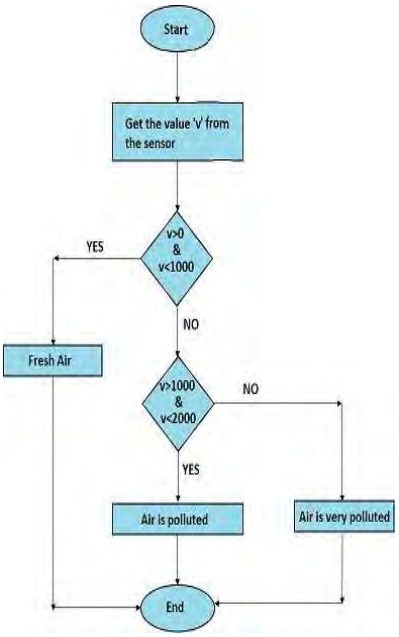

Figure 2. Flowchart

VI. RESULT & DISCUSSION

Arduino based air quality monitoring detector gadget design involves hardware and connection and eventually the collection of information from the detector via code for the Ardunio. To obtain actual time air pollution records (in PPM), we have taken reading using our customized sensor-detector in different environmental pollutions. We have used coil burning smoke, automobile smoke from street etc. The following values depicts for mosquito coil within 1 meter.

TABLE I. MOSQUITO COIL SMOKE DATA ANALYSIS

Time(second)	Value(PPM)	Distance (meter)
2	70(Fresh Air)	0.7
4	110(Polluted Air)	0.4
6	95(Fresh Air)	0.5

8	98(Fresh Air)	0.5
10	125(Polluted Air)	0.3
12	170(Polluted Air)	0.2
14	150(Polluted Air)	0.2
16	165(Polluted Air)	0.2
18	188(Polluted Air)	0.15
20	201(Very Polluted Air)	0.1

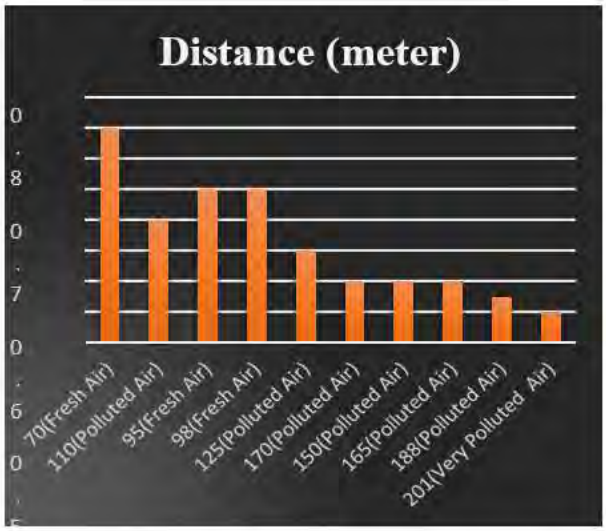

Figure 3. Graphical representation of data from coil smoke

From this facts analysis we can finish that for mosquito coil its miles safe to be a ways from the coil while burning at least 2 or three meters.

TABLE II. VEHICLE SMOKE DATA ANALYSIS

Time(second)	Value(PPM)	Distance (meter)
2	180(Polluted Air)	3.5
4	250 (Polluted Air)	2.5
6	270(Very Polluted Air)	2.3
8	245(Very Polluted Air)	2.6
10	260(Very Polluted Air)	2.4
12	200(Polluted Air)	3
14	290(Very Polluted Air)	2
16	230(Very Polluted Air)	2.7
18	199(Polluted Air)	3
20	215(Very Polluted Air)	2.8

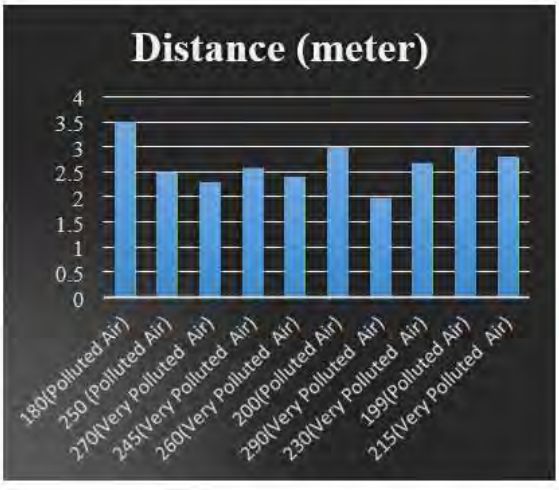

Figure 4. Graphical representation of data from vehicle smoke

From this facts analysis we can finish that for vehicle smoke its miles safe to be a ways from the smoke at least 4 or 5 meters.

VII. CONCLUSION

This task "Arduino based air quality checking framework" is skilled to identify the air quality given in a situation. It tracks the air quality and shows the given outcome as ppm and displays it on the LCD screen. In light of its presentation in the earth it tends to be said that it is anything but difficult to utilize and more affordable than the current systems. It is easy to understand just as effective to utilize. The framework can assists with making familiarity with the nature of air that one relaxes.

VIII. ACKNOWLEDGEMENT

We sincerely thank our guide Mr. Bhushan Nemade for his guidance and constant support and also for the stick to our backs. We likewise thank the undertaking organizers for masterminding the vital offices to complete the venture work. We thank the HOD, Dr. Rajesh Bansode, the Principal, Dr.B.
K. Mishra, and the school the executives for their help.

Smart Water Level Monitoring and Quality Monitoring System

Hemant Yadav, Jaikishan Yadav, Alok Yadav

Department of Information Technology Thakur College of Engineering & Technology, Mumbai, India
yhemant110@gmail.com, jaikiy15@gmail.com, yadavalok929@gmail.com

Abstract— **Internet of Thing from the past few years is emerging bent on be popular technology and it now features a huge demand in market thanks to its easy and easy integration with different technologies. Water may be a scarce resource and it should deplete over coming years thanks to overuse. The bad quality, overflowing water from tanks, leakage in pipes, and inefficient usage of water are the most cause which results in the wastage of water. So it's necessary have control on water wastage and usage furthermore by introducing or building a system which can overcome the water wastage related issues using Internet of Things (IOT) [6]. one amongst the main problems faced by most of the countries is that the issue of water scarcity within the world and wastage during transmission has been identified as a serious culprit; this is often one amongst the motivations for this research, to deploy computing techniques in creating a barrier to wastage so as to not only provide more financial gains and help the environment furthermore because the water cycle which successively ensures that we save water for our future. IOT based Water Level Monitoring system is an innovative system which can inform the users about the amount of liquid and can prevent it from overflowing. To demonstrate this the system makes use of containers, where the ultrasonic sensors placed over the containers to detect the liquid level and compare it with the container's depth. The system makes use of Arduino, GSM Module for sending data about the amount and quality to mobile phone and a buzzer. the ability supply is given through power jack in GSM and External battery in Arduino [1]. The liquid level is highlighted as distance from the underside in cms to point out the amount of liquid present within the container with the assistance of a SMS to the user. The buzzer starts ringing when the set limit of the liquid is crossed. Thus this method helps to forestall the wastage of water by informing about the liquid levels of the containers.Keywords – IOT, GSM, Arduino**

Introduction:

Water is one in all the natural resources that's most significant to our survival as humans, it's used for various purposes reception like for drinking, washing and bathing, in Agriculture it's used for irrigation, within the field of engineering it's employed in hydro power plants and atomic energy plants for power generation, it's also employed in the industries for various manufacturing needs. Its vast usage to our day to day activities highlights the necessity for correct management this natural resources. The common method of water level control for many homes is just to begin the feed pump at a coffee level and permit it to run until the next water level is reached within the cistern. This can be not properly supported for adequate system. Usually, this type of system provides visual multi-level also as continuous level indicator.

SMS notification at desired level and about the standard value supported user's requirements is included during this management system. Most of the buildings nowadays have overhead tank for water storage. Unfortunately, most users find it tedious and difficult to grasp the extent of water in their water tanks thanks to energy and time required to climb an overhead tank and therefore the absence of water level indicator. Thanks to this, there's wastage of huge volume of water. The answer to those problems is catered in our project, designing an automatic water level monitoring .This device includes a sensor which sense the extent of water within the cistern.

Problem Definition:

To design a microcontroller (IOT) based Water Level Monitoring that will continuously indicate the level of the water and automatically switch ON/OFF based on the threshold levels. The system should also measure the value of different quality parameter. Notification should be send through SMS about the water level and quality values and gives alert when water level reaches to threshold values.

Proposed System:

The proposed system is mainly developed to be implemented where water tanks are more commonly used such as Housing societies, Hotels, etc.

In this system, an application is developed which is used to indicate water level in the tank. The water levels are labeled as Low, Moderate and Full and gives Popup about the water level periodically [4]. The system also 87 sends notification about the quality of water through cell phone [3]. The Application also consist of controls through which the motor can be switched ON/OFF. The system provides the user with the feature to analyze the usage of water on monthly, weekly or daily basis from a website.

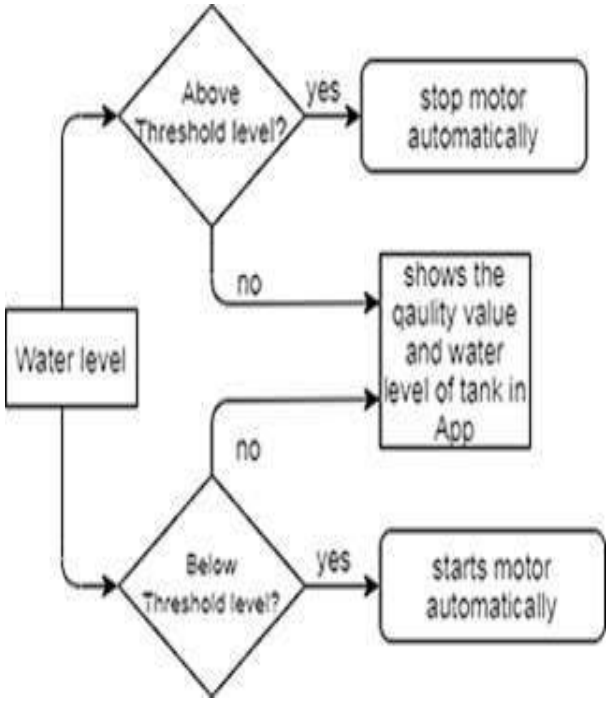

Fig 1: Flow diagram of working of system

Features :

→ **Water Maximization**: A water level controller can maximize the water usage and results in an appropriate level of water at all times being maintained.

→ **Live Notification**: User or the organization will get the live notification about the level of water and it's quality through SMS and also an indicator will be there indicating it's level through LED**.**

→ **Easy to Install:** Installation of all the systems are easy and the connection between them is quite simple for anyone.

Methodology

In this system we are going to check the water quality in the tank along with the water level. Water quality is also equally important. Due to some of the reasons water in the tank will be contaminated. For example dry leaves and dust. In the present system we initially connect the ultrasonic sensor to the core controller and place it on the top of the tank. pH sensor determines the amount of alkalinity present in the water pH range should always be between 0-14 for any liquid .The turbidity indicates the degree at which water loses its transparency. Relay and the water pump is used for pumping the water into the tank and it will stop automatically when tank is full. All the values of sensor and the level of water will be notified through SMS and for that we will use GSM Module. So there will be real time notification of the data to the user or organization. In this system we can control the flow of water in the tank using an application and also system can automatically switch off the flow of water only if tank is full. Hence by this system we can control the flow of water in tank manually as well as automatically [5]. User can monitor usage of water on daily, weekly, or monthly basis as the data is frequently uploaded at ThingSpeak which provides a platform to analyzing the data, visualize the data, etc. [2]

Feasibility study:

→**Technical Feasibility**: Here one has to test, whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the solution is technically feasible.

→**Economic Feasibility**: As part of this, the costs and benefits associated with the proposed system compared and the project is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So the proposed system is economically feasible.

→**Operational Feasibility**: It is a standard that ensures interoperability without stifling competition and innovation among users, to the benefit of the public both in terms of cost and service quality. The proposed system is acceptable to users. So the proposed system is operationally feasible.

Understanding:

In this after understanding the topic the project feasibility was analyzed by performing different types of feasibility studies and by also planning the project tools, their project schedule, timeline charts, etc. Feasibility study will help in better understanding the various feasibilities associated with the project and helping to make the correct decisions and completing the project within the schedule, budget, etc.

The tools were specifically identified stating which technology can be feasible and how conveniently the project can be completed. This helps to understand the technology and tools that can be used for the project.

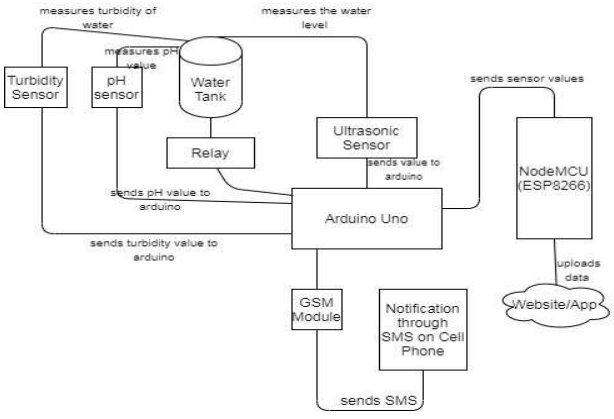

Fig 2: Block Diagram of System

Future Scope:

As the world's water resources become increasingly stressed, effective systems for management become more important. Several water monitor systems are available but most of them are either expensive or requires man power. Since wired technology is used in our proposed system there is scope to further modify it by using wireless RF technology. Thus, the communication between the controller and the driving element can be established wirelessly. Improvements can be made with minor changes in this model by eliminating the operator and providing the complete control to microcontroller (automatic level control). It can be used for level monitoring and control in industries. The system can also be extended to efficient functioning of dams. Therefore, a major future work can be possible in which a centralized control of all the dams in a state using GPRS or other wireless technology under central government can be beneficial to the whole country. On a local level, the control of all the water storage tanks in a society using wireless technology under a trusted authority can be beneficial as well.

I. CONCLUSION

The project is based on a single water level monitoring system with different levels indicated. The proposed mechanism of water control reduces the water wastage, ensures efficient use of available water resources and generates more precise and accurate results. There is no requirement of human laborer for monitoring the level, because the system manages the water level automatically. Also, operation execution time is less. Because of its cost efficiency this system can be installed in various rural areas where the water problems are on a rise. We have also included the GSM based system where the notification is send through SMS to the user. Also we have included the pH value and turbidity for the water quality analysis which helps us to improve the better understanding of the comparative efficiency of major drinking water disinfection practices against the currently most important resistant viruses.

IOT based Intruder Alert System using Raspberry Pi, Pi camera and PIR sensor

Mr. Nikhil Valmiki, Mr. Shivam Tiwari, Mr. Amit Singh
Information Technology Thakur College of Engineering & Technology Mumbai
nikhilval1999@gmail.com, tiwarisomprakash.2000@gmail.com, singhamitrocks1999@gmail.com

Abstract— **In the realm of Internet Of Things (IOT) when we have all the innovations to alter our life, it's a good thought to build up a framework which can be controlled and observed from anyplace. There are numerous sorts of good security frameworks and cameras out there for home security yet they are a lot of costly so we will construct a minimal effort basic Raspberry Pi based Intruder Alert System, which alert you through an email as well as sends the image of Intruder when it recognizes any. This framework distinguishes the nearness of Intruder and rapidly alarms the house proprietor by sending an email alert. This mail will likewise contain the image of Intruder caught by Pi camera. This framework can be introduced at the fundamental entryway of office or home and can be checked from anyplace on the planet utilizing email over the web.**

Keywords – IOT, Raspberry pi, Pir sensors,security

I. INTRODUCTION

Remote security is the prevention of unauthorized access. The point of this task is to explore a practical arrangement that will give controlling of home apparatuses remotely and will likewise empower home protection from interruption without mortgage holder. The framework utilizes most recent remote correspondence like Bluetooth, Infrared and Wi-Fi access to the framework for security and mechanized machine control. Home security is viewed as a significant issue where wrongdoing is expanding and everyone needs to take appropriate measures to forestall interruption. SMS notice at wanted level and about the quality worth dependent on client's necessities can be remembered for this administration framework.

II. PROBLEM DEFINITION

- Getting Raspberry pi ready with its fundamental setup
- Getting pi-camera and Pir sensors ready
- Gathering the logic for the project
- Testing with data gathering and execution
- E-mail notification
- E-mail investigation with respect to proper alert and accuracy
    - Final deployment of the system

Every one of the previously mentioned themes has its own intricacy The configuration of the point is as per the following. It begins with the learning destinations, subject review, recommended readings and exercises that might be a few hands-on ventures followed by a speedy test to test the understanding, conversation themes for in the class and for email and afterward some valuable web joins giving most recent references identified with the point. All points follow a comparable example.

III. HARDWARE USED

The Raspberry Pi is a mini computer by the Raspberry Pi Foundation to advance the educating of essential software engineering in schools and in creating nations. The first model became unquestionably more well known than foreseen, selling outside its objective market for utilizations, for example, mechanical technology. It does exclude peripherals, (for example, consoles, mice and cases). In any case, a few adornments have been remembered for a few official and informal packs.

Infrared radiation is electromagnetic radiation (EMR) with longer wavelengths than those of observable light, and is thusly vague to the human eye. It is now and again called infrared light. The next task right now is to detached (PIR sensor) which is an electronic sensor that uses infrared (IR) light exuding from objects in its field of view. They are routinely used in PIR-based development discoverers. All articles with a temperature above preeminent zero exude heat essentialness as radiation. Commonly, this radiation is impalpable to the human eye since it transmits at infrared wavelengths, yet it might be distinguished by electronic devices proposed for such an explanation. The term uninvolved right now to the manner in which that PIR contraptions don't make or radiate any essentialness for area purposes. They work totally by recognizing the essentialness transmitted by various articles. PIR sensors don't perceive or measure "heat"; rather, they recognize the infrared radiation released or reflected from an item. The Raspberry Pi Camera Module v2 supplanted the first Camera Module in April 2016. The PI Camera Module has a 5-megapixel sensor Vision The Camera Module can be utilized to take top notch video, just as stills photos. It's anything but difficult to use for

fledglings, yet has bounty to offer propelled clients in case you're hoping to extend your insight. There are loads of models online of individuals utilizing it for time-pass, slow-movement, and other video shrewdness. You can likewise utilize the libraries we group with the camera to make impacts.

IV. WORKING

Framework will deal with the different distinctive remote correspondences and most recent mobiles for security reason. The proposed framework qualities include remote controlling of machines, interruption location, framework security and auto arrangement with the end goal that framework naturally modifies the framework settings on running equipment bolster check. The primary goals of the framework are: To create home security framework that

- Wrongdoing can be forestalled by making quick move.

- To the mortgage holder caught picture and sound will be appeared to interloper. Kids at home will stay safe because of approval and confirmation of a framework.

- Effective correspondence will happen by utilizing remote correspondence innovation.

Design and Architecture:

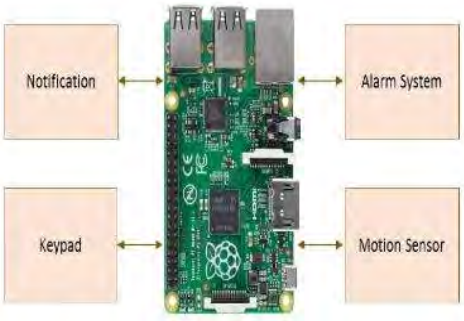

Fig .1. Block Diagram of IOT based Home Security

- Segments related with Home Security, (For example, PIR and piezo ringer and so forth.) are associated with the R-PI as portrayed in the figure above. The Movement sensor for example PIR sensor which represents Uninvolved Infrared Sensor is utilized to identify the nearness of gatecrasher in the home. Piezo Signal is utilized to raise an alert when the nearness of a gatecrasher is distinguished in the house with the assistance of PIR Movement sensor. Keypad is utilized to arm or incapacitate the security of the framework with the assistance of remarkable password for them two individually.

- The Framework contains different modules, for example, interruption identification, movement discovery and alert are examined in detail underneath:

Interruption Location: People emanate heat in type of radiation which isn't noticeable to the unaided eye, despite the fact that they can't be seen it very well may be distinguished. Latent Infrared Sensor recognizes this radiation to identify the nearness of any person. Hence PIR sensor is used to identify the nearness of gate crasher in the house.

- Alert: When the nearness of any human is distinguished through the PIR Movement Sensor and the present time is checked for, example in the event that the present time is past 11:00 PM, at that point the caution is raised.

- Warning: When the caution is raised a 30 seconds time period is designated to kill the alert, if the debilitate code is entered and on the off chance that it coordinates the correct impaired code got from the database inside the time frame(30 sec) at that point the caution is killed else the Proprietor and Law Implementations are told.

It expands the utilization of portable innovation to give basic security to our homes and for other control applications. The proposed home security framework catches data and transmits it to the individual mail utilizing the web. Raspberry pi works and controls movement locators and camcorders for remote detecting and reconnaissance, streams live video and records it for future playback. It can likewise locate the quantity of people situated with the assistance of the Infrared sensor. For instance, when movement is distinguished, the cameras naturally start recording and the Raspberry pi gadget alarms the proprietor of the conceivable interruption having an advanced cell. Raspberry-Pi has two primary parts communicating with one another. we can capable send it to the email consequently. We can ready to caution the individuals utilizing IOT innovation.

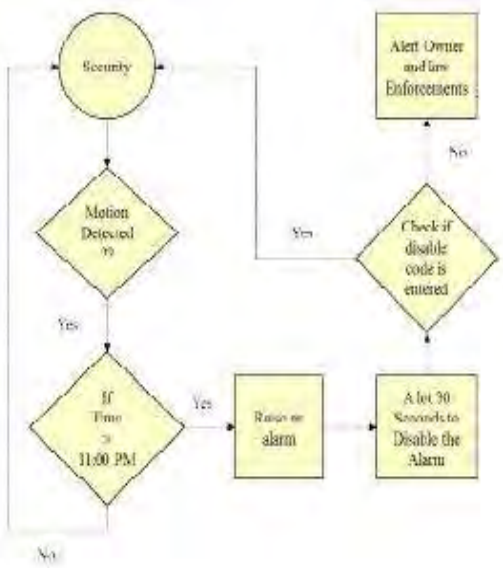

Fig.2.Flowchart of Home Security

V. RESULT & DISCUSSION

The surveillance controller system implemented using Raspberry Pi. Raspberry Pi is powered by 5V adapter. The desktop of Raspberry Pi is accessed remotely from putty software which is installed on laptop.

User seeks surveillance on webpage using Wi-Fi router's IP address. This system is useful for the owner to get a remote view of his home and to keep an eye on his valuables. If the face is detected, it is recognized and then camera is activated, image is captured and sent to the user. After that, motion software is triggered, image is recorded and notification is send to user.

Fig.3. Module of Home Security

VI. CONCLUSION

We have planned and built up an ongoing reconnaissance framework utilizing IOT module and Raspberry Pi. It is a functioning reconnaissance framework which will alarm the client when the occasion occurs. Live picture gushing is an extra bit of leeway of this framework. we have made web server which causes the client to see the live picture. This framework sends gatecrasher's caught video to the proprietor by the android versatile. The IOT based shrewd observation framework has been meant to plan so that it can satisfy the necessities of the client for specific reconnaissance region. It has incalculable applications and can be utilized in various situations and situations.

Fish Tank Monitoring System

By Jayesh Pandey, Dheeraj Poojary, Nigam Ojha
Thakur College of Engineering & Technology, TCET MUMBA

Abstract—**In light of the exploration, there are a portion of the comparable items identified with this present venture. One of the items which known as "A Multi- utilitarian Aquarium Equipped with Automated Thermal Control/Fodder-Feeding/water Treatment utilizing a Network Remote Control System" create by (Min-Chie Chiu, 2010). Subsequent to dissecting on their item, found that there have a couple of solidarity and shortcoming on their item. In the item, (PC) is utilized as primary controller to deal with all the sensors. The sensors were associated with the PC controlling framework through various module. The module is the ADC (Analog to Digital) which convert the simple sign from the sensors to advanced sign with the goal that the PC can peruse and group the qualities. At that point, by means of the VB interface, the customer PC can speak with server-PC to screen and control the aquarium dependent on the information from sensors. The quality of the item is the utilization of PC as controlling framework. PC has high preparing force and it can control the information got from the sensors by means of modules quicker contrasted with microcontroller which has constrained handling power. Be that as it may, there are a few shortcomings existing right now. From the start is the expense of the item. The item comprises of a PC as focal point of the framework which control and deal with the entire framework. It is extremely costly to distribute an entire PC just to deal with the aquarium framework. Second is the versatility of the item. The utilization of PC as focus some portion of framework make it hard to move the item starting with one spot then onto the next. The answer for the expense and convenientce issue can be tackled utilizing a microcontroller called Arduino Uno, to supplant the PC to work as principle controller of the framework to work the framework.**

Keywords:- IOT,ultrasonic sensor,Esp 8266

The term “Internet of Things (IoT)” (Huang & Li, 2010; Uckelmann, Harrison, & Michahelles, 2011) has been around for the past few years and is gaining recognition with the breakthrough of advanced wireless technology. Although there are several definitions for the phrase “Internet of Things” the best interpretation would be the integration of the physical world with the virtual world of the Internet. IoT is a network of physical objects that contain embedded technology to communicate and sense or interact with their internal or the external environment. Throughout the years, there have been many products built based on the IoT concept, for example, smartphones, smart watches, laptops, household electronic devices and other monitoring electronic system devices. Among these devices, the aquarium monitoring system is an electronic monitoring system that is grabbing a lot of attention nowadays.

What is an aquarium? An aquarium is a container or an artificial pond in which living aquatic animals or plants are kept. Aquarium is used for fishkeeping purpose for hobby and for indoor and outdoor decoration. Besides that, fishkeeping in aquarium is also related to various cultures, for example it is related to Vastu for Indians and Feng Shui for Chinese. According to Vastu, the aquarium is a perfect combination of harmony and balance. The water symbolizes the flow of life, growth and activities of living things. The motion and sounds of the bubbling water as it moves throughout the fish tank activates and increases the positive energy around the area, thus, bring good fortune, wealth and abundance. Meanwhile, according to Feng Shui principles, placing an aquarium in the home or office is an excellent way to attract auspicious chi into the space, especially for good luck, abundance and prosperity. The aquarium monitoring system was then introduced order to properly maintain the aquarium. Besides that, with the help of Iot devices such as aquarium monitoring system, users can monitor and manage their aquariums and fishes, anytime and from anywhere through the internet.

I. INTRODUCTION:

Presently the world is moving towards automation,everyone needs a solace living. In this day and age of connectedness, individuals are getting familiar with simple access to data. So by utilizing this innovation manual work is being diminished to incredible degree . In this manner, by this task we are endeavoring to supplant the manual observing of an aquarium with remote mechanization by means of web . In existing frameworks one can't sustain the fish in their nonappearance, it might bring theat to angles, temperature of the water can't be resolved as it very well may be changed by the seasons and fishes may experience the ill effects of this.It's difficult to screen everything going on inside your aquarium nonstop . With ordinary consideration and upkeep, you're probably going to get issues on the off chance that they happen just at your essence. Oceanic lives in the aquarium are effortlessly influenced with the progressions of the aquarium conditions, for example, temperature, bolstering, and the lighting. These conditions are basic for the getting by of the sea-going lives in the aquarium.

Right now world articles speak with one another and demonstration astutely. Web of Things is a developing innovation which understands this present nature of processing. Aquarium the executives needs opportune get-together of water parameter esteem changes. These progressions may influence the life of amphibian creatures in the aquarium. The proposed framework gathers sick supplant the manual upkeep of fish aquarium with its computerized capacities. the ongoing information from aquarium condition utilizing sensors, forms it and updates the temperature of water continuously accordingly of any

negative circumstances through temperature test. The undertaking's crowd is the gathering of individuals intrigued to keep angles at their homes or workplaces however don't have the opportunity to deal with, or they are stressed to continue soliciting their neighbors to take care from the fishes in their nonattendance. The venture is a computerized framework to deal with angles.

1.2 Problem Definition:

The time, labor, fish passing on because of deficient upkeep of aquarium is more. To beat these issues we got ready for shrewd aquarium to tackle all of referenced above issues.

II. PERIODS OF PROJECT

● Phase 1: Planning, Analysis, Designing and Implementation.

Examination: Getting away from of the venture title and doing research on it we will get our definition and after that then we will initially make the Literature Survey of the extend and do the entire documentation.

Arranging: After investigation we will initially learn about it and do some examination on it for our better comprehension of the undertaking and furthermore getting an unpleasant picture about what might be our concern definition for the specific venture.

Structuring: Then we will build the plan of the undertaking and as per that, will list down all the necessities required for the development for the model of our task.

Usage: After securing the necessities we initially built up the associations of the equipment segments (Arduino, Ultrasonic sensor and so on) and afterward included the coding part later with assistance of Arduino information link to the Arduino.

Phase 2: Testing and Deployment.

Testing: After the model is prepared we will initially interface the equipment with the doled out code and afterward we will check on the off chance that it bolsters the instrument or not. If not we will explain the issues with respect to it and will check once more.

Arrangement: After, complete mix and testing of task constant running and activity of the framework will be finished and useful.

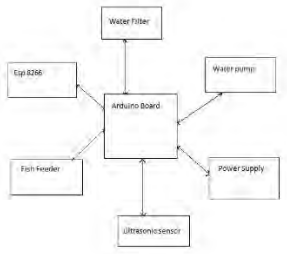
III. METHODOLOGY USED:

The square graph of Arduino based aquarium observing framework is appeared in figure1 Arduino board are use as the primary controller to screen and control the sensors,lights,radiator. The Arduino Uno is essentially a little microcontroller. Here the force transfer is utilized to control the aquarium lights, the dc engine is utilized to angle nourishing reason, temperature sensor is utilized to detect the water temperature and sends the warning in like clockwork, if the water temperature is low the warmer is utilized to changes the ordinary temperature. The LCD show is utilized to show the temperature and by observing LCD show.We can work the lights and dc engine for nourishing fishes and This undertaking can be work in three distinct modes. Web Of Things (IOT), it sends refreshes in at regular intervals so we can screen the aquarium temperatures when we are away from home.Utilizing infrared sensors it can worked by remote control On-Screen menu that can be constrained by up-down catches by observing the LCD show.

2.2 Summary:

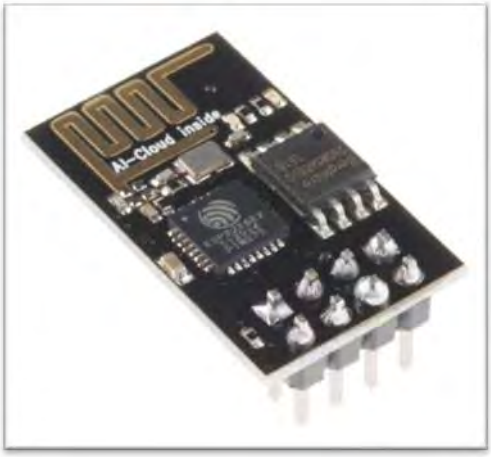
This audit is proposed to help a total computerized aquarium . Microcontroller in the framework guarantees about increment in framework's life by lessening the force utilization bringing about lower power utilization. Computerized aquarium framework has a tremendous interest and future degree in fish cultivating for large scale manufacturing of fishes. It is efficient, prompted evacuation of human blunder in modifying accessible water levels and to amplify their net benefits in understanding to factors like deals, quality and development of their item.

2.3 Block diagram



2.4 System Components: ESP8266:

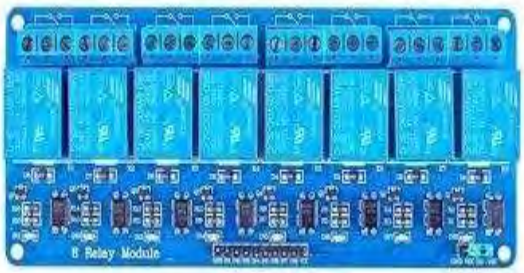
The ESP8266 is an ease Wi-Fi microchip with full TCP/IP stack and microcontroller capacity delivered by maker Espressif Systems in Shanghai, China. The chip previously went to the consideration of Western producers in August 2014 with the ESP-01 module, made by an outsider maker Ai-Thinker.



Ultrasonic sensor:

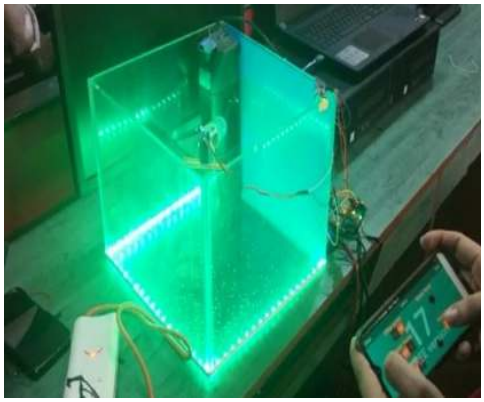
Ultrasonic sensors work by radiating sound waves at a recurrence unreasonably high for people to hear. They at that point trust that the sound will be reflected back, figuring separation dependent on the time required. This is like how radar quantifies the time it takes a radio wave to return in the wake of hitting an article.

8-relay channel:



This is a 8-channel LOW level trigger relay and it very well may be applied to Arduino and Raspberry Pi. Relays are reasonable for driving high force electronic gadgets, for example, lights, electric fans and cool. A relay can be utilized to control high voltages with a low voltage by interfacing it to a MCU.

IV. RESULT:



V. CONCLUSION:

In the present world everything is moving towards motorization to diminish work weight of human. As indicated by the composing overview as of late arranged systems over not too capable at their working and moreover not financially reliable in the point of view on use. Particularly microcontroller based introduced systems has less memory size close by the most distant point in interfacing peripherals this prompts slack in the plan of the structures. In like manner here proposed and automated Arduino based aquarium watching structure that engages straightforward direction over the couple of issues of aquarium, for instance, temperature assortments, empowering timetable, turbidity level, lighting system which contains sensors to aggregate the information required for needed incitation using Arduino controller. Which gives beneficial electronic direction over the issues.

VI. FUTURE SCOPE:

The rule purpose of this endeavor is to develop a structure that can screen the status of the aquarium reliably and engage the customer to screen status of the aquarium by marking on to the database system and perform appropriate exercises through the web itself or let the structure itself perform instructed decisions and exercises. Other than that, system furthermore should be flexible, accompanied straightforwardness, uses low power, supportive and successful. To vanquish the issues referenced more than, a couple of measures have been executed for this endeavor:

The incorporation of this system is obliged to little quantify aquariums, for instance, 10-30 galloon fish aquarium.

The point of confinement of the region used is simply inside a particular extent of the home or office which has a not too bad web incorporation, as the system needs to

invigorate the customer on the status of the aquarium by methods for the web.
The adventure requires programming capacity to manage the Arduino uno.

Abstract— **Streetlights are the basic a part of any city since it facilitates better night visions, secure roads, and exposure to public areas but it consumes a quite large proportion of electricity. within the manual streetlight system lights its powered on from sunset to sunrise with maximum intensity even when there's sufficient light available. This energy wastage may be avoided by switching off lights automatically. The saved energy may be efficiently utilized for other purposes like residential, commercial, transportation etc. this will be achieved using an IOT enabled streetlight management system. The project uses Light Emitting Diodes (LED) that don't consume an infinite amount of electricity to exchange the facility consuming traditional HID lamps. LED lights together with LDR enables the intensity variation which is infeasible with the HID lamps. As LEDs are directional light sources it can emit light in specific direction thereby optimizing the efficiency of the streetlights. This work is implemented employing a programmed Arduino board for providing the desired intensity of sunshine at various times. The proposed work has achieved a far better performance compared to the present system.**

Keywords – Street Lights; IOT; Light Emitting Diodes HID (High Intensity Discharge Lamps); Arduino;Automatically.

I. INTRODUCTION

IOT is that the network of physical devices Now a days, human has become too busy, and is unable to search out time to change of the lights wherever not necessary. Streetlights are an integral a part of any developing locality. they're present on all major road-ways and within the suburbs too. this system is just like the lights are switched on within the evening before the sun sets and that they are transitioned the following day morning after there's sufficient light on the surface. the road lighting is one in all the biggest energy expenses for a city. An intelligent street lighting system can cut municipal street lighting costs the maximum amount as 50% - 70%. An intelligent street lighting system could be a system that adjusts light output supported usage and occupancy, i.e., 0automating classification of pedestrian versus cyclist, versus automotive. An intelligent street light management proposes the installation of the wireless based system to remotely track and control the particular energy consumption of the road lights and take appropriate energy consumption reduction measures through power conditioning and control. The smart street light controller must be installed on the sunshine pole which carries with it microcontroller together with various sensor and wireless module. The smart street light controller installed on the road light pole will control LED street lighting looking on movements of the thing within the street. Whenever a vehicle passes by, the LED will increase its intensity then decrease it whenever the roads are idle.

II. PROBLEM STATEMENT

In most of the cities, the road lights are ON when it's not need and it's OFF when isn't needed. due to these situation the large energy expenses for a city gets wasted. Usually the lights are ON within the evening after the sunset, it continuous to air till the sun rises within the subsequent day morning. This paper focuses on reducing the energy by automatically switching ON and OFF street lights. When vehicles come to the street/road the sensor will capture ande movements of the vehicles then lights automatically ON. Otherwise automatically OFF the lights. In sunny and rainy days, ON time and OFF time differ significantly which is one of the major disadvantage of using timer circuits or manual .

II. BACKGROUND

The key indicators of India's energy problems include; Over 40 per cent of the households (particularly rural areas) in India still don't have electricity, a couple of third of our total primary energy supply to rural areas still comes from non-commercial sources (biomass, dung) and currently India faces an infinite demand supply gap of about 15-25% energy shortage.

Due to shortage of the energy supply till today several villages haven't facilitated with electricity and whether or not provided, the provision of the electricity is proscribed to few hours in a very day and face serious problems because of unlimited power cuts. During the day time we get enormous amount of sunshine energy from sun and also the problem for pedestals are common during the evening time. Though most of the streets are equipped with street lights in each and each village areas but because of the uncontrolled power failures/power cut it's becoming a significant problem.

A simple and effective solution to the present problem would be dimming the lights during off peak hours. Whenever presence is detected, the lights around it'll glow at the conventional (bright) mode. this could save lots of energy and also reduce cost of operation of the streetlights. we are able to check the status of street light on internet using IOT (Internet of 01things) from anywhere in real time and solve the problems if happen during the processing.

III. IMPORTANCE OF THE PROJECT

The internet of things (IoT) are ready to implement transparently a really great deal of heterogeneous end systems, while digital service provides open access to sub

set of information. With Smart street light system it's possible to systematically help the pedestrian to succeed in the destination within the remote rural areas which face serious power supply problem.

• This project is targeted on the controlling intensity of the sunshine considering the item movement.

• This smart light system automatically detects the movements of the item on the road.

• This Smart light system is employed to scale back energy consumption.

• This smart system is employed to avoid unnecessary usage of electricity. the whole smart system is meant to control using artificial energy source.

• This smart system is best suited to street lighting in remote urban and rural areas where the traffic is extremely low.

IV. OBJECTIVES AND SCOPE

The main objective of this project is to implement a IoT based Automatic Street Light System. because the traffic decreases slowly during late-night hours, the intensity gets reduced progressively by detecting the movement of vehicles till morning to save lots of energy and thus, the road lights activate at the dusk then flip at the dawn, automatically. the method repeats a day..

White Light Emitting Diodes (LED) replaces conventional HID lamps in street lighting system to incorporate dimming feature. The intensity isn't possible to be controlled by the high intensity discharge (HID) lamp which is usually utilized in urban street lights. LED lights are the long run of lighting thanks to their low energy consumption and long life. LED lights are fast replacing conventional lights because intensity control is feasible by the heartbeat width modulation.

This proposed system uses an Arduino board. Strings of LED are interfaced to the Arduino board. A programmed Arduino board is engaged to produce different intensities at different times of the night in keeping with the movement of vehicles. This project is enhanced by integrating the LDR to follow the switching operation precisely and IOT to display the status of street on browser and help in controlling it.
The main objectives are as follows:

• To avoid unnecessary Waste of sunshine.

• Provide efficient, automatic and smart lightning system.

• Totally supported Renewable energy sources.

• Longer life.

• Energy Saving

VI. PHASES

- Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting clear idea of the project title and doing research on that we are going to get our definition and at the moment then we are going to first create the Literature Survey of the project and do the entire documentation.

Planning: After analysis we are going to first study about it and do some research on that for our better understanding of the project and also getting a rough picture about what would be our problem definition for the actual project.

Designing: Then we are going to construct the look of the project and in line with that, will list down all the necessities needed for the development for the prototype of our project.

Implementation: After acquiring the necessities we first developed the connections of the hardware components (Arduino, MQ2 sensor etc) so added the coding part later with help of Arduino data cable to the Arduino.

- Phase 2: Testing and Deployment.

Testing: After the prototype is prepared we are going to first connect the hardware with the assigned code and so we are going to check if it supports the mechanism or not. If not we are going to solve the problems regarding to that and can check again.

Deployment: After, complete integration and testing of project real time running and operation of the system are done. User must check the worth.

VII. METHODOLOGY

Recent days, Smart Street Light System is major component of a sensible City Infrastructure. The important function is lighting town streets using sensor's to avoid wasting the present or power energy
.In existing system using normal street lamps. It takes more current and costs too. So use LED lamps to avoid wasting the present in low amount of power.

VIII. HARDWARE

1. ARDUINO UNO: Arduino may be a single-board microcontroller, intended to form the applying of interactive objects or environments more accessible. The hardware consists of an open-source hardware board

designed around an 8-bit Atmel AVR microcontroller, or a 32-bit Atmel ARM. Current models feature a USB interface, 6 analog input pins, yet as 14 digital I/O pins which allows the user to connect various extension boards. The Arduino board exposes most of the microcontroller's I/O pins to be used by other circuits. The Diecimila, Duemilanove, and current Uno provide 14 digital I/O pins, six of which may produce pulse width modulated signals, and 6 analog inputs.

2. IR SENSORS: An infrared sensor is an instrument that's accustomed sense certain characteristics of its surroundings by either emitting and/or detecting actinic ray. it's also capable of measuring heat of an object and detecting motion. Infrared waves don't seem to be visible to the human eye. within the spectrum, actinic ray is that the region having wavelengths longer than actinic radiation wavelengths, but shorter than microwaves

Key benefits of infrared sensors include low power requirements, simple circuitry and their portable feature. the primary IR LED is wired to emit IR waves and therefore the second LED is wired to transmit a proof when it receives an IR input. When an object comes within range of the emitting LED, it reflects the IR back to the receiving LED and produces a proof.

3. LIGHT DEPENDENT RESISTORS:

A LDR or a photograph resistor may be a device whose resistivity may be a function of the incident radiation. Hence, they're light sensitive devices. they're also called as photo conductors, photo conductive cells or just photocells. When light falls i.e. when the photons fall on the device, the electrons within the valence band of the semiconductor material are excited to the

conduction band. These photons within the incident light should have energy greater than the band gap of the semiconductor material to form the electrons jump from the valence band to the conduction band.

Hence when light having enough energy is incident on the device more & more electrons are excited to the conduction band which ends up in sizable amount of charge carriers.

4. LED: An LED may be a two-lead semiconductor source of illumination, which emits lights when activated. When an appropriate voltage is applied to the LED terminal, then the electrons are able to recombine with the electron holes within the device and release energy within the sort of photons. the colour of the LED is decided by the energy band gap of the semiconductor. The forward voltage require to show ON a LED, depends on the colour of the LED. If you're feeding the precise value of forward voltage then you'll be able to connect a LED on to the source. If the voltage may be a on top of use a resistance serial with the LED.

5. JUMPER WIRES: Jumper wires are used for creating connections between items on your breadboard and your Arduino's header pins.

6. USB CABLE: this can be a regular A-B USB Cable. It will be accustomed connect your computer to Arduinos that use a full-sized B-type USB connection, like the Uno and Mega2560.

7. BREADBOARD: Breadboard provides temporary connections between individual electronic components, to style and assemble demonstration circuits. Breadboard is convenient because you'll be able to quickly change the circuit without excessive or complicated modifications, making breadboard ideal for circuit development and testing. Breadboard consists of a grid of contacts with contacts typically
spaced one-tenth of an in. apart.

IX. BLOCK DIAGRAM

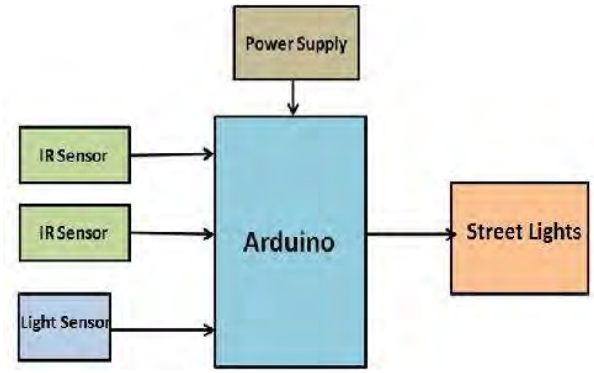

FIG1: BLOCK DIAGRAM

X. CIRCUIT DIAGRAM

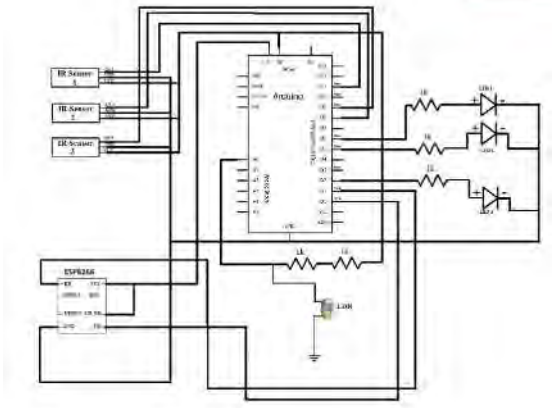

FIG2: CIRCUIT DIAGRAM

XI. RESEARCH GAPS

Every project has some gaps in it which can be implemented in future. No project is 100% efficient. There are some gaps in this project too. They are as follows:
1. As this system is currently not WiFi enabled, we cannot detect which LEDs are not working. By adding WiFi

module we can detect damaged LEDs from a web server and the manual help can be sent only to those locations.
2. Also, the system does not GPS connection so we cannot detect the exact location of LED.
3. A SOS button can also be implemented in future, which can send notification whenever some emergency in the surrounding is detected.

XII. CONCLUSION

Uuse of power electronics is increasing exponentially across various sectors of human life. The components employed in the project, like Arduino and sensors are slowly becoming an important a part of our daily routines. So, it's only fitting that we use them to boost efficiency in every walk of life. Keeping in mind the urgent need for energy conservation, Smart Street Light System with IoT is a wonderful and effective solution. It combines safe lighting protocols with consumption of minimal amount of power by reducing the intensity of the lights when not in use whereas in present system the lights are on fully intensity even when the road is totally empty which causes unnecessary use of electricity..

An Obstacle Avoiding Robot using Arduino

Tanvi Pradhan, Pradyumn Rai, Yash Sarda
TCET, Mumbai
pradhan.tanvi500@gmail.com, raipradyumn1999@gmail.com, yashsarda189@gmail.com

Abstract—**Trajectory planning is one of the most significant essential focuses in pick and spot undertakings done by mechanical controllers. Right now, we have displayed a robot, which is minimized, independent and completely practical. This robot or a brilliant vehicle is worked to detect any hindrance in its way, to keep away from it and helps in maintaining a strategic distance from the mishaps (accidents) to happen. IR sensors were adjusted to execute constant obstacle occurring framework for wheeled robots, with the goal that the robot can persistently identify environment, maintain a strategic distance from snags, and move securely. Right now obstruction avoider framework is being presented with snag evasion and furthermore mishap anticipation for vehicles. This will give a higher likelihood to diminish the mishaps occurring each day on the streets (particularly mishaps happening on the streets in uneven zones). Here an Arduino based model has been produced for mishap evasion which is ease and proficient. All through the development of this model, we instructed ourselves to the Arduino Coding language, and thoroughly with the working of an Infrared Sensor and its highlights. Taking everything into account, through this venture, we plan to develop a model of a savvy vehicle that is useful to the quotidian issues of the present age.**

Keywords – Arduino UNO, Motor Driver, IR Sensor, Servo Motor, Battery, Connectimg Wires, etc.

I. OVERVIEW

Obstacle avoidance is one of the most significant parts of versatile mechanical autonomy. Without it robot development would be exceptionally prohibitive and delicate. This report clarifies obstruction shirking utilizing infrared sensors. Presently day's numerous enterprises are utilizing robots because of their elevated level of execution and unwavering quality and which is an incredible assistance for people. The obstruction shirking mechanical autonomy is utilized for distinguishing snags and maintaining a strategic distance from the crash. This is a self-governing robot. The plan of obstruction evasion robot requires the reconciliation of numerous sensors as per their undertaking.

A. Background

From its introduction during the 1950s, present day robots have made some amazing progress and established itself as a permanent guide in the headway of mankind. Over the span of time, robots took numerous structures, in view of its application, and its size shifted from a mammoth 51 feet to infinitesimal level. Over the span of innovative improvements of robots, one angle stayed instrumental to their capacity, and that is versatility. The expression "obstruction evasion" is presently utilized in current mechanical technology to signify the capacity of robot to explore over an obscure domain without having any crash with encompassing articles (Arduino-Apply autonomy, 2013). Deterrent evasion in robots

can get greater adaptability moving in fluctuating situations and would be substantially more productive as ceaseless human observing isn't required. This venture built up a snag staying away from robot which can move with no crash by detecting obstructions on its course with the assistance of ultrasonic separation sensors. Robots guided with this innovation can be placed into broadened utilizes, e.g., looking over scenes, driver less vehicles, self-governing cleaning, computerized grass cutter and overseeing robot in ventures.

B. Importance of Project

- Use new technology that uses Internet of Things (IOT).
- To improve traversing in an unknown environment.
- To achieve cost savings.
- To enhance the ability of a device to research.
- Helps in damage control for a robot by avoiding obstacle.

C. Motivation

Numerous robots for mechanization and route have been created as of late like divider following, edge-following, human after and obstruction maintaining a strategic distance from robots. The obstruction keeping away from robot will avoid deterrents it experiences in its way towards its operational objective. Because of the unwavering quality, openness and cost viability of utilizing versatile robot in industry and specialized applications, the hindrance maintaining a strategic distance from robots are significant in manufacturing plant floor. Then again, Unmanned Aeronautical Vehicles (UAVs) are assuming a fundamental job in barrier just as non-military personnel applications. The military applications incorporate observation, reconnaissance, fight harm appraisal and correspondences. Then, non-military personnel applications incorporate debacle the board, remote detecting, and traffic observing, and so on. Huge numbers of the UAVs applications need the capacity to explore in urban condition or obscure territories that have numerous snags of various sorts and sizes. Fundamental necessity of self-governing UAVs is to distinguish snags in its way and stay away from them. This paper proposed

a case of the snag evading robot calculation and plan of the robot base utilizing IR and PIR sensors. The created robot can be utilized as a stage for a few applications in instructive, look into or mechanical.

D. Objective And Scope

The Objective of this project is to implement a low cost, reliable and scalable obstacle avoiding car that can be used in unknown terrain and carry out research work if needed. The Scope can be was as by adding new sensors we can advance the features by expanding and improvising according to need.

- To make a System easy and to avoid accidents.

- To help the aged / old ones to make their driving safer.

- These new technologies are not only helpful but also provide us with security while driving. The objective is to make driving safe using this IOT based technology.

II. LITERATURE SURVEY AND PROPOSED WORK

In this section, we present literature survey done related to this project and relating work in progress.

A. Introduction

Obstacle avoidance is an essential necessity of any self-ruling portable robot. Obstacle shirking robot is configuration to permit robot to explore in obscure condition by keeping away from crashes. Snag maintaining a strategic distance from robot detects obstructions in the way, keep away from it and resumes its running. There are some renowned strategies for robot route like divider following, edge discovery, line following. One of the business frameworks utilizes divider following technique on a story cleaning robot for long passages. A progressively broad and normally utilized technique for obstruction shirking depends tense identification. A burden with hindrance shirking dependent nervous distinguishing is the need of the robot to stop before a deterrent so as to give an increasingly exact estimation. Every single portable robot highlights a crash shirking, extending from crude calculations that identify an impediment and stop the robot so as to dodge an impact, utilizing some modern calculations that empower the robot to reroute snags. The last calculations are increasingly perplexing, since they include location of a deterrent just as a quantitative estimation concerning the obstruction's measurements. Once these have been resolved, the impediment shirking calculation needs to direct the robot around the snag and resume movement toward the first objective. Right now, directing calculation guarantees that the robot doesn't need to stop before a deterrent during its route. Thus, the robots may beat a portion of the issues during route, which are examined above and it can explore easily during its activity maintaining a strategic distance from the impacts. We have introduced an essential calculation and structure which can be additionally improved relying on the necessary applications.

B. Literature Survey

From this research paper we got definite data of the subject IoT. We got a thought of forestalling accidents with the assistance of IoT utilizing various segments. We got information about the pace of accidents occurring in India and how to forestall it and get decrement in the proportion of mishaps [1]. A Basic yet powerful snag avoider for the IARA Self- governing vehicle this paper gave a thought of utilizing IR Sensor for utilizing hindrance shirking [2].

C. Problem Definition

These days, mechanical advances have gotten increasingly significant since a great deal of industry is attempting to improve their hardware weapons. This innovation has created step by step to ensure a great outcome. As of late, by time passes by, a ton of mechanical robots have been designed to

help people groups running their day by day life. Snags Shirking Portable Robot is really a straightforward impact evasion machine. Other than that, its future advancement is extremely large to investigate. By utilizing this straightforward impact evasion framework, a ton of new and assortment versatile robot with numerous capacities can be developed. Constant obstruction evasion is one of the key issues to fruitful uses of versatile robot frameworks. Every single portable robot highlights a crash evasion, running from crude calculations that recognize a deterrent and steer the robot shy of it so as to dodge an impact, through complex calculations, that empower the robot to bypass hindrance. Once these have been resolved, the hindrance evasion calculation needs to control the robot around they obstruction and resume movement toward the first objective.

D. Phases of Project

- Phase 1: Arranging, Examination, Planning and Execution.

Arranging: After examination we learned about our subject and did some exploration on it for our better comprehension of the undertaking and furthermore to get an unpleasant picture about what might be our concern definition for the specific venture.

Examination: We got the away from of our task title by doing research on it and will conclude our definition and after that we previously made the Writing Overview of the venture and did the entire documentation.

Structuring: At that point we will develop the plan of the task and as per that, will list down all the necessities required for the development for the model of our venture.

Execution: In the wake of obtaining the necessities we continued for the development of the application.

- Phase 2: Testing and Arrangement.

Testing: After the model is prepared, we will initially interface the equipment with the allocated code and afterward we will check in the event that it underpins the instrument or not. If not, we will illuminate the issues with respect to it and will check once more.

Arrangement: After, complete coordination and testing of task ongoing running and activity of the framework will be finished. We are relied upon to approve against their recently put away information.

III. ANALYSIS AND PLANNING

Obstruction shirking is an essential necessity of any self-sufficient versatile robot. Snag evasion Robot is configuration to permit robot to explore in obscure condition by staying away from crashes. Hindrance maintaining a strategic distance from robot detects impediments in the way, dodge it and resumes its running. There are some well-known techniques for robot route like divider following, edge identification, line following. One of the business frameworks utilizes divider following strategy on a story cleaning robot for long foyers. A progressively broad and usually utilized strategy for snag evasion depends tense recognition. A
hindrance with deterrent evasion dependent nervous recognizing is the need of the robot to stop before a snag so as to give a progressively exact estimation. Every single portable robot highlights an impact evasion, running from crude calculations that identify a hindrance and stop the robot so as to maintain a strategic distance from a crash, utilizing some refined calculations that empower the robot to bypass impediments. The last calculations are progressively perplexing, since they include discovery of a snag just as a quantitative estimation concerning the deterrent's measurements. Once these have been resolved, the snag shirking calculation needs to control the robot around the impediment and resume movement toward the first objective. Right now, guiding calculation guarantees that the robot doesn't need to stop before an impediment during its route. Consequently, the robots may conquer a portion of the issues during route, which are talked about above and it can explore easily during its activity dodging the impacts. We have exhibited an essential calculation and plan which can be additionally improved relying on the necessary applications.

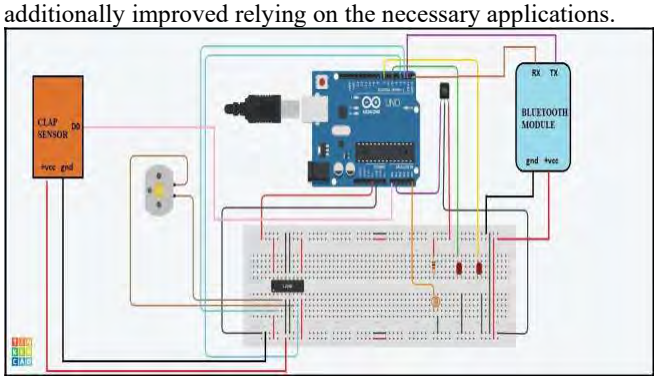

Fig.01 Circuit Diagram *A. Feasibility Study*

In this step, check whether the proposed frameworks are in fact possible or not. i.e., all the innovations required to build up the framework region practical promptly or not. Specialized Practicality decides if the association has the innovation and aptitudes important to do the task and how this ought to be acquired. The framework can be doable on account of the accompanying grounds:

- All essential innovation exists to build up the framework.

- This framework is excessively adaptable and it very well may be extended further.

- This framework can give assurances of exactness, convenience, dependability and the information security.

- This framework can give moment reaction to ask.

- Our venture is in fact doable in light of the fact that, all the innovation required for our undertaking is promptly accessible.

microcontroller. Arduino Uno has 14 advanced inforaation/yield pins (out of which 6 can be utilized as PWM yields), 6 simple information sticks, a USB association, A Force barrel jack, an ICSP header and a reset button.

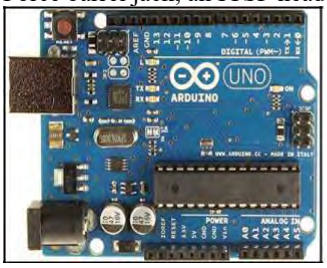

Fig.02 Arduino UNO Fig.03 IR Sensor

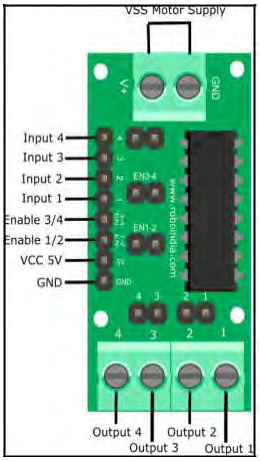
IR Sensor (Fig.03): As referenced that the model is IR sensor situated it deals with some standard. Infrared sensors deal with the guideline of reflected light waves. Infrared light reflected from articles or sent from an infrared remote or signal. Infrared sensors are additionally used to quantify separation or closeness. The reflected light is recognized and afterward a gauge of separation is determined among sensor and article.

Motor Driver (Fig.04): The Motor Driver is a module for engines that permits you to control the working velocity and course of two engines all the while. The Motor Driver which we are utilizing is structured and created dependent on L293D IC.



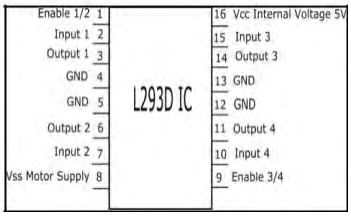


Fig.04 Motor Driver Fig.05 L239D IC

L239D IC (Fig.05): The L293D is a 16 pin IC, with eight pins, on each side, to controlling of two DC engine at the same time. There are 4 Info pins, 4 Yield pins and 2 Empower pin for each engine

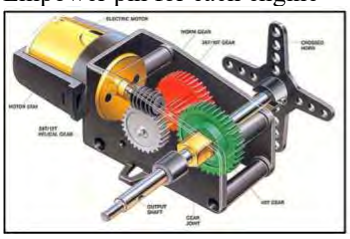

Fig.06 Servo Motor

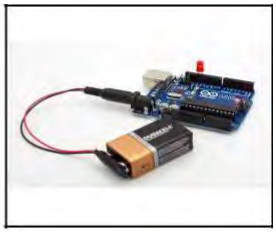

Fig.07 Battery

B. Implementation Details

Arduino Uno (Fig.02): It is a microcontroller board dependent on 8-piece ATmega328P microcontroller. Alongside ATmega328P, it comprises of different segments, for example, precious stone oscillator, sequential correspondence, voltage controller, and so forth to help the

Servo Motor (Fig.06): The servo motor position can be controlled more correctly than those of average DC engines, and for the most part, they have three wires like force, GND, and control. Capacity to these motors ceaselessly applied, with the servo engine control circuit changing the attract to drive the servo engine. These engines are intended for increasingly

careful assignments where a motor position should be clear absolutely like moving a mechanical arm or controlling the rudder on a pontoon or robot leg inside a specific range.

Battery (Fig.07): The Arduino Uno can be fueled by means of the Smaller than usual B USB association, 6-20V unregulated outer force supply (pin 30), or 5V directed outside force supply (pin 27). The force source is consequently chosen to the most elevated voltage source. So you can interface battery positive to VIN pin and negative to Ground pin legitimately.

C. Features of the project

The project contains the following features:

- To create a working model of an obstacle avoiding car, having the following features:
- Damage control
- Remote operated
- Reverse mechanism
- Obstacle avoidance
- Dead-end avoidance

D. Methodology used Algorithm Step 1: Start

Step 2: Initialize IR Sensor, Servo Motor, Motor Driver and Batteries

Step 3: If Obstacle detected on the path then

Move backward and produce a beep sound by piezo buzzer

Else Move in the same direction

Step 4: If we come across a Dead end on the path then

Move backward and produce a beep sound by piezo buzzer.

Else Move in the same direction Step 5: Stop

IV. RESULTS AND DISCUSSIONS

A. Output

Based on the sensor use, we are able to achieve the desirable outputs as follows:

1. As an when infrared sensor detects the obstacle it acts immediately and gives response to Arduino board

2. The piezoelectric sensors produces a beep sound in response to the obstacle activity

3. The infrared sensor also detects the dead end it uses a call back mechanism and the robot goes back as response.

B. Outcome

Phase 1 Analysis: Creating the synopsis, literature survey

and feasibility study for proposed solution which will act as an input to the design phase.

Phase 1 Planning: Proposing Statement of work, scope definition and scope boundary for definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done.

Phase 1 Designing: Proposing design architecture of Arduino and Control using IOT system for implementing the surveyed case studies and synopsis.

Phase 1 Implementation: Various modules will be created like connection of sensors. Completion of coding Collecting data from sensors

Phase 2 Testing:

Case 1: IR blaster remote connection Components/things required: IR blaster remote, Arduino UNO, IR sensors after connection as shown in the circuit diagram, the car was operated with the help of remote, and it was successfully moving as instructed. And whenever any obstacle encountered the car was automatically going into halt state. The IR blaster remote was tested successfully and was in working condition.

Case 2: IR sensor. Components required: IR sensor after connection as shown in the circuit diagram, the predicted results were successfully observed. Whenever the obstacle encountered or if deep distance between the car and the ground surface encountered the car successfully stopped.

Case 3: Sound Transducer producing alert signal: Components required: IR Sensor, Sound transducer after connection as shown in the circuit diagram, they predicted results were successfully observed. Whenever the obstacle encountered at that time the sound transducer was generating sound as an alert signal.

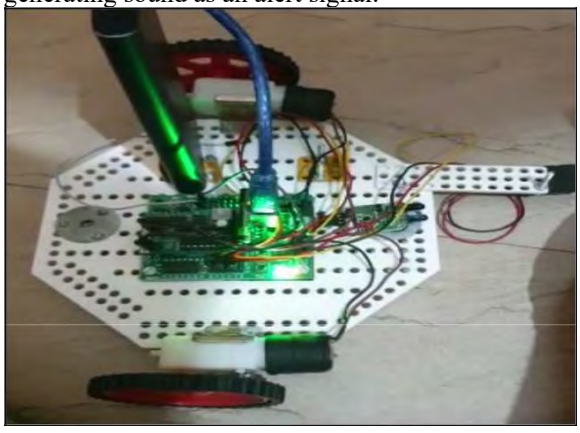

Fig.08 System Design

V. CONCLUSION

The code was transferred utilizing Arduino IDE and the code ran effectively. The circuit outline was made utilizing Tinker lowlife application and the circuit was effectively associated alluding to the circuit chart obstruction staying away from robot was effectively executedand was proficient to utilize. We manufacture an automated vehicle which moves in various ways like Forward, Backward, Left, and Right when information is given to it. The objective of our venture is to make an independent robot which cleverly recognizes the obstruction in his way and explore as indicated by the activities that we set for it.

Smart Gas And Flame Leakage monitoring System

Taher Yusuf Ali, Yash Yadav, Aakash Gupta
TCET,Mumbai
taherwasanwala@gmail.com, ygyadav1423@gmail.com, gupta29470@gmail.com

Abstract - **Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology. In case of construction areas, residential and commercial buildings, there are high chances of domestic fire. Moreover, mining industry being the most fire prone area, there is requirement of a system that can generate information of the region to the miner on the basis of the gas getting generated while mining. Gas is generated first and then fire. The objective of this project is to build a gas and fire leakage detection sms alert system based on IoT technology. A Gas detector is a device which senses the gas and based on the Gas Quantity that is present in the atmosphere it will provide alerts to the beholder. A fire detector will sense the temperature above the threshold value and alert the owner by giving alert message. Nowadays, Gas Detection and sms alert System has been the basic requirement in various regions as the damage caused by the fire accidents is catastrophic. Also, as now the apartments are pretty close and congested, fire can spread very quickly. So, if gas detection and sms alert system is installed while building the apartment, the fire can be suppressed while it is in the small area and further loss of life and property due to fire can be prevented. The output of the gas detectors were been shown according to different test cases and thus the gas-flame detection and sms alert system become more responsive then those currently in use.**

KEYWORDS: Gas, Flame , Alaram,Threshold,SMS.

II. INTRODUCTION

Commercial buildings, Mining Regions, Factories, etc. Nowadays has become more prone to fire because of some or the other issues like short circuit, gas leakages etc. So there is a need of Gas and fire detection and sms alert system that can help us to overcome the damage to the lives and valuables. It is the fact that Gas is the first to come and then the fire. Hence detecting the fire at the gas level can help avoiding the fire to cause catastrophic destruction. The Gas detection and sms alert system is a Device that detects relevant amount of gas in the region and based on that it generates the output that there is a fire or not and based on the output of the further actions by fire- fighters and the administrations can be taken. Moreover now a days there has been an increase in this these days, this project also take an initiative to overcome that by discussing about it in the future scope.

III. BACKGROUND

Gas and Fire leakage detection has become a crucial aspect in design of buildings, both commercial and domestic, as opposed to about 70 years ago when automatic detection was rarely provided in buildings. Before introduction of gas and sms alert, fires resulted in the loss of human lives and damage of property and it was mainly attributed to lack of a mechanism for early detection of gas. Early developments in design of gas alarm began in 1922 with observations by D. Bhattacharjee [3] and later by Walter Jaeger in 1930. However, early gas detectors required high voltage power input. Further research was done and power requirement in gas detectors was reduced to make battery power viable and this made widespread installation in residences highly feasible. Later developments in gas detectors have sought to improve their performance, reduce power requirement and improve their nuisance alarm sensitivity and also to continuously monitor their status. The most recent advances in gas detectors have been motivated to make them “smarter”. Gas can be detected either optically (photoelectric) or by physical process (ionization). Detectors may use either or both methods.

IV. IMPORTANCE OF THE PROJECT

The requirement of the gas and fire leakage detection and sms alert system is because of the increase in the fire prone areas in the localized region where there is life like kitchen, buildings, construction region, mining industries petrol pumps etc. Hence, there is great importance of the project in day-to-day life. Importance of the Gas and fire Leakage Detection and Sms alert system are as below:

● Sms alert system are primarily designed to warn occupants
of a fire so they can safely evacuate the premises.

● Correctly maintained and operating sms alert system are effective and proven life saving devices.

● Failure to take advantage of this early warning, due to poor performance of gas detection system, has cost people their lives.

● Sms alert system are important in providing occupants of
buildings prompt warning if a fire occurs.

You need to carefully consider the benefits that you can achieve by reducing the number of unwanted alarm activations generated at your premises.

V. MOTIVATION

The various issues related to fire incidents occurred in the past year, i.e. 2017. Some of them are as:

1. The Saki-Naka fire incident that killed 12 workers, the fire incident at Omar Asif1[6] building where celebrities reside, and the Kamala Mills tragedy on a Friday night that killed 14 people – a blatant disregard for fire safety norms.

2. Be it slums, high-rises, restaurants, industrial units, studios or old buildings – each has witnessed massive fire incidents in this year. The violation of fire safety regulations has turned each into a tinder box, said experts.

Such incidents created a great loss of life and property both at the same time. And along with this due to the incident that happened in our classroom of AC caught fire. In this incident the air conditioner of our class first released some smoke in the environment and then it suddenly caught fire hence there was no such system that could inform about the fire. Hence, going through the above incidences and motivation to do something for the society we decided to develop a smoke alarm system using the IoT technology.

VI. OBJECTIVES

Tanvira Ismail said sometimes [4] it happens that fake leakage alarms are generated which can cause a loss of more than
$12,000 US dollars. So to avoid and tackle that we can use the camera and delay by 30 second in alarm which means if the leakage is detected to be above the threshold quantity, the detector will send the video to the operator and if the operator
approves that it is a legitimate fire in the region, the alarm will be horned and within 30 seconds of no reply from the user, the alarm will ring and accordingly the further actions can be taken.

• Leakage detection and alarm system can be used with quad copter and this quad copter can be used to detect the regions of the fire or going to catch the fire, thus can be used to protect things.

• Moreover it can be used by people in mining industries to help them for saving their lives.

It can also be used in F1 cars as there is high possibility of catching the fire when car runs at that speed there is high possibility of them catching fire due to the web based output it can be conveyed to the driver and thus he can save his life and win the race.

VII. PROBLEM DEFINITION

To design a microcontroller (IoT) based Gas & Fire Leakage detection and Alarm System that will continuously monitor the presence of significant amount of leakage and activate an alarm and based on that information about the region, solution can be provided.

VIII. PHASES OF PROJECT

● Phase 1: Planning, Analysis, Designing and Implementation. Analysis: Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation. Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project. Designing: Then we will construct the design of the project and according to that, will list down all the requirements needed for the construction for the prototype of our project. Implementation: After acquiring the requirements we first developed the connections of the hardware components[7] (Arduino, MQ135 sensor,IR Flame Sensor etc.) and then added the coding part later with help of Arduino data cable to the Arduino.

● Phase 2: Testing and Deployment. Testing: After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again. Deployment: After, complete integration and testing of project real time running and operation of the system will be done. User need to check the value.

IX. FEATURES OF PROJECT

The Project consists of the following features:

1. Safety Signs: For showing the safeness of the project there is use of a buzzer .where buzzer will show the signs of leakage. If buzzer rang then there is a need to be alarm else there is whole safety.

2. High sensitivity and fast response: The smoke sensor used is highly sensitive to the amount of smoke generated each point of time in the region as soon as it senses the smoke above threshold it starts the alert system.

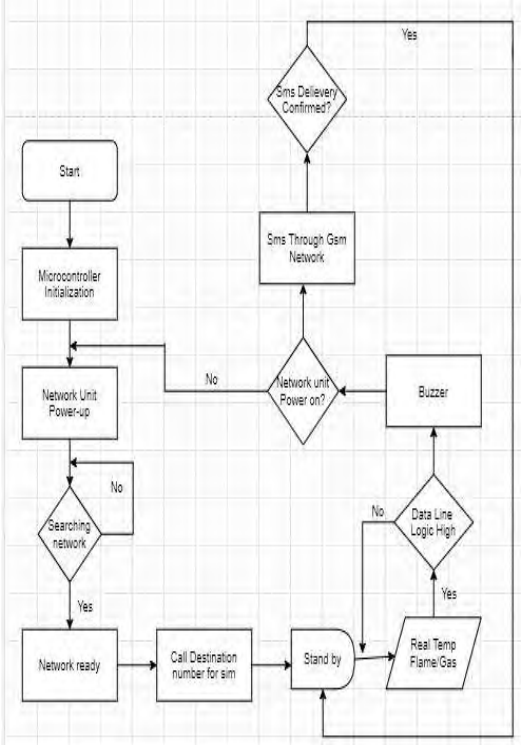
3. Long life and stable: The usual fire alarms are short lived because of the components used are of low grade here in this the sensor and the alert system does give an output to the Simple drive circuit.

4. The connections and the circuit design of this system is simple hence it is much more convenient to develop and find error in the system.

X. METHODOLOGY

The proposed method takes an automatic control action upon detection of gas. Initially if there is a Leakage detected then the electronic sensor i.e. the gas sensor that obeys the principle of sensor senses any fire in the region[5], if any leakage or fire is sensed then the output of this sensor goes high. This high signal is monitored by the microcontroller and it will identify the hike *Multicon-W 2020* in

the leakage amount. If there is a leakage or smoke detected, the consumer is informed about it through the LED light and



Sound of the buzzer.

Figure1: Flowchart of Proposed System.

XI. CIRCUIT DIAGRAM

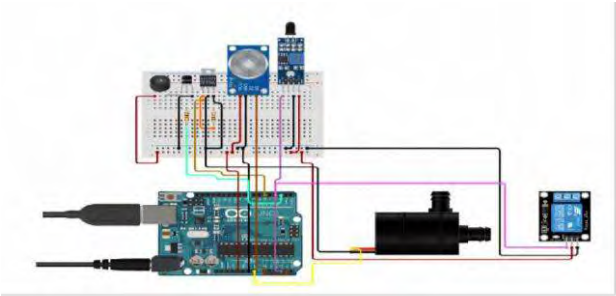


Figure2: Circuit diagram of Proposed System.

XII. RESULT & DISCUSSION

In this experiment, Flame and LPG gas are used for flame and gas leakage detection. Flame is detected by IR flame sensor and LPG gas is detected by MQ-135 sensor in various modes of parts per million**.** When the gas level was below the

threshold value the environment is safe and lcd shows the respective status.

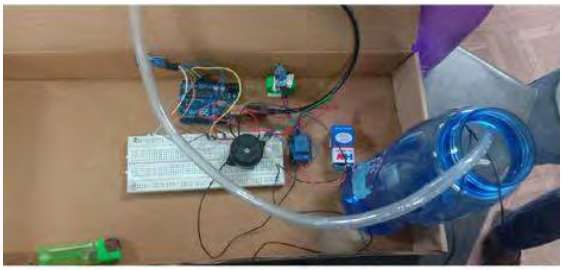

Image 1: Final System Orientation.

XIII. CONCLUSION

Through this system it's successfully shown the detection of Gas Leakage by IOT based project is possible which can detect Gas leakage and warn owners and remote contacts of an alarm situations. The alarms are detect reliably even in situations where there is high ambient noise. A weakness of the system is in the processing overhead used to constantly monitor the audio input of the phone. This application demonstrates the mobile phones ability to be used as a advanced warning device in the event of a smoke alarm activation, its automated group alert system reduces the chance of harm to people who have not been able to respond to an alarm.

XIV. FUTURE SCOPE

1. Gas Leakage detection and alarm system can be used with quadcopter and this quadcopter can be used to detect the regions of the fire or going to catch the fire, thus can be used to protect things.2. Moreover it can be used by people in mining industries to help them for saving their lives.

3. It can also be used in F1 cars as there is high possibility of catching the fire when car runs at that speed there is high possibility of them catching fire due to the web based output it can be conveyed to the driver and thus he can save his life and win the race.

IoT Enabled Smart Greenhouse using Arduino and NodeMCU

Jigar Vaishnav, Harshit Tripathi, Krishna Vishwakarma
Department of I.T.
TCET, Mumbai
jigar207844@gmail.com, tharshit07@gmail.com, mrkvishwakarma@gmail.com

Abstract—**Internet of Things (IoT), is currently the most trending field in the Branch of Information and Communication Technology. In the case of farming or agriculture, due to extreme weather conditions, the crops may get damaged and as a result, there are huge losses. Moreover, due to climate change the occurrences of floods, droughts, etc. which indicates that farming through traditional means will only increase loss in that field. A Greenhouse is a structure in which plants are grown in a closed controlled environment. Greenhouse warm up during the day when sun-rays penetrate through it, which heats the plant, soil and the structure. Greenhouses help protect crops from several diseases, particularly those that are soil-borne. Greenhouse temperature should not go below a certain degree, High Humidity can result to crop transpiration, condensation of water vapor on greenhouse surfaces, and water evaporation from the soil. To overcome such challenges, this system comes into rescue. After studying the literature survey, it was decided to overcome the research gaps and the system was tested using the test cases and then the outputs were generated. The output has been shown according to different test cases and thus the automated greenhouse system proved to be more responsive than those currently in use.**

Keywords – Internet of Things; Greenhouse; Sensors; Automation; Information and Communication Technology; Climate Change; Arduino; Programming;

I. INTRODUCTION

Internet of Things refers to the interlinking of ordinary everyday objects which are equipped with little or no intelligence, with software, electronics, network, and sensors which enables them to collect and exchange data. Internet of Things i.e. IoT enables us to automate certain processes and tasks which earlier required human intervention. Now a day's in our surrounding everything can be controlled and operated automatically. But there are some sectors where automation has not been adopted[1]. Agriculture is one such field. IoT will increase the ubiquity of the Internet by integrating every object for interaction via embedded systems, which leads to a highly distributed network of devices communicating with human beings as well as other devices[2].

A Greenhouse is an important part of agriculture. Mainly greenhouse is used to grow plants under controlled climatic conditions. Greenhouses which control and monitor many parameters like temperature, humidity, soil moisture and light intensity are important for better plant growth. In recent years, the greenhouse industry has got greater progress and improved agricultural labor productivity[3]. For controlling all these parameters and growth of plants without human involvement we can design automated greenhouse. Automation can replace human resources completely to yield quality products.

II. BACKGROUND

India demands at enhancing the adaptive capacity of the farmers so that they can cope with climate variability in the vulnerable districts to achieve climate-resilience and make it socio-ecological agriculture. Under NICRA, this technology is demonstrated and implemented in more than 151 climatically vulnerable districts of the country.

The rise in global temperature is not only causing drastic changes in climate but also it's contributing to the irregular rainfall patterns. Uneven rainfall patterns led to increased temperature, elevated CO2 content in the atmosphere are one of the important climatic parameters which adversely affects the crop production in India. Studies indicate that these weathering parameters influence (67%) to the growth compared to other factors like soil and nutrition (33%) during the cropping season. For every 1°F increase in the temperature, the crop yield falls by 3% to 5% in India. Hence, there is a need to study the dependence of the temperature on crop productivity, stability, yield, and quality to uplift the country's economy.

III. OBJECTIVES AND SCOPE

The objective is to implement a low cost, reliable and scalable Smart Greenhouse which will also be automated and it will also provide the various parameters of a plant online which can be accessed from anywhere which will help the farmers to a greater extent.

- To make a System which is self-sufficient and needs a minimum amount of human interference.
- To monitor the various critical parameters of the plant's environment.
- To grow any plant in an artificially controlled environment.
- To perform analysis on the data which is generated from the sensors and sent to cloud for improving the system's efficiency.

The scope of this system is to implement a Smart Greenhouse which can sense various environmental parameters like temperature, humidity, soil moisture,

water level, light intensity and upload these values to the cloud where it can be accessed via a smartphone.

IV. HARDWARE AND SOFTWARE REQUIREMENTS

Hardware and Sensors Used:

- Arduino UNO
- NodeMCU
- Relay Module
- DHT11 (Temperature Sensor)
- Soil Moisture Sensor
- LDR
- Ultrasonic Sensor
- LED Light

A short description of some important hardware components is as follows:

Arduino UNO:

It is a microcontroller board based on 8-bit ATmega328P microcontroller. It consists of components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller.

Fig.1 Arduino UNO

NODEMCU:

NodeMCU is an open-source LUA based firmware developed for ESP8266 Wi-Fi chip. By integrating functionality with ESP8266 chip, NodeMCU firmware comes with ESP8266 Development board/kit.

Fig.2 NodeMCU

Software Used:

- Windows 10
- ArduinoIDE
- Blynk

V. DESIGN AND FLOW

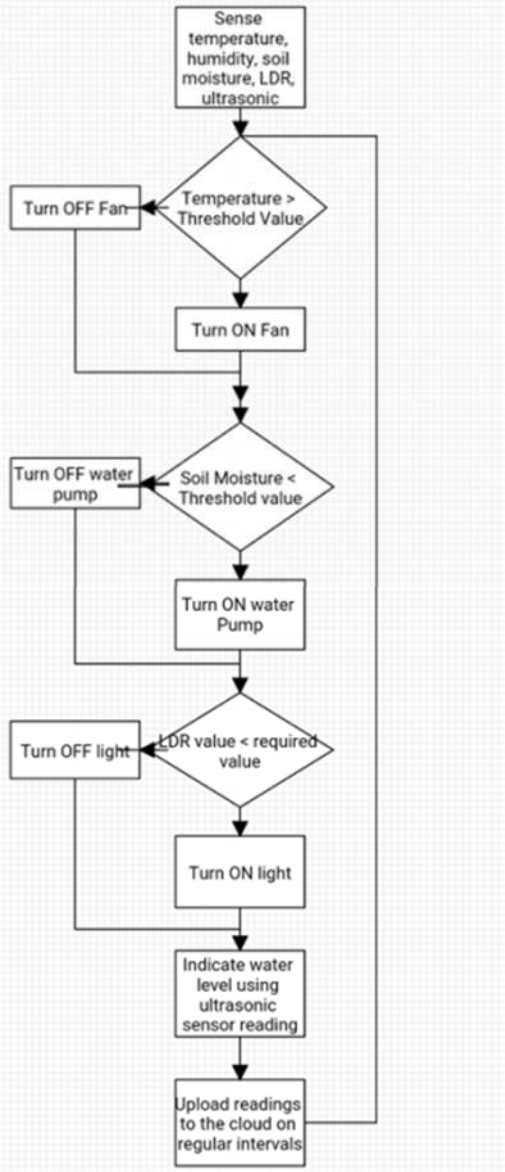

Fig.3 The Flow of System

VI. PLANNING AND METHODOLOGY USED

Phase 1: Designing

Proposing design architecture of Arduino and Control using IoT system for implementing the surveyed case studies and synopsis. Various modules will be created like the connection of sensors and actuators. Completion of coding and collecting data from sensors.

Phase 2: Implementation

i. DHT11 sensor is used to sense Temperature & Humidity inside the greenhouse. If the temperature is above the required value, the fan is turned on.

ii. The soil moisture sensor senses the moisture content of soil & turns on the water pump if the moisture is low.
iii. The LDR is programmed to detect shadow. This reading is used to turn on LED grow light if it is too dark.
iv. The Water Level of the tank is indicated using an Ultrasonic Sensor.
v. All these readings are sent to the cloud using a Wi-Fi connection by NodeMCU

Phase 3: Testing

i. In the first phase of testing, the readings of the sensors are obtained to check if there are any ambiguous readings. The soil moisture sensor is calibrated by taking a value in dry soil and another in wet soil. The sensors were tested successfully and were in working condition.
ii. In the second phase, the actuators are connected with the relay module which is in turn connected with the Arduino. Relay completes the circuit when a signal is sent by the Arduino. The threshold values are set to automatically trigger the actuators when the readings go beyond certain values.
iii. In the third and final phase, NodeMCU is connected to the Wi-Fi and the sensor readings are uploaded to the cloud at regular intervals.

VII. RESULTS AND DISCUSSIONS

Output: Based on the sensor use, we can achieve the desired outputs as follows:

1. As the DHT11's temperature reading goes beyond the threshold value, Arduino sends a signal to the relay module which turns on the fan of the Greenhouse.
2. When the soil moisture sensor value goes below the moisture limit which is required by the plant, the water pump is switched on by the relay module.
3. Also when the analog reading of the Light Dependent Resistor goes below the limit (which indicates shadow), the grow light of the greenhouse is switched on.
4. The readings of every sensor are uploaded to the cloud by the NodeMCU at regular intervals and a real time visualization is generated which can be accessed from anywhere in the world using a smartphone.

A screenshot of the dashboard inside the Blynk app interface is given below. Here we can keep track of the current conditions inside the greenhouse.

Fig.4 Blynk App Interface

Along with the functionality to keep track of the conditions inside the greenhouse, a graphical interface was also provided which displayed the variation of different weather parameters with respect to the chosen time duration.

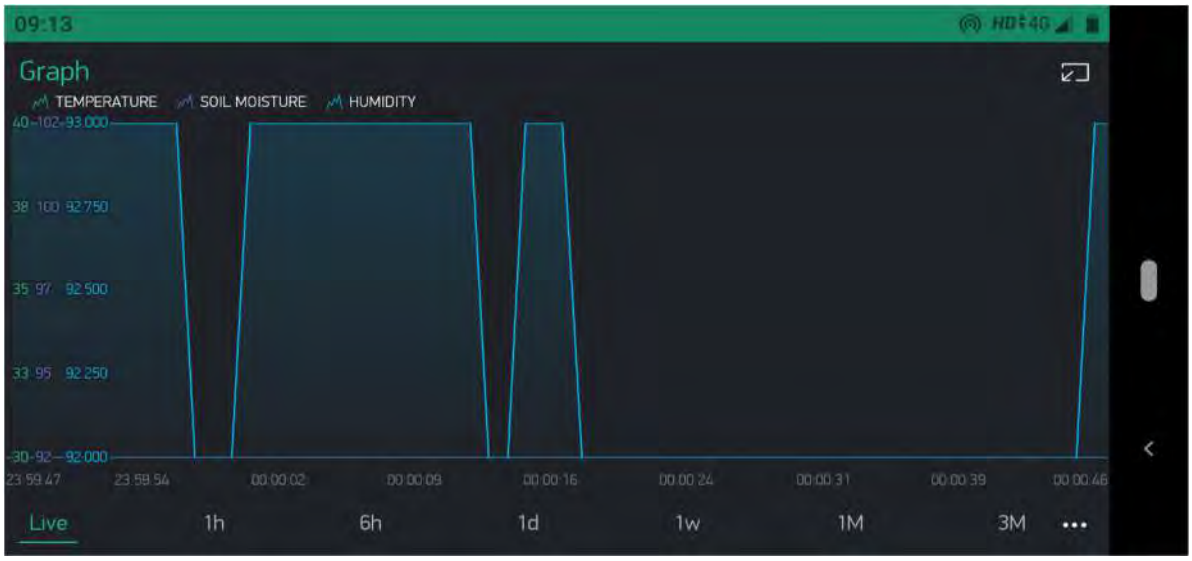

Fig.5 Graphical Representation

The proposed system is designed to function independent of human intervention. It can be programmed to maintain different weather conditions irrespective of the natural conditions. This enables us to grow a wide variety of crops which require a specific environment. Any anomaly in the system can be detected by just glancing at the dashboard.

Smart greenhouses have a very vast field of application. They enable farmers to grow crops which require certain specific climatic conditions. The farmers previously were majorly dependent on rains and other natural factors. These factors vary significantly every successive year which gives an uncertainty in the yield of crops. Greenhouses can help overcome these factors by simulating specific climate inside them. This enables farmers to grow crops which are not native to their region. Smart greenhouses will help collect data which when analyzed can give us some very valuable insights on the changing environmental factors inside the greenhouse and can help us build better greenhouses in the future. Smart Greenhouses are a step towards a smarter future.

VIII. CONCLUSION

In this project, we created a working model of a Smart Greenhouse by carefully analyzing all the parameters in an automated greenhouse. This model performs several functions which are as follows:

- Water is supplied to the plant when the water content of the soil is low.
- The fan is switched on to bring the temperature down as soon as it goes beyond a limit.
- When the amount of light available to the plant decreases, the LED light is switched on.
- The water level of the tank is also indicated.
- Sensor data is regularly uploaded to the cloud.

The above points indicate that our model is working as intended. The greenhouse is performing all the functions as it was planned earlier. This project will act as a contribution to the field of smart farming. Hence, we have successfully achieved our objective to create an automated greenhouse which is IoT enabled.

Importance of Project:

1. Use new technology that uses the Internet of Things (IoT) concept.
2. To grow any plant in an artificially controlled environment.
3. To achieve cost savings.
4. To enhance the ability of a device to research by collecting data.
5. To automate the process of farming.

Rfid Access Control System

Omkar Punekar, Prasad Paradkar
Tcet, Mumbai
kartikpunekar7@gmail.com, prasadparad37@gmail.com

Abstract – **There has been raising interest for secure system that must be reliable and fast react for the businesses and friends. RFID (Radio Recurrence Identification) is one of the steady and quick methods for recognize the material article. In the sometime in the past the scanner tags are progressively ideal when contrasted with RFID in light of their expense however now daily's RFID are effectively accessible and are increasingly advantageous to utilize. Research has rolled out some extreme improvements which makes its programming significantly shorter and simpler is a direct result of supplanting microcontroller with Arduino. Arduino makes the circuit and programming significantly more obvious. Paper depends on security get to utilizing RFID and Arduino module**.

Index Terms— RFID tags, Arduino UNO, RFID Reader.

I. INTRODUCTION

This paper gives information on radio recurrence recognizable proof (RFID) innovation. At first RFID labels were made to in the long run supplant scanner tags in various chains. Their points of interest are that they can be perused remotely and with no observable pathway, contain a bigger number of information than scanner tags, and are more grounded. As the paper depicts The on-going innovation, incorporate the recurrence ranges utilized and gauges required. With the expansion in universality

of RFID labels, in any case, protection became unease. The paper diagrams plausible assault that can conflict with one\'s security and it additionally portrays negate measures. The RFID innovation didn't stop at thing-level labelling. Since the utilizations for RFID labels are so broad, there is an enormous enthusiasm for bringing down the expenses for generation of RFID labels. Things being what they are, printing labels may turn into a conceivable option in contrast to customary creation.

II. BACKGROUND

Today individuals are confronting extra issues approximately security in all finished world, nowadays security is the maximum fundamental difficulty anywhere on the planet; so, safety of the whole thing increases increasingly elevated importance as of overdue. Here in this paper, endeavoring to copy the thorough writing study recognized with the one-of-a-kind entryway bolts and gate protection frameworks that are critical within the fields, for example, home, agencies and vehicle safety where potential outcomes of invasion are increasing step by means of step. In beyond days, the exploration is long gone onspecific entryway bolt safety frameworks like normal safety frameworks which give signs and symptoms utilizing caution. Because of the headway in past due strategies, some entryway bolt protection frameworks rely on microcontroller, GPS, numerous sensors, programming like MATLAB, PROTEUS, and biometrics like face acknowledgment, Iris scanner, RFID, Smart Card and mystery key and so on. Every framework has its own factors of hobby and weaknesses. In the greater a part of frameworks, SMS method is utilized for correspondence so the framework will move in the direction of turning into savvy, extra dependable and it'll require less investment to bring message. As security ends up real trouble in recent times, the security checking frameworks today desires to make utilization of the latest innovation. In some papers, the creators have added entryway bolt protection looking at framework in mild of inserted and Zigbee and occasionally the bolt is ensured via programmed secret key henceforth it couldn't without a good deal of a stretch hack through programmers. Additionally, the upgraded safety frameworks are on hand in mild of android stage, remote methods and inserted frameworks. A amazing deal of adjustment takes places in special Gate bolt security from the maximum recent couple of years, in subsequent coming years several progressions will happens. RFID, Radio Frequency Identification is a modest innovation, may be carried out for some applications, for example, protection. RFID (Radio Frequency Identification) is one of the predictable and brief methods for distinguish the material protest. In the long-earlier the standardized tags are more perfect while contrasted with RFID in light of their cost however now daily's RFID are effortlessly accessible and are more helpful to utilize. Research has rolled out a few brilliant upgrades which makes its programming a considerable.

III. OBJECTIVES

The objectives of project:

It will also use to monitor the access to door.

It can reduce chances of entry of trace passer (unknown person).

It can avoid time consumption of manual attendance records

It improves whole system by making it online and high-tech. It helps to find who and when accessed the system.

IV. PROBLEM DEFINITION

Security represents protection of our lifestyles and assets. Ensuring protection of peoples and their precious things is very vital for the prevention of illegal handling. Hence, especially specializing in door lock protection or gate security is very crucial to keep away from the further troubles in monitored area. Even with the usage of mechanical locks, the crime, robberies get happened because of the reality that such locks were easily broken. So, there's a want to invent other type of locks which cannot be easily broken. So, we through our venture we are presenting a lock that is a RFID Door Lock that could be a easy door lock that can be connected to any ordinary door. It unlocks when the presence of the RFID tag is close by and locks when it is not detected. There is also a LED that lets the user recognize while the door is locked and

unlocked. It provides the safety of a normal door lock without the problem of keys.

V. SYSTEM COMPONENTS

RFID tags: A RFID tag is a smooth card of Visa size which is perused by using a RFID according to person. It works at 125kHz and accompanies a one in every of a kind 32-piece ID. Ordinarily, every tag has top notch ID range which cannot be changed. We can discover its thrilling ID thru programming.

Arduino Uno Board: It is an open supply hardware prototyping stage dependent on bendable, simple to-utilize gadget and programming. It is proposed for craftsmen, fashioner, experts and anyone eager on producing specific shape for objects or ecological reason. Arduino UNO is a board primarily based on ATmega328 microcontroller. It contains of 14 computerized input/yield pins, six easy statistics sources, a USB connect for programming the on-board microcontroller, manage jack, an ICSP header and a reset catch. It is paintings due to 16MHz precious stone oscillator and consists of everything predicted to help the microcontroller.

RFID Scanner: A RFID consistent with-consumer is the cerebrum of the RFID framework and is vital for any framework to work. Per -users, likewise called questioners, are gadgets that transmit and get radio waves so as to speak with RFID labels. RFID in step with -customers are often partitioned into unmistakable sorts – Fixed RFID Readers and Mobile RFID Readers. Fixed per users stay in one location and are regularly set up on dividers, on work areas,

into entryways, or other desk bound areas. A regular subset of constant in keeping with customers is coordinated per users. A coordinated RFID according to user is a consistent with consumer with a worked in receiving twine that usually incorporates one greater reception equipment port for the association of a discretionary out of doors radio twine too.

Buzzer: We are utilising piezoelectric bell. This is an admonition/signal that invalid endeavour is achieved to get right of entry to framework.

Servo motor: It can be utilized to expose show off of entryway or door opening.

LED: The LED motive is whilst a correct entry is made it glows.

Arduino IDE: The IDE is a special program strolling on a laptop that lets in one to write down sketches for the Arduino board in easy language version after processing the language.

VI. METHODOLOGY

The undertaking has the accompanying work process: on landing at the entryway where the entrance control is introduced, one is approached to surmised their RFID tag to the per user. The per user peruses the tag and the microcontroller think about the tag's UID for match and award get to if there is a match and deny get to if there is no match. A RFID tag can be included or expelled through the Arduino IDE or some other programming language that Arduino gets it. For changes made on the sketch (for example including or evacuating a tag) to be viable on our framework, the sketch must be re-transferred to the Arduino board to

supersede past sketch. In other to include another client, we should initially enrol the client with the framework at that point, relating client data is consume in RFID tag. The new label will presently be open through the framework.

VII. BLOCK DIAGRAM

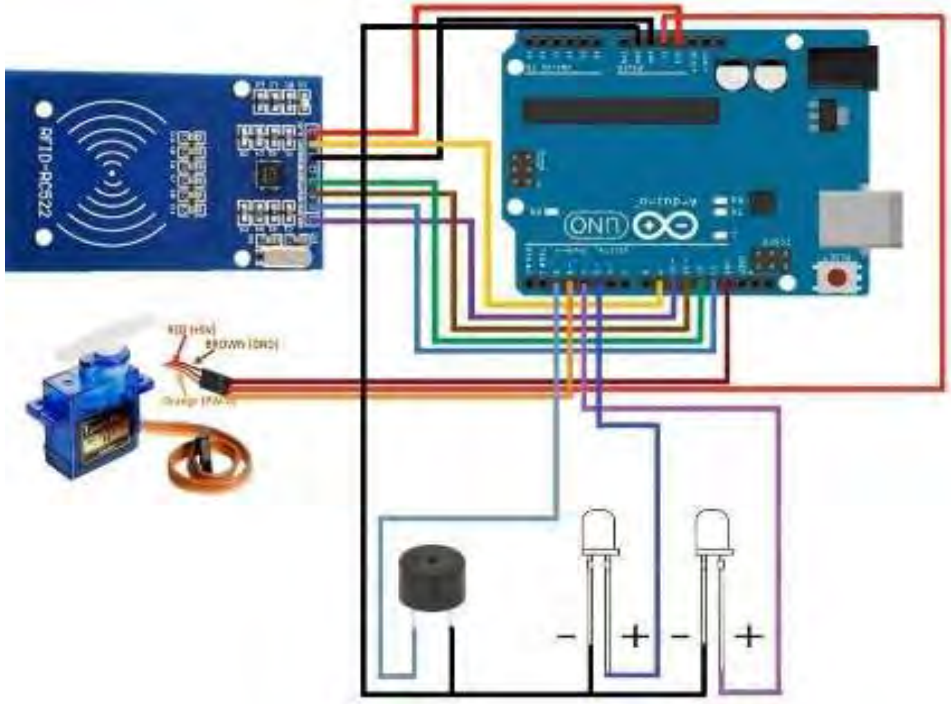

Fig1: Block Diagram

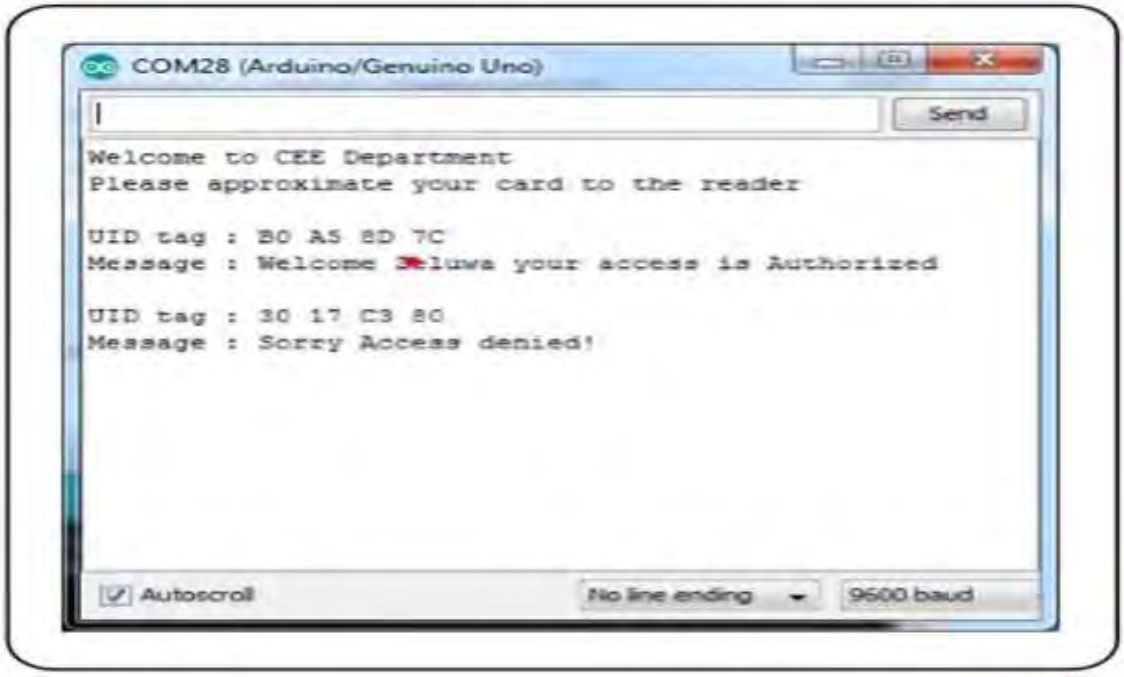
VIII. GUI SCREENSHOT



IX.

Fig 2: GUI Screenshot

X. OUTCOMES

In this project, a prototype of automatic access control system for use in an environment is presented. The system uses radio frequency identification (RFID) with Arduino technology to differentiate between authorized and unauthorized users. The RFID reader reads RFID tag issued to the user and matches it with stored UID on the Microcontroller. On a successful match, the microcontroller grants access or deny access if no match was found. An automatic access control system using

Arduino and RFID has been prototyped and functioned as desired. The system can be installed at the entrance of a secured environment to prevent an unauthorized individual access to the environment. The Arduino board became programmed through Arduino IDE. All

necessary information about all customers is stored within the gadget.

XI. TESTING & DEPLOYMENT

The Arduino board became programmed through Arduino IDE. All necessary information about all customers is stored within the gadget. In other to add a new user, we should first register the consumer with the machine then, corresponding consumer statistics is burn in RFID tag. The new tag will now be accessible via the device. Access control device changed into analyzed using the following criteria: cost, electricity consumption, speed, user satisfaction, and stability. The improvements come within the location of cost, strength consumption, speed, and stability.

XII. FUTURE SCOPE

An RFID access control management system turned into designed for organizations. Ideas had been supplied for making whole system online the usage of portable tool and 3G cellular technologies. The future expectations from this task are to in reality implement such device for one or more agencies if sufficient budget is supplied to us.

XIII. CONCLUSION

The RFID enterprise goes to go into an energizing period wherein expanded selection will provide the manner to innovation providers to put resources into new, energizing developments. Alongside the brand-new improvements depicted above, headways in materials, herbal polymers, Nano innovation, and extraordinary territories will trade the manner RFID is fused into items. It relies on how unique one should be to enhance the utilization of this venture.

Wireless Notice Board

Apurva Dalvi, Shweta Mishra, Fatema Ujjainwala
TCET,MUMBAI
apurvapdalvi@gmail.com, shwetamishra5499@gmail.com, fatemaujjainwala97@gmail.com

Abstract— **The Internet of things (IoT) is currently the most trending field in the Branch of Information Communication Technology. It is the extension of Internet connectivity into physical devices and everyday objects. IoT is a rapidly expanding field in the world of technology. It helps ease life for a person by means of internetworking physical devices, automotive, home appliances and other items embedded with electronics, software, sensors and actuators.**
Nowadays conveying messages on a large-scale using notice boards is used widely from schools to various organizations. The significance of notice boards in public areas like bus stands, railway stations, airports, and banks, etc. is known by us. But changing these boards every day is a laborious task and a waste of time. At present, all electronic boards are designed with a wired system. The major drawback of designing these boards is; not flexible and cannot be located anywhere due to messy wire.

To overcome this problem, a wireless board is designed to display the latest information. The main objective of this project is to develop a solution that provides real- time notices; so, a Wireless Notice Board using Arduino and GSM technology was developed that displays messages sent from the users mobile. It has a very wide scope rather than just being a simple notice board.
Keywords – Arduino, GSM, Wireless Notice Board, Messages.

I. INTRODUCTION:

The Internet of things (IoT) is the extension of Internet connectivity into physical devices and everyday objects. IoT is a rapidly expanding field in the world of technology. It helps ease life for a person by means of internetworking physical devices, automotive, home appliances and other items embedded with electronics, software, sensors and actuators.
All present electronic notice boards are designed with a wired system. The major drawback of these boards is that, it's not flexible and cannot be located
anywhere due to messy wire. Also, some of the places need urgent notices like in college, railway stations share-market, and this notice should be in real-time; so we need a real-time notice. So to provide a solution that displays notices in real-time, a wireless board is designed to display the latest information using the GSM technology.

GSM network is widely used today whether it is for calling or SMS. When a mobile user sends the information from his mobile, it is received by a SIM slot, which is integrated into a GSM modem at the receiver end. Once the information is received, it is displayed on the notice board. It has a very wide scope rather than just being a simple notice board.

II. BACKGROUND:

Traditional Notice Boards are often ignored as there is a lot of information on the board. They can become untidy and irrelevant as time passes and it is difficult to maintain and regularly update the information on the board. Also, when the information on the notice board is to be displayed, a hardcopy is required that leads to the usage resources like paper and finances that are recursive.

The alternative for Traditional Notice Boards is a Hard-Wired Digital Notice Board. These Notice Boards decrease the recurring financial expenditure. But whenever the information on this notice boards is updated it has to be done from an allotted system you cannot update the information from remote locations or any other location except the allotted one.

As there is a need of real-time update of information, a wireless board is designed to display the latest information using the GSM technology. This allows us to display notice in real-time by sending the information from a mobile, which is received by a SIM slot that is integrated into a GSM module at the receiver end. Once the information is received, it is displayed on the notice board.

III. IMPORTANCE OF THE PROJECT:

The requirement of Wireless Notice Board is because of the need of real-time notices in some of the places like in college, railway stations share- market, etc. which require urgent notices. Hence, there is great importance of the project in day-to-day life. Importance of the Wireless Notice Board are as below:

The Notice that is displayed on the LCD screens is repeated unless there is a new notice that is to be displayed.

Correctly maintained and constantly updated notices are effective and proven to benefit the Organization.

Constantly updated notices keep the people updated about the situations.

IV. OBJECTIVES AND SCOPE OF THE PROJECT:

The main objective is to design an automatic self-enabled highly reliable electronic notice board, a display connected to a server system should continuously listen for the incoming call from client or user process it and display it on the LCD screen message displayed should be updated every time the user sends new data only

authenticated people should be able to able to access the server.

The proposed system provides efficient ways to outspread notices through LCD Screen. The LCD Screen is interfaced with GSM module through Arduino.

When we send SMS from mobile phone to GSM module then GSM receives that SMS and sends it to Arduino. Now Arduino read this SMS and extract main notice message from the received string and stores in another string.

And then sends the extracted message to 16x2" LCD by using appropriate commands. Which is displayed on the LCD Screen.

V. SUMMARY:

Due to advances in wireless communication it is possible to control devices without physical movement. This is possible with the use/design of an embedded system in communication giving comfort and safety to human life. The main aim of our project is to design a Wireless Notice Board that can replace the currently used programmable electronic display. The Receiver and display board can be programmed from an authorized transmitter. The microcontroller receives the SMS and displays the desired information. Such a system is helpful for immediate information transfer

VI. PROBLEM DEFINITION:

To design a Wireless Notice Board using Arduino and GSM Technology that will display urgent notices, information in real-time that are sent by user's mobile, which can replace currently used conventional notice boards.

We will use various components such as GSM 900a Module and the 16*2 LCD for displaying the received SMS, Arduino UNO as a processor which turns out to be the best and most suitable option, Breadboard and Jumper Wires to make connections among all the components. Overall the system provides a complete solution for the problem.

VII. RESULTS:

A. Outputs:
When all the components are connected properly, the LCD shows the respective status.

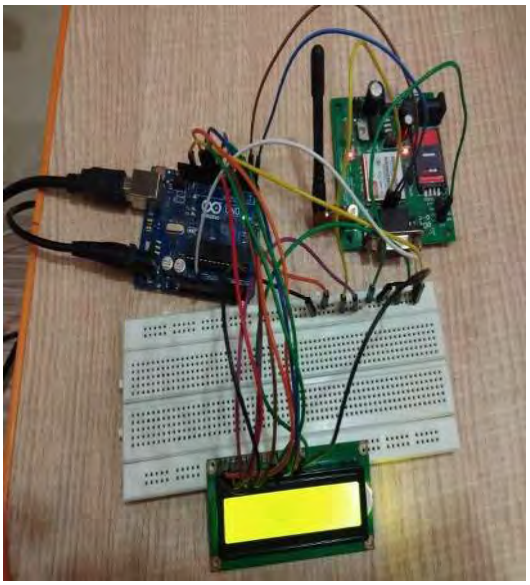

Fig1: All components connected together

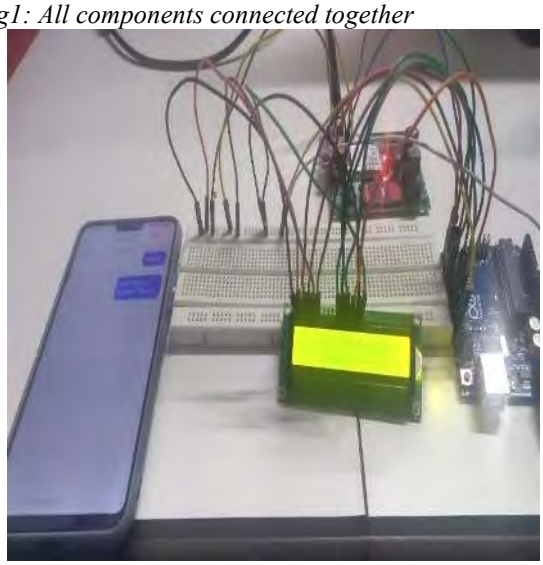

Fig2: Working model of the project

VIII. OUTCOMES:

Phase 1:
1.Analysis:
Creating the synopsis, literature survey and feasibility study for proposed solution which will act as an input to the design phase.

2.Planning:

Proposing Statement of work, scope definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done.

3.Designing:

Proposing the design architecture for the prototype.
4.Implementation:

Implementation of Arduino UNO with the help of code running in the Arduino IDE environment.

PHASE 2:

1.Testing:

IX. SCREENSHOTS:

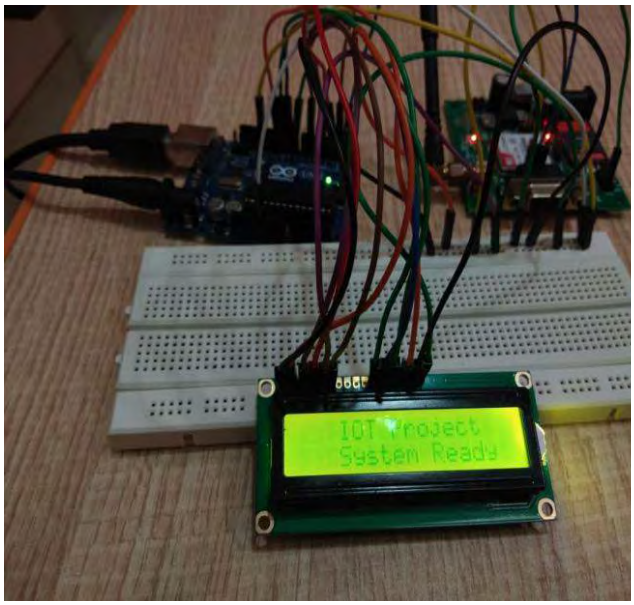

Fig 3 : Wireless Notice Board

Fig 4 : SMS interface of the project

Testing was done by sending messages multiple times to the GSM module.The testing of the model successes are mentioned in the above figures.

X. IMPROVEMENTS IN RESEARCH GAPS (FINDINGS):

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

We can integrate Artificial Intelligence with the existing system, which will analyze the data and situations of the surroundings and display urgent notices on its own. For instance, Displaying the urgent message “Evacuate Building” in case of fire emergency.

We can use Wi-Fi Module instead of GSM Module, to increase the efficiency of the system.

We can use LED Screens to display notices, which might reduce the power usage.

XI. FUTURE SCOPE:

Electronic Notice Board is one of the applications where WIFI and Raspberry pi can be used effectively. It can also be used in Malls and Highways for Advertisement purpose. A moving display with variable speed can also be used in place of static display.

1.In this project we are sending messages over a GSM network and displaying it on an LCD by the use of AT (ATtention) commands.

2.The same technique can be applied to control electrical appliances at distant locations.

3.Robots can be controlled in a similar manner by sending the commands to the robots. This technique can be used for spy bots at distant locations, utilized by the defense organizations to monitor the movement of enemy troops.

4.Alphanumeric LCDs have limitations on size as well as number of characters. These can be replaced with large LED displays which are not only eye catching but display characters in a moving fashion one after the other.

XII. CONCLUSION:

As the technology is advancing every day the display board systems are moving from Normal hand-writing display to digital display. Further to Wireless display units. This paper develops a wireless notice board system with GSM modem connected to it, which displays the desired message of the user through an SMS in a most populated or crowded places like railways, bus stations, airports and also at roadside for controlling the traffic and in emergency situations. It is economical system and very easy to handle. Use of papers in displaying of notices is avoided. The information can only be updated by the authorized persons.

XIII. ACKNOWLEDGMENT:

The success and outcome of this project required a lot of guidance and assistance from many people and I am extremely privileged to have completed the project successfully. I would like to thank everyone for their guidance.

We sincerely thank our principal, Dr. B. K. Mishra, Vice Principal, Dr. Deven Shah, Mentor Dean, Dr. Kamal Shah and HOD, Dr. Rajesh Bansode for always encouraging us to do our best. We highly indebted to our

guide Mr. Anil Vasoya, who supported and constantly supervised us throughout the project and helped us in not only completing this project but also provided us with ample amount of knowledge that was beneficial to us.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staffs of IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in laboratory for their timely support.

We would like to express our gratitude towards our parents for their kind co- operation and encouragement which helped us in completion of this project.

Intrusion Detection System

Mr. Abhijeet Varma, Mr. Subhesh Singh
Information Technology, Thakur College of Engineering and Technology, Mumbai
abhivarma58@gmail.com,subheshs99@gmail.com

***Abstract*— Intruder detector performs the process of detection of any undesirable person or object that might pose some threat in house or an area and the implementation of some important measures to be performed so as to alert the members of the house or an area and increase the security of that place simultaneously. At times**
If an intrusion can be shown on the monitor in a graphical manner then it will enable the user of the system to understand the security of the area in a much more better manner. There is a rise in the requirements of affordable and effective security solutions. In the near future people will prefer security options that require very security system will find it very easy to monitor the safety of their important environments. Thus, this system will alert the owner about intrusion activities and can also take certain measures for protecting the area.
Keywords – Intrusion detection, security using IOT.

I. OVERVIEW INTRODUCTION:

Intrusion, the act of someone that you don't know, who enters into your area without your permission, is on the rise. A human intrusion detection system is devised to detect an unauthorized entry as, if it enters into the building premises it might pose threat to the security hence it must be denied access and an alert must be generated to the security officials to take necessary actions against the possible vulnerability. The purpose of using Security Systems is to safe guard the area of concern hence it finds many of its applications in commercial areas, residential, and in military areas. One cannot always trust humans for security as they might not be completely reliable. In such cases, this system provides proper detection of intruder and provides security. By using this system, we can reduce robbery by detecting the intruder. So we can respond quickly such that no harm takes place in our home or the area of concern. The action that has to be taken would depend on the area of use, like we can have a simple alarm if the intruder enters a residential area. Now a days there is less dependency on the humans for security as they might not be as efficient as security systems and hence they cannot be always relied.

If an intrusion can be shown on the monitor in a graphical manner then it will enable the user of the system to understand the security of the area in a much more better manner. There is a rise in the requirements of affordable and effective security solutions. In the near future people will prefer security options that require very less maintenance. Using the Internet of things technology in the domain of Security will enhance its overall effectiveness and efficiency to a great extent. Using the internet one can monitor, maintain, or modify the security system. Therefore it will enable the user to have complete access to the features and capabilities of the security system and this can be achieved independent of the location of the user that is by using internet.

II. IMPORTANCE OF THE PROJECT:

• Intrusion detection system using Radar can be used in small scale security applications.
• The applications where a cheap security is needed is the biggest market as the system is quite cheap and affordable.
• It can help achieve security for us and the security personnel can see a GUI based RADAR on their screen which will make the managing of the security easier and more user friendly.

III. PROJECT MOTIVATION:

In this present scenario, we can observe that the security systems that we find in the market are quite expensive and there is a big scope for a cheaper security system. We also needed to make a very user friendly application for security, we have hence made a RADAR which enables the user to detect where exactly the intruder is. The user can see the distance and the degrees of the location of the intruder. There are also many restricted places which cannot be monitored at all times hence there we can deploy a cheap and cost effective monitoring system and once the intruder is detected the security officials can see the location of the intruder on their monitoring screens.

IV. PROBLEM DEFINITION:

Theft and Robbery are some of the dangerous threats across the globe in recent times. The home security systems have been constantly failing to safeguard houses and offices. According to a survey conducted by FBI, all the intrusion problems are being occurred in absence of the owners in the home. In the year 2012, a house is being invaded by the intruders for every twenty seconds. Among these, only 10% of them end up in arrests, and rest of them are still suffering from intruders. There are many solutions for this problem like home automation systems, alarm detection systems etc. but there is a chance of producing false alarms by these Systems.

V. LITERATURE SURVEY

IoT Based Human Intrusion Detection System using Lab View

Now a days there is a rise in thefts. This creates a very bad environment for people to live in fear. The issue with home security in the today's world is a cause for concern. The traditional intruder detection system now we are using are very expensive and there can be a possibility of false alarms. This issue can be solved by building a home intruder detection system that can precisely detect a human intruder,

while filtering out movements that are caused due to any other moving objects using LabVIEW and Python. [1]

Internet of Things for Smart Cities

The purpose of this paper is to discuss a general reference framework for the design of an urban IoT. It describes the specific characteristics of an urban IoT, and the services that may drive the adoption of urban IoT by local governments. [2]

The Future Internet of Things: Secure, Efficient and Model-Based

This paper proposes a solution for the possible problems regarding privacy and security. It presents an Architecture applying process knowledge to provide protection through abstraction and privacy through remote data fusion. [3]

VI. FEATURES OF THE PROJECT:

1. Simple and easy to install and configure.

The project contains simple components which do not require complex understanding and can be very easily deployed by the users of this project. There is one ultrasonic sensor and one servo motor that is used also one buzzer has been used to generate an alert.

2. Saving energy and resources, so that it can be utilized in proper way and amount.

3. Automating many of the tasks in the security may help to improve the safety.

One does not need to continuously manage the system as it automatically scans the area and alerts the user if an intrusion is detected.

4. Detection of intruders in real time by using buzzer and radar.

The use of buzzer is simple yet effective as it can signal the intrusion very effectively, the Radar GUI used shows the exact position of the intruder so if the security personnel wants to catch the intruder they exactly know where to go.

5. Automated Intrusion Detection System uses ultrasonic sensors to help security personnel maintain safety.

VII. ANALYSIS AND PLANNING

COMPONENTS	**COST (Rs.)**
Arduino uno	345
Ultrasonic sensor x 1	100
Jumper wires	100
Servo Motors ×2	240
Active Piezo buzzer x 1	60
TOTAL	845

Table 3.1 Cost

HARDWARE:

Arduino UNO ×1:

Fig. 3.1 Arduino UNO

The Arduino Uno is an open-source microcontroller board based on the Microchip ATmega328P microcontroller and developed by Arduino.cc. This board consists of sets of digital and analog input/output pins that may be interfaced to various expansion boards and other circuits.

Servo Motors x 1:

Fig. 3.2 Servo motors

Servo motors are DC motors that allows for specific control of angular position. The servo motors are actuallyDC motors whose speed is gradually lowered by the gears. The servo motors usually have a revolution cut- off from 90° to 180°. A few servo motors also have revolution cut-off of 360° or more. But servo motors do not rotate constantly. The rotation of the servo motor is restricted in between the fixed angles

Jumper wires:

Active Piezo Buzzer:

Fig.3.5 Piezo buzzer

An active piezo buzzer will generate a tone using a internal oscillator, so all that is a DC voltage. It can be used as an alarm for indicating an event in a project.

Software:

Fig. 3.3 jumper wires

The jumper wires are used to transfer electrical signals from one point to another point in the circuit. The wires are used for modifying the circuits or to detect problems within a circuit. Jumper wires can have various colors and sizes depending on the area of application. Jump wires are used in breadboards to set up connections between the central micro controller and other devices such as buttons and sensors.

Breadboard:

Fig. 3.4 Breadboard

A breadboard is a construction base for prototyping of electronics. In the 1970s the solder less breadboard became available, nowadays the term "breadboard" is commonly used to refer to these.

Arduino IDE:

It is software package used to program microcontrollers by writing a program in high level Arduino language which is then compiled to binary and uploaded to development board at correct baud rate depending on the board itself.

Circuit Diagram:

Fig. 3.6 Circuit DiagramDESIGN OF PROJECT:

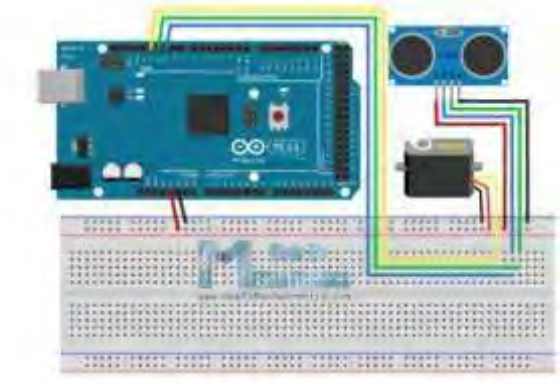

Fig. 3.7 Design of Project

VIII. FLOWCHART

many people will get attracted towards this system. For future scope we can add more functionalities, to make a more holistic device and increase its acceptance.

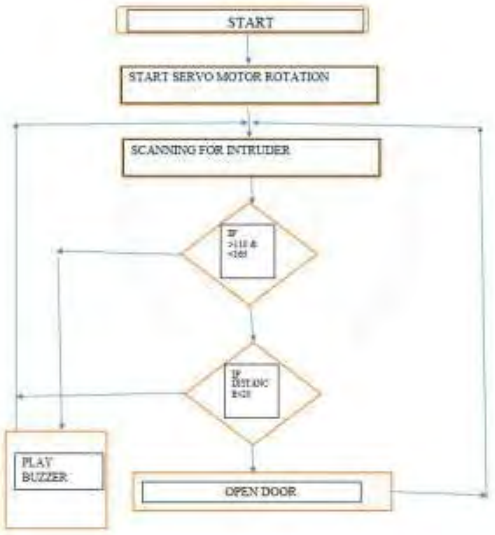
Its future scope is quite vast. The project made by us is a simple prototype and an actual model can be made using simple ultrasonic sensor and a servo motor. Many features can be added to the existing project like enabling the user to

be able to view the current status of the concerned area on a mobile phone. Another feature that can be added is generating SMS to the user and also Email may be send on the users' device.

One can also add features such as a dashboard online on a website which would show the intrusion attempts that were made in the past week, past month, past day, or any time period specified by the user of the security system. By analyzing all these parameters one can improve their security furthermore by seeing its severity.

IX. V. RESULT

We have developed a device that can detect intrusion of any person in restricted place. If someone trespasses then he will be alerted using a buzzer. A display show the location of the person, distance that how long he/she is and at what degree. If a person detected than radar becomes red indicating presense of a person. We have Lessen the cost of this security device, so that it can be made available on a small scale.



X. WORKING:

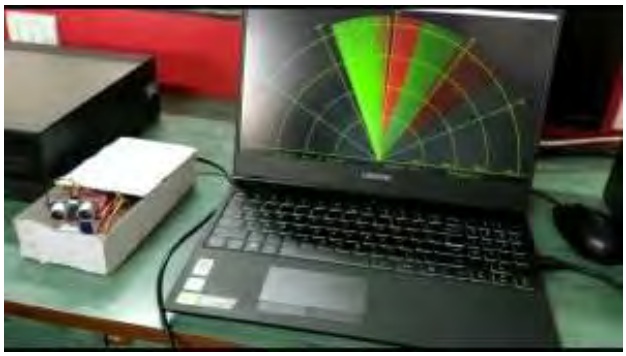


Fig. 3.8 Flowchart

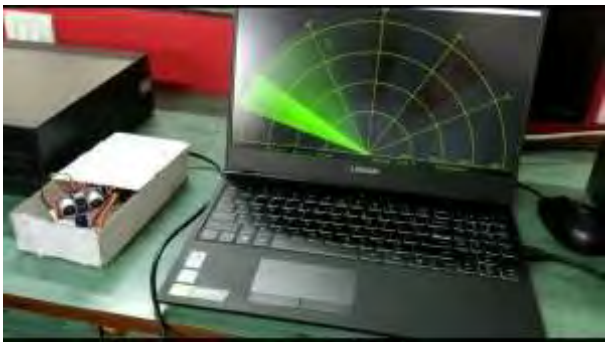

Fig 5.1 Actual Working model

The Arduino device needs to be connected to the laptop device where the GUI of the RADAR has to be seen. After this the Ultrasonic sensor that is attached to the Servo motor will start scanning the surrounding area. This can be seen on the Laptop. If there is any intruder in the given range then it will be marked by red on the RADAR GUI. If the intruder enters the region which sensitive then the buzzer will get activated. When the intruder goes out of boundary then the buzzer will automatically get triggered off.

XI. SCOPE OF THE PROJECT :

This project can have application where a simple and a cost effective security is needed. If the security is busy in some other task then their system will detect and alert any intruder in restricted area. As it is quite affordable

XII. CONCLUSION

Generally, these days' people make use of CCTV cameras for security of their home or offices but it has a few disadvantages like, it can simply record the area and if theft takes place you can see the recording for any information related to the trespasser, but we want a mechanism or arrangement to alert the owner about the threat so that it can take immediate action or some predefined action can be carried out. Therefore we have created our simple and affordable solution for the problem of intrusion in an area of concern. Now with our human intrusion detection system we are able to keep a constant watch over the house. As soon as the system detects any intervention, it will start buzzing and will alert the surrounding. We won't require any memory storage because we are not functioning like a CCTV camera. As this system does not contain any expensive components, this system is affordable and can be used at places where a cost effective security solution is desired.

Hand Gesture Controlled Wheelchair

Anjali Chauhan, Pradum Chauhan, Vaibhav Dixit (Te-Ita-21)
Thakur College of Engineering and Technology, Mumbai, India
chauhananjali8991@gmail.com, chauhanpradum1681@gmail.com, vaibhavdixit313@gmail.com

Abstract—**Research suggests that an estimated 1% of the world's population, or just over 65 million people, need a wheelchair. Joystick-controlled wheelchairs are available on the market these days whose cost range ranges from Rs 60,000 to Rs 90,000. This Hand Gesture Controlled wheelchair will be prepared in less than Rs 15,000. This paper is to design a Hand Gesture Controlled Wheelchair for the bodily disabled people who face difficulty moving in today's life from one place to another. This paper is intended to build a wheelchair helpful to the physically handicapped person which can be controlled by hand gesture by using accelerometer. This uses a mechanism that controls the user's hand gestures in the wheelchair and interprets the user's motion and moves accordingly. The user can use simple hand gestures to move the wheelchair without any external help or support. This can be used in both hands and can be operated from a distance to reach the user.**

Keywords – IoT, Arduino UNO, gesture control, Accelerometer, transmitter, receiver, wheelchair

I. INTRODUCTION

The term IoT refers to things we use on a daily basis that also connect to the Internet, allowing us to monitor or receive data about the "thing" from our smartphone or computer. Internet of things helps us to work smarter, live smarter and deal with our lives, but it also supports behind the scenes wellbeing. Research says that One billion individual, or 15% of the world's population, experience some form of disability, and handicap commonness is higher for developing countries. It is therefore extremely important to build a system in order to make their lives easier and more versatile. Most people now need a wheelchair because of the growing percentage of elderly people and people with disabilities who want to make their personal mobility easier.

This article introduces a hand gesture-based wheelchair system for handicapped person, who are partially paralyzed. In this process the physical movement of the hand is sensed with sensors and accordingly the wheelchair is controlled. This paper is to demonstrate that accelerometer can be used to control wheelchair using simple hand gestures. The purpose of this project is to control a wheelchair using an accelerometer and RF module. The system is enabled and working based on user hand gestures. Accelerometer is a profoundly sensitive sensor and capable of detecting the tilt. It senses the tilt and the signal is transmitted to the receiver via transmitter; interfaced with Arduino and accelerometer. The sensed signal is transformed into electrical signal and then the signal is transmitted after converting analog signal into digital signal. If the tilt is on the right side then the wheelchair moves to right direction or to left if the tilt is to the left side. Wheelchair movement can be controlled in Forward, Right, backward and left direction by using accelerometer and RF module transmitter and receiver.

Most of the times, disabled people find difficult when they need to move from one place to other place hence, depends on others to move from one location to other location. The wireless wheelchair is designed in such a way that it can be operated by the user by using simple hand gestures. This can be used in both hands and can be operated from a distance to reach the user. The wheelchair is designed in such a way that commands can be sensed and transmitted within the range of 20 meters.

The gesture-based wheelchair is suitable for the elderly and the physically challenged individual who, due to paralysis, birth or old age, are unfortunate to have lost mobility in their limbs. Elders find it difficult to travel to travel inside the house for day to day activities without support or external aid. The hand gesture control wheelchair can be used by older or physically challenged move inside or out the home without trouble an outside guide. The low cost design is one of the main concerns to develop this wheelchair.

II. SYSTEM DESIGN

The wheelchair system design and the required components are discussed in this section. The wheelchair system contains two parts, they are transmitter and receiver. The block diagrams of transmitter and receiver are shown in figure A and figure B respectively. The components are classified into two types, one is hardware and the second one is software component.

A. Hardware Components:

Arduino UNO: The Arduino UNO is an open-source microcontroller module based on the Microchip AT mega 328P microcontroller. The board is fitted with sets of digital and analog input/output pins that can be interfaced with different boards and other circuits. The board has 14 Digital pins, 6 Analog pins, and can be programmed using a type B USB cable with the Arduino IDE.

Accelerometer: The MPU6050 is a Micro Electro-Mechanical Systems that contains a 3-axis Gyroscope inside it. It allows us to calculate a device or object's acceleration, velocity, orientation, displacement and many other parameters related to motion. This module is also fitted with a Digital Motion Processor (DMP) which is powerful enough to perform complex calculations and free up the work for Microcontroller. The accelerometer is interfaced with transmitter of RF module and Arduino UNO.

RF Module: An RF module (radio-frequency module) is a small electronic unit used between two devices for transmitting and/or receiving radio signals. The transmitter and receiver are interfaced via RF module. The RF module receiver and communicate with another wirelessly.

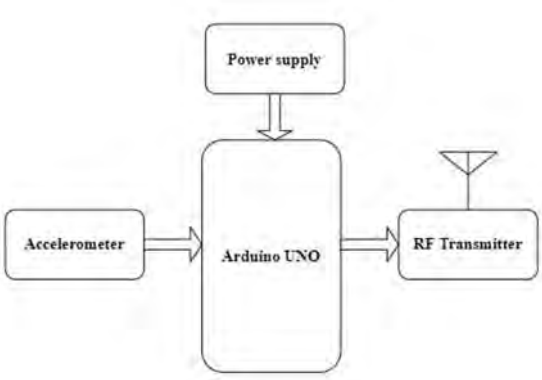

Figure A Block Diagram of Transmitter

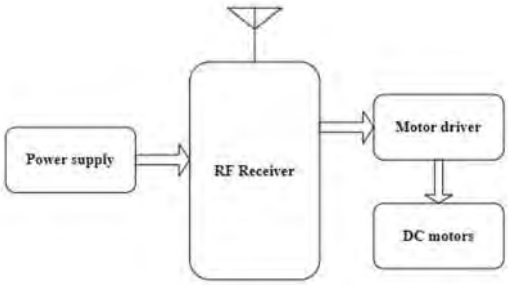

Figure B Block Diagram of Receiver

DC Motor driver: The DC motor-driver (L293D) controls the DC motor in possible rotations. In the present work the motor-driver controls two DC motors simultaneously. That means it controls the direction of two motors simultaneously which will help in moving vehicle wheels synchronously.

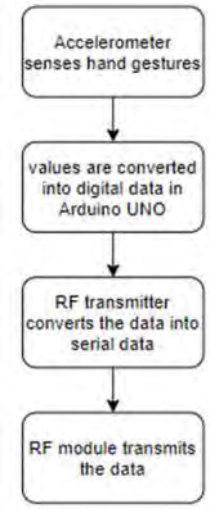
B. Software Component:

Arduino IDE: Arduino IDE is an open source software primarily used to compile and write the code into the Arduino Module. The IDE environment mainly includes two basic parts: Editor and Compiler where the former is used to write the necessary code and later to compile and upload the code into the provided Arduino Module.

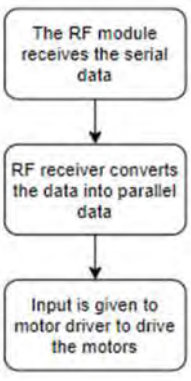
III. IMPLEMENTATION

The hand gesture controlled wheelchair is designed by using Arduino UNO, RF module and accelerometer. An accelerometer sensor is used to detect different hand gestures to move the wheelchair. In the present work MPU6050 is used as accelerometer sensor. The sensor can be either fixed directly with the hands of the person or can wear with hand gloves. Both MPU6050 accelerometer and Arduino UNO is connected to the transmitter of RF module which enables to move the wheelchair with some simple hand gestures. The hand gestures are sensed by the accelerometer and transmitted to the RF receiver. RF receiver receives the signal from MPU6050 via transmitter. RF receiver receives the signal from MPU6050 via transmitter. When the signal is received to the receiver form the transmitter, it triggers the Motor driver which results in movement of the wheelchair.

Data flow diagram:



a) Transmitter side



b) Receiver side

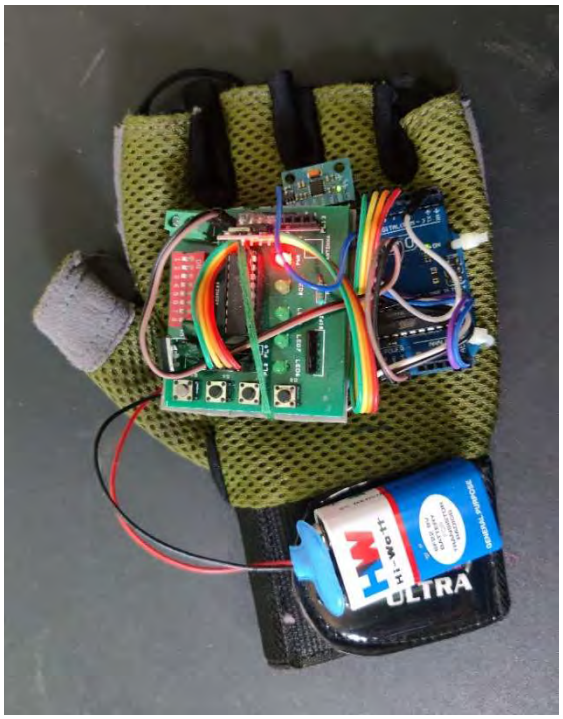


Figure C Prototype of Transmitter

Figure D Prototype of receive

Figure E Prototype of model design

IV. RESULT

The functional operations are implemented in the Arduino IDE software. The action of various commands used in the program is shown in table 1. When the palm movement is upward and downward, wheelchair moves backward and forward respectively. When the hand gesture is towards left or right the wheelchair moves towards left or right direction respectively. When the palm is set to horizontal, wheelchair stops.

Table 1 Functional Table

Palm Movement	Action
Upward	Wheelchair moves backward
Downward	Wheelchair moves forward
Left	Wheelchair moves left
Right	Wheelchair moves right
Horizontal	Wheelchair stops

V. FUTURE SCOPE

- Along with hand gestures, joystick can also be used to control the wheelchair.
- The wheelchair can be controlled by using smartphone.
- Voice commands IC's can be used to control the movement of the wheelchair.
- The wheelchair can also be controlled by using EEG brain waves.
- In future the wheelchair can be operated by using hand and head gestures, joystick, smartphones and brain signals, all in one.

VI. CONCLUSION

This paper presents a hand gesture controlled wheelchair with many benefits such as reduced complexity, simple control, low cost and high reliability compared to other traditional wheelchairs. The gesture controlled wheelchair is designed by using Arduino UNO, RF module and accelerometer. The wireless wheelchair is designed in such a way that it can be operated by the user by using simple hand gestures as shown in table 1. The gesture operated wheelchair can be used without trouble and without external help by elderly or physically disabled moving inside or out the house.

Arduino Based Hand Gesture Control Of Your Computer

Parth Ranawat, Aditya Salvi, Simran Saroj, Amey Sawant
TCET, Mumbai

Abstract - **With progression of Automation innovation, life is getting less complex and simpler in all perspectives. In this day and age Automatic frameworks are being favored over manual framework. With the fast increment in the quantity of clients of web over the previous decade has made Internet an a vital part of life, and IoT is the most recent and developing web innovation. Internet of things is a developing system of regular item from modern machine to shopper merchandise that can share data and complete undertakings while you are occupied with different exercises. Secure and brilliant home (SSH) utilizing IoT is a framework that utilizes cell phones to control fundamental home capacities and highlights naturally through web utilizing voice control.**
The segments utilized are LED Indicators, Switches, Touch Screens and LCD Displays as a piece of HMI gadgets to speak with PC or robots. Another approach to speak with machines like Robots or Computers is with the assistance of Hand Gestures.Instead of utilizing a console, mouse or joystick, we can utilize our hand signals to control certain elements of a PC like play/stop a video, move left/right in a photograph slide appear, look up/down in a website page and some more.
Arduino based hand signal control where you can control hardly any elements of your internet browser like exchanging between tabs, looking all over in site pages, move between errands (applications), play or interruption a video and increment or reduction the volume (in VLC Player) with the assistance of hand motions.
Keywords – LED indicators,Touch screen,Arduino Nano, UltraSonic Sensors, Jumper wires etc.

I. INTRODUCTION

The internet of things, or IOT, is an arrangement of interrelated figuring gadgets, mechanical and advanced machines, items, creatures or individuals that are given extraordinary identifiers (UIDs) and the capacity to move information over a system without expecting human-to-human or human-to-PC communication.

A thing in the internet of things can be an individual with a heart screen embed, a livestock with a biochip transponder, a vehicle that has worked in sensors to alarm the driver when tire pressure is low or some other characteristic or man-made item that can be relegated an IP address and can move information over a system

Literature Survey

1Real –Time natural Hand Gestures,2005-B.Yi, F.C. Harris Jr., L. Wang and Y Yanapplied multivariant Gaussian dispersion to perceive hand signal utilizing non-geometric features.The input hand picture is portioned utilizing two diverse methods,skin shading based division by applying HSV shading model and bunching based thresholding techniques.Some tasks are performed to catch the state of the hand to extricate hand feature.The altered Direction Analysis Algorithm are received to discover a connection between statical parameters from information and use to figure object incline and pattern by finding the bearing of the hand motion

2 Apparatus and Method for Gesture Recognition, 2012-Pratik Bhatt, Deval Mehta, Nirav Faraswamiproposed a collaborating method for constant following of hand catching motions through a web camera and Intel Pentium based individual computer.This framework is actualized without theutilization of modern picture handling calculation and hardware.It utilizes coin measured accelerometer sensor for controlling the application.Hand signal procedures is done progressively condition utilizing vision based systems.

3Automated Mobility and Orientation System for Blind or Partially Sighted People, 2013-Abdel Ilah Nour Alshbatatdesigned an assistive innovation gadget called the electronic glove to fill in as a portability help for daze and outwardly disabled individuals. The creator executes the glove with an ergonomic plan and an installed electronic framework, which fits inside the handle of the glove. The framework was structured utilizing hepatic sensors to identify the impediment above thewaistline. It works in such a manner when the obstructions isdetected the glove vibrates or makes a sound. This framework just recognizes deterrents over the waistline.

4Hand Gesture Recognition System using camera, 2014-In 2014, Viraj Sinde, Tushar Bacchav, Jitendra Pawar and Mangesh Sanap created "Hand Gesture acknowledgment framework utilizing camera" they center around utilizing guiding practices for a characteristic interface toward group the dynamic hand motion, they built up a straightforward and quick movement history picture based framework. This paper shows low multifaceted nature and motion acknowledgment unpredictability and progressively appropriate for controlling constant PC framework. It is material just for the use of intensity point introduction

5Remotely controlled Power point presentation navigation using hand gesture, 2012-In 2012, Ram Rajesh J, Nagarajunan D and Aarthi R, "Remotely controlled force point introduction route utilizing hand motions" built up the framework which slides of intensity point introduction without utilizing any marker and gloves. In the wake of

distinguishing hand estimation is utilized for hand figures. On the off chance that the figures are not extended appropriately while making a signal, at that point application doesn't work appropriately.

Requirement Specification

Useful Requirements**:** Functional necessity are the capacities or highlights that must be remembered for any framework to fulfill the business needs and be satisfactory to the clients. In light of this, the practical prerequisites that the framework must require are as per the following: The framework ought to have the option to anticipate a rough offer cost. The framework should gather exact information from the site in predictable way.

Non-Functional Requirements**:** Non-practical necessity is a portrayal of highlights, qualities and trait of the framework just as any limitations that may restrain the limits of the proposed framework. The non-useful necessities are basically founded on the exhibition, data, economy, control and security proficiency and administrations. In light of these the non-practical prerequisites are as per the following:

1. The framework ought to give better precision.

2. The framework ought to have straightforward interface for clients to utilize.

3.To perform productively in short measure of time.
Methodology
The Arduino ought to be modified to peruse the separation of hand from the US sensor. The total program is given toward the finish of this page; just beneath I have given the clarification for the program. On the off chance that you are new to Ultrasonic sensor, simply experience Arduino and Ultrasonic Sensor Based Distance Measurement. By perusing the estimation of separation we can land at specific activities to be controlled with signals, for instance right now have customized 5 activities as a demo.

Step 1: When both the hands are put up before the sensor at a specific far separation then the video in VLC player should Play/Pause.

Step 2: When right hand is set up before the sensor at a specific far separation then the video should Fast Forward one stage.

Step 3: When left hand is set up before the sensor at a specific far separation then the video ought to
Rewind one stage.

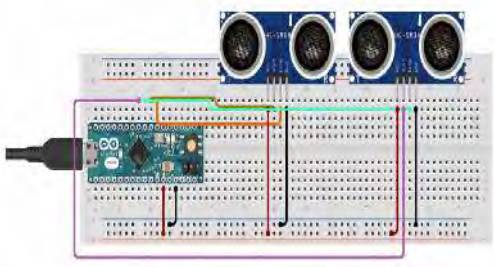
Step 4: When right hand is set up before the sensor at a specific close to separation and afterward whenever moved towards the sensor the video should quick
advance and whenever moved away the video ought to Rewind.

Step 5: When left hand is put up before the sensor at
a specific close to separation and afterward whenever moved towards the sensor the volume of video
should increment and whenever moved away the
volume should Decrease.
Technology

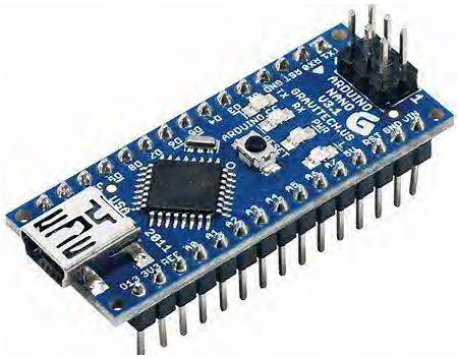
The source code for the IDE is discharged under the GNU General Public License, form 2. The Arduino IDE bolsters the dialects C and C++ utilizing extraordinary principles of code organizing. The Arduino IDE supplies a product library from the Wiring venture, which gives numerous basic info and yield strategies. Client composed code just requires two fundamental capacities, for beginning the sketch and the principle program circle, that are arranged and connected with a program stub primary() into an executable cyclic official program with the GNU toolchain, likewise included with the IDE appropriation. The Arduino IDE utilizes the program avrdude to change over the executable code into a book document in hexadecimal encoding that is stacked into the Arduino board by a loader program in the board's firmware

II. DESIGN PHASE

Circuit diagram



Software



Arduino Nano

UltraSonic

Jumper wires

1. Arduino IDE:

It is programming bundle used to program microcontrollers by composing a program in elevated level Arduino language which is then incorporated to double and transferred to improvement board at right baud rate contingent upon the board itself.

2. Python

Python is a mainstream programming language. It was made in 1991 by Guido van Rossum.

It is utilized for:
Hardware
eb development (server-side)

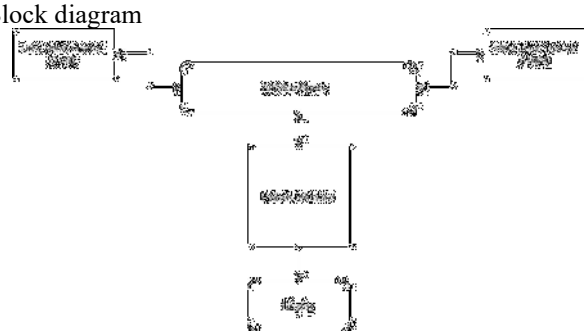
- software development

III. WORKING PRINCIPLE OF THE SYSTEM

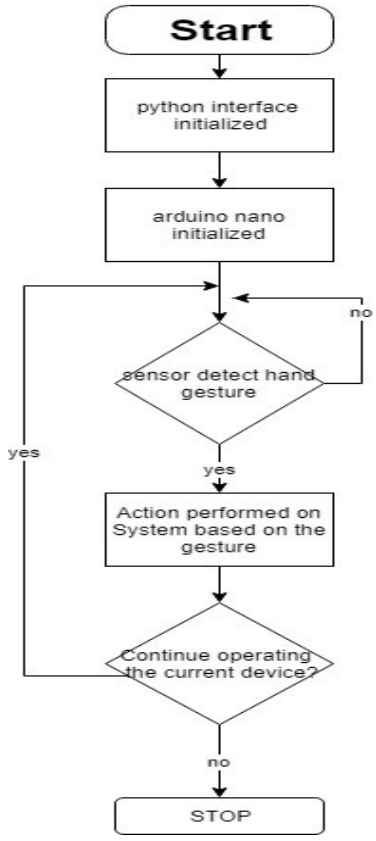
Algorithm
Step 1**:** Open Windows Command prompt and change the directory to the folder where you have installed python.
Step 2**:** Inside your python directory use the command *python –m pip install –upgrade pip* to upgrade your pip. Pip is a tool in python which helps us to install python modules easily. Once this module is upgraded (as shown in picture below) proceed to next step.
Step 3**:** Use the command "*python –m pip install pyautogui*" to install the pyautogui module. Once the process is successful you should see a screen something similar to this below.
Step 4: Now run the code on IDE.
Step 5: Make connections as per circuit diagram.

Step 6:Perform hand gestures and control your machine.

Block diagram



Flow chart



IV. RESULT AND OUTCOME

User can deal with application from separation without utilizing console and mouse by this strategy. This application gives a novel human PC interface by which a client can control media player (VLC) utilizing hand motion. The application characterizes some motion for controlling the elements of VLC player. The client will give signal as a contribution as indicated by intrigued work

V. CONCLUSION

In current world numerous offices are accessible for giving contribution to any application a few needs physical touch and some without utilizing physical touch (discourse, hand signal etc.).But relatively few applications are accessible which are controlled utilizing present and savvy office of giving info which is by hand motion .By this strategy client can deal with application from separation without utilizing console and mouse. This application gives a novel human PC interface by which a client can control media player (VLC) utilizing hand motion. The application characterizes some signal for controlling the elements of VLC player. The client will give motion as a contribution as indicated by intrigued work. The applicationprovides an adaptability of characterizing client intrigue signals for explicit order which make the application progressively helpful for genuinely tested
individuals, as they can characterize the motion as per their achievability.

Arduino Based Smart Blind Stick

Sandeep Pandey, Prem Patel, Riddhi Patel
Information Technology, Thakur College Of Engineering and Technology, Mumbai, India
Sp348220@gmail.com, patelprem616@gmail.com, patelriddhi1519@gmail.com

Abstract— **In the present scenario, a visually impaired individual is constrained to depend on someone else and can't make a trip autonomously to wherever without the assistance of others. So, here we propose an smart blind stick that allows visually challenged people to navigate with ease using advanced technology. The blind stick is integrated with ultrasonic sensor, soil moisture sensor along with tilt sensor. On detecting obstacle, the sensor passes this information to the microcontroller. The microcontroller then processes this information and figures if it is sufficiently close If the obstacle is close the microcontroller sends a signal to sound a buzzer. If the obstacle isn't that nearby the circuit sits idle. It also detects water or mud and sounds a buzzer in different pattern and alerts the blind. By using tilt sensor blind man could remotely locate his stick. We have also used a motor vibrator which provides different vibration pattern for alerting the user. Thus, proposed system helps the people who are visually impaired in the aspect of mobility and making it safer by avoiding accidents.**

Keywords – Ultrasonic sensor, Soil Moisture Sensor, Tilt Sensor, Arduino UNO, Smart Blind Stick

I. INTRODUCTION

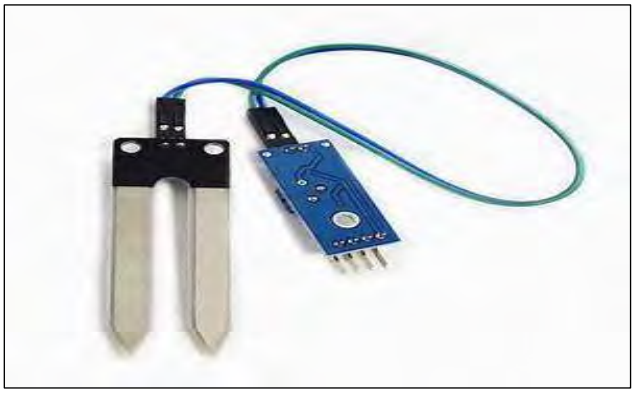
Visual deficiency is a common regular inability among the peoples throughout the world. As per the World Health Organization (WHO) 285 million individuals are outwardly impeded around the world, 39 million are visually impaired and 246 have low vision. About 90% of the world's outwardly impeded live in developing nations. Visually impaired persons have difficulty to interact with their environment. They have a very little contact with surroundings. Physical movement or mobility is a challenge for visually impaired persons, because it can become difficult to recognize obstacles appearing in front of them, and they are not able to move from one place to other. Smart Blind Stick is specially designed to detect obstacles which may help the blind to navigate care-free. The audio messages will keep the user alert and comparatively reduce accidents. The proposed system contains the ultrasonic sensor, Soil moisture sensor, Buzzer and Arduino UNO. The main objective of the paper is to discuss about development work of a stick that could communicate with the users through voice alert and vibration, which is named Smart Blind Stick which involves coding as software and physical installation as hardware part.

II. PROBLEM DEFINTION

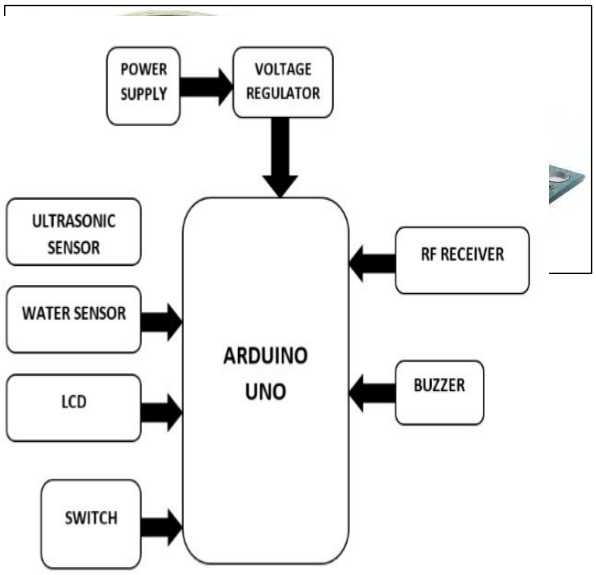
Physical movement is a challenge for visually impaired person. The conventional walking stick used by them is inefficient in detecting obstacle. The disadvantage of conventional cane, However, is its failure to detect obstacles outside of its reach. That is the user has to tap to the ground or obstacle to detect it. The visually challenged people can avoid the object better if the walking stick can produce sound and vibration warnings when there is a object in specified range.

III. BACKGROUND

More than 161 million people worldwide are visually impaired. Among them, 124 million have Low vision and 37 million are blind. Another 153 million people suffer from visual impairment Due to uncorrected refractive errors such as near-sightedness, far-sightedness or astigmatism. Virtually all these people could restore normal vision with eyeglasses or contact lenses. More than 90% of the world's visually impaired people live in low- and middle-income countries. Blindness is a condition of lacking visual perception and it is always described as severe visual impairment with residual vision. The blind people's life and activities are greatly restricted by loss of eyesight. They can only walk in fixed routes that are significant in their lives, with blind navigation equipment's and the accumulated memories in their long-term exploration. This situation has resulted in many difficulties to them in their normal work, lives, activities, and so on. Based on the investigation about daily activity characteristics and modes of the blind, the study found that the main difficulties encountered in a trip of the blind included walking on the road, finding way, taking a bus and looking for usual life-arena Several devices have been developed for mobility and navigation assistance of the blind and are typically known as travel aids or blind mobility aids.

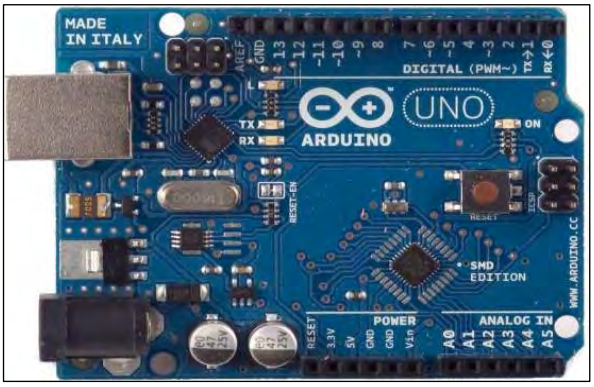


IV. BLOCK DIAGRAM



V. HARDWARE REQUIREMENTS

1. Arduino UNO:



Arduino UNO is a microcontroller board based on ATmega328p. It has 20 pins out of which 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. It contains everything needed to support the microcontroller. The Operation Voltage is 5V simply connect it to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. You can tinker with your UNO without worrying too much about doing something wrong.

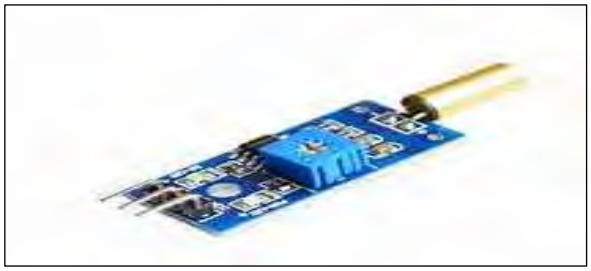
2. Ultrasonic Sensor:

As the name suggest, ultrasonic sensors measure distance by ultrasonic waves. The sensor head emits an ultrasonic wave and receives the wave reflected back from the targeted object. Ultrasonic Sensors measure the distance to the object by measuring the time between the emission and reception. An optical sensor has a transmitter and receiver, whereas an ultrasonic sensor uses a single ultrasonic element for both emission as well as reception. In a reflective model of ultrasonic sensor, a single oscillator emits as well as receives ultrasonic waves alternately.

3. Soil Moisture Sensor:

Soil moisture sensors measure the volumetric water content in soil. The direct measurement of free soil moisture process includes drying, removing, and weighing of a sample.Soil moisture sensors calculates the volumetric water content indirectly by using various property of the soil, such as dielectric constant ,electrical resistance or interaction with neutrons, as a proxy for the moisture content. Soil moisture sensors is used to estimate or calculates volumetric water content. There is a separate class of sensors that measure another property in soils called water potential; these are usually known as soil water potential sensors and which includes gypsum blocks and tensiometers.

4.Tilt Sensor:



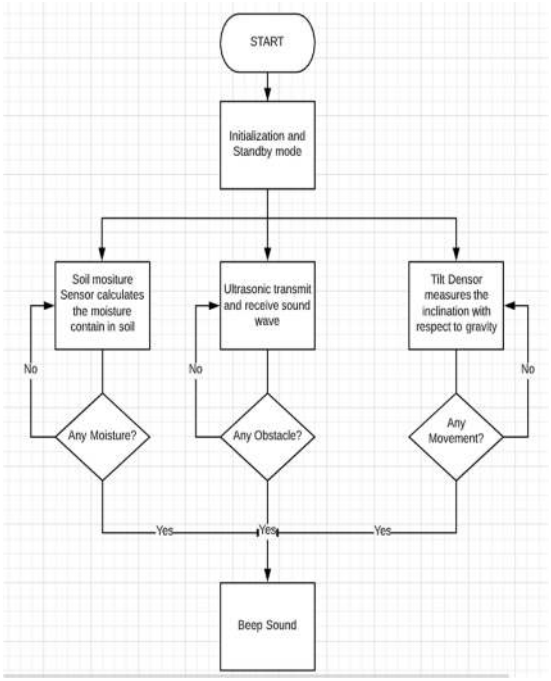
A tilt sensor is an instrument that is used for measuring the tilt in multiple axes with respect to particular plane. Tilt sensors measure the tilting position with respected to gravity and are used in number applications. They enable the easy detection of orientation or inclination of a object. Similar to mercury switches, they also be known as tilt switches or rolling ball sensors. The capability of tilt sensors is influenced by factors together with vibration, gravity, linearity, 0 offset, temperature, cross-axis sensitivity, acceleration/deceleration, shock, clean line of sight between the user and the measured point, and calibration of tilt sensors.

5.Buzzer:

A buzzer is a small efficient component to add sound to our project/system. It is compact and small with 2-pin structure hence can be easily mounted on breadboard, Perf Board and even on PCBs which makes this a widely used component in most electronic applications. There are commonly two types of buzzers available. First one is a simple buzzer which will make a Continuous Beeeeppp.... sound and other type of buzzer is called as readymade buzzer which looks bulkier than simple buzzer and produce a Beep. Beep. Beep. Beep Sound is produced because of the internal oscillating circuit present inside it.

6. Bread Board:

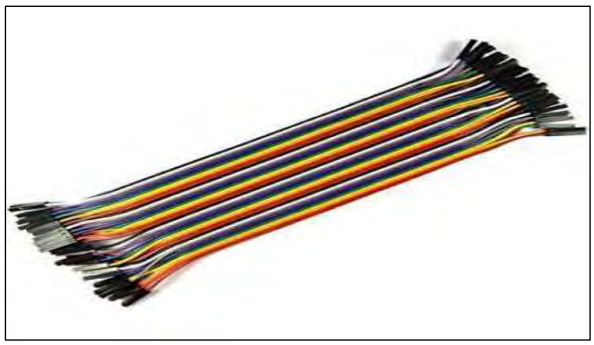
A breadboard is a solderless device for prototype



model with hardware and test circuit structures. Components in electronic circuits can be interconnected by inserting their terminals into the holes and then making required connections through jumper wires. The breadboard has metal strips underneath the board and which connect the holes on the top of the board.

7. Jumper Wires:

A jumper wire is a conducting wire which is used to



transfer electrical signals between two ends in a circuit. The wires can be used to modify circuits as well as to diagnose problems within a circuit. Jumper wires typically vary in size and color depending on what they are being used for. Jumper wires are used to establish connections between the central micro controller and other devices such as sensors and buttons..

VI. SOFTWARE REQUIRMENTS

The Arduino Integrated Development Environment (IDE) is a cross-platform application for Windows, Linux, macOS that is written in functions from C and C++. It is used to write and upload various programs to Arduino compatible boards, also, with the help of third party cores, other vendor developmental boards.

The source code for IDE is released under the GNU General Public License v2. The Arduino IDE supports the languages C++ and C with special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many input-output procedures. User defined code requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program into an executable cyclic executive program with the GNU tool-chain, also included with the distribution of IDE. The Arduino IDE provides the program avrdude to convert the executable code into text file in hexadecimal encoding format that is loaded into the Arduino board by a loader program in the firmware of board.

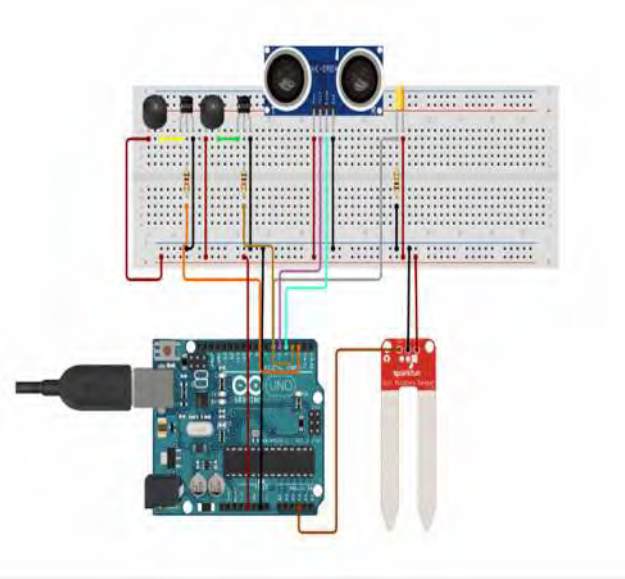
VII. DESIGN AND DEVELOPMENT:

1. Flowchart:

When circuit is switched ON the sensors placed on the stick goes into active state. There are three sensors mounted on the stick which are ultrasonic sensor to detect obstacle in front of the stick, soil moisture sensor to detect water on the ground and tilt sensor which enables the user to locate the stick from ground. Ultrasonic sensor transmit and receive sound wave which in turn helps to detect obstacle. If any obstacle is detected within a specified range then it will produce a beep sound or else do nothing. Soil moisture sensor

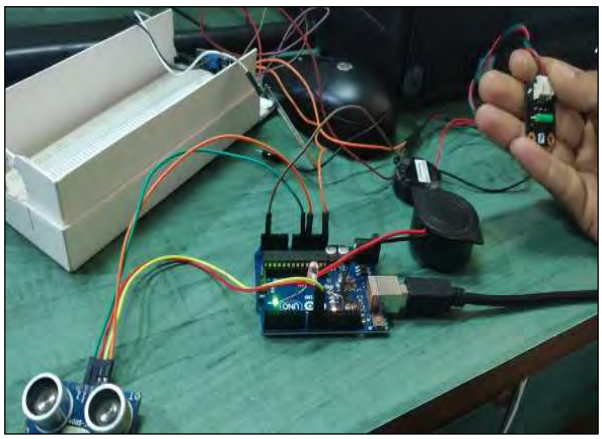
calculates moisture contain in soil.is any moisture contain is detected in the soil then the stick will produce beep sound or else do nothing. Tilt sensor measures the inclination of the stick with respect to gravity. If the stick is inclined then it will produce a beep sound or else do nothing.

2. Circuit Diagram:



VIII. WORKING OF SYSTEM

Smart Blind Stick is basically designed to make sure that the people with visual disabilities can work on their own without being dependent on others for their living. This innovative Stick allows visually challenged people to navigate on their own. This blind stick is integrated with Ultrasonic Sensor so that people with disabilities can walk with a sense of obstacle in between. This ultrasonic sensor makes sure that when there is any obstacle in front of the stick it indicates the user. Ultrasonic sensor senses the obstacle and passes this data to microcontroller. Then this microcontroller will process the data and calculate if the obstacle is close enough or not. If the obstacle is not close enough then it does nothing. If obstacle is close enough then it will produce a buzzing sound so that the user can understand that there is obstacle in front. Buzzer is used so that it can produce a sound when obstacle is ahead. This stick also contains soil moisture sensor. Soil moisture sensor is used so that the user can indicate the path where there is no detection of water and hence selecting a simple path to walk. Soil moisture sensor is connected at the bottom of the stick and when the sensor detects water in the soil then it produces a buzzing sound to indicate the user that the path is not safe. We made use of vibrator motor for the people with hearing as well as visual disabilities. This motor vibrates while buzzing which in turn helps them to detect obstacle in between. This stick includes a tilt sensor which will help to locate the stick on the ground. Tilt sensor is of a great use to the people with visual disabilities. When this stick falls of the ground from the hand of the user then this stick produces a buzzing sound so that the user can easily locate the stick. This tilt Senor measures the angle of the stick with respect to gravity and then detect the inclination to decide whether to produce buzzing sound or not. This stick also contains a LDR which helps to produce light on the stick at times of dark which will allow the people surrounding the user to be aware and hence avoid collation.



This project is designed in such a way that the people with visual disabilities can easily use this stick and be independent. The look of this project is just like a normal stick with some sensors attached which does not give any problem to the user to use this stick.

IX. FUTURE SCOPE

By adding a GPS and GSM module to the stick we can track the actual location of the person as well as establish communication between mobile device or a computing machine. We can also add Vibrator motor which helps to make a vibration by recognizing it the

person holding the stick and also feel the vibration and act accordingly, by this motor this stick can be used by people with hearing disabilities.

X. CONCLUSION

The project proposed a layout, design and architecture of a new concept of Smart Electronic Guiding Stick for blind people. It aims to solve the problems faced by the millions of visually impaired people worldwide in their daily life. The proposed system takes measures to ensure their safety and the main advantage of the system is that it can prove to be very low-cost solution to millions of visually impaired people worldwide with the proposed combination of various working units. It is a real-time system that monitors position of the user and provides dual feedback making navigation more safe and secure than the traditional cane. It can be further improved to have more decision taking capabilities by integrating various types of sensors such as GPS, GSM module and thus could be used for different applications. This our hope is to consider this stick as smart eye for the visual impairments. It is worth mentioning at this point that the aim of this study which is the design and implementation of a smart walking stick for the blind has been successfully achieved.

ayushjangida30@gmail.com, sarthakjain3006@gmail.com, prkjha25@gmail.com

Abstract **- There is a surge in pollution of air and sound in recent years. To bring it in check, its monitoring is majorly recommended. To overcome this issue, we are introducing a system through which the the existence of the harmful gases in the surroundings can be detected. The growing pollution at such an alarming rate has started creating trouble for the living beings, may it be high decibels or toxic gases present in the environment, it leaves a harmful effect on human's health and thus needs special attention[1].**

This monitored data can often be obtained from remote locations without actually visiting it, thanks to the access of the internet. The framework of this monitoring system is a combination or collaboration of affective distributed sensing units and information system for data composition. The role of IoT is the new concept that is added in air and sound pollution measurement, which allows data access from remote locations[2].

The level of pollution has increased with time. A lot of factors like the increase in population, increased vehicle use, industrialization and urbanization have harmful effects on human wellbeing by directly affecting the health of the population exposed to it. In order to monitor these effects, in this project we are going to develop an IOT Based Air Pollution Monitoring System through which we will monitor the Air Quality over a web server and mobile application using the internet and will display and analyze the amount of gas present with addition to the temperature and humidity of the given environment. The gases which will be detected are smoke, LPG & CO (carbon monoxide). In this IOT project you can monitor the air quality from anywhere using your computer or mobile[5].

Keywords - Pollution, IoT, Air Quality, Environment, Sensors, NodeMCU, MQ2, DHT11

I. INTRODUCTION

The main objective of IOT Air quality Monitoring System is to highlight the issue of Air and Sound pollution these days. It is necessary to monitor air quality and keep it under check for a better future and healthy lifestyle. Due to flexibility and low cost, the Internet of things (IoT) is getting popular day by day[2].
With urbanization and with an increase in vehicles on road the atmospheric conditions have considerably deteriorated[1]. Harmful effects of pollution include mild allergic reactions such as irritation of the throat, eyes and nose, as well as some acute problems like bronchitis, heart diseases, pneumonia, lung and aggravated asthma.
Monitoring gives measurements of air pollutant concentrations, temperature, and humidity , which can then be analyzed, interpreted and presented. This information can then be applied in many ways. Analysis of monitoring data allows us to assess and measure how bad air pollution is from day to day[4].

II. BACKGROUND

Air quality detection and monitoring has become a major aspect for day to day needs of many professions, from various practical experimentation to detecting the air quality of a specific region and to get the actual observation of air quality.

This system helps to detect the gases present in real time in parts per million in mobile application. It gives the user interface for gauge reading of the gases present and based on some parameters determine whether the air quality is Fresh Air, Poor or Hazardous[6]. However, preceding gas detectors required high voltage power input, further research on power requirement in gas detectors has reduced to make battery power viable making widespread installation of this system in residences highly feasible.

Later developments in gas detectors have sought to improve their performance, reduce power requirement and improve their nuisance alarm sensitivity and also to continuously monitor their status. The most recent advancement in gas detectors have been motivated to make them "smarter"[1]. Gas can be detected either optically (photoelectric) or by physical process (ionization). Detectors may use either or both methods[2].

A - Importance of Project

The requirement of the Air Quality Detection and Monitoring System is because of an increase in the fire prone areas in localized urban regions such as kitchen, buildings, construction region, mining industries petrol pumps. Also to check the real time scenarios of air quality in any other surrounding to determine how good the air is for health and also for further analysis to check the quality of certain regions[6].

- Analysis of certain regions to check temperature, humidity, and other hazardous gases present.

- Display real-time values of the output captured by the sensor.

- Failure to take advantage of this early warning, due to poor performance of the gas detection system, has cost people their lives.

- Easy to transmit data through the internet as the project implements wifi-module[6].

III. TEST AND MEASUREMENTS

A - Testing of hardware

NodeMCUis an open source IoTplatform. It includes firmwarewhich runs on the ESP8266 Wi-FiSoC from Espress if Systems, and hardware which is based on the ESP-12 module. The term "NodeMCU" by default refers to the firmware rather than the development kits. The firmware uses the Luascripting language.Tests will be done by checking the connections everytime and then running a simple test code to blink the inbuilt light to test if everything is working correctly [4].

MQ-2 gas sensor

The Grove - Gas Sensor (MQ2) module is a useful sensor for detecting gas leakage detection (in industry and home). It is also suitable for detecting Smoke,CO,LPG. Due to its high sensitivity and fast response time, measurements can be taken as quickly. The sensitivity of this sensor can be adjusted by using a potentiometer. This should be tested repeatedly by running a test code to blink lights at different levels of Smoke, CO, LPG levels.

DHT 11 Temperature and humidity sensor DHT11 is a low-cost digital sensor for sensing humidity and temperature. This sensor can be easily interfaced with any micro-controller such as Raspberry Pi, Arduino, etc., to measure temperature and humidity instantaneously.

The smoke sensor, DHT11 is highly sensitive to the amount of smoke generated at each point of time in the region. As soon as it senses the smoke above threshold limit, it starts the alert system.

Testing: After the prototype is ready, we first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding it and will check again.

IV. FEATURES AND DESIGN REQUIREMENT

A - Features of the Project

The Project consists of the following features:

- LCD display and chart: All the collected input from sensors (DHT11 & MQ2) are sent to the BLYNK server and thereby the GET request is made and the front-end interface of mobile displays the real time value on mobile application Also on the other hand the data is sent to Thingspeak server where it is analyzed in the form of chart.

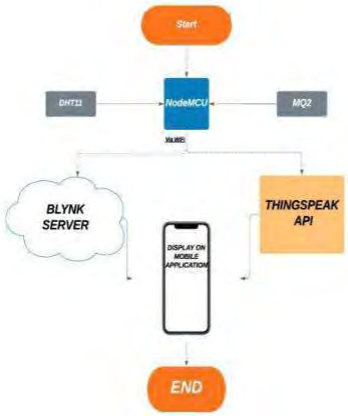
- High sensitivity and fast response: The smoke sensor, DHT11 sensor is highly sensitive to the amount of smoke generated at each point of time in the region. As soon as it senses the smoke above the threshold limit, it starts the alert system.[3]

- Simple drive circuit: The connections and the circuit design of this system is simple hence it is much more convenient to develop.

B - Methodology

The proposed method takes an automatic control action upon detection of gas, temperature and humidity. Our always contains the gases(CO, LPG, Smoke) in some small amount of level, the problem arises when these gases reaches to certain level which harmful to humans and this happens only when there is some sort of leakage detected on the types of gases, whenever the display and analysis of the environment is needed, all that is needed to be done is to plug the nodemcu and the data is sent through Internet to mobile to display and it also displays if the air is fresh, poor or hazardous depending on the ppm level received of LPG,CO & smoke and also the analysis is displayed on thingspeak server[6].

A-Block Diagram



B. Circuit Diagram

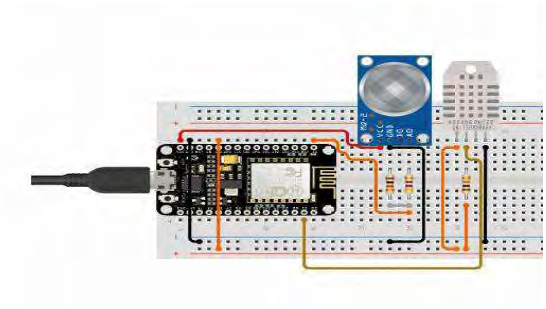


Fig. 2. Circuit Diagram

The above circuit diagram represents the different components and circuit used to connect these components. The Hardware and Software Requirement is discussed later in this paper.

C. GUI Screenshot

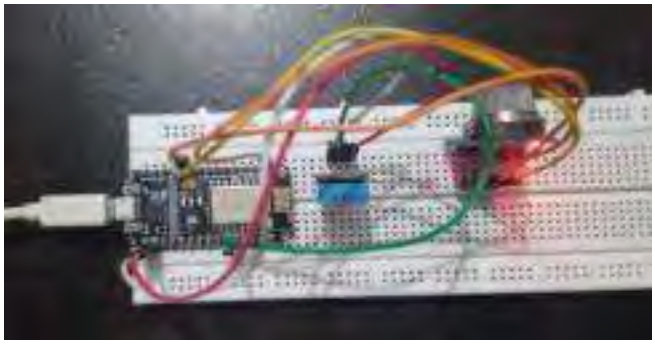

Fig. 1. Block Diagram

The above block diagram represents the actual working of our project. NodeMCU contains inbuilt WiFi, which enables us to send the data captured by the DHT11 and MQ2 sensors to be displayed on Blynk Mobile Application, ThingSpeak Server, and an email notification if level of pollution reaches hazardous level.

Fig. 3. GUI Screenshot

The above image is the actual implementation of Fig. 2.

D. Hardware and Software Tools

TABLE I. HARDWARE AND SOFTWARE TOOLS

Software Tools

E. Feasibility Study

- **Technical Feasibility:** Here one has to test whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the solution is technically feasible[4].

- **Economic Feasibility:** As part of this, the benefits and costs associated with the proposed system compared and the project is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So the proposed system is economically feasible.

- **Legal Feasibility:** Legal issues can affect a system's acceptance by users, its performance , or the decisions on whether to use it in the first place. Therefore it is best to consider these explicitly in system design. Clearly, the behavior of those being enrolled and recognized can influence the accuracy and effectiveness of virtually any biometric system.

- **Operational Feasibility:** It is a standard that ensures interoperability without stifling competition and innovation among users, to the benefit of the public both in terms of cost and service quality. The proposed system is acceptable to users. So the proposed system is operationally feasible.

- **Social Feasibility:** The acceptability of a biometric system depends on the social and cultural values of the participant populations. A careful analysis and articulation of these issues and their

identification can improve both acceptability and effectiveness.

V. RESULTS

A - Output

- All the levels of output received from DHT11 sensor i.e temperature & humidity and From MQ2 sensor i.e LPG, CO, and Smoke are shown as gauge reading in mobile app and the LCD in mobile displays the quality of air.

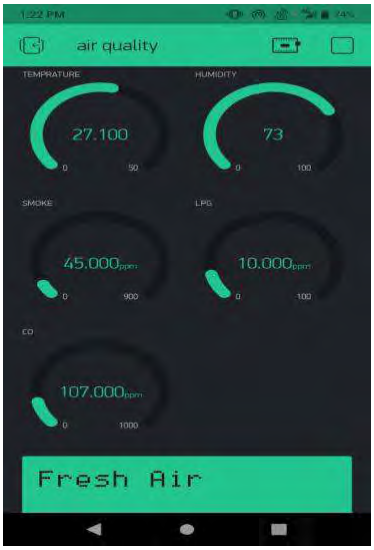

Fig. 4. Blynk Mobile Application

● The second part, that is for the analysis, the data is sent to thingspeak server as POST request and the analysis is displayed in the form of chart.

Fig. 5. ThingSpeak Server

● If the air quality level reaches a hazardous level, then the user gets an email regarding the same that, 'The air quality is currently hazardous'.

Fig. 6. Email from Blynk Application

VI. DISCUSSION

A - Future Scope

● A publicly available website can be implemented and the real time and past analysis of gases, temperature and humidity can be shown of many areas, also after gathering enormous data, Machine Learning can be implemented which can predict the values of those parameters for future and also classify the diseases which can be caused if the gases goes above poor air quality level by classifying the PPM levels

● It can also be used in F1 cars as there is a high possibility of catching fire when a car runs at that speed there is high possibility of them catching fire due to the web based output it can be conveyed to the driver and thus he can save his life and win the race.

B - Conclusion

We have successfully shown the detection and monitoring of Gas, temperature & humidity and by IOT based project is possible which can display and analyze Gases present in a given environment, analyze and monitor them on real time basis using various online tools Thingspeak & Blynk platform also an email is sent to user if the gas reaches to hazardous level, the data here can useful for other organization for further analysis purpose[6]. This application demonstrates the mobile phone's ability to be used as a advanced warning device in the event of a smoke alarm activation, its automated group alert system reduces the chance of accidents to people who have not been able to respond to an alarm.

ACKNOWLEDGMENT

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staff of the IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in the laboratory for their timely support.

Arduino Based Dual Axis Sun Tracking Solar Panel

Miloni Shah, Swati Solanki, Prakash Upadhyay
Tcet, Mumbai
miloshah55@gmail.com, swatisolanki4206@gmail.com, upadhyay.prakash1999@gmail.com

Abstract – **The variation in solar energy occur daily due to variation in the day-night cycle and also because of seasonal variations throughout the year. The population of the world is increasing very rapidly. From the past decade of years, the non-renewable energy sources like coal and oil are extinguishing and so it becomes a serious problem for providing he reliable energy to the world. But solar energy plays an important source of primary energy. In this project, we propose a dual-axis solar tracking system by which it is possible to catch the maximum amount of solar energy by using Arduino as the main processing unit.**

KEYWORDS: Dual axis solar tracker, Arduino, LDR Sensor, Servo motor.

I. INTRODUCTION

In the present scenario, the variation in the climatic changes has reached a critical level. The main reasons for climatic changes are due to natural causes and man-made destructions like global warming and greenhouse gases are affecting the climatic conditions around the world. In the past decade of years, there is an increase in demand for reliable and abundant electrical energy derived from renewable energy sources renewable energy plays an important role in the energy crisis of the country. The government started to decrease the usage of conventional energy sources and encouraging people to use renewable energy sources like hydro and solar. One such example of renewable energy is solar power. The solar power received by the earth is approximately 1.8*1011MW.The system will tend maximize the amount of power Absorbed by Photo voltaic systems. It has been found that making the use of a Dual axis tracking system, over a fixed system, can increase the power output by 40% - 60%.. In general, the power developed in such applications depends upon the amount of solar energy captured by the collector, and thus the difficulty of developing tracking schemes capable of following the trajectory of the sun throughout the course of the day on a year- round basis has received significant coverage in this project.

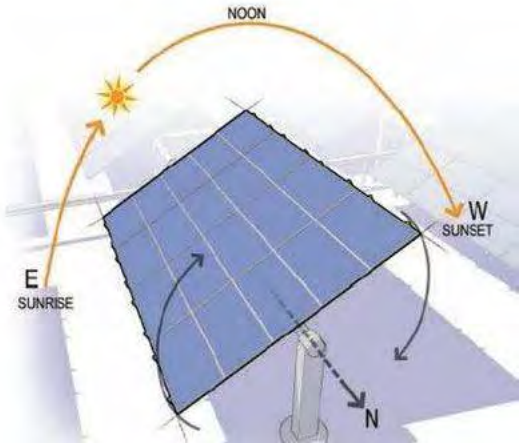
II. SCOPE AND OBJECTIVE

The solar project was implemented using two servo motors.The Arduino IDE was used for the coding. Mumbai has coordinates of 22.5726°N, 88.3639°E and therefore the position of the sun will vary in a significant way during the year. In the tropics, the sun position varies considerably during certain seasons. There is the design of an input stage that facilitates the conversion of light into a voltage by the light-dependent resistors, LDRs. There is a comparison of the two voltages, then the microcontroller uses the difference as the error. The servo motor uses this error to rotate through a corresponding angle for the adjustment of the position of the solar panel until such a time that the voltage outputs in the LDRs are equal. The difference between the voltages of the LDRs is received as analog readings.

The difference is transmitted to the servo motor and it thus moves to ensure the two LDRs are an equal inclination. This means they will be receiving the same amount of light, and the Solar panel will receive the sunlight at 90°, (the plane of PV panel will make an angle 90° with the Sun, and the perpendicular drawn on the plane makes an angle 0° with the Sun, to ensure maximum illumination: Lambert's cosine Law) The procedure is repeated throughout the day.

THE SOLAR TRACKER

A solar tracker is a device which is used to collect the solar energy emitted by the sun. Solar tracking is Nothing but changing the position of panel With respect to the sun. usually, the photovoltaic module assembled in the solar tracker is more powerful than critical irradiance in the fixed system. Solar trackers are classified on basis of performance, coast respectively. by tracking system we can catch 40-50% more efficiency compared to fixed panel. Among them dual axis provides increased efficiency of 48% as compared with single axis tracker



III. HARDWARE REQUIREMENT

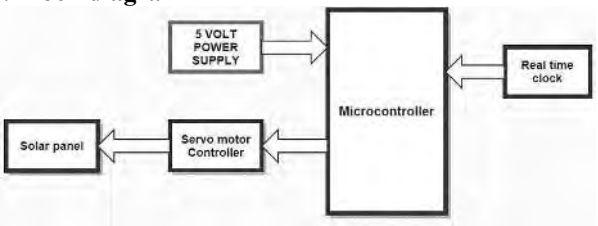
Since it is hard ware based project the main components are LIGHT DEPENDENT RESISTORS(LDR), Servo motors, Arduino as main controller.

A .Light Dependent Resistor (ldr) B .Servo motor C .Solar panel

D .Arduino

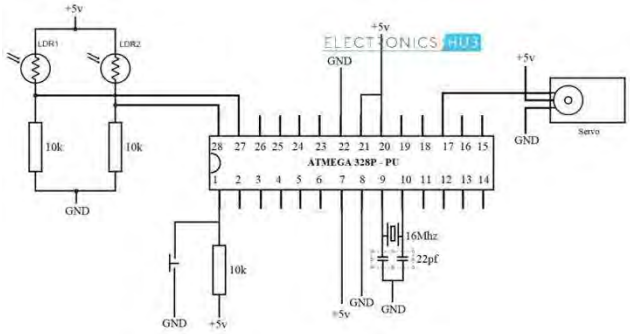
IV. IMPLEMENTATION

A. Block diagram



The principle of the solar tracking system is done by Light Dependant Resistor (LDR). Four LDR's are connected to Arduino analog pin AO to A4 that acts as the input for the system. The built-in Analog-to- Digital Converter will convert the analog value of LDR and convert it into digital. The inputs are from analog value of LDR, Arduino as the controller and the DC motor will be the output. LDR1 and LDR2, LDR3 and LDR4 are taken as pair .If one of the LDR in a pair gets more light intensity than the other, a difference will occur on node voltages sent to the respective Arduino channel to take necessary action. The DC motor will move the solar panel to the position of the high intensity LDR that was in the programming.

B. Circuit diagram



C. Algorithm

Step 1: start the program.

Step 2: initialize all the values.

Step 3: calculate the difference of ldr.

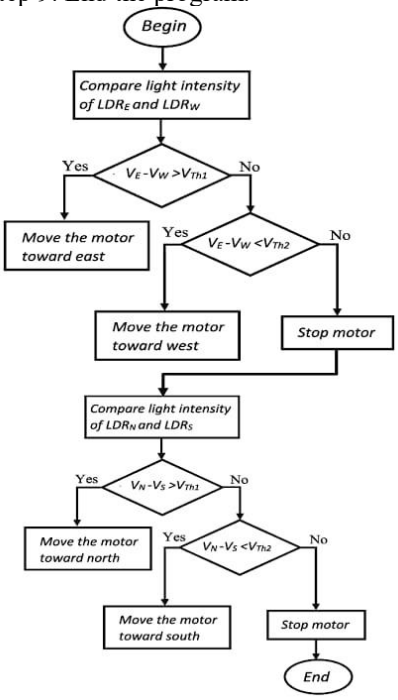
Step 4: if ldr1>>ldr 2,3,4,5servo motor go towards right

Step 5: if ldr2>>ldr 1,3,4,5servo motor go towards centre

Step 6: if ldr1>>ldr2,3,4,5 servo motor go towards right.

Step 7: if ldr1>>ldr2,3,4,5 servo motor go towards right.Step 8: if ldr1>>ldr2,3,4,5 servo motor go towards right.

Step 9: End the program.



Power generated with and with out tracking

Graphical View of Voltage Drawn By Solar Tracking

V. RESULTS

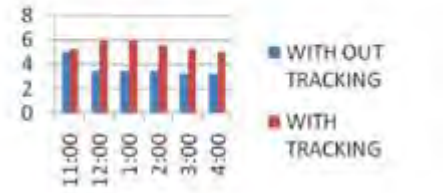
The following tables shows voltage drawn by solar panel with and without tracking respectively.

Time	Voltage without tracking	Voltage with tracking
11:00AM	4.955v	5.262v
12:00PM	3.467v	5.875v
1:00PM	3.447v	6.002v
2:00PM	3.447v	5.515v
3:00PM	3.15v	5.275
4:00PM	3.15v	5.015
Time	Voltage without tracking	Voltage with tracking

11:00AM	3.682watt	3.467watt
12:00PM	4.112watt	2.452watt
1:00PM	4.2watt	2.39watt
2:00PM	3.86watt	2.307watt
3:00PM	3.692watt	2.205watt
4:00PM	3.5watt	2.205watt

Power generated with and with out tracking

Graphical View of Voltage Drawn By Solar Tracking



VI. EXPERIMENTAL SETUP

VII. MERITS AND DEMERITS OF SOLAR ENERGY

Merits:

Once a solar panel is installed, the energy is produced at reduced costs.

Whereas the reserves of oil of the world are estimated to be depleted in future, solar energy will last forever.

It is pollution free.

Solar cells are free of any noise. On the other hand, various machines used for pumping oil or for power generation are noisy.

Once solar cells have been installed and running, minimal maintenance is required. Some solar panels have no moving parts, making them to last even longer with no maintenance.

On average, it is possible to have a high return on investment because of the free energy solar panels produce.

Demerits:

Solar panels can be costly to install resulting in a time lag of many years for savings on energy bills to match initial investments.

Generation of electricity from solar is dependent on the country's exposure to sunlight. That means some countries are slightly disadvantaged.

Solar power stations do not match the power output of conventional power stations of similar size. Furthermore, they may be expensive to build.

Solar power is used for charging large batteries so that solar powered devices can be used in the night. The batteries used can be large and heavy, taking up plenty of spacend needing frequent replacement.

FINALLY,

VIII. IMPROVEMENTS IN RESEARCH

With the available time and resources, the objective of the project was met. The project is able to be implemented on a much larger scale. For future projects, one may consider the use of more efficient sensors, which should also be cost effective and consume little power. This would further enhance efficiency while reducing costs.

If there is the possibility of further reducing the cost of this project, it would help a great deal. This is because whether or not such projects are embraced is dependent on how cheap they can be. Shading has adverse effects on the operation of solar panels. Shading of a single cell will have an effect on the entire panel because the cells are usually connected in series. With shading therefore, the tracking system will not be able to improve efficiency as is required.

XI. CONCLUSION

In this 21st century, as we build up our technology, population & growth, the energy consumption per capita increases exponentially, as well as our energy resources (e.g. fossils fuels) decrease rapidly. So, for sustainable development, we have to think alternative methods (utilization of renewable energy sources) in order to fulfil our energy demand.

In this project, Dual Axis Solar Tracker, we've developed a demo model of solar tracker to track the maximum intensity point of light source so that the voltage given at that point by the solar panel is maximum. After a lot of trial and errors we've successfully completed our project and we are proud to invest some effort for our society

Abstract— **The advancement of multipurpose sensors over the final decades has been examined with the point of creating inventive gadgets with applications in a few areas of innovation, counting within the nourishment industry. The integration of such sensors in nourishment bundling innovation has cleared the way for cleverly nourishment bundling. These coordinates' frameworks are competent of giving dependable data around the quality of the pressed items during their capacity period. To achieve this objective, brilliantly packs utilize a assortment of sensors suited for observing the quality and security of food products by recording the advancement of parameters just like the amount of gasses, temperature, stickiness, light exposure and capacity period. This innovation, when combined with IoT, is able to supply a part more information than customary nourishment review advances, which are constrained to weight, volume, colour and perspective assessment. The first framework depicted in this work depends on a basic but successful strategy.**

I. INTRODUCTION

mugginess are significant variables. So the checking framework fit for estimating temperature and stickiness fluctuation during transport and capacity is of prime significance. Today nearly everyone is getting influenced by the nourishment they expend, it's about the shoddy nourishment, yet all the stuffed nourishments, vegetables, items devoured and utilized in day by day life, as every one of them don't offer quality since their temperature, dampness, oxygen content differ now and again. Likewise inappropriate putting away of nourishment materials can make lead wastage of nourishment. Brilliant nourishment observing framework centers around safe stockpiling of nourishment by checking and controlling different parameters influencing nourishment materials.Sanitation and cleanliness is a significant worry so as to forestall the nourishment wastage. The Quality of the nourishment should be checked and it must be kept from spoiling and rotting by the environmental components like temperature, stickiness and dull. In this way, it is valuable to send quality checking gadgets at nourishment stores. These quality observing gadgets keep a watch on the ecological factor that cause or pace up rot of the nourishment. Afterward, the natural elements can be controlled like by refrigeration, vacuum stockpiling and so on.

Fig 1: Block Diagram

Background

II. SUBJECT HISTORICAL DATA

The activity of a control and checking frameworks is to watch out for specific thing or action and to ensure that it remains in the ideal way. Observing can be accomplished utilizing different electronic sensors. Further these recorded qualities can be utilized to control. The information got from sensors can be contrasted with the ideal qualities. In the event that the sensor readings are seen as inconsistent to the ideal qualities, at that point the control circuit will come vigorously to control the allotted action to keep it in wanted way. We recommend utilization of this rule for building a framework which can save crude nourishment. Keen nourishment checking framework is intended to screen and control nourishment materials and keep it from harms happening because of environmental or climatic changes.

Nourishment cleanliness and security is a significant issue for human wellbeing. There are numerous components prompting food contamination, regularly changes in temperature and Despite the fact that we appreciate one of the most secure nourishment supplies inside the planet, foodborne sickness stays regular inside the India where foodborne ailment episodes influence millions and murder a great many individuals. These episodes likewise undermine customer trust in influenced items, end in enormous reviews, and reduce showcase request.

A significant number of foodborne ailment episodes result from poor cleanliness rehearses. Microorganisms can get by in nourishment preparing and dealing with situations. they're by and large brought into the nourishment condition through crude materials, bugs, air, water, and workers. Typically, the normal utilizations of fabulous sanitation rehearses can control these microorganisms inside the nourishment preparing and taking care of conditions. Be that as it may, if tainting levels are high or sanitation methodology are insufficient, microorganisms may build up and _ought to pollute nourishment items prompting foodborne disease flare-up.

Different pathogenic microorganisms like E.coli, Listeria monocytogenes , and Salmonella spp. have settled narratives of being potential contaminants in nourishment taking care of conditions. Consequently, it is imperative to watch the clean condition inside the nourishment fabricating office for the get together of high caliber and safe nourishment items. An ecological observing project (EMP) will evaluate the viability of the general sterile works on during an office and give vital data to forestall conceivable microbial pollution of nourishment items. restrict mind that EMP doesn't make nourishment safe. Or maybe, it gives important information

(source and focus) on marker living beings, waste life forms, and pathogens of worry during an auspicious way.

To diminish the risk of microbial item tainting, one must have understanding into actualizing a proficient EMP during a nourishment office and appropriately deciphering the information to start fitting remedial activities.

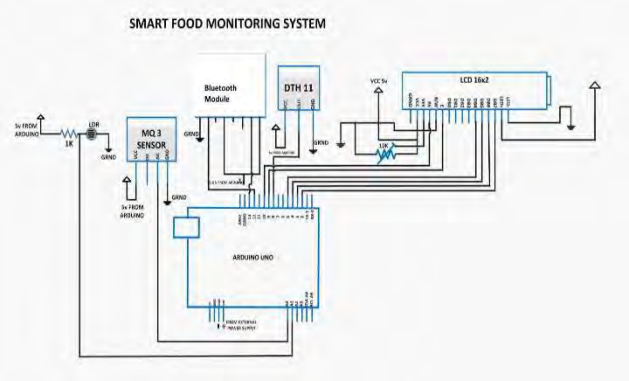

Fig 2: Food Enviromnment Monitoring System Circuit Diagram

Motivation

The various issues related to food incidents occurred in the past year, i.e. 2018. Some of them are as:

1. On 16 July 2013, at least 23 students died, and dozens more fell ill at a primary school in the village of Dharmashati Gandaman in the Saran district of the Indian state of Bihar after eating a Midday Meal kept in environment not favorable for food.

2. In Germany and the Netherlands, meat and milk were found with elevated dioxin concentrations. The dioxin was traced to citrus pulp from Brazil that had been neutralized with lime contaminated with dioxin. 92,000 tons of citrus pulp was discarded. The citrus pulp market collapsed in some European countries. A tolerance level for dioxins in citrus pulp was set by the European Commission. 1999 – In Belgium, animal feed contaminated with dioxins and polychlorinated biphenyls affected more than 2500 poultry and pig farms.

Such incidents created a great loss of life and resources both at the same time Hence, going through the above incidences and motivation to do something for the society we decided to develop a Food Environment Monitoring System using the IoT technology.

III. SUBJECT DESIGN AND CURRICULUM

A. PHASES OF PROJECT

- **Phase 1: Testing and Deployment**

1. **Testing**: System was tested in various environments where the foods are stored like bakeries, cold food storage areas etc and calibrated the readings of the sensors to give the exact output.

2. **Deployment**: The proposed system can be deployed wherever there is a large amount of food is stored and need constant monitoring of the food.

Project planning (Resources, Tools used, etc.):

1. Arduino uno

Fig 3: Arduino Board

The Arduino UNO is an open-source microcontroller board based on the Microchip ATmega328P microcontroller and developed by Arduino.cc the board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits.

2. DHT-11 Sensor

Fig 4: DHT-11

The DHT11 is a commonly used Temperature and humidity sensor. The sensor comes with a dedicated NTC to measure temperature and an 8-bit microcontroller to output the values of temperature and humidity as serial data. The sensor is also factory calibrated and hence easy to interface with other microcontrollers.

1. MQ3 Sensor

Fig 5: MQ3 Sensor

The Grove - Gas Sensor (MQ3) module is useful for gas leakage detection (in home and industry). It is suitable for detecting H2, LPG, CH4, CO, Alcohol. Due to its high sensitivity and fast response time, measurements can be taken as soon as possible. The sensitivity of the sensor can be adjusted by using the potentiometer.

Implementation:

IoT device should be installed in a food store. Once it is properly installed and powered on, it connects with the internet via Bluetooth modem and start reading data from the interfaced sensors DHT-11 temperature and humidity sensor, MQ3 and LDR sensor. DHT11 temperature and humidity sensor is a digital sensor with inbuilt capacitive humidity sensor and thermistor it relays a Real- time temperature and humidity reading every 2 seconds. The sensors operators on 3.5 to 5.5 V supply and can read temperature between 0 degree C and 50 degree C and relative humidity between 20% and
95%. The MQ3 sensor senses the presence of gases in the atmosphere and provides the output and thus making us aware about the quality standards of food.

IV. FINAL OUTPUT

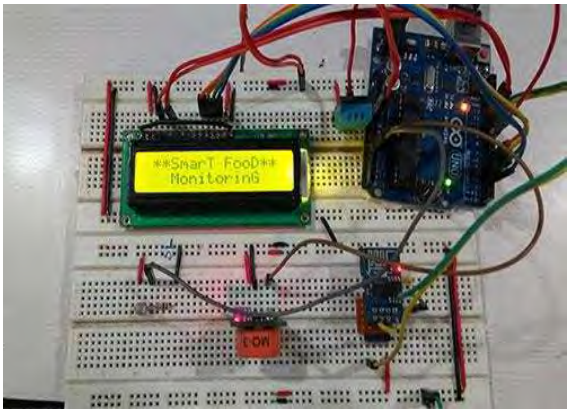

Fig 6: Final Output

The above figure shows the final circuit connection using the block diagram and the circuit diagram. The data is collected using the sensors connected in the circuit and its given to the arduino uno. The arduino uno then compiles the data and the data is displayed on to the serial screen in the computer as well as on the LCD screen

Features of the project

The Project consists of the following features:

1. **Quick Monitoring:** The resulted output is clearly displayed in the LCD (16*2) which is connected in the circuit and hence any fluctuation can be observed through the LCD.

2. High sensitivity and fast response: The alcohol sensor used is highly sensitive to the amount of alcohol generated each point of time in the region as soon as it senses the alcohol above threshold it starts the alert system.

3. **Long life and stable**: The components used are of high grade hence they can be active for a very long time

1.

4. **Simple drive circuit**: The connections and the circuit design of this system is simple hence it is much more convenient to develop

Improvements in Research Gaps (Findings)

Every project has some gaps in it. No project is 100% efficient. There are some gaps in this project too. They are as follows:

1. As this system is currently not WiFi enabled, the data collected is only displayed on the LCD screen. So, respective actions cannot be taken with regard to that. If it is made WiFi enabled, the data can be shown to the owner through a website with a message showing values with c=their respective units.

2. Also, the MQ-3 gas sensor is prone to corrosion due to moisture, which may result in improper functioning of the sensor and can result in serious harm. So, a time-to-time sensor check notification can be sent to the owner, so that a regular check of the sensor is done and improper functioning is prevented.

V. CONCLUSION

In this study, we proposed the food monitoring system that managers and consumers can check the freshness of food. Proposed system consists of temperature sensor, humidity sensor, MQ3 sensor, LDR. To validate the effectiveness of the proposed system, we were monitoring the freshness of milk by the environmental. The freshness of milk can be confirmed through pH at 4°C, 13°C and 22°C. PH of fresh milk is 6.5 to 6.9. And spoiled milk is fewer than 6.5. If improved further this system can be used on almost every store and consumer can get the best quality food and thus improving the life balance. However still lot of improvement is needed in this dynamic real world and we hope that through this prototype there can be further research and future scope possible.

By using this automated system in a cold storage, we can evaluate and monitor the various data by our mobile phone or via PC's. If any abruption takes place then it can be also made automated to turn on/off any external relay module which can operate/condition the temperature and humidity inside a cold storage.

Future Scope

The quantity of IoT gadgets expanded multi year-over-year to
8.4 billion out of 2017 and it is assessed that there will be 30 billion gadgets by 2020. The worldwide market estimation of IoT is anticipated to reach $7.1trillion by 2020. IoT includes broadening web network past standard gadgets, for example, work areas, workstations, cell phones and tablets, to any scope of customarily idiotic or non-web empowered physical gadgets and regular items. Installed with innovation, these gadgets can convey and interface over the web, and they can be remotely observed and controlled

1. Food environment systems can be installed inside the bakery cabins where the food are kept for storage and hence can be continuously monitored and the environment can be maintained for the food kept in them.

2. These food environment monitoring systems can be used inside the cold storages to monitor the environment around the food kept.
3. These monitoring systems can also be used in the restaurants where buffets are used to serve the food.

VI. ACKNOWLEDGMENT

The author would like to thank subject lecturers (current and previous), education designers and other staff members from the School of Computing and Mathematics who previously designed, developed and taught this subject at various times. This work is based on the current author's (who is also the present lecturer and coordinator for the subject) TOL design and development work of the subject.

An IOT based Smart Medical Box

Divyam Choudhary, Abhishek Gupta, Sanya Gandhi, Shivkumar Chauhan
Department of IT,Thakur College of Engineering and Technology
divyamchoudhary@hotmail.com, abhisekgupta1599@gmail.com, gandhisanya99@gmail.com, cshiv3333@gmail.com

Abstract—**IoT, i.e. Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology. In the medical field when a patient is diagnosed and has been prescribed medication by a doctor, there are chances that the patient forgets to take his medication. When the patient doesn't take the medication on time or forgets to take it, some microbes may survive and they develop resistance to that medicine/drug which leads to antimicrobial resistance (AMR), or drug resistance. The objective of this project is to build a Smart Medicine Box based on IoT technology. It will help in reminding the patients to take their medicines and it will help in monitoring, analysis and controlling the device. Hence we have come up with a smart system that can monitor the patient's medicine intake. The Arduino board will be interfaced with the box that will contain prescribed medicines for the patient. The box will have its own timing information which will be continuously compared to real world time. If the information matches the alarm will start to ring and will remind the patient to take his *medicine.***

Keywords – IOT, Medicine Box, Arduino Uno, ESP8266 Wi-Fi Module, LDR

I. INTRODUCTION

A lot of individuals out in our community need constant help especially elderly people, family members. These are mostly the elderly as they are one of the largest consumers of medicine. But as a human starts to age, different issues arise such as - poor eyesight and poor memory. People may forget to take their medicines on time. In order to eliminate the need for constant observation (through nurses, relatives, guardians, caretaker, etc.) or taking a risk of a missed dose, we had to find an easy, portable and efficient solution. [1]

Nowadays, a modern healthcare IOT platform with an intelligent medical box has a great potential in medical field. Research has found out that about 60% of people above 60 years have poor record of medical history. An intelligent home-based smart medical box will be able to keep the track of medicine intake of the patient and also let the doctor to see the patient's dosage history over the internet. So, if a smart medical box is used which will remind people when to take the medicine, people can keep record of their medicine intake and the doctors will also get a update on daily basis about their patients medicine intake. [2]

The major reason is to bring medical field and technology field closer and make something innovative to reduce the current medical problem. The aim of this study is to build a Smart Medicine Box for reminding the patient to take their medicine at the prescribed time. When the pill time has been set, the medicine box will remind clients or patients to take
pills utilizing light of the LED which will blink when they will set the time to take their medicine.

II. PROBLEM DEFINITION

The Smart Medical Box provides the solution to a very common problem of forgetting to complete a medicinal course by reminding the patients in a very effective manner with proper reminding mechanism.

III. SURVEY

Fig 1: Survey taken with the students at Thakur College of Engineering and Technology. Total 50 students participated

To understand the need of such a reminder tool; a survey of students studying in Thakur College of Engineering and Technology, Kandivali, India was conducted on 19th November, 2019. According to the survey, only 37.5% of students said that they always completed their medicinal course. The survey also emphasizes the statistics that 58.8% had their grandparents on medicinal course who tend to forget to take medicines. The suggestions had obvious solution of a smart reminder.

IV. LITERATURE REVIEW

A Smart Medical Box which can remind us to take the medication has become a necessity nowadays. Before this technology people often tend to forget about taking their medication at the right time which leads to the disease inside the human body get the time to develop antibodies for the medication in that case human would not be able to get treated. It was mainly because patients tend to forget to take their medication in the daily hustle bustle of the life. [3]
Early developments to develop electronic medical boxes started in 2006 by [4]. However, the early electronic medial boxes did not have a monitoring system which can check the intake of the medicines by the patient. Later developments in the electric medical boxes made them smart which uses WIFI modules which connects it to internet and also continuously monitor their status. The most recent advances have added many more functionalities to the smart medical box like it sends the feedback about the pills from the user and send purchase orders to the medical shops.The importance of the Smart Medical Box is starting to become more of a necessity because many patients tends to forget to take their medication on time and with the help of Smart Medical Box which can remind them to take their medicines can really

help them to get cured. [5] Smart Medical Box provides a Stress-Free Reminder
System for taking medicines on time.
The pills are the pillars of medicines, being used as direct treatment of some sort of illness as to assuring some medical condition remains stable.

Failure to take the pills on time will lead to the disease developing immunity to it and patient will not be able to get cured by the same medicine or the same dose of the drug.
We need to carefully make the medical box user face such that it reminds the patient to take the right medicine at right time or sometimes old patients forgets that they have already taken the medicine and they take an overdose of the medicine.

It was found that a large number of medical complications are caused on the grounds that the patients do not take their drugs in the right amount, at the right time. In most cases they either overdose or under dose their medications being forgetful and this deteriorates their health. The patients suffering with Alzheimer have forgetfulness and reduced intellectual capacity as the primary symptoms. This disease is also as a result of expanding age and thus the dominant age group is that of 65 and above. Furthermore, patients may not be able to manage the cost of a caretaker, so dealing with cost viability motivates to build a simple reminder system which is low cost and simple that can be used by a patient [6].

Even patients with less benign illness often forget to take their medicines or sometimes overdose which can cause dysfunction in their bodies. A simple reminder system will reduce the cost but also allow doctors, caretakers, relatives to monitor patients' medical intake. The product can be used for patients who are given home rest through which they can take care of getting their medicines on time and it will not require the help of family members or nurses. It can be upgraded to take the feedback of the medicine from user and the box will be able to place medical orders for the medicine to nearby pharmacies. [4] [7]

Implementation of an IOT based Smart Medical Box which reminds to take medicines on the specified time period and senses the intake of medicines has been done. This Project helps the patients, their families and Doctors to maintain records. The complications caused by incomplete course by patients can now be reduced to a great extent. The circuit has a minimal cost and is affordable in comparison with the manual take care of the patients. This project aims to help all kind of patients with every kind of medicine intake course with proper notifications and reminder. [6]

V. OBJECTIVE

People often forget to take their medicines or sometimes they forget that they have already taken their medicines and they take overdose of the same medicine which can cause dysfunction in their bodies. In order to avoid keeping nurses to check on the patients to take their medicines; it's a user friendly cost effective device which will help the patient to take their medicines on time without fail. It will also allow doctors, caretakers, relatives to monitor patients' medical intake.

VI. REQUIREMENT ANALYSIS

The next step was to understand hardware and software requirements of the project. After looking for a variety of available chipsets and development kits, the Arduino Uno paired with an ESP8266-01 Wi-Fi module were chosen. The cost of the system should also be feasible and hence we came to an understanding for the following components:

Quantity	Components
1	Arduino Uno
1	ESP8266-01 Wi-Fi Module
1	LDR Module
2	LED Lights
14	Jumper Wires
1	Breadboard
1	10K Resistor

Table 1: Hardware Components

As for the software requirement, we use the Arduino IDE which based on the C Programming language.

VII. WORKFLOW AND CIRCUIT DESIGN

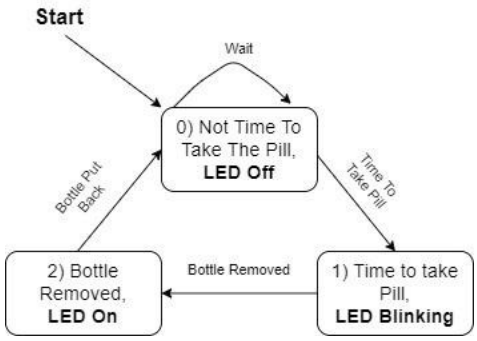

Fig 2: Workflow diagram

The Workflow diagram shows the expected behavior of the IOT solution in a real case scenario. It is depicted in three states:

1. The timer for the medicine reminder is set with the initialization of the system. In this step, the system sits idle and waits for the time of reminder. The LED does not blink.

2. When it is time to take the medicine, the LED will start blinking. This reminds the patient to consume the

medicine. The system continues to stay in this phase until the medicine box is picked up by the user.

3. In this step, the patient picks up the medicine box. The LED stops blinking; the LDR sensor in the system shall senses light from the surroundings and keep the LED turned on. As soon as the medicine is kept back on the medicine box, the LDR cannot sense any incoming light and thus the LED is turned off and the timer is reset again. [8]

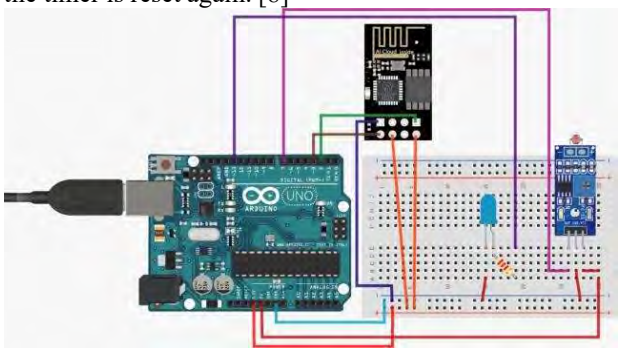

Fig 3: Circuit Diagram

The Circuit Diagram shows how the idea of the workflow is implemented in real time situation. The solution uses Arduino Uno for the circuit. The data collected by Arduino will be light intensity data collected by the LDR sensor. The same data will be transmitted through the ESP8266-01 Wi-Fi module to the Thing Speak API and recorded. Thus, one will be able to record whether the patient took the medicine, or not. Through this data, the patient's family, doctor and patient themselves will be able to see the medicine records and they be relieved of remembering to take their prescriptions.

Fig 5: Smart Medicine Box- LED starts to blink when the time take the medicine was set and it will keep on blinking until the user picks up the medicine on the box.

Fig 6: Smart Medicine Box- As the patient lifts the medicine for intake; the LED will glow continuously until medicine is kept back on place. The system will then again until the next time arrives

VIII. RESULTS

Fig 4: Smart Medicine Box- System is active and waiting for the time of medicine to be taken. LED is turned off.

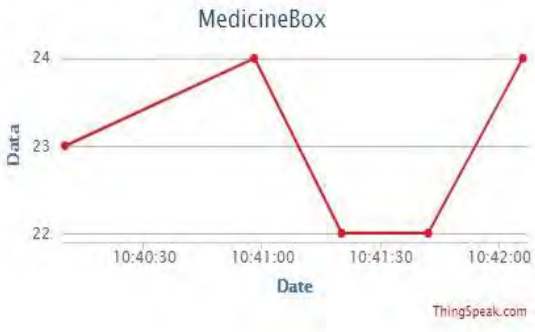

Fig 5: Think Speak Dashboard

As per the purpose of this system, it reminds the patients to intake medicines. After the medicine box is picked up and the medicine is consumed, one can keep the box again at its place; by which there is a cut-off of the light to the LDR module and is a signal of medicine consumption. The recorded light frequency is plotted on the 'Think Speak' Dashboard for the purpose of reporting it to the respective doctor and family member.

IX. RESEARCH GAPS

This being done, there are search some research and technical gaps. Even though this model is working perfectly fine, the user still will not be able to set the time to take its medicine without altering the code. It still needs user input board so that the time can be set by the user manually. As the model is connected with a WIFI module, we can create an android/IOS application for this very model so that the users can control the Smart Medical Box through their mobile phones which will make this model very user friendly. It is also limited to reminding about only one medicine course. A user here has the chances of picking up and keeping it back without the consumption of the medicine.

X. FUTURE SCOPE

Many a times the patient often forgets to take their medication especially old people. Some of them might be suffering from Alzheimer and they always require help from someone else, but what if the medicines they are taking are about to get over and they need new medicines. We can add a device which can detect what kind of medication the patient is taking and the system will automatically detect if the medicines are about to finish or getting near its expiration date and it will automatically send a purchase order to a nearby medical store which will deliver the medicines to the patients' homes.

1. It can have a Mobile Application to make the device more user friendly for non-technical people.
2. Many patients will be able to use it which will make them more self-reliable and they won't be requiring anyone's help.
3. It can be used to send the reports of the patient's intake of medicine to their doctors, and on the basis of those reports the doctor can think of further procedures for the patient.
4. It can be used for more than one type of medicine and remind with a system of adding different medicines with separate buzzers and light indications.
5. A weight sensor can further be added to sense the weight of the medicine box and recheck if the medicine intake is actually done.
6. The device can be linked to online prescription system and will check if all the prescribed medicines are contained in the medicine box.
7. The device can further scan the QR code of the medicine chip notify for expiration of the same.

XI. CONCLUSION

Smart Medical Box is a user-friendly; low-cost which can remind the patients when they should take their medicine was successfully created. Lot of patients who are on a large amount of medications and have a hard time remembering at what time which medication is to be taken will be helped. Doctors can easily keep a record of their intake of through the Think Speak App.

Blood Type Detection Using Photoelectric Sensor And Laser Diode

Suyog Khadke, Ashish Kumar, Rupali Bajpai
TCET , MUMBAI
imsuyog1307@gmail.com, ashishkumar15999@gmail.com, rup.bajpai@gmail.com

Abstract— **The objective of this project is to build a blood type detection device based on IOT technology. The device uses the change in frequency of the light when it is passed through the blood sample to detect the blood type of the patient. Now days the process of blood type detection has become extremely important due to the high blood transfusion rates as well as organ transplantation rates and any mistake in this process can result in the loss of a life that is the patient and due to the above risk the hospitals prefer using only O+ blood type for blood transfusions as they are universal donors but to the ever increasing population using only one type of blood group is not feasible. Thus a device is required which can do the blood type detection process accurately and also with high efficiency. Moreover now a days there has been an increase in wrong blood type determination of a person, this project also take an initiative to overcome that by discussing about it in the future scope**

Keywords–BloodType;Transfusion;Photoelectric Sensor

I. INTRODUCTION

IOT, i.e. Internet of Things currently is one of the most trending fields in the Branch of Information Communication Technology. In case of blood type detection in hospitals and clinics the process which is traditionally used to detect the blood type of a person takes a large amount of time and the precision of that machine is also not very good. The cost of the machine which is
traditionally used to detect the blood type in laboratories is also very high. Therefore for the following reasons there is a requirement of a device which has high precision rate, which is cost effective and provides the result fast.

The objective of this project is to build a blood type detection device based on IOT technology. The device uses the change in frequency of the light when it is passed through the blood sample to detect the blood type of the patient. Now days, due to the ever increasing population the rate of blood transfusions and organ transplantations has increased rapidly and because of this the blood type detection of a person needs to be fast as well as accurate because any mistake in this process can lead to the loss of a life. Therefore for the following reasons a device is required which can detect the blood type in few minutes and that to with high accuracy rate.

After studying the literature survey it was planned to overcome the research gaps in the traditionally used blood type detection devices and the device was tested using the test cases and then the outputs were generated. The output of the device was shown according to different test cases and thus the readings provided by the blood type detection device became more accurate.
A discussion forum is also run for the subject through the subject interact2 page where students can discuss various new and recent topics and can share their experiences with each other. Most students participate actively in the discussion forum and the lecturers just monitor the discussion. Lecturers only participate in the forum discussion when it is required either to provide some answers to a specific question asked or if there is some new information that the lecturer thinks may be useful for a particular discussion.

II. BACKGROUND

Blood type detection has become a crucial aspect in blood transfusions and organ transplantations as opposed to about 90 years ago when automatic blood detection was not developed. Before introduction of blood type detection devices, wrong blood transfusions and organ transplantations has resulted in the loss of human life . Early developments in detection of blood type of a person began in
1901 and the first ABO-System was detected by Landsteiner K in 1901. Further research was done and different subgroups in ABO- System were discovered.

Later developments in the blood type detection systems used the technological advances that have been integrated with the health care industry which in turn increased the accuracy of blood type results thus preventing wrong blood group transfusions and other medical related threats and the time required to get the result was also reduced to great extent.

e subject design and the curriculum. Section IV presents CSU's Graduate Learning Outcomes (GLOs) and their relationship with the subject. Finally, Section V concludes the article.

III. IMPORTANCE OF PROJECT

The requirement of a IOT based device to detect the blood type of a patient is to make the process of blood type detection more fast and also to increase the accuracy of the results obtained.

An average of 200 to 300 blood samples are analyzed within 2 to 3 hours by the traditional blood detection method but when the proposed device is used the

same task can be completed within a short period of time with good precision.

The proposed device can also reduce the human error which can be caused in the laboratories.

The device will cost less than the traditional blood detecting systems hence more cost effective.

You need to carefully consider the benefits that you will get from the device and also the impact of this device in the health care sector.

IV. OBJECTIVES

- The proposed idea is to replace the manual work in clinical laboratories for identifying the blood group.
- To provide a cost effective and affordable method as compared to the traditional method for detecting blood type.

- For large data may misdeed to maintain the blood sample and records accurately. In this new technique, the LASER source and photocell are used to analyse the ABO blood grouping (A, B, O) and Rhesus type testing (Rh Positive and Negative).

It can also be integrated with other sensors to monitor heart pulses and it can also act as a medicine reminder for a patient by integrating a Wi-Fi module and the appropriate sensor for the same.

V. SUMMARY

The proposed idea is to replace the manual work in clinical laboratories for identifying the blood group. For large data may misdeed to maintain the blood sample and records accurately In this new technique, the LASER source and photocell are used to analyse the ABO blood grouping (A, B, O) and Rhesus type testing (Rh Positive and negative)Blood Type Detecting Device ,which helps to save many lives in emergency from Human damage. The project focus on building an IOT based Blood Type Detecting Device System using Arduino as platform. Before the project starts there is the first chapter which speaks about the background of the project, why it is required and also it adds about the need and motivation for the project . This Prototype help the future projects to be very effective and efficient As This is very first time to develop such type of Device in low cost.

04

The Project consists of the following features:

In this new technique, the LASER source and photocell are used to analyse the ABO blood grouping (A, B, O) and Rhesus type testing (Rh Positive and negative).

An average of 200 to 300 blood samples are analysed within 2 to 3 hours by the traditional blood detection method but when the proposed device is used the same task can be completed within a short period of time with good precision.

Blood typing is a test that determines a person's blood type. The test is essential if you need a blood transfusion or are planning to donate blood. Not all blood types are compatible, so it's important to know your blood group. Receiving blood that's incompatible with your blood type could trigger a dangerous immune response.

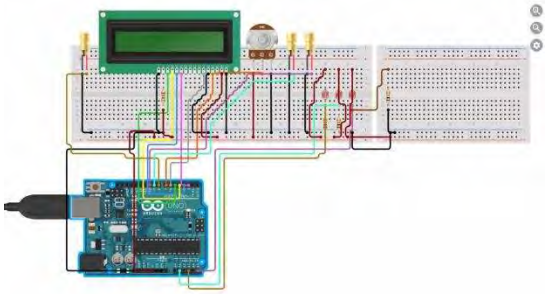
VI. TRADITIONAL APPROACH

The presence or absence of blood stains often provides important information for those investigating criminal cases. For this reason, forensic scientists are often called on to determine whether or not a particular stain is blood, and if so, whose. The detection of blood is usually based on one of three classes of methods. Crystal tests Haem forms crystals when reacted with certain reagents. The most common such reagent is pyridine, which
forms characteristic pink crystals. Catalytic tests these tests rely on the fact that haem can catalyse the breakdown of hydrogen
peroxide. As the H2O2 breaks down, another substance in the reaction mixture is oxidised, producing a colour change. It is important to note that a positive test does not mean that a given stain is blood, let alone that it is human blood, as various enzymes and certain metals can also give positive results. Instrumental methods Chromatography can be used to identify the presence of haemoglobin. These tests are used practically for several different purposes. These include both the
confirmation of the nature of visible stains (i.e. that they probably are or definitely are not blood), the detection of non-visible stains (e.g. on plants or washed clothing) and the enhancement of hard to see stains. Stain enhancement is useful for situations where a footprint, handprint, fingerprint etc. is faintly outlined in blood, as chemical methods can enhance that stain so that the print can be measured and matched with suspects. In all of these tests it is important to ensure that the chemical reactions do not prevent later tests being done to help to identify who the blood belongs to.

VII. IOT BASED APPROACH

Blood sample for which blood group is to be identified is placed in the glass slide between the LASER beam and photocell. After these arrangements, the voltage from the photocell is decreased due to the variations in LASER beam intensity. Then a drop of antigen is added to a drop of blood sample which is on the transparent glass slide. If the clumping (the agglutination reaction) occurs, then the density of the blood sample changes (high) which in turn changes intensity of light to the photocell. If the clumping reaction does not occur, then the density of blood sample does not change. So there will be no changes in the level of energization of photocell According to photocell reading we write program for any microcontroller by using ADC

or comparator to change this voltage in digital value nothing but 0
& 1. Here the circuit diagram of device :



After sensing the input from the sensor it is then send to Arduino and then processed using the following logic table

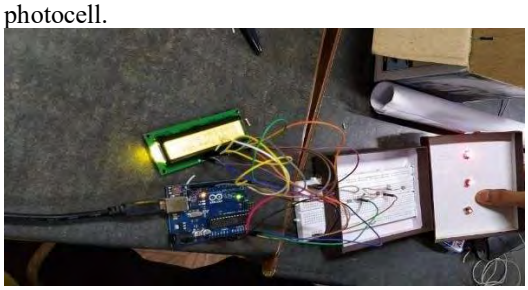
Let us consider a we have sense on first sensor we get the output as high and similarly on other two sensor we get output as low in this case the combine output of case will be A- blood group as it satisfies the all condition .

Anti A	Anti B	Anti D	Blood Group
1	0	1	A +
1	0	0	A -
0	1	1	B +
0	1	0	B -
1	1	1	AB +
1	1	0	AB -
0	0	1	O +
0	0	0	O -

VIII. RESUT & DISCUSSION

Outputs:

1) Blood sample for which blood group is to be identified is placed in the glass slide between the LASER beam and photocell.



2) Lcd display of blood type detection using photocell and laser diode.

IX. OUTCOMES

(1) Creating the synopsis, literature survey and feasibility study for proposed solution which will act as an input to the design phase;
(2) Proposing Statement of work, scope definition and scope boundary for planning the prototype from the problem definition to decide what needs to be done and what not to be done;
(3) Proposing design, architecture for the prototype;
(4) Implementation of the Arduino model with the help code running it in the arduino IDE environment;
(5) Testing was done with the LASER source and photocell are used to analyze the ABO blood grouping (A, B, O) and Rhesus type testing (Rh Positive and negative).The testing of the model was a success are mentioned in the above figures;
(6) Real time sensing was done with the LASER source and photocell are used to analyze the ABO blood grouping (A, B, O) and Rhesus type testing (Rh Positive and- negative)Thus the model works efficiently.

X. FUTURE SCOPE

1) Determining of blood types is very important during emergency situation before administering a blood transfusion. Presently, these tests are performed manually by technicians, which can lead to human errors. Determination of the blood types in a short period of time and without human errors is very much essential**.** The developed method is useful in emergency situation to determine the blood group without human error.
2) The proposed idea is to replace the manual work in clinical laboratories for identifying the blood group.
3) We can design fully automatic machine for this sensor which will help us to improve the response of the system.

XI. CONCLUSION

An average of 200 to 300 blood samples are analysed within 2 to 3 hours by the traditional blood detection method but when the proposed device is used the same task can be completed within a
short period of time with good precision.

One more added advantage of this proposed device is that it is extremely affordable and we can also add extra features such as heart monitoring system etc and thus it can also act as a virtual doctor.(Future project model)

We can design fully automatic machine for this sensor which will help us to improve the response of the system.

Iot Enabled Smart Parking System

Abhishek Singh, Hrithik Singh
TCET, Mumbai
7227abhishek@gmail.com, hritiksingh1999@gmail.com

Abstract— ***IoT, i.e. Internet of Things is currently the most trending field within the Branch of information Communication Technology. In Residential buildings, malls, commercial enterprise buildings in which parking is an important concern as parking is not easily available. In places with a limited place for parking the vehicles, due to ineffective management, parking becomes an issue the objective is to build a smart parking system which will allow effective and consistent solution for the parking issue. Nowadays Smart parking is a demand for the management of these places because of the populace which is increasing with the aid of day. Also, as of now with the dropping expenses of automobiles parking is a real hassle. due to ineffective parking, it leads to visitors jam which prices everyone their time. So, with powerful management, this hassle can be reduced quite a bit. After studying the literature survey, it turned into a plan to triumph over the studies gaps and the system become tested the use of a model with dummy cars. A smart parking system can help to resolve this trouble. In a smart parking system while the parking spot is empty it's going to let the car in and if any parking spot isn't empty it's going to let the driver recognize the parking spot at the entrance through the LCD screen. Moreover, there may be an increase in these scenarios nowadays, this mission additionally takes an initiative to conquer that by discussing it in the future step.***

Keywords – Arduino UNO, IR Sensor, Servo Motor, Battery, Connectimg Wires, Automation, Smart parking etc

I. INTRODUCTION

Internet of Things or IoT is a widely - used enterprise buzzword offering widespread transformation possibilities for corporations. An IoT solution includes sensors and actuators, communication channels, statistics collection at the cloud, and applications. It comes with its demanding situations of scale, diversity, connectivity, privacy, safety, and regulatory compliance. IoT platforms enforce common reference architecture comprising the Edge, Platform and Enterprise tiers and help groups triumph over technical challenges. Any smart applications include sensors, which are deployed in the environment, collect the information from the device/sensor is processed and analyzed to manage the applications. This approach would reduce the cost of manpower and increase productivity. Commercial buildings, residential homes, etc. Nowadays are much more crowded, due to this population increases the want for powerful management of parking machine. A smart parking machine can help clear up this problem. In clever parking gadgets when the parking spot is empty it'll permit the car to enter and if any parking spot is not empty it will permit the driver to know about the parking spot at the entrance through the LCD screen. Moreover, there may be a boom in these eventualities nowadays, this undertaking additionally takes an initiative to overcome that with the aid of discussing it in the future step.

A. Background

The automated car parking system refers to a mechanical system devised to park a largen number of cars with maximum efficiency. Automated Parking System was first developed in 1905 in Paris, France at the Garage Rue de Ponthieu. The necessity for an automated parking system works based on one's need for a space to park and the undersupply of it. With our focus firmly on customer experience, our Australasian-based technology division, alongside a rapidly growing global network of expert partners, aims to bring our intelligent parking system and integrated smart parking solutions to the world. this example might be taken as a chance so as to make advancement within the efficiency of parking resources which will reduce the searching time, traffic jam and road accidents The System is mainly used in Europe, the USA and Japan (Shaheen et al., 2005) is evolved with the incorporation of advanced technologies and researches from various academic disciplines. With its deployment inside the car park, it's far hoped that it'd solve the aforementioned troubles faced by the patrons within the car park.

B. Importance of Project

The requirement of the smart parking system is because if the increasing population of the cars at the commercial building, residential building's mall, etc. Hence there is great importance for this project in Day-to-Day life. Importance of the smart parking system are as below

- Use new technology that uses Internet of Things (IOT).
- LCD screen will let the driver know about the empty spot so they don't waste time in finding the parking spot.
- Effective management will not make the area crowded.
- As soon as spot is emptied it change the status in the LCD screen which will inform the driver about the status.
- To achieve cost savings.
- Human force would decrease because of automatic opening and closing of the gate

C. Motivation

The increase in town traffic is one of the foremost effects of growth, particularly in urban areas. because of this looking for a vacant car park throughout peak hours isn't solely long however additionally leads to wastage of fuel. A Smart Parking System like this enables drivers to construct good choices that may cut back congestion and construct the foremost of accessible areas. Finding a car parking zone has come to be a daily challenge of late, which is anywhere the incentive for this assignment came up. With the evolution of technology, we've smartphones, sensors that find the presence of any object and my plan has a system anyplace parking regions are ready with the Infrared sensors that tell

concerning the occupancy standing of the parking spaces on the LCD screen this is displayed out of doors the park. The drivers keep finding out appropriate automobile parking space that increases traffic. Increasing the volume of transport exhaust creates a negative impact on the surroundings. hence a smart parking system has become the requirement of the day

D. Objective And Scope

The Objective of this project is to implement a low cost, reliable parking system which helps in efficient parking and utilization of space it also helps to scale back pollution and traffic. The Scope are often an android based application are going to be used with a connected database through which a user can book a parking slot consistent with his time.

- To reduce with continuous effective flow of parking spot.
- To provide safe and secure parking slots within limited area.
- To scale back pollution by decreasing drive time.
- To save time by making parking easily available.

II. LITERATURE SURVEY AND PROPOSED WORK

In this section, we present literature survey done related to this project and relating work in progress.

A. Introduction

Various methods are prevalent for the development of autonomous or intelligent parking systems. The study of these systems shows that these require a little or more human intervention for the functioning. One of the intelligent systems for car parking has been proposed by making use of IR sensor LCD and servo motor. In this work, I have developed a Smart Parking System that can monitor available empty slots economical and reliable and consider contributing to fuel and time-consuming. In this work, the most widely used sensors are Infra-Red (IR) sensors.[3] These sensors are used for monitoring the vacancy of a parking slot. The reason for using these sensors is they are cheap and use less memory as compared to the camera if used as sensors. The sensor will monitor whether the car is parked or the slot is empty. If the slot is empty, then the sensor would sense it and give the notice to LCD so in the LCD the vacant parking slot would be displayed Servo motor is used as gate for opening and closing of the gate tail Thus, we aim to propose a car parking system that represents a fully automated model with minimum human intervention and overcome the limitations of existing system

B. Literature Survey

From this research paper we got definite data related to problem caused by traffic. A Reservation – based Smart Parking System by Hongwei Wang and Wenbo He – April 01, 2016. We got information about how IOT based smart parking can be implemented with help of sensors and how cloud storage can be used for Y. Rahayu, F. N. Mustapa, ":A secure parking reservation system using gsm technology a smart and secure parking reservation system based on GSM technology.

C. Problem Definition

To design an IOT based SMART PARKING SYSTEM that will continuously monitor the presence of the car at the parking and show the appropriate output in the LCD at the entrance. Smart parking may be a solution to metropolitan cities to scale back congestion, cut vehicle emission totals and save persons' time by helping them find a spot to park. Smart Parking may is and advanced parking system, usually a parking system replacement of the traditional parking system. Smart parking system equipped with special sensors to detect the available parking slots at any parking lot.This is an application supported Internet of Things (IoT) that in Real-Time environment have sensors and devices embedded into parking spaces, transmitting data on the occupancy status; and the vehicle drivers can search for parking availability using the information displayed on the LCD screen. Hence the driving force would know where there's an available spot to park his vehicle in less time, reducing the energy consumption and pollution

D. Phases of Project

- Phase 1: Arranging, Examination, Planning and Execution.

Arranging: Arranging: After examination, we learned about our subject and did some exploration on it for our better comprehension of the undertaking and furthermore to get an unpleasant picture about what might be our concern definition for the specific venture.

Examination: We got the away from our task title by doing research on it and will conclude our definition and after that, we previously made the Writing Overview of the venture and did the entire documentation.

Structuring: At that point, we will develop the plan of the task and as per that, will list down all the necessities required for the development of the model of our venture.

Execution: In the wake of obtaining the necessities, we continued for the development of the application.

- Phase 2: Testing and Arrangement.

Testing: After the model is prepared, we will initially interface the equipment with the allocated code and afterward we will check in the event that it underpins the instrument or not. If not, we will illuminate the issues with respect to it and will check once more.

Arrangement: After, complete coordination and testing of task ongoing running and activity of the framework will be finished. We are relied upon to approve against their recently put away information.

III. ANALYSIS AND PLANNING

Getting a clear plan of the project title and doing analysis thereon we are going to get our definition and at that time then we are going to 1st produce the Literature Survey of the project and do the total documentation. once analysis we are going to 1st study concerning it and do some analysis

thereon for our higher understanding of the project and conjointly obtaining a rough image concerning what would be our drawback definition for the actual project.

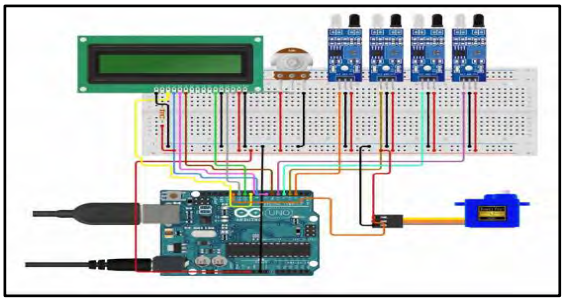

Fig.01 Circuit Diagram

A. Feasibility Study

1. Technical Feasibility: Here one has got to check, whether or not the projected system is developed victimization existing technology or not. It's evident that the mandatory hardware and software package area unit obtainable for the development and implementation of the projected system. Hence, the answer is technically possible.

2. Economic Feasibility: As a part of this, prices| the prices} and advantages related to the projected system compared and therefore the project is economically possible given that tangible or intangible advantages to outweigh costs. System development prices are going to be important. So, the projected system is economically possible.

3. Legal Feasibility: Legal problems will affect a system's acceptance by users, its performance, or the selections on whether or not to use it within the initial place—so it's best to contemplate these expressly in system style. The behavior of these being registered and recognized will influence the accuracy and effectiveness of just about any biometric system.

4. Operational Feasibility: it's a regular that ensures ability while not stifling competition and innovation among users, to the advantage of the general public each in terms of price and repair quality. The projected system is suitable for users. So, the projected system is operationally possible.

B. Implementaiom Details

Arduino Uno (Fig.02): It is a microcontroller board dependent on an 8-piece ATmega328P microcontroller. Alongside ATmega328P, it comprises of different segments, for example, precious stone oscillator, sequential correspondence, voltage controller, and so forth to help the microcontroller. Arduino Uno has 14 advanced information/yield pins (out of which 6 can be utilized as PWM yields), 6 simple information sticks, a USB association, A Force barrel jack, an ICSP header, and a reset button.

Fig.02 Arduino Uno

Fig.03 IR Sensor

IR Sensor (Fig.03): As referenced that the model is IR sensor situated it deals with some standard. Infrared sensors deal with the guideline of reflected light waves. Infrared light reflected from articles or sent from an infrared remote or signal. Infrared sensors are additionally used to quantify separation or closeness. The reflected light is recognized and afterward a gauge of separation is determined among sensor and article.

Fig.04 Servo Motor

Servo Motor (Fig.04): The servo motor position can be controlled more correctly than those of average DC engines, and for the most part, they have three wires like force, GND, and control. Capacity to these motors ceaselessly applied, with the servo engine control circuit changing the attract to drive the servo engine. These engines are intended for increasingly careful assignments where a motor position should be clear absolutely like moving a mechanical arm or controlling the rudder on a pontoon or robot leg inside a specific range.

Fig.05 LCD Screen

Fig.06 Potentiometer

LCD screen (16*2) (Fig.05): LCD modules area unit normally utilized in most embedded comes, the rationale being its low-cost value, availability, and computer programmer-friendly. Most people would have bumped into these displays in our day to day life, either at PCO's or thus because; it's 16 Columns and a couple of Rows. There are unit tons of mixtures out there like, 8×1, 8×2, 10×2, 16×1, etc. however the foremost used one is that the 16×2 alphanumeric display. So, it'll have (16×2=32) thirty-two characters in total and every character will be manufactured from 5×8 component Dots.

Potentiometer (Fig.06): A potentiometer could be a three-terminal electrical device with a slippy or rotating contact that forms Associate in Nursing adjustable potential divider. If solely 2 terminals area unit used, one finish and also the wiper, it acts as resistance or resistance. The measuring device referred to as a potentiometer is a potential divider used for mensuration voltage (voltage); the part is Associate in Nursing implementation of an equivalent principle, hence its name.

C. Features of the project

The project contains the following features:

1. It ensures fast and automatic parking and simple retrieval of vehicles.

2. best suited for parking in offices, malls, and similar places.

3. Low maintenance levels area unit needed by the system.

4. Sensors used have high sensitivity and area unit simple to handle

5. The low price system, providing the most ` automation.

6. It doesn't need line-of-sight operation.

7. Friendly reorientation of cars for driving in and out.

8. Safety of automobiles.

D. Methodology used Algorithm

Step 1: Start

Step 2: Initialize IR Sensor, Servo Motor and LCD screen.

Step 3: If car approaches to the gate IR detect and the gate opens

Else it remains close.

Step 4: If: car is parked in the slots show the slots full and increase the count by one.

Else: car is making an exit decrease the count by one.

Step 5: Stop

IV. RESULTS AND DISCUSSION

A. Output

Based on the sensor use, we are able to achieve the desirable outputs as follows:

Based on the sensor use, we can achieve the desired outputs as follows:

1. When the infrared sensor detects the approaching vehicle it sends the response Arduino board

2. As the board detects the info from the Arduino the servo motor acts accordingly.

3. As the vehicle enters the parking arena the total count of vehicle increases by one which is displayed on the LCD screen.

B. Outcome

Phase one Analysis: Creating the outline, literature survey associates degreed practicableness study for the planned resolution which can act as an input to the planning section.

Phase one Planning: Proposing Statement of labor, scope definition and scope boundary for definition and scope boundary for designing the paradigm from the matter definition to come to a decision what has to be done and what to not be done.

Phase one Designing: Proposing style design of Arduino and management mistreatment IoT system for implementing the surveyed case studies and outline.

Phase one Implementation: Various modules are created like the affiliation of sensors. Completion of cryptography grouping information from sensors.

Phase 2 Testing:

Case 1: IR obstacle sensor connection

Components/Things Required: IR Sensor, Arduino UNO.

After connections as shown in the circuit diagram, whenever the car was detected by the infrared sensor it gave output to the Arduino.

The IR sensor was tested successfully and was in working condition.

Case 2: Servo motor.

Components required: Servo motor

After connection as shown in the circuit diagram, the predicted results were successfully observed. Whenever servo motor received input from Arduino it worked correctly and raised its arm.

Case 3: IR sensor.

Components required: IR obstacle sensor

After connection as shown in the circuit diagram, the predicted were tested successfully observed. Whenever the car was detected through these sensors the LCD screen showed the appropriate parking spot.

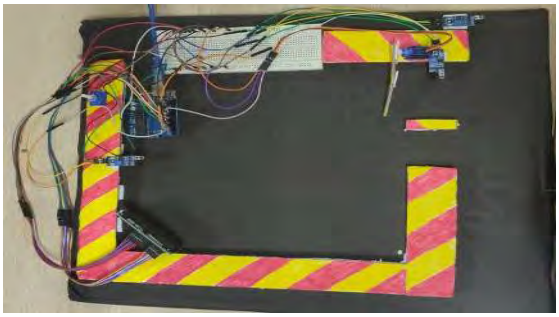

Fig.07 System Design

V. CONCLUSION

The system provides a true-time method and data of the parking slots. This paper enhances the performance of saving users time to find AN acceptable parking lot Analysis of the model needs to be done whereas developing a life-size model. The mechanical model has been designed and also the package still because the negative feedback circuit has been enforced with success. It demonstrates the operating of the planned machine-driven sensible parking system. the most benefits are house improvement, value effectiveness, and security. The code was enforced exploitation Arduino IDE and also the code was dead with none trouble. The circuit diagram was designed exploitation Circuito.io and by referring the circuit diagram the connections were integrated adequately. As for the long run work the users will book a parking lot from an overseas location. GPS, reservation facilities and vehicle plate scanner will be enclosed within the future.

Dynamic traffic light system

Kashish Jain, Khem Agarwal, Rohan Singh
Thakur College of Engineering and Technology, Mumbai India
jainkashish37@gmail.com, khemagarwal1@gmail.com, rohanrsingh9@gmail.com

Abstract— **Our project presents a traffic controller that m anages traffic flow in a group of intersections in an autono mous, centralized and optimal manner... The device obtai ns information from a network of cameras, and can detect the number of vehicles in each of the roads by machine vi sion algorithms. The Fuzzy system uses this information to select the sequence of phases that optimize global traffic fl ow. To assess controller performance, a scenario was developed where two adjacent intersections could be simulated through artificially created videos. Comparison of system performance vs. fixed time controller. The total waiting time of each vehicle was used as control variable. The results show that the performance of the sys tem increases by about 20 percent over situations with hea vy traffic conditions and that the controller can adapt smo othly to different flux changes.**

Vehicle traffic is on a tremendous increase around the globe, especially in large urban areas. In this study, inspired by recent advanced vehicle technologies, we take account of the improvement of the flow of traffic in real- time problems. To solve the problem, we propose a new approach for managing traffic flow at the intersection in real time via traffic light scheduling control. The proposed approach is based in particular on the theory of process synchronization and connected vehicle technology, in which each vehicle can interact with others. In case of high traffic volume the traffic deadlock is also taken into account. The simulation shows the possible results compared with the current traffic management system.

Keywords: Object Detection, traffic, signal, traffic lights.

I: INTRODUCTION

Nowadays world possesses a serious mobility problem, which affects a great part of the citizens and harms drastically its productivity and competitiveness. One of the main reasons, which contributes to this situation, is the use of inefficient and obsolete traffic controllers, which are not capable to manage in an efficient way. These fixed time controllers, require a periodical configuration based on statistical flow analyses, which generally do not reflect in an accurate way the real traffic flow conditions. To solve the problem we have come up with many solutions. Although the performance of these systems easily exceeds the performance of fixed time controllers, they present a maintenance problem mainly concerning the kind of sensors used. This kind of deployment leaves them exposed to all kind of physical interactions, which reduce drastically their useful life. To avoid this problem, our system was developed, which is capable of managing the flow of the traffic in a controlled manner.

II: BACKGROUND

Below, the most relevant terms and investigations in the area of traffic controllers and vehicle detection inside images are mentioned.

A. Traffic controllers there are two main kinds of traffic controllers: static ones and dynamical ones. The first ones are those where a sequence of actions previously programed are followed, while the other kind makes use of a certain acquisition method, which allows the system to identify the state of the traffic flow on the roads and guide his actions to optimize the traffic flow. On the other hand, it is important to define a basic terminology: phase, cycle and coordination. A phase is a traffic signal which allows a flow of non-conflictive movements. For example, Phase 1 showed in Figure 1 allows traffic flow from west to east and vice versa. In the same way, a succession of phases which is repeated continuously is considered a cycle. Finally, coordination is the action of programing the signalized intersections in such a way, that the flow of a corridor can achieve a constant speed without detentions, generating what is known as green waves.

B. In object detection field, there are two main strategies concerning the vehicle detection task: the first one is based on background and optical flow estimation, while the second one uses machine learning techniques. Background estimation analyzed the difference between a predefined model (image) of an empty road and an image of the incoming traffic, obtaining perturbations that overlapped to the predefined modern interpreted as vehicles. Examples of methods used within this area are: Boosted Cascade of hear Features, Sift (Scale Invariant Feature Transform) matching and neural networks Portion of the work is used in helping the scenario which will be very helpful for further evaluation. Classifier is an operator which uses the features of a data set, identifying the class or group to which each of these data belongs. Algorithms are used for boosting the content and accuracy if the system which will be used for further evaluation. There are plenty of investigations in the area of vehicle detection through images; the following are some of the most important researches in this field: an on road vehicle detector was developed through a Hear feature detector, obtaining an accuracy detection of 88, 6% and 76% respectively.

III: IMPORTANCE OF THE PROJECT

The requirement of the dynamic traffic light system is because of the increase in the pollution due to traffic on the traffic junctions. Hence, there is great importance of the project in day-to-day life. Importance of the Dynamic traffic light system are as below:

Dynamic traffic light system are primarily designed to reduce pollution caused due to static cars present on the traffic junction.

Correctly maintained and operating dynamic traffic light system are effective and proven lifesaving.

Dynamic traffic light system also saves time of all the passengers as the traffic time reduces.

Air pollution is reduced drastically.

Even noise pollution is being reduced.

An effective flow of traffic is crated.

Seamless traffic is being achieved.

IV: MOTIVATION

As the population of the world increases day by day the number of vehicles on the road also increases. As the number of vehicles increases more and more the traffic also increases. Which in turn increases the pollution in the environment.

So our main motive towards this project was a social cause that is to reduce pollution in the environment. So by reducing the pollution we are protecting our mother earth but also matter of ease and benefit to the people to have a smooth and faster commute.

V: OBJECTIVES AND SCOPE OF THE PROJECT

Our main objective is to create a dynamic traffic light system so that it can reduce pollution by reducing traffic on roads. With the help of cameras attached to every traffic junction we will apply object detection algorithms to each and every lane and will give appropriate timers to each and every lane.

Vehicular traffic keeps on increasing day by day. This have been a real issue in this world. Improving the traffic flow has become a necessary gesture towards the society.

Each of the above-mentioned topics has its own web page in the subject interact2 site. The format of the topic is as follows. It starts with the learning objectives, topic overview, suggested readings and activities that may be some hands-on projects followed by a quick quiz to test the understanding, discussion topics for in the class and for the online forum (through subject interact2 site) and then some useful web links providing latest

References related to the topic. All topics follow a similar pattern.

VI: SUMMARY

Dynamic traffic light system are primarily designed to reduce pollution caused due to static cars present on the traffic junction.

Correctly maintained and operating dynamic traffic light system are effective and proven lifesaving. So our main motive towards this project was a social cause that is to reduce pollution in the environment.

So by reducing the pollution we are protecting our mother earth but also matter of ease and benefit to the people to have a smooth and faster commute.

Not only reducing the pollution but also reducing the wait time of the people is our concern.

The requirement of the dynamic traffic light system is because of the increase in the pollution due to traffic on the traffic junctions

VII: FEATURES OF THE PROJECT

The Project consists of the subsequent features:

1. Led lights: We are providing display of traffic lights with the assistance of led bulbs which can indicate proper traffic lights.
2. Fast response: the thing detection model used may be a high accuracy model which provides a faster response.
3. Simple drive circuit: The connections and therefore the circuit design of this method is straightforward hence it's far more convenient to develop.
4. Detection of traffic is carried out.
5. Object detection models are used to detect the traffic density.
6. The type of vehicles are also detected in our system.
7. The system will be more efficient with many factors being considered into the system

VIII: METHODOLOGY

The steps of the execution of our project or the system are being considered in according to the steps.

These steps are mentioned below:

1. Firstly, with the assistance of cameras attached to the traffic signal junction we are fetching the photographs then processing it.
2. Once the processing is completed we get the count of the vehicles. After the count we set the timers for every and each signal supported the count
3. If the count of a sign is high we'll set the timer more and if it's low we'll keep the timer low.
4. We'll change the traffic controller in an exceedingly cyclic manner in order that no lane lefts out.
5. Traffic flow is a real issue. We have developed a system which will detect it and handle the request.

6. Traffic efficiency is a big issue which can be tackled by many means.
7. Main means are only two which are traffic flow and timer.
8. Only making traffic timer is not sufficient.
9. We have to develop traffic flow accordingly to accommodate traffic density.
10. Once the processing is completed we get the count of the vehicles.
11. After the count we set the timers for every and each signal supported the count.
12. If the count of a sign is high we'll set the timer more and if it's low we'll keep the timer low.
13. If there are many cars on one side of the lane we will give that lane preferences.
14. Other lanes will not be given preference.

IX: BLOCK DIAGRAM

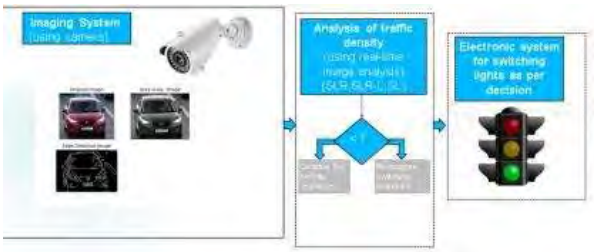

Figure 1: Block Diagram

X: SCREENSHOT

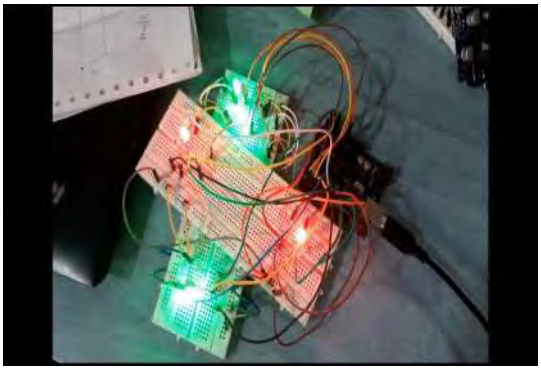

Figure 2: Screenshot

XI: DETECTING CAR USING OBJECT DETECTION:

Figure 3: Object Detection

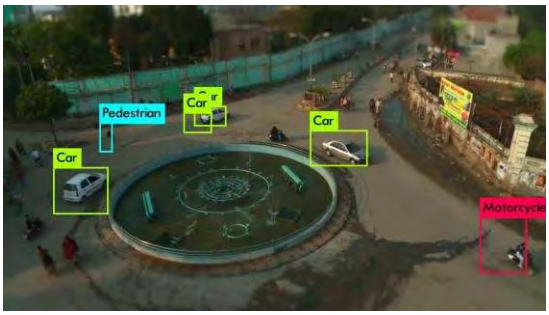

Figure 4

XII: CONCLUSION

We have successfully demonstrated vehicle detection by using object detection algorithms that can detect the vehicles on every traffic junction lane.
Once the analysis is complete we get the vehicles count. After count we set the timers based on count for each and every signal. If a signal count is high we set the timer higher and if it is low we keep the timer down.
We'll cyclically change the traffic controller so no lane is left out. So we completed successfully the IOT-based project model.

Smart Agriculture

Aditya Pai, Siddham Shah, Ritik Bohara
Thakur College *of* Engineering *and* Technology
aditya.bondgai@gmail.com,sidshah628@gmail.com,ritik2701.rb@gmail.com

***Abstract*— Internet of Things (IoT) technology has brought revolution to each and every field of make a self-configuring network. The development of Intelligent Smart Farming IoT based devices is day by day turning the face of agriculture production by not only enhancing it but also making it cost-effective and reducing wastage. The aim / objective of this paper is to propose a Novel Smart IoT based Agriculture Stick assisting farmers in getting Live Data (Temperature, Soil Moisture) for efficient environment monitoring which will enable them do smart farming and increase their overall yield and quality of products. The Agriculture stick being proposed via this paper is integrated with Arduino Technology mixed with various sensors and live data feed can be obtained. The product being proposed is tested on Live Agriculture Fields giving high accuracy over 98% in data feeds.**

***Keywords* – Agriculture IoT, Agriculture Precision, Arduino Mega 2560, DHT22 Temperature Sensor, Smart Farming, Soil Moisture Sensor,**

I. INTRODUCTION

Today, individuals have access to an array of smart applications like smartphones, laptops, smart televisions, refrigerators, microwave ovens, etc. However, there aren't many smart devices for the bedroom department of the house. One prominent and important feature that exists in the bedroom is a wardrobe or closet. In fact, over 80% of the respondents we surveyed agreed to have access to a wardrobe. Smart wardrobe helps users manage their clothes inside their wardrobe. Besides having an attached screen to show the status of each cloth, it can also push all data into a cloud and further sync up data with a mobile application. User can get suggestions on what to wear today from their phone app based on the events in their calendar and the weather.

India is a country where majority of our population are dependable on the agriculture to live their daily life. In this modern technological era poor farmers of india cannot get enough assistance from others to help them with technology and make their work easier. This project made automatic field monitoring & controlling system that can be utilize to improve the condition of green houses. Arduino Uno microcontroller is the main controlling unit of whole unit

our goal is to put together a set of technologies into a system that could be used to aid the farmers to locate the defect in their farms

PROPOSED SYSTEM

To design a microcontroller (IoT) based Smart Agriculture that will detect the soil moisture and tempreture and thereby, will help farmers to locate the problem in their fields easily.

II. BACKGROUND

The demand for smart technologies such as Big Data, cloud-based services, GPS, and the IoT is gaining pace in the agriculture industry. Driven by the rising need for high precision crop analysis, automated farming techniques, and collection of data from the field, the world is likely to witness the agriculture industry get smarter with the implementation of aforementioned technologies in the coming years. Data thus derived from implementing smart technologies can help farmers yield high quality and larger quantity of crops.

The rapid escalation of food demand due to the growing population worldwide is boosting the demand for smart agriculture. The smart agriculture engages advanced technologies such as Big Data, GPS, IoT and connected devices. Smart agriculture helps in automated farming, collection of data from the field and then analyses it so that the farmer can make accurate decision in order to grow high quality crop. The field data are collected with the help of sensors, cameras, micro controllers, and actuators. Then the collected data are transferred via internet to the operator or the farmer for decision making.

III. IMPORTANCE

To survive in the highly competitive and rapidly changing agriculture market of the twenty-first century, a farmer's passion for working on the land and hard work is no longer enough. Innovative farming technologies require more and more professional skills.A modern farmer should be an expert in agricultural regulations, data analysis, accounting, budgeting and now in technology too.The good news is that as more new farming technologies emerge, they get more affordable. There are many free apps for farmers who are new to tech. What's more, most of the smart farming products offer exhaustive educational material since thoughtful tech providers adapt their products to the needs and capabilities of farmers.

IV. OBJECTIVES AND SCOPE OF THE PROJECT:

Soil Moisture and Temperature detecting machine

The main objective of this project was to design a greenhouse monitoring system that is be highly reliable and is useful for harvesting crops. Our project mainly focuses on the control of parameters such as-temperature, methane quantity, soil moisture Can fit perfectly in every house and in daily life of people

1. Supply water according to moisture level of soil.

2. Automatic alarming system to avoid the burning of plants by excessive temperature of atmosphere

3. Reusing process of excessive water in the field..

V. FEATURES OF THE PROJECT

The Project consists of the following features:

4. Simple drive circuit: The connections and the circuit design of this system is simple hence it is much more convenient to develop.

5. Time saving: the project helps us to save time by doing all the search work with the help DHT22 Tempreture and Moisture sensor.

3. Hassle-free: no mess and untidiness to find the problem in the field which was In the case of traditional method of farming.

VI. DESIGN PHASES OF PROJECT

Phase 1: Planning, Analysis, Designing and Implementation.

Analysis: Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation.

Planning: After analysis we will first study about it and do some research on it for our better understanding of the project and also get a rough picture about what would be our problem definition for the particular project.

Designing: Then we will construct the design of the project and according to that, will list down all the requirements needed for the construction for the prototype of our project.

Implementation: After acquiring the requirements we first developed the connections of the hardware components (Arduino, LEDs etc) and then added the coding part later with help of Arduino data cable to the Arduino.

Phase 2: Testing and Deployment

Testing: After the prototype is ready we will first connect the hardware with the assigned code and then we will check if it supports the mechanism or not. If not we will solve the issues regarding to it and will check again. Deployment: After, complete integration and testing of project real time running and operation of the system will be done. User need to check the value.*Subject Learning Outcomes and Contents*

VII. ANALYSIS AND PLANNING

A. Feasibility Study

Getting clear idea of the project title and doing research on it we will get our definition and after that then we will first create the Literature Survey of the project and do the whole documentation. After analysis we will first study about it and do some research on it for our better understanding of the project and also getting a rough picture about what would be our problem definition for the particular project.

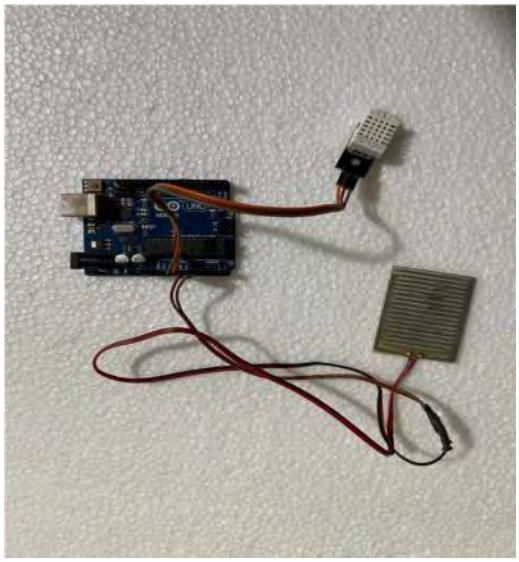
Technical Feasibility: Here one has to test, whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the solution is technically feasible.

Economic Feasibility: As part of this, the costs and benefits associated with the proposed system compared and the project is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So the proposed system is economically feasible.

Smart Wardrobe

B. *Cost estimation:*

Components	Cost
Arduino uno, jumpers, resistors, led,bread board	Rs. 720
DHT22 Temperature and Moisture sensor	Rs. 250
Total	Rs. 970



C. Project planning (Resources,Tools used, etc.) Hardware Tools:

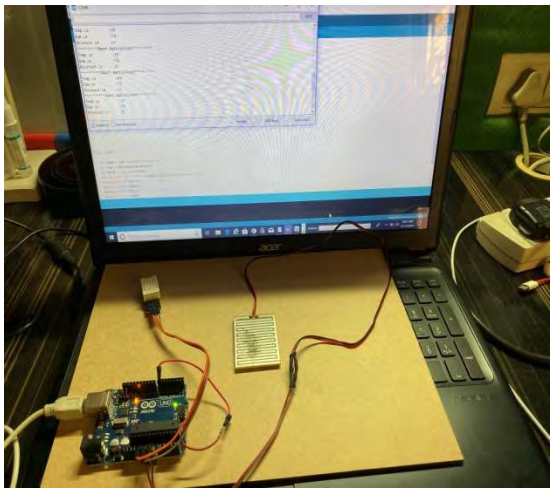
Hardware Components

1. Arduino Uno
2. Breadboard
3. DHT22
4. Connecting wires

D. Software Tools:

1. Arduino uno

E Result(Expected Ourtcome):



VIII. CONCLUSION

IoT-Based temperature and humidity detecting system provide an efficient and definitive system for monitoring agricultural parameters. The corrective action can be taken. IoT-Based monitoring of field not only allows user to reduce the human work and time, but it also permits user to analyze accurate changes in the atmosphere and for taking possible action. It is cheaper in cost and consumes less power. The GDP per capita in agro sector can be increased. This IoT-based system can be extended for controlling different electronic and electrical apparatus from remote locations and the system can also extended for soil moisture and cattle monitor.

IX. ACKNOWLEDGEMENT

We would like to thank subject lecturers (current and previous), education designers and other staff member from the Thakur College of Engineering and Technology who previously designed, developed and taught this subject at various times. The success and final outcome of this project required a lot of guidance and assistance from many people and we am extremely privileged to have completed the project successfully. We would like to thank everyone for their guidance.

Smoke Detector using Arduino

Vivek Mishra, Ritesh Mishra, Ashish Mishra
TCET, MUMBAI
vm105224@gmail.com, imritesh198@gmail.com, vibhormishra98.vm@gmail.com

Abstract— **Over the years, IoT, i.e. Internet of Things, is the currently the most trending field in the Branch of Information Communication Technology. In case of construction areas, residential and commercial buildings, there are high chances of domestic fire. Moreover, mining industry being the most fire prone area, there is requirement of a system that can generate information of the region to the miner on the basis of the gas getting generated while mining. Gas is generated first and then fire. The objective of this project is to build a smoke detection system based on IoT technology. A smoke detector is a device which senses the gas and based on the Gas Quantity that is present in the atmosphere it will provide alerts to the beholder.**

Nowadays, Gas Detection System has been the basic requirement in various regions as the damage caused by the fire accidents is catastrophic. Also, as now the apartments are pretty close and congested, fire can spread very quickly. So, if gas detection and system is Installed while building the apartment, the fire can be suppressed while it is basically in the Small area and further loss of life and property due to fire can be prevented. After studying the literature survey, it was planned to overcome the research gaps and the system was tested using the test cases and then the outputs were generated. The output of the gas detectors were been shown according to different test cases and thus the gas detection system become more responsive then those currently in use.

Keywords – Smoke Detector; LCD screen; Mobile Application; Arduino MQ135

I. INTRODUCTION

Commercial buildings, Mining Regions, Factories, etc. Nowadays has become more prone to fire because of some or the other issues like short circuit, gas leakages etc. So, there is a need of Gas detection system that can help us to overcome the damage to the lives and valuables. It is the fact that Gas is the first to come and then the fire. Hence detecting the fire at the gas level can help avoiding the fire to cause catastrophic destruction. The Gas detection a system is a Device that detects relevant amount of gas in the region and based on that it generates the output that there is a fire or not and based on the output of the further actions by fire-fighters and the administrations can be taken. Moreover now a days there has been an increase in such cases these days, this project also take an initiative to overcome that by discussing about it in the future

Gas leakage detection has become a crucial aspect in design of buildings, both commercial and domestic, as opposed to about 70 years ago when automatic detection was rarely provided in buildings. Before introduction of gas alert, fires resulted in the loss of human lives and damage of property and it was mainly attributed to lack of a mechanism for early detection of gas. Early developments in design of gas alarm began in 1922 with observations by Greinacher and later by Walter Jaeger in 1930. However, early gas detectors required high voltage power input. Further research was done and power requirement in gas detectors was reduced to make battery power viable and this made widespread installation in residences highly feasible. Later developments in gas detectors have sought to improve their performance, reduce power requirement and improve their nuisance alarm sensitivity and also to continuously monitor their status. The most recent advances in gas detectors have been motivated to make them “smarter”. Gas can be detected either optically (photoelectric) or by physical process (ionization). Detectors may use either or methods. Subject

II. SUBJECT HISTORICAL DATA

In this section, we present the previous research done by the people by reading their papers published. Also, the problem definition, features of the project and methodology is explained and learned in detail.

A. Literature Survey

A literature review surveys scholarly articles, books, dissertations, conference proceedings and other resources which are relevant to a particular issue,
area of research, or theory and provides context for a dissertation by identifying past research.

Research tells a story and the existing literature helps us identify where we are in the story currently. It is
up to those writing a dissertation to continue that story with new research and new perspectives but they must first be familiar with the story before they
can move forward.

B. Problem Definition

We need to design a fire alarm system that all family members can use in single-family residences. It must be able to detect fires at all locations, residents must be able to activate it from convenient locations themselves, and it must alert residents in all portions of the house. This system should reduce the cost of fire-insurance protection as well as provide security for the homeowner. A new housing development opening in 12 months is going to include this product in a list of
options for homeowners to purchase when finishing their new home.

C. Features of the Project

Smoke Detectors are very useful in detecting smoke or fire in buildings, and so are the important safety parameters. In this DIY session, we are going to build a Smoke Detector Circuit which not only sense the smoke in

the air but also reads and displays the level of Smoke in the Air in PPM (parts per million). This circuit triggers the Buzzer when Smoke level becomes higher than 1000 ppm, this threshold value can be changed in the Code according to the requirement. This circuit mainly uses MQ135 Smoke/Gas sensor and Arduino to detect and calculate the level of smoke. MQ 135 gas sensor is also sensible to LPG, Alcohol, and Methane etc.

The features of our project can be highlighted in following points:

•Simplified automation.
•Minimal controls
•Cost efficient
•Can be upgraded if needed

D. Methodology Used

The proposed method takes an automatic control action upon detection of gas. Initially if there is a Leakage detected then the electronic sensor i.e. the gas sensor that obeys the principle of sensor senses any fire in the region, if any leakage or fire is sensed then the output of this sensor goes high. This high signal is monitored by the microcontroller and it will identify the hike in the leakage amount. If there is a leakage or smoke detected, the consumer is informed about it through the LED light and Sound of the buzzer

II. ANALYSIS AND PLANNING

Analysis is an important part of any project to know calculate the wrongs and rights of the project i.e. the economic study tells us the capital used, the planning tells us about the time taken, resources used gives us all idea about how well the project is being going on.

A. Fesiability Study

Analysis is an important part of any project to know calculate the wrongs and rights of the project i.e. the economic study tells us the capital used, the planning tells us about the time taken, resources used gives us all idea about how well the project is being going on.

1. Economic Feasibility:

As part of this, the costs and benefits associated with the proposed system compared and the project is economically feasible only if tangible or intangible benefits outweigh costs. The system development costs will be significant. So, the proposed system is economically feasible.

2. Technical Feasibility:

Here one has to test, whether the proposed system can be developed using existing technology or not. It is evident that the necessary hardware and software are available for development and implementation of the proposed system. Hence, the solution is technically feasible.

3. Operational Feasibility:

It is a standard that ensures interoperability without stifling competition and innovation among users, to the benefit of the public both in terms of cost and service quality. The proposed system is acceptable to users. So the proposed system is operationally feasible.

B. Assumption Risk:

a) Assumption:

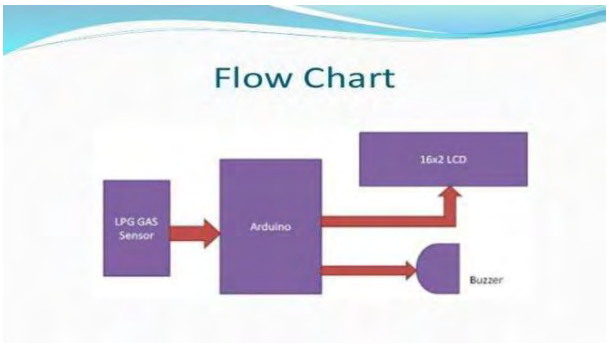
Management will ensure that project team members are available as needed to complete project task and objectives. The team members will participate in the timely execution of the Project Plan (i.e., timely approval cycles and meetings when required.)

b) Risks:

Accurate identification of the system requirements, interpretation and design depend on the patience and commitment of the team members in focus.

IV. DESIGN REQUIREMENTS

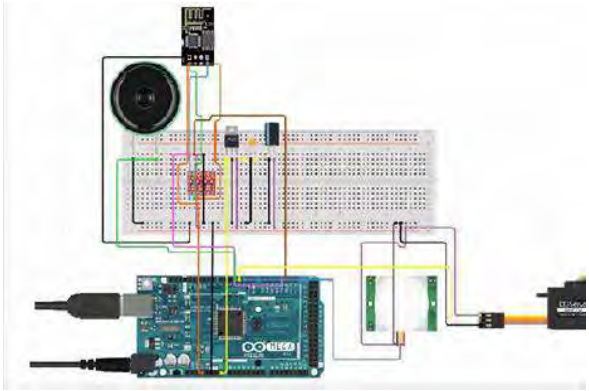
C. Process Flow



This is the process flow of the project.

D. Block Diagram

The following is the Breadboard implementation of the project which can also be converted to a PCB in order to make the assembly smaller.



V. RESULT

OUTPUTS:

When the smoke level was below the threshold value the environment is safe and LCD shows the respective status and when high makes a beep sound.

VI. CONCLUSION

We have successfully shown the detection of Gas Leakage by IOT based project is possible which can detect Gas leakage and warn owners and remote contacts of a alarm situations. The alarms are detecting reliably even in situations where there is high ambient noise. A weakness of the system is in the processing overhead used to constantly monitor the audio input of the phone. This application demonstrates the mobile phones ability to be used as a advanced warning device in the event of a smoke alarm activation, its automated group alert system reduces the chance of harm to people who have not been able to respond to an alarm.

VII. FUTURE SCOPE

Sometimes it happens that fake smoke alarms are generated which can cause a loss of more than $12,000 US dollars. So to avoid and tackle that we can use the camera and delay by 30 second in alarm which means if the smoke is detected to be above the threshold quantity, the detector will send the video to the operator and if the operator approves that it is a legitimate fire in the region, the alarm will be horned and within 30 seconds of no reply from the user, the alarm will ring and accordingly the further actions can be taken in future.Gas Leakage detection and alarm system can be used with quad copter and this quad copter can be used to detect the regions of the fire or going to catch the fire, thus can be used to protect things.

VIII. ACKNOWLEDGEMENT

We sincerely thank our guide Mr. Anil Vasoya for his guidance and support for carrying out our project work. We also thank all the project coordinators for arranging the necessary facilities to carry out the project work.

We thank our Principal, Dr. B.K Mishra, HOD, Mr. Rajesh Bansode and the College Management for their support. We would like to thank all our classmates & faculty members for their inputs and valuable insights.

IoT based Child Tracking Security

Rachita Mishra, Anushka Puranik, Kimaya Patil
Department of IT Thakur College of Engineering and Technology
rachitamishra.rsanp@gmail.com, puranikanushka@gmail.com, kimayapatil427@gmail.com

Abstract—**The era of the Internet of Things (IoT) has already started and it will profoundly change our way of life. While IoT provides us many valuable benefits, IoT also exposes us to many different types of security threats in our daily life. Before the advent of IoT, most security threats were just related to information leakage and the loss of service. With IoT, security threats have become closely related to our non-virtual lives and they can directly influence physical security risk. The Internet of Things consists of various platforms and devices with different capabilities, and each system will need security solutions depending on its characteristics. There is a demand for security solutions that are able to support multi-profile platforms and provide equivalent security levels for various device interactions. In addition, user privacy will become more important in the IoT environment because a lot of personal information will be delivered and shared among connected things. Therefore, we need mechanisms to protect personal data and monitor their flow from things to the cloud.**

I. INTRODUCTION

Child safety and tracking is a major concern as the more number of crimes on children are reported nowadays. The chance of missing children is going in rampant. With this motivation, in order to reduce this problem, a smart IoT device for child safety and tracking is developed using Arduino Uno and GPS tracker so that parents can be able to locate and monitor their children.

This system is used for tracking the information of the lost child using Google Map along with the position and location of that child through GPS.

This process operate simply by keeping the "tracking system device" into the bag of that particular child, who is going to school or outside world and now if in case that child is lost or missed then the parents of that particular child can simply track him/her by the device which has been kept inside that child bag.

In this way the parents get the real time location by receiving the exact position of the child along with the longitude and latitude of that place then it will be copied into the Google map and the location of that lost child can easily be accessed. The above system ensures the safety and

Tracking of children.

Now a day's child tracking system is widely used all over the world and it gives the assurance to the parents that their child is safe from suspicious action. In this project we have shown the system requirement for tracking the child and describe the implementation feature.

To implement such system a GPS with high accuracy is required, if the low accuracy GPS is used in this system. System may give some error of that child location. In this system GPS of that device send the longitude and latitude to the GSM module, GSM module receive the information about longitude and latitude of that child location, further this message will be sent to the parents for tracking the location of that lost child. The Arduino is a small micro controller which is used for controlling whole process in this system. This project is for developing a low cost, high accuracy and user-friendly system by using Google map. Google map can improve the accuracy of GPS. Improvements are proved by Google map that make high accuracy.

II. BACKGROUND

People cannot predict or determine what will happen next to them in next seconds. This is the same scenario as people cannot acknowledge of when will be targeted, but can make precaution prevent it from happening. As for the great parents, their greatest concerns are their child, especially regarding the safety of the child.

The parents start to take care of the child since born. The parent is not possible to always stay beside of them as most of the parents needs to go for work to earn some money to sustain a family. Parents will start to feel anxious about their child current status every second because they cannot see what their child is doing currently or what affairs will happen on them.

Today's child is easier influenced by their friends, and they might even get cheated or kidnapped by any of the strangers, as what had happened to a girl, named Nurlin Jazlyn, who had gone missing on August 20, 2007 after she went alone at a night market in Kuala Lumpur. She was found dead in a sports bag after a month of investigation by police (Theage.com.au, 2016).

To minimize this tragedy from happening again, an action needs to be taken to deal with the problem. Thus, in order to resolve these problems the child tracking system is proposed..

III. SCOPE OF PROJECT

This project is actually developed for parents to keep track the child whereabouts. Nowadays, child is easier influenced by their friends, and they might even get cheated or kidnapped by any of the strangers. By developing this system can track child current location.

The application is mindful to keep track the location of the device. In this application the parent track for the route their child traversed during a certain period of time. The application in the device will give the real time location of the child. Parents can take immediate action if any inconvenience happens when the location not found or track.

IV. SUMMARY

The effectiveness of this project depends on how the products are detailed and how the components are used. The most important part is of the GSM module and GPS tracker as GSM is used for communication and GPS is used to get the location and if it works to fail then it is not possible that the model can work. The cost is also low as per our model requirements.

V. LITERATURE SURVEY

So during literature survey we came across few projects where the first one named "Child Tracking System" was about 2 users' namely parent and child. The parent sends a request to the server for the location of the child, and the server will send the request to the child app about the request. When the request received and location retrieved, the child app will send the request again to the server about the newly detected location. The server then will send the details to alert the parent about the new location and show the latest location inside the map of the app.

The second was similar namely "Smart IoT device for Child Safety and Tracking" which proposes Child safety as GSM module is used. Parent will send message to GSM module. According to message received GSM module to reply back with particular details of the child. The location can be seen on Google map. When a child is in any emergency situation, device button should be pressed so that the device captures the image along with the user information to the enrolled mobile number. The life of children can be saved within no time.

The following paper "IoT based Unified approach for Women and Children Security using Wireless and GPS" presents a wireless method which will alert and communicate with secure medium. It will also capture image via camera. When the sensor kit button is pressed the camera will captures the image and will collect the information of the user. This information will be sent to the registered phone number along with the image link. Children security can also be done by using the GPS tracking mechanism. This Unit will locate the bus and all its travelling routes. Alert messaging will be done on the registered phone numbers.

The last was "IoT based Smart GPS Device for Child and Women Safety Applications" in which an Android based solution to aid parents to track their children in real time. The concerned device is connected to server via internet. The device can be used by parents to track their children in real time or for women safety. The proposed solution takes the advantage of the location services provided by GSM. It allows the parents to get their child's location on real time by SMS.

VI. PROBLEM DEFINITION

1) Increasing rate of child kidnapping.
According to News Strait Times Newspaper, of the 567 children, another 193 children are still missing and being investigated. A majority of cases were due to family problems, seeking freedom and running off with lovers or friends. (Bukit Aman CID (Investigations and Legal) deputy director Datuk Law Hong Soon, June 4, 2016)

2) Lack of tracking technology for child.
The parent is hardly to keep a watch on their child without the use of technology, especially when the child is in the outdoor. The parent even cannot avoid the negligence that will make by children in the future day.

3) Limited application for child monitoring.
There is very limited application available for tracking child when they are out of parents control and let kidnapping or missing cases occurred.

VII. FEATURES OF PROJECT

The proposed system can reduce the child missing cases. This system provides tracking solution for the parent to keep tracking their child location in the outdoor by using GPS as where it allows determining the exact location of the child. Moreover, help to minimize this tragedy from happening again and again in future. This project is simple and cost efficient.

VIII. METHOLOGY USED

As crime's are increasing day-by-day safety for all children have become a concern for all parents. In this project we have use GSM module and GPS tracker which will help to track the exact location of child in real time.

1X. DESIGN RQUIREMENT

A) BLOCK DIAGRAM

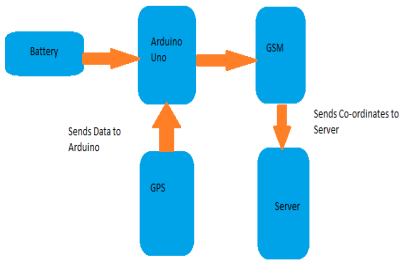

FIG 1X.1 block diagram of IoT based Child Tracking System.

B) SCHEMATIC DIAGRAM

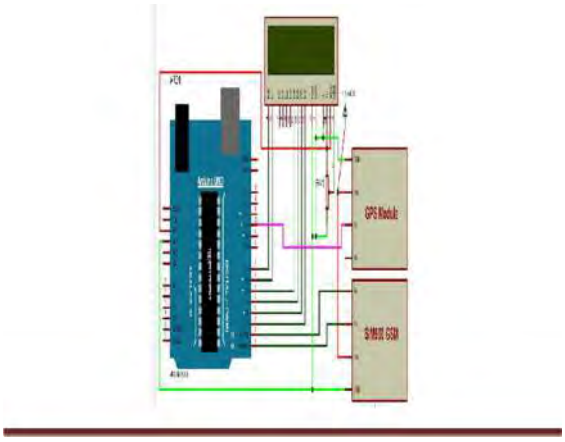

FIG IX.2 schematic diagram/ circuit diagram showing all the necessary connection that need to be made.

X. RESULT

Results show that everything worked as anticipated, although some high pings in the network may cause minor occasional lag in the connection and data exchange, however, there was no major lag detected affecting the model control and testing. The lag maybe a casual effect of using 3G connection. This project was successful to track and get the current location on mobile phone.

- When Location is tracked SMS is send on parents' mobile phone which contains coordinates of current location of child
- After clicking on the SMS link a google map is open in which location can be seen.

FIG X.1 Tracked Location

FIG X.2 Parent Message Screenshot

XI. FUTURE SCOPE

This research demonstrates Smart IoT device for child safety and tracking helping the parents to locate and monitor their children. If any abnormal values are read by the sensor then an SMS is sent to the parents mobile and an MMS indicating an image captured by the serial camera is also sent. The future scope of the work is to implement the IoT device which ensures the complete solution for child safety problems.

XII. CONCLUSION

The child tracking system has been experimentally proven to work satisfactorily by trying to track the current location using GPS and see the location on mobile phone.
Hence, the idea to create a fully working child tracking system with facility to track the location has been finally realized. The output of this project is that, this project can be of huge help to parents where security of children is concerned.
This project is a successful outcome of continuous and tireless effort from all the project members, supervisors, college faculty, colleagues and other helping hands. Thus, a low-cost child tracking system was successfully designed, implemented and tested.

Abstract- **In wireless communications, the world is undergoing a major technological resolution that will provide ubiquitous access to communication to people wherever they are. The exponential evolution of wireless technologies, services and enterprise applications has resulted within the deployment and use of wireless and mobile networks on an outsized scale. The mobile wireless advanced in a totally quick span of time. Wireless access technologies are about to be built to hit its fifth generation (5G). Looking back, wireless access technologies have taken different evolutionary paths towards a single goal: performance and productivity in highly mobile environments. The first generation fulfilled the simple mobile voice while capacity and coverage were added by the second generation. This was followed by the third generation which aims at higher speeds fir data, The fourth generation provides access to a wide variety of telecommunication services which are supported via mobile and fixed network. This paper provides an outline of the evolution of Mobile Wireless Communication Networks from 0G to 5G.**

Keywords – wireless, Mobile wireless communication, 0G, 1G, 2G, 3G, 4G, 5G,GSM

I. INTRODUCTION

Nowadays, the wireless technology is getting popular and important within the network and in Internet field. Mobile communications are clearly showing major enhancements in terms of capabilities of mobile networks. the following generation of wireless services, besides improving the general capacity, will create its own unique demands in terms of localization, personalization, etc., which is able to successively, drive the event and continuous evolution of services and infrastructure. In this paper we briefly introduced the history background of 0G to 5G, compared them, and illustrated how 5G may match for more convenient and powerful in the future. There are many improvements from 0G,1G, 2G, 3G, and 4G to 5G in the world of telecommunications. Evolution of 4G is based on the limitations of 3G and it fulfils the amount of an inspiration that's WWWW, World Wide Wireless Web, offering more services and smooth global roaming with inexpensive cost.

II. EVOLUTION OF MODILE CELLULAR NETWORK

Zero Generation Telecommunication (0G) :

0G – Mobile radio telephone (also known as "0G"). 0G alludes to pre-cellphone portable communication. These frameworks are called 0G (zero age) frameworks. Advances utilized in 0G frameworks included PTT (Push to Talk), MTS (Mobile Telephone System), IMTS (Improved Mobile Telephone Service), and AMTS (Advanced Mobile Telephone System). Since they were the antecedents of the original of cell phones, these frameworks are once in a while retroactively alluded to as pre-cell (or some of the time zero age) frameworks.

1G Technology :

These phones were the first and the premier cell phones to be used. In 1979, 1G was propelled economically in Tokyo city of Japan by NTT DoCoMo firm.

1G is a simple innovation and the telephones commonly had poor battery life and voice quality was huge absent a lot of security, and would frequently encounter dropped calls. The most extreme speed of 1G was 2.4 Kbps.

1G innovation wasn't completely analog. Information transmissions were done in simple structure at 150 Mhz or more recurrence of radio waves. This was the greatest downside of 1G innovation. This prompted instability of calls. Likewise, because of less recurrence transfer speed for 1G, information transmission speed was excessively low and was attainable for calls as they take low information to convey the expected signs.

Call was the main medium to pass on your message to the next individual. Information transmission speed was around 3-4 kbps. Because of low-recurrence transfer speed and simple type of information transmission, it used to take bunches of vitality to transmit information to far separations and furthermore signals would get upset while arriving at their specific beneficiary. Information transmission used to take loads of vitality. The other large downside was roaming that was not upheld in 1G innovation.

Downsides of 1G:

- Poor voice quality
- Poor battery life
- Large telephone size
- No security
- Limited limit
- Poor dependability

2G Technology :

2G or second era of remote innovation was first propelled financially in Finland in 1991. It used analog signals for voice transmission. Crucial focus of this innovation was on advanced signals and offered administrations to pass on content and give picture messages at low speed (in kbps). It used the data transmission of 30 to 200 KHz. This gave us smaller gadgets, a progressively secure association, better call quality, and a higher limit with regards to network.

During the 2G period, there were many progressions made inside the range itself, for example, GSM, GPRS and EDGE.

- GSM: Short for Global Systems for Mobile Communication empowered information move over voice correspondence at speeds around 30-35 kbps.
- GPRS: General Packet Radio Service worked on the comparable 2G innovation as GSM with some refinements which gave it higher information speeds (110 kbps) .

• EDGE: Enhanced Data rates for GSM Evolution presented in 2003 was to some degree known to be 2.9G or 3G because of its noteworthy headways over GPRS and GSM. It offered high speeds of 135 kbps.

2G: SMS and MMS

• The 2G phone innovation presented call and content encryption, in addition to information administrations like SMS, picture messages, and MMS.
• The max speed of 2G with General Packet Radio Service (GPRS) is 50 Kbps or 1 Mbps with Enhanced Data Rates for GSM Evolution (EDGE).
In 2G, three major highlights were added and improved contrasted with 1G and they are:

1) Data transmission for telephone discussion got completely digitized and encoded.
2) Internet information administration and SMS like plain content, picture messages, MMS administration were started notwithstanding calls.
3) 2G empowered gadgets turned out to be progressively effective to get and impart signs with higher infiltration levels for wide radio waves range.
Better voice quality, more than one medium to convey acquired another change remote correspondence innovation. With information encryption strategy, transmission turned out to be increasingly productive and quick with better quality and information security. Just a specific beneficiary could get the proposed message by means of encryption procedure.
The digitized transmission prompted advancement of littler mobiles since simple parts were disposed of with this age. The battery life improved because of digitization of information transmission which normally took less vitality to transmit. This occurred because of two diverse multiplexing principles on which 2G innovation depended on : GSM (Global Systems for Mobile) in light of TDMA (Time Division Multiplexing Access) and CDMA (Code Division Multiplexing Access). This additional the circuit exchanging area which permitted a solitary association progressively. On the off chance that the system bounced from one base station to other base stations, at that point the association would in general disengage and everything must be re-started. Information transmission speed was additionally expanded to 14.4 kbps contrasted with 3-4 kbps in 1G.
Downsides of 2G:
• Required solid advanced signs to enable cell phones to work. On the off chance that there was no system inclusion, advanced signs debilitated.
• Systems couldn't deal with complex information like recordings.

2.5G Technology :

2.5G was an intermediate stage between 2G and 3G innovation. Packet switching domain was included. This empowered the sending of any solicitation to arrange bases as little packets as opposed to a real-time connection. It assisted with sparing battery much more as the transmissions were in little packet structure. This forestalled the need to retransmit the information.

2.5G or GPRS image :

2.5G speaks to handsets with information capacities over GPRS. Packet exchanging space sped up to 50-60 kbps than in typical 2G innovation. This started web convenience and furthermore presented GPRS(General Packet Radio Service). GPRS was indicated utilizing G symbol.

2.75G Technology :

2.75G or EDGE (Enhanced Data rates for GSM Evolution). 2.75G was improved GRPS frameworks to EDGE (Enhanced Data Rates for GSM Evolution) frameworks with 8PSK encoding strategy. This improved the information rates by 3-4 times. In 8PSK encoding, a solitary transporter image used to convey 3 bits rather than 1 piece utilized in GPRS. This further improved voice call quality. Information transmission hypothetically expanded to 1Mbps (down to earth assessed speed is 500 kbps). EDGE or 2.75G is generally indicated by the E symbol close to the versatile system.
EDGE innovation is an all-inclusive form of GSM. It permits the unmistakable and quick transmission of information and data. It is likewise named as IMT-SC or single transporter. EDGE innovation was concocted and presented by Cingular, which is currently known as AT& T. EDGE is radio innovation and is a piece of third era advances. EDGE innovation is favored over GSM because of its adaptability to convey packet switch information and circuit switch information.
EDGE moves information in less seconds in the event that we contrast it and GPRS Technology.

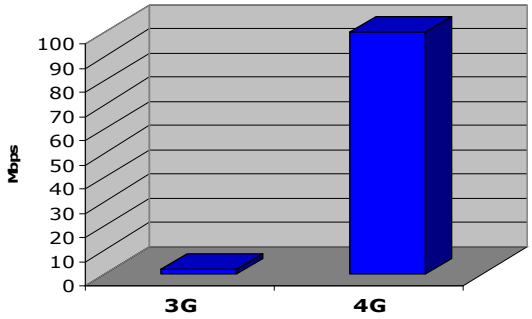
3G Technology :

3G systems were presented in 1998 and represent the cutting edge right now. 3G introduced quicker information transmission speeds empowering video calling and internet usage.
The maximum speed of 3G was assessed to associate with 2 Mbps for immobile gadgets and 384 Kbps in moving vehicles. The hypothetical max speed for HSPA+ is 21.6 Mbps.
3G had and has speed abilities of up to 2 mbps. It empowered cell phones to give quicker correspondence, send/get huge messages and messages, give quick web perusing, video gushing and greater security among others. It was generally founded on CDMA2000 (Code-division numerous entrance) and EDGE advances. It empowered numerous channels to impart at one same along these lines ad libbing on the over speed and availability.
The primary qualification somewhere in the range of 2G and 3G that permitted media spilling to happen is that 3G uses packet exchanging information transmission as opposed to circuit exchanging. Information is separated into little pieces or parcels and afterward sent to the goal. Utilizing this technique for transmission extraordinarily speeds up, permitting one to send information through various diverts in equal instead of one direct in arrangement. This innovation additionally permits clients to pay for information utilized as opposed to time spent on the web.
3G innovation gives better voice quality and better availability because of wide recurrence transmission capacity. W-CDMA standard is broadly utilized in 3G

innovation as it gives preferred information transmission speed over UMTS.
3G innovation upgraded information transmission and offered better information rate in any event of 384kbps for moving position and 2Mbps for stationary position. Quicker information rates and availability permitted organizations to grow. Better scrambling/encoding strategy used to transmit information included a superior information security. 3G gadgets decreased in size and furthermore battery life improved with better recurrence and encoding strategy.

3.5G or HSPA image :
3.5G or state HSPA (High Speed Packet Access) was an upgraded form of WCDMA innovation dependent on GSM models. Hypothetical information rate was improved to 14Mbps at the uplink/transfer side and 5.76Mbps at the downlink/download side.

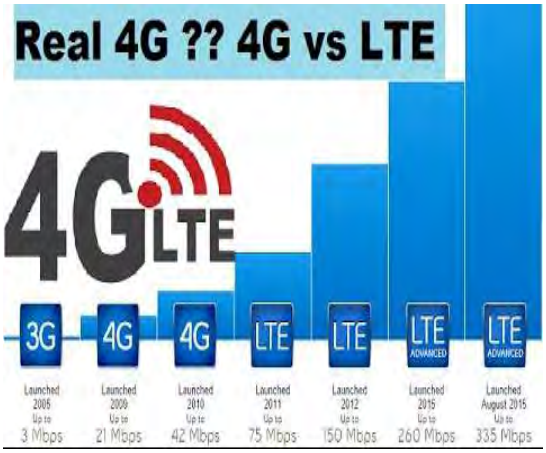
4G Technology :
4G network is the further evolution in the wireless network aiming to provide much faster ans secure network than the generations before as it aimed towards better reception, faster information and data exchanges and less dropped data.
4G simply means "fourth generation". The first generation 1G came in existence 1981 where the means of transmission was analog, and 1992 saw the transformation to 2G where the means of transmission was digital. 3G first came into use in 2001 and included different multi-media support along with highest data transfer rate of at least 200 kilobits per second. It thus justifies, that 4G means "fourth generation" and represents a number of advancements and enhancements over the 3G technology.



4G POSSIBILITIES :
- Experience improved remote capacities that convey portable gaming cooperation with latency under five milliseconds.
- Play online multiplayer games while going at high speeds or sitting outside.
- Individual Media Repository.
- Make an individual media vault that can be gotten to from home and on the road to see photographs, watch films and tune in to your own music choices
- Broadband Access in Remote Locations
- 4G systems will give a remote option in contrast to broadband access to private and business clients.
- Also, 4G will give the first chance to broadband access in remote locations without a framework to help link or DSL get to.

Table 1 3G vs 4G

Technology	**3G**	**4G**
Data Transfer Rate	3.1MB/sec	100MB/sec
Internet services	Broadband	Ultra Broadband
Mobile-TV Resolution	Low	High
Bandwidth	5-20 MHz	100+ MHz
Frequency	1.6-2 GHz	2-8 GHz
Network Architecture	Wide Area Network	Hybrid Network
Signal Quality	Good	Best
Communication Type	Circuit Switching	Packet Switching



4G Access Options:
- Making end user devices 4G compatible.
- Develop mobile personal gateways .
- Develop external interfaces with 4G peripherals.

4G advantages:
- High voice quality.
- High spectral efficiency
- Easily access internet, streaming media, video calling etc.
- Very low latency.
- Simple protocol architecture.
- Efficient multicast/broadcast.

Disadvantages of 4G:
- New frequencies means new components in cell towers.
- Higher data prices for consumers.
- Consumer is forced to buy a new device to support the 4G.
- It is impossible to make your current equipment compatible with the 4G network.

5G (5th generation) :

Problematic advances, for example, independent vehicles and Internet of Things (IoT) in the present occasions have given a driving force for 5G innovation. For instance, DHL's IoT following and checking framework tracks everything from vehicle conduct to bundles to natural sensors in the airways . In this way, information volume and peak rates are going increment over the wireless transmissions. Thus, the portable correspondence industry is thinking of 5G arranges as a successor to 4G.

Over the most recent three years, the 5G systems have begun getting footing with institutionalization endeavors at European Telecommunications Standards Institute . Sooner, portable administrators in the European Union (EU) and USA began certifiable preliminaries of 5G systems. With 5G, accelerate to 10 Gbps can be accomplished.

Accordingly, a portion of the application regions where 5G assumes a noticeable job incorporate Smart Homes, self-driving autos and VR/AR applications.

5G remote system or 5G net. As we probably am aware, 2G (second Generation) remote system began in the mid 1980s and fundamental telephone with voice and information administrations was advertised. Next, 3G (third era) remote system were presented offering information move with max download speeds going up to 4.4 Mbps for HSPA and 168 Mbps for HSPA+. With 3G, video calling administrations were empowered.

Here are some challenging elements which should be tended to before we get 5G out into the normal man's hand:

• At this point, most geo-areas are not open enough to oblige 5G receiving wires. The earlier predominant radio wires' set up should be moved up to convey new ones that will keep up the 5G range.

• There is a worry with respect to the Clouding of the Air Interface and range movement. Be that as it may if Air Interface is 5G Clouded, powerful allotment of 2G, 3G, 4G, and 5G web will be allowed, and that thus will guarantee help of a smooth procedure to the extent relocating the range.

• Since undoubtedly, the Distributed Antenna System (DAS) – the one we have right now – doesn't flaunt enough ability to help 5G, to satisfy this interest a flat out reestablishment of the current advanced framework will be required if without hiccup migration of 5G is to be directed throughout the following scarcely any months.

	4G-LTE	**5G**
Download real-world	42 Mb/s	100 Mb/s
Uplink real-world	25 Mb/s	50 Mb/s
Download Theoretical	1 GB/s	20 Mb/s
Uplink Theoretical	500 Mb/s	10 Mb/s
Spectral Efficiency (Downlink)	15 bps/Hz	30 bps/Hz
Spectral Efficiency (uplink)	6.75 bps/Hz	15 bps/Hz
Latency (Control plane)	100 ms	50 ms
Latency (User plane)	10 ms	1 ms
Frequency Bands	700-2100 MHz	28-40 GHz

III. CONCLUSION

Wireless technology is becoming widespread and important nowadays in both the network and the internet field. In future, new work can be done on these technologies by introducing new features to them and combining two or more technologies which can be used to get better results. In this paper we briefly introduced the history background of 0G to 5G, compared them, and illustrated how 5G may match for more convenient and powerful in the future. There are plenty of improvements from 0G,1G, 2G, 3G, and 4G to 5G within the world of telecommunications. In the novel impending 5G technology is offered in the market in affordable rates, and high peak future and far reliability than its preceding technologies.
