PREFACE

It is a great honour for us to write a message for the INTERNATIONAL CONFERENCE ON INTELLIGENT COMPUTING AND NETWORKING (IC-ICN 2020) scheduled during Feb.28-29, 2020.

This is the eleventh event in the series of international conferences organized by TCET under the umbrella of MULTICON since the first event ICWET 2010. This event is organized in view of strengthening the research culture among its stakeholders namely students, faculty and Industry. Moreover, need of the time is technological development in the areas of Intelligent Systems and Communication Engineering which can simplify our life in the eco-friendly environment with better connectivity and security. The 11th Annual International Conference, IC-ICN 2020 has affiliation with Scopus Indexed journal for Intelligent systems, leading publication house Springer, McGraw Hill, and Conference proceeding with ISBN number. It serves as a premier platform that gathers all academicians, researchers and professionals, in the relevant engineering disciplines and domains, to showcase their research contributions and share their thoughts. IC-ICN 2020 has gained wide publicity through website, social media coverage, and visits to various colleges by the team of faculty members and our well-wishers. As a result, this event has got overwhelming response.

TCET has strong belief in quality and relation building. Therefore, a lot of care has been taken for branding the event, identifying resources, logistic support required for event, compilation and printing of conference proceeding, souvenir etc. Effort has been taken to make the delegates feel at home though away from home with confidence of doing something for development of nation.

TCET has successfully held in the past ten international events in a row. ICWET 2010, 11, 12 and Multicon-W 2013, 14, 15,16,17,18 and 19 in association with International journals of repute and multinationals in the IT industry with an objective to reach a new horizon. We feel that the present endeavour could not have been possible without moral support, strong belief and time to time motivation from management of Thakur Educational Group.

During the two days there were about 235 presentations from national as well as International Researchers and Industrial personnel, Idea presentations with deliberation by delegates and resource persons. Our best wishes and good luck to all.

We thank to all the members of organizing and editorial committee for supporting the event and extending their cooperation to make it a grand successful event.

Abstract**. In India, farmers are facing more problems compare to other coun-tries because of economical condition. Actually farmers has problems like a lack of knowledge about weather, unaware of soil contents, plant diseases, in-sufficient water level, quality of seeds and traditional way of farming. Indian farmers are not aware of new way of farming. Various Machine Learning tech-niques are developed to improve agriculture field. This review article not gives the all categorized of agriculture field it mostly focuses on yield prediction, dis-ease detection, weed detection, crop quality, species recognition, water man-agement and soil management. The presented articles demonstrate how agricul-ture will benefit from machine learning technologies, deep learning and big da-ta. By applying machine learning to the problems of agriculture field; farmers will improve fruits quality and crop production. Smart farming is the need of today's farmers.**

Keywords: Machine learning, Deep learning, Big data, deep convolutional neural networks (CNNs), Support Vector Machine (SVM).

I. INTRODUCTION

Machine learning is an imminent field of computer science which can be applied to the farming sector quite effectively. Machine Learning learns from past experiences and is able to build a model which would most likely be able to comprehend future instances. Machine Learning and Big Data are two different domains there is no direct relation between them; but before training data set there is need to prepossessed the data where the big data will comes before applying algorithm. Machine Learning usually works with huge chunks of data (Big Data). Big data machine learning would be totally irrelevant, because to learn anything from data there is a need to have a large number of 'training samples' so that all possible scenarios are exhausted and also to avoid faulty training due to few erroneous datasets. One of the main reasons why big data and machine learning are used together is because big data is more likely to be a preprocessing step to machine learning. In agriculture, big data analysis presents the availability of hardware and software, techniques and methods for big data analy-sis [1]. Big Data is defined by several characteristics beyond size, particularly, the volume, velocity, variety, and veracity of the data [2].

Deep learning is a subfield of machine learning. It technically is machine learning and functions in the same way but it has different capabilities. Deep learning is based on neural network models and work well on large sample sizes rather than small sam-ple sizes. Deep learning provides high accuracy, existing commonly used image processing technique which is use for classification or prediction. The overall benefits of deep learning are encouraging for its further use towards smarter, more sustainable farming and more secure food production [3].

Bayesian Networks can be advanced [4] in three areas of agricultural. These areas are: Text Mining, Sensor Data, and Dynamic Bayesian Networks. Cheap sensor de-vices will allow future Bayesian Network designers to either: a use exclusively data-driven construction methodologies or augment manually constructed systems with data-driven techniques. Data mining techniques like artificial neural network, Baye-sian networks and support vector machines in agricultural domain was developing early. According to authors [5] there is need to understand how these techniques can be used with complex agricultural datasets and used for crop yield prediction with an integration of both seasonally and spatially using GIS technologies.

II. LITERATURE SURVEY

Various researchers provide the new way of farming by introducing machine learning techniques in agriculture field. New researchers are needed to know where to use these techniques to improve crop production. Authors [6], have been proposed Crop Selection Method (CSM) which use to solve crop selection problem, and maximize net yield rate of crop.

According to authors [7] there are three SOM based models, namely, supervised Kohonen networks (SKN), counter-propagation artificial networks (CP-ANN) and XY-fusion (XY-F) which use to predict within field variation in wheat yield, based on on-line multi-layer soil data, and satellite

imagery crop growth characteristics. The SKN model can be used to predict wheat yield and to classify field area into different yield potential zones.

Novel active learning method proposed by authors [8] that can recognise crop and weed species by using differences in their spectral reflectance. Best results for the active learning were achieved by using SOM and MOG based one-class classifiers while mediocre results were obtained using auto-encoder network and SVM based one-class classifier.

According to authors [15] extreme learning machines (ELM), multivariate regres-sion splines (MARS), M5 Tree and support vector regression (SVR) use to improve the original DRASTIC method for groundwater contamination risk mapping, in the complex aquifer system.

The smartphone based system that uses the classification model learnt to do real-time prediction of the state of health of a farmer's garden [20]. Remote sever can determine the state of disease of a plant through the uploaded image.

Authors [28] have been employed SVM using different kernel functions including Cauchy kernel, Invmult Kernel and Laplacian Kernel. Grid search and N-fold cross-validation techniques which extract relevant features related to image of tomato leaf and to detect and identify type of disease that infects tomato plant.

For an automatic crop disease recognition method the probabilistic neural networks (PNNs) classifier used by authors [30], which combined the statistical features of leaf images and meteorological data.

Principle Component Analysis (PCA) and Support vector machine (SVM) were classifying infected/uninfected tomato fruits according to its external surface; it uses feature fusion method with color and texture features [31]. The proposed system, grading tomato fruits based on surface defects.

To identify the phenological stage classification of rice crop with multitemporal co-polar X-band SAR images authors [32] were used Support vector machines (SVM) with linear and nonlinear kernel, k-nearest neighbors (kNN), and decision trees (DT).

Support vector machine (SVM) and a random forest (RF) method used by authors [33] for assessing the feasibility of in-season winter wheat mapping and investigating potential classification. It is improvement by using SAR (Synthetic Aperture Radar) images, optical images, and the integration of both types of data in urban agricultural regions with complex planting structures in Southern China.Authors [34] used Convo-lutional Neural Network (CNN) to predict the type of previously unseen images of plant seedling.

Following table gives detail about methodology used on particular problem of agriculture field with future scope provided by researchers.

Table 1. Survey on agriculture problem with machine learning.

Methodology	Purpose	Future Scope
Multidisciplinary model based on Sen (Io sor T), s, Clo ud- Computing, Mo bile - Computing, Big- Data analysis [9].	Increase in agricultural pro- duction and for cost control of Agro-products.	Focusing on interfacing different soil nutrient sensors with beagle black bone. Use various data mining algorithms for agricultural Big-Data analysis for getting the preferred outcome.

III. SUMMARY AND DISCUSSION

3.1 A Subsection Sample

Table 1 provides brief literature about yield prediction, disease detection, weed detec-tion, crop quality, species recognition, water management and soil management. by referring Table 1 new researchers get the knowledge about to which algorithm or methodology used by previous researchers and it also provides future scope to partic-ular problem. It is observed that the deep convolutional neural networks (CNNs) and probabilistic neural networks (PNNs) classifier used to identify plant diseases. The deep convolutional neural networks (CNNs) applied on various plants like tomato, rice, banana to identify their diseases. Also it is used to predict types of images of plant seedling, counting fruits, plant identification and exacting plant images. Whenever we need to solve a problem involving with plant images and object detection from the image in that case we can apply deep convolutional neural networks (CNNs). The Support Vector Machine (SVM) is used with other techniques for soil estimation, healthy & diseased plant leaf, ripeness of fruits, plant diseases and stages of crops or fruits. Fuzzy Rule-Based Classification approach (FRBCS) also identify ripeness of fruits. The Support Vector Machine (SVM) applied on various plants like tomato, rice, grapes, wheat. A new time series model based on Long Short-Term Memory (LSTM) used to predict water table depth, especially in areas where hydro-geological data are difficult to obtain. Extreme learning machines (ELM), multiva-riate regression splines (MARS), M5 Tree and support vector regression (SVR) for groundwater contamination risk mapping, in the complex aquifer system. Smart Irri-gation Decision Support System (SIDSS) estimates the weekly irrigations needs of a plantation. Groundwater prediction is also has a more scope to develop new algorithm to improve crop productions.

IV. CONCLUSION AND FUTURE SCOPE

4.1 Conclusion

The aim of this article is to motivate more researchers to analyze and experiment with machine learning. To apply it for solving various agricultural problems involving yield prediction, disease detection, weed detection, crop quality, species recognition, water management and soil management. The overall benefits of survey are encourag-ing for its further use towards smarter, more sustainable farming and increase crop production. This article performed a review of machine learning, deep learning and big data in agriculture. Researcher were identified and analyzed, examining the prob-lem they addressed, tools/techniques, the proposed solution and future scope. Based on this article, the researchers can be informed about which types of agricultural applications currently use by machine learning, deep learning and big data. Survey pro-vides various methodologies used on different plant/fruits so researchers can identify other plants/fruits for their research for existing problems in agriculture field. Table 1 summarizes the methodology, purpose of methodology and future scope for those particular problems in the area of machine learning, deep learning and big data.

Future Scope. Whenever we need to solve a problem which involving with plant images and object detection from the image in that case we can apply deep convolu-tional neural networks (CNNs). So researchers can find new other

problems where they can use deep convolutional neural networks (CNNs). The Support Vector Machine (SVM) is used to identify problems related with ripeness, diseases of plants/fruits based on images. Researchers can identify different plants/fruits for exist-ing problems where they can apply SVM. A Groundwater prediction is also has a more scope to develop with new algorithm to improve crop productions. Various algorithms of Machine learning can be used for water problems. Need to improve various techniques in identification of crop and weed species with Machine learning.

Categorization of Plant Leaf using CNN

Suhasini Parvatikar,Dr.Deepa Parasar
Computer Engg. Department, SCOE,Kharghar
CSE, ASET,Amity University,Panvel
er.suha@gmail.com,dparasar@mum.amity.edu

***Abstract*— As plants are main part of environment. There are variety of trees in this environment ,it is unable to recognise different kinds of plant leaf . Thus, this paper studies about plant leaf detection using CNN method. This method will help us to classify leaf, which would indirectly help us to classify different kinds of plants. Combination of deep neural networks forms a Convolutional Neural Network(CNN), which is used for recognition of plant leaf .In neural networks, Convolutional neural network mainly used for recognition of images, classifying different types of images , face recognition etc., CNN image takes image as an input , process that image and classifying it under different type of category.**

Keywords—Neutral Networks, CNN, pooling, leaf classification.

I. INTRODUCTION

There are billions of plants in the environment. Imagination of life on earth without plants is not possible, they are our source of oxygen and also balances our ecosystem. It is very difficult for a scientist,botanist or expert to recognise a leaf of a plant from such a large volume of plants. For this , we require some effective classification algorithms. Machine and deep learning technique could help to solve problems by recognizing the leaf of a particular plant.As deep learning technique performs feature extraction process automatically. We could use Deep Learning method for simplifying our process. Thus, as we are taking image as an input, we propose a method called CNN (convolutional neural network) for identifying leaf of a plant.

II. LITERATURE SURVEY

Wei Liu, Zhifang Li, Jialun Lin, Danning Liang [1], designed a system for the classification of the plant. The following steps are carried out: the images are preprocessed before giving it to classifier. Using the classification algorithm SVM (Support Vector Machine). The leaves are then classified. Next, the parameters of the SVM design are optimized using the PSO algorithm (Particle Swarm Optimization), which is then used to design and optimize the leaf recognition and classification algorithm.

Francis Rey F. Padao [7], authors here used naïve Bayes classification algorithm for identifying plant leaf. Texture and shape of leaf is given as input to the classifier. The output of naïve Bayes algorithm shows high accuracy of the model.

Prof. Meeta Kumar et al. [10], is survey paper. The researcher contrasts different classification strategies such as k-Nearest Neighbor Classifier, Probabilistic Neural Network, Genetic Algorithm, Support Vector Machine, and Principal Component Analysis. The aim of this survey is to provide knowledge of different techniques of classification which can be used to classify the leaf of a plant.

Abdul Kadir, Lukito Edi Nugroho, Adhi Susanto and Paulus Insap Santosa [11], designed a system using Principal Component Analysis (PCA) is the technique for increasing variable space dimensionality by describing uncorrelated variable space. The goal of authors is to improve grade of leaf identification system. Shape, color, texture of leaf is given as input to system. Using the identification system, the PCA algorithm was used to transform the features into orthogonal features and the results were then given to the classifier using Probabilistic Neural Network (PNN). PCA's output increases the accuracy on datasets of the leaf identification system.

Samuel E. Buttrey, Ciril Karo [13] designed a system using a hybrid(composite) classifier. The authors have used two classifiers by using k-nearest neighbor (kNN) and classification trees. The inputs are given first to classifier to extract features and then classify them using k-NN which reduced processing load associated with k-NN, and the result shown where better than individual algorithm.

III. PROPOSED METHODOLOGY

The Proposed workflow is given below Figure 1.

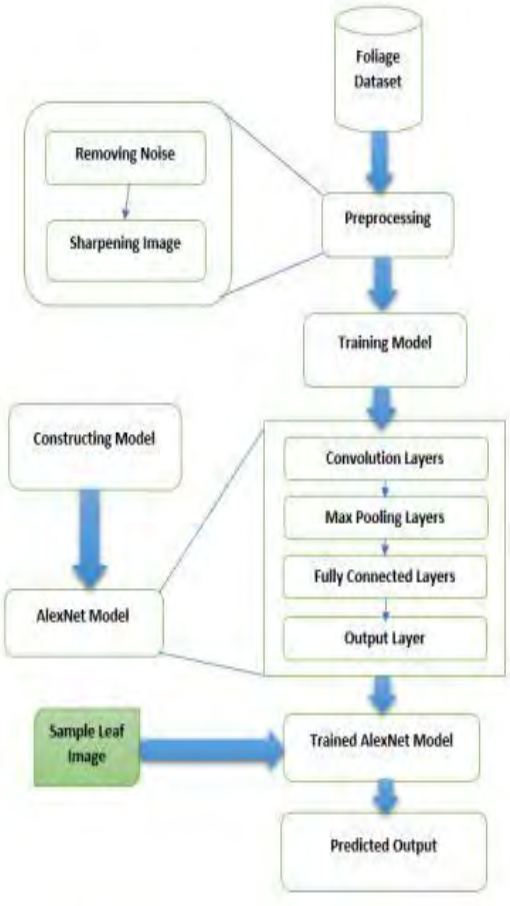

Figure 1: Flow Diagram of Proposed System

The proposed system uses CNN to classify the leaf. This application uses the specific features of each leaf which are computed and then further used for classification of them.

IV. CONVOLUTION

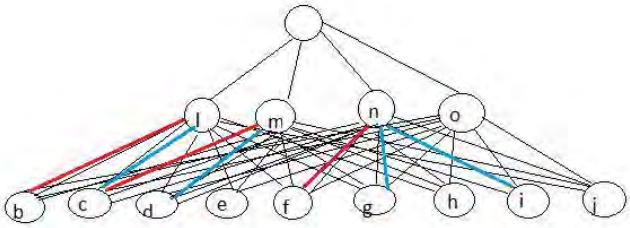

Figure 2: Fully connected network

A CNN can be implemented[19] as a feedforward neural network wherein only a few weights are active (in color) and the rest of the weights (in black) are zero. The working of CNN and information flow is as shown in Figure 2.

V. CONVOLUTIONAL NEURAL NETWORK

The use of CNNs for [18] deep learning has become increasingly popular as CNNs remove the need for manual extraction of features — the features are learned directly from CNN. Convolutional neural networks work as Neural Network in which each neuron receives some input. The only difference is the input provided to a CNN is in the form of image or a time series data on which each neuron performs operations and generates an output.

Input Layer >> Hidden Layers >> Output

Here, input layer takes the input and output gives the desired output. That means hidden layer is doing the feature extractions work as shown in Figure 3[3].

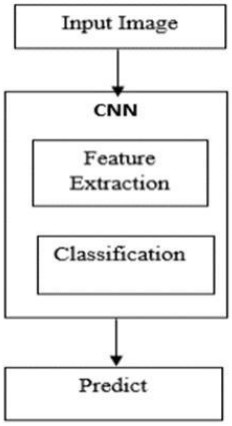

Figure 3: System Composition

The steps in CNN can be summarized [15] as:

a. Input image is given to Convolutional layer.
b. Filters / feature maps are applied to the image, which gives us a convolutional layer.
c. Apply rectifier function.
d. Perform pooling to reduce dimensionality size.
e. We then flatten our pooled feature map before inserting into an artificial neural network i.e. fully connected network.
f. Output the class using an activation function and classify images.

Step 1: Convolution: The input image is multiplied with every element by filter matrix to produce a output to reduce the size of input image. Only main features that are important are considered in this step.
Example:7 x 7 image matrix convolution is multiplied by 3 x 3 filter matrix which gives output called "Feature Map" as shown in Fig 2[17].

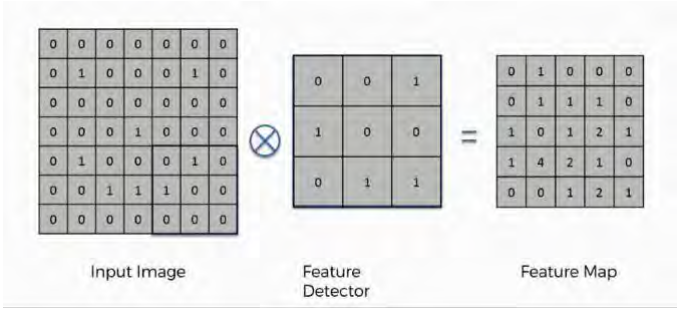

Fig 2: Convolution Process

Step 2: Apply Rectifier function**:** In NN, we use activation function to transform summed weighed Input into output. RELU is a nonlinear activation function which allows complex relationship in data to be learned **.**

This function returns 0, for negative input and x for positive value. It returns that value back. So, it can be given as:

$$f(x) = \max(0, x) \quad \text{..... eq(1)}$$

Step 3: Pooling: Its function is to gradually reduce the number of parameters and network computation. The pooling layer operates independently on each feature map. It takes a function map of each matrix of 2x2 and selects the value present in that box. Then, 2x2 matrix is passed through the entire feature map choosing the value in each pass from left to right. These values then form a pooled map of features a new matrix.

Different categories [17] of Pooling:

- Max Pooling: Maximum value is picked
- Average Pooling: average value is picked

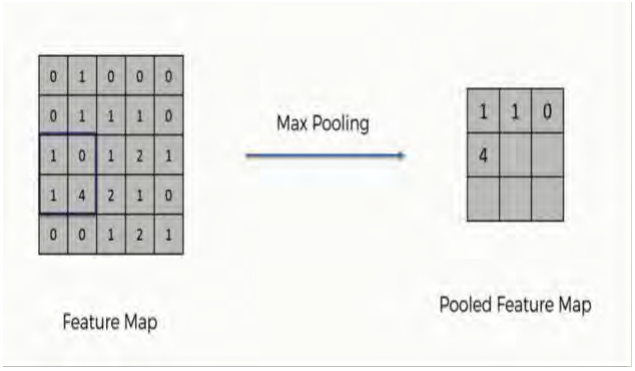

Fig 3: Pooling

Step 4: Flattening: Flattening[20] transforms the entire matrix of the pooled feature map into a single column that is then fed into the processing neural network.

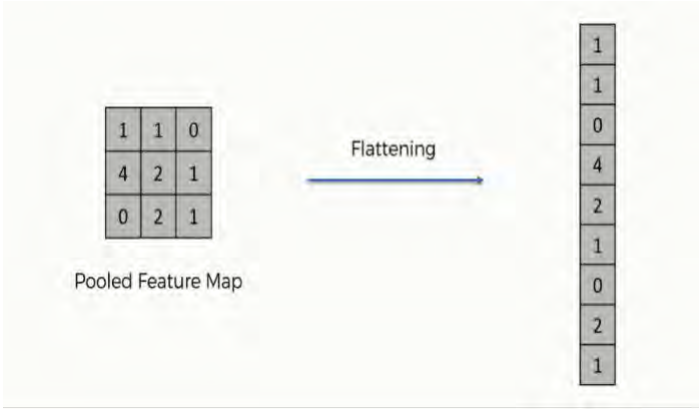

Fig 4: Flattening

Step 5: Full Connected Network: Fully connected layers[21] are an essential component of Convolutional Neural Networks (CNNs), which have been proven very successful in recognizing and classifying images for computer vision. The data will be transmitted through the network and the prediction error will be measured. It is done by the using the function as shown in eq (2):

$$f_j(z)_j = \frac{e^{z_j}}{\sum_{k=1} e^{z_k}} \quad \text{.....eq (2)}$$

The error is then propagated back to boost the prediction through the process. It is important that output produced by output layer must be scaled between 0 and 1 which represents probability of each class.

VI. DATASET

The foliage Dataset is taken from Flaviasourcsfourge.net with 32 different classes. Each of the images in the used datasets here are preprocessed in order to generate standardized input data for the training process of the network.

VII. CONCLUSION

In this paper, we studied a new method to classify leaves using the CNN model. We studied layers of simple CNN model. There are many architectures of CNN like AlexNET, GoogleNet, LeNet etc. with little difference in architecture. CNN is mostly used for input images. Thus, in fully connected network accepts weights from each node while in convolutional layer each neuron is only connected to a nearby neurons only which helps to extract only relevant information.

Krishak Sahayata : Prediction Of Best Crop Yield

Dr. Mrs. Gresha S Bhatia, Urjita Bedekar, Simran Bhagwandasani, Rahul Bhatia, Pranit Naik
Vivekanand Education Society's Institute of Technology,
Mumbai, India

Abstract**. Agriculture is one of the most critical occupations practiced in our country. It is an economic sector that plays an important role in the overall development of the country. Thus, the modernization of agriculture is significant and thus will lead the farmers of our country towards profit. Earlier sowing of crops was performed by considering the farmer's knowledge in a particular field and crop. However, as the weather conditions change very rapidly, farmers cultivate more and more crops that do not give an expected yield. Being this as the current situation, many of them do not have enough knowledge about the new crops and are not entirely aware of the benefits they get while farming them. Also, farm productivity can be increased by understanding and forecasting crop performance in a variety of environmental conditions. Thus, the proposed system takes the location of the user as an input. From the location, the nutrients of the soil, such as nitrogen, phosphorous, potassium is obtained. The processing part also takes into consideration two more datasets i.e. one obtained from the weather department, forecasting the weather expected in the current year, and the other data being static. This static data is the crop production and data related to the demands of various crops obtained from various government websites. The proposed system applies Machine Learning algorithms to identify the pattern among data and then process it as per input conditions which in turn, will propose the best feasible crops according to given environmental conditions. Thus, this system will only require the location of the user, and it will suggest several profitable crops providing a choice directly to the farmer about which crop to cultivate. Since historical data is also taken into account, the output is expected to be much more accurate.**

Keywords. Machine Learning, Yield Prediction, Indian Agriculture.

I. INTRODUCTION

Agriculture in India has a full-size history. More than 60 % of the land in the country is used for agriculture to cater to the needs of 1.2 billion people. Nowadays, India is ranked second worldwide in farm output. Agriculture and other sectors like forestry and fisheries accounted for 16.6 percent of GDP in 2009 [1][2]. The monetary contribution of agriculture to India's GDP is regularly declining. The production of crops relies on different factors like climatic, geographical, and organic elements. Accurate statistics about the character of an ancient yield of the crop is a critical modeling input, which is useful to farmers and authorities organization for decision-making techniques in establishing the right policies associated with subsequent manufacturing. The advances in computing and information storage have mainly provided at the maximum of information. The project has been to extract expertise from these statistics mining that may be able to bridge the understanding of the facts to the crop yield estimation. This task aimed at statistics mining strategies and follow them to the various variables consisting inside the database to set up if significant relationships may be discovered and the usage of fuzzy common sense to discover the circumstance of crops on a diverse situation of climatic conditions.

II. LITERATURE SURVEY

Literature survey is the most important part which guided us in our research. We had a look at previous papers aiming same objectives which we have and on the basis of study we plan to improve the limitations, challenges faced and various drawbacks analysed from those papers. Referring to the work done by Kunal Teeda, Nandini Vallabhaneni and Dr. T.Sridevi, [3] we understood that climatic analysis based on location, rainfall, soil type, yield capacity, irrigation techniques is a fundamental prerequisite that needs to be carefully implemented to plan better farming structures for a satisfactory yield. Farming risks have greatly reduced with the advent of technologies. In order to predict the weather parameters, empirical approaches like regression, artificial neural network, fuzzy logic and institution approach of statistics have been employed. For prediction of rainfall, clustering and classification methods of data mining have been used. The work done by D.S Zingade [4] is spectacularly presented. They have considered significant parameters mainly soil contains, water level and temperature. For the soil measure they have considered nitrogen, phosphorus and potassium along with the pH value of the soil. Taking Zinc and Sulphur nitrate into consideration along with these can help to improvise the system. Moreover, we have chosen to perform classification using random forest classifier which overfits the linear regression used above, since the parameters are quite significant in number. Analysing the Farmer's handbook published by Desai Fruits, [5] we have an understanding of choosing the sufficient parameters required for selecting the type of crop suitable for the cultivation. Project by P Priya, published in International Journal of engineering science and research technology have performed the prediction of crop yield Focusing only Tamil Nadu district[6].

We Intend to build a system that satisfies majority places of possible farming in India. Random Forest Algorithm has worked with great accuracy amongst all the other algorithms.

III. CHALLENGES IN EXISTING SYSTEMS

IoT based Plants : For constant analysis of the fields and crop growth, many projects have obtained to install IoT devices for data gathering, which are way costlier and require regular maintenance.[7]

Web Interface : Many projects have their UI based on python which are hosted on web server, our Mobile application is very much user friendly and we intend to bring the information available in the locale languages which are region specific.[8]

Parameters Under Consideration : The existing projects have a limited number of parameters considered for training. We intend to consider majority of parameters which are accountable for the plants growth. [9]

IV. PROPOSED PROBLEM STATEMENT

Accurate yield estimation would be essential for farmers to sow the crops accordingly. Machine Learning Systems are being widely used in building decision support tools for the contemporary farming system to improve yield production while reducing operational cost and environmental impact. The capability of Machine Learning algorithm to access tons of data and mold them into relatable format helps in predicting the future results when a particular test case is provided to the trained system, thereby it would provide a great support in predicting the estimated yield of a particular crop provided with sowing area, time, climatic conditions of that particular crop. Our system proposes to use an algorithm which will work accurately even when the number of parameters under consideration are more.

V. PROPOSED SYSTEM

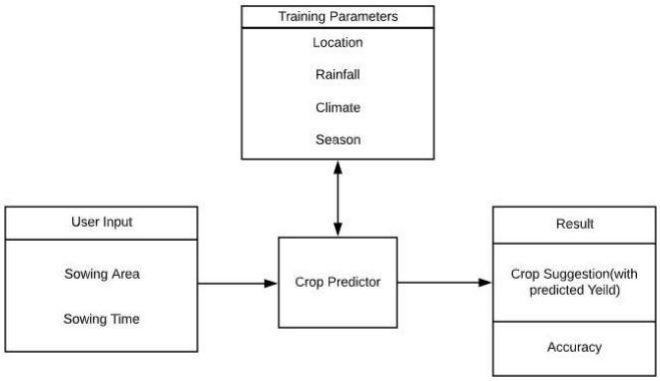
Since other systems developed are using Data Mining techniques to predict the optimal crop yield, our system aims to provide an accurate yet effective result based on more number of parameters dependent on climatic conditions to provide maximum profit, reduced risks and more than expected yield to the farmers. The proposed solution is represented in figure 1 and is described as follows :

Input : The prediction of the crop is dependent on various factors such as weather and past crop production to predict the crop correctly. The location of the user is taken as an input, which helps to get the weather conditions like humidity, temperature.

Data Acquisition : Depending on user location, the system mines the weather conditions like humidity, the temperature in the respective area from the other datasets. In a similar approach, earlier crop yield is extracted from previous data. This would give an excellent idea about the demands of crops in the location

Output : The random forest algorithm creates a forest with a number of trees. The most suitable crop is predicted by the system using the Random Forest Algorithm, and the user is provided with the best-suited crop for a given set of climatic conditions.

Fig .1. BLOCK DIAGRAM OF FARMER'S GUIDE



Sowing area and sowing time will be entered by user as parameters. Our classification algorithm will be analyzing climatic conditions such as rainfall based on the location and sowing time. Algorithm will then suggest best crop to plant for getting the maximum yield and this can be used by farmers to acquire maximum profit as observed in figure

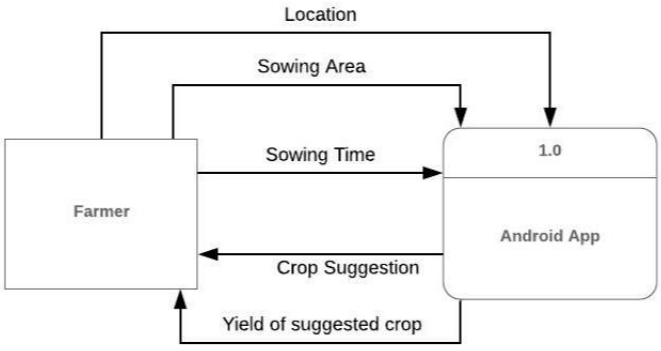


Fig .2.DATA FLOW DIAGRAM

The farmer provides location access to the android application and also provides the inputs such as the sowing area and expected sowing time. The Android Application then suggests the most suitable crop along with the expected yield.

VI. EVALUATION MEASURES

Accuracy :Accuracy can be defined as the degree to which the result of a measurement, calculation, or specification conforms
to the correct value or a standard. The Accuracy for a system is defined with the formula given as : (TP / TN) / (P + N).[10]

Error Rate :Error rate refers to the frequency of errors occurred, defined as "the ratio of total number of data units in error to
the total number of data units transmitted." The Error Rate can be calculated by using the formula : (FP+FN)/(P+N) or (1 - Accuracy).[11]

Sensitivity : Sensitivity measures the proportion of actual positives that are correctly identified as such. The sensitivity of a
system can be defined using the formula : (TP)/(P)[12].

Precision : Precision or positive predictive value, is the fraction of relevant instances among the retrieved instances. The
precision of a system can be calculated using the formula : (TP)/(TP+FP)[13].

VII. OUTPUTS OBTAINED

The parameters that we have selected to evaluate our system include accuracy, error rate and precision. Since the system is being evaluated on parameters like location, rainfall, season and climate, the quality of being precise is about 87.88% for the system developed. Having an error rate of 12.12% in a dataset of 500 trees .

VIII. CONCLUSION AND FUTURE WORK

The proposed system takes the data related to weather, and past year production and suggests which are the most suitable crops that can be cultivated in environmental conditions of various parts of India. As the system lists out the best-possible crop, this would help the farmer in the decision making of which crop is appropriate to cultivate. Since this system takes into consideration past production, it will help the farmer get insight into the demand of crops cultivated at the stipulated time in the market. The main aim of this research paper is to provide a methodology so that it can perform descriptive analytics on crop yield production in an effective manner. The future scope of the project is to collect soil nutrients for every particular piece of land and combine the trained system and data about soil nutrients to get a cumulative output on the basis of all these factors.

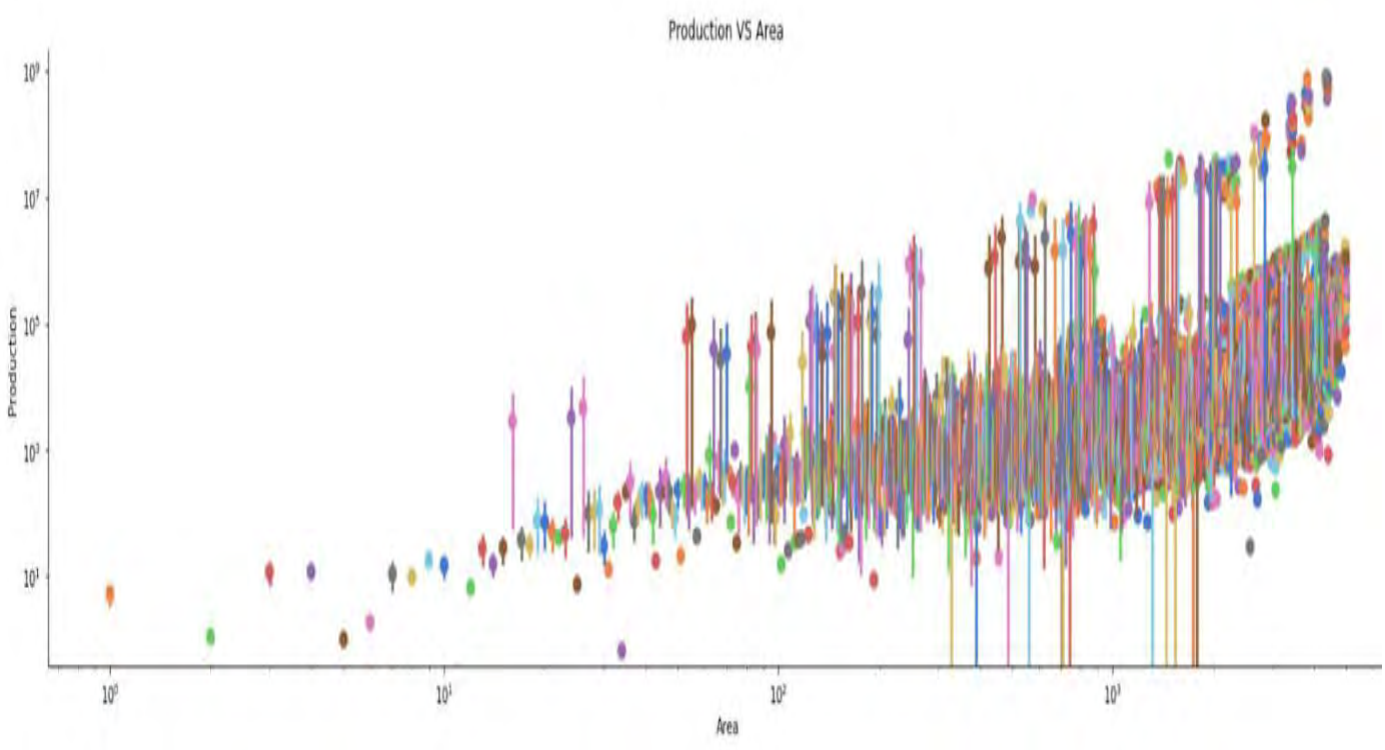

Fig. 3.Plot for Yield vs Area(Insight from data

Abstract.
It is found that the malaria disease is a prime and major cause to the human health. The pernicious trappings of malaria stooge to the physical body can't be making light of it. In this research work, a fuzzy based expert system for the total handling of malaria disease had granted for providing judgment support platform to the specialist and healthcare researchers in the same endem-ic province. The proposed and implemented system consists of major compo-nents which include the Cognitive content, the Fuzzification, the Inference en-gine and De-fuzzification for decision making. The fuzzy inference engine de-veloped during this work is that the Root Sum Square. This method is the de-piction of inference that was designed and developed to infer the info from the fuzzy based rules used in this algorithm. Triangular fuzzy membership function was accustomed that shows the degree of attendance of every input specifica-tion and therefore the de-fuzzification technique employed during this research is that the centre of gravity. This fuzzy based expert system had been developed to help and to support clinical perception, diagnosis and therefore the expert's proficiency. For validation and empharical analysis the data of thirty patients with malaria defection was used. The results that were calculated are within the range of that was predefined and predicted by the territory proficient.

Keywords: Malaria, Fuzzy Logic, Cognitive Content, Fuzzy Expert System.

1 Introduction

The ruinous accouterments's of malaria parasites to the human being as well as other animal cannot be undervalue. Malaria is a harmful disease that caused principally by plasmodium falciparum. P. falciparum and three alternative malaria bedbugs that taint human (p. vivax, p.ovale, and p. malariae) are impart by many type of species of Anopheles mosquitoes widely in the tropics [1][2][3]. Malaria disease is that the

fa-miliar explanation for mortality within the tropics. Today's nature is one beside ex-panding approach to intelligent systems. In new time, Artificial Intelligent methods have undoubtedly been utilized in medical applications and research exercise are po-tent on doctor systems as reciprocal solution to standard technique for locating solu-tion to medical problems [10] [12]. The evolution of data technology has opened un-paralleled convenience in health healthcare delivery system because the demand for intelligent and knowledge-based systems has heightened as contemporary medical practices now a day become highly knowledge-intensive. The diagnosing of regional diseases embroils several steps of hysteria and imprecision [11].The assignment of health problem diagnosis and handling it is compound due to the various functionality involved. It's difficulty level is high due to tons of imprecision and uncertainties. It is not possible for patients to illustrate indeed how they feel and sense, medical practi-tionars and nurses cannot understand exactly what they identify or observe, and la-boratories finding are dotted with some possible errors caused may be by the care-lessness of lab workers or improper functioning of the equipments in lab.

Medical workers many not squarely identify how diseases transform the traditional working of the body [12]. Out of these ramifications in practice make long-established quantita-tive path of study disproportionate. Computer workstation tools help to arrange, stock up and reclaim relevant medicinal information desired by the practitioner in handle with each severe case and suggesting appropriate diagnosis, prognosis, remedial deci-sions and decision-making procedure [13]. A specialist framework is a savvy PC code that uses the information storehouse of at least one specialists and conclusion methods for issue taking care of

[14]. Human specialists take care of issues by utilizing a union of genuine information and thinking capacity. In a specialist framework, proposals two imperative are contained in two separate however related segments: an informa-tion base and an induction motor. The information base get ready explicit realities and rules about the subject and the derivation motor set up the thinking capacity that empowers the master framework to shape result. Master frameworks additionally give advantageous apparatuses as UI and elucidation offices. UIs, similarly as with any application, empower individuals to shape doubt, furnish data and connect with the framework. The application and use of fuzzy based perception to medical review and diagnosis of diseases are reviewed in these literatures [13] [16][17]. This experimen-tation work represents a fuzzy expert system for the administration of malaria disease. It was developed by considering clinical perception, medical diagnosis and the do-main experts. The main aim of this work is to provide a decision backing stack to scientists working on and other medicinal healthcare practitioners. This system will help medical practitioners for diagnosing and decision making in case of malaria where there is a shortfall of doctors in the benefit of society.

2 Literature Review

The symptomatic choices taken by restorative specialists rely on recognition, expe-rience, aptitude, information, capacity, and impression of the therapeutic researcher. As the unpredictability of framework builds, it is difficult to pursue a specific way of finding with no error. Fuzzy-based rationale introduces incredible thinking strategies that can deal with vulnerabilities and imprecision. Numerous frameworks have trans-formed into noteworthy in the extension and continuance of the human services zone. As of late, much research exertion has been fixed in structuring knowledge frame-works. A few reciprocal works have indicated that tropical sicknesses garbage a sig-nificant general wellbeing contest in the tropics [4] [5]. Be that as it may, the delibe

rate endeavor is constantly been made to control the acceleration and transmission of tropical ailments inside and between neighborhoods. In the work vehicle tried out by [6], it was accounted for that month to month jungle fever rate rates and vector densi-ties were utilized for reconnaissance and adaptable tuning of the ecological adminis-tration procedures; which brought about an elevated level of work. Inside 3-5 years, intestinal sickness related casualty, grimness and commonness rates were diminished by 70-95%. In an ongoing report, it was inferred that the jungle fever control program that underline natural administration were profoundly viable in minishing grimness and mortality [12]
the framework was to sponsorship restorative master in the difficult and burdensome errand of diagnosing and giving treatment to tropical illnesses. The framework gave a structure that will help the therapeutic workforce in provincial regions, where there are a shortage of specialists, during the time spent commitment to essential human services to the individuals. In a similar perspective, [3] built up a fuzzy-based master framework approach utilizing various specialists for gainful follow-up of endemic infections.

In the design of LEPDIAG the significant highlights that were been itemized are a various master condition, a homeostatic capable containing the model of safe return, a presentation evaluator that can relate the watched signs and indication with those foresee by the homeostatic master and a prognostic master which improves the administration agenda for the patients. In [17] they investigate the issues of under-treatment and uncertainty condition of acute asthma cases in ED. A novel approach, known as the fuzzy logic principle is employed to determine the severity of acute asthma. The fuzzy set theory, known as Fuzzy Rule-based Expert System for Asthma Severity (FRESAS) determination is embedded into the expert system (ES) to assess the severity of asthma among patients in ED. A medical expert system for managing tropical diseases was suggested by [2]. The proposed Medical Expert Solution (MES) system was to assist medical doctors to diagnose syndrome related to a given tropical disease, suggests the likely ailment, and advances possible treatment based on the MES diagnosis.

The objective of the research was to apply the concept of fuzzy logic technology to determine the degree of harshness on tropical diseases. The root sum square of draw-ing belief was employed to ascertain the data from the rules developed.In another examination did by [13], the financial results of jungle fever control ar-ranging were featured. The utilized of master frameworks in therapeutic applications is powerful this can be found in [14] [15]. A decent number of master frameworks have been a development on tropical ailments. In [13] a specialist framework is created on tropical ailments to help paramedical staff during exercise and in the understanding of numerous basic illnesses exhibited at their facilities. In another exami-nation completed by

[14], a specialist framework on endemic tropical ailments was developed. The objective of the framework was to be a wellspring of training for spe-cialists, and for therapeutic understudies, on the analysis of a portion of the essential tropical endemic illnesses. In [8] they planned a paper to sponsorship clinical judg-ment making. The paper centers around the separation between three sorts of clinical choice help devices: for data the board, centering thought, and patient-explicit as-sessment. There are numerous master frameworks for restorative determination and remedies of some tropical tainting dependent on choices are presented in [7] [9] [10]

[11] [14]. In [15] authors have explained the seriousness of setting preference for health research. In their paper, the point was to organize inquire about in dismissed tropical illness than prominent tropical maladies. An expository strategy that depends on the prioritization system of the worldwide discussion of wellbeing research was utilized for information examination.

In [4] scientists stress the mindfulness that examination is basic in the battle against tropical illness. In any case, the tight assets empty can support just a small amount of the promising exploration space. Thus, prioritization is fundamental for wellbeing research and observable exercise has gone into creating a powerful prioritization framework [4] [12] [13]. Tropical sickness look into Special Program for Research and guidance in Tropical Diseases, was made to address the requirement for an ex-amination into underestimated tropical malady that speaks to significant general med-ical issues in advancing nations [14]. In [17] researchers broke down and assessed Decision Support Systems and Expert Systems which are utilized as help for clinical choices just as potential outcomes to redesign the osmosis and empower the more prominent compromise of these frameworks in the present arrangement of the human services. These creators went to the accompanying results: instruments that are uti-lized in the clinical choice frameworks are classified as per specialized accessibility, and in that way, their utilization is tight and particularly their absorption with new frameworks for quality medicinal services. Along these lines, the advancement of new frameworks for clinical choice help is huge. Creators in [9] built up a structure for the use of information innovation to the administration of tropical infections. The point of

3 Fuzzy Logic

As stated by authors in [16], Fuzzy-based rationale is settled as a lot of numerical standards for information portrayal dependent on degrees of investment as opposed to on fresh enrollment of traditional paired rationale. This amazing asset to accessory imprecision and vulnerability was at first acquainted by [16] with improved agree-ment, durability and ease answers for genuine issues. Fuzzy-based sets have been applied in numerous fields in which inner conflict assumes a key job. Restorative determination is a praiseworthy case of equivocalness and vulnerability. Fuzzy-based set hypothesis is an input to the interest for thoughts and approaches for dealing with non-measurable vulnerability. A fuzzy-based set is a set with fuzzy edge. Characte-rized fuzzy-based sets or classes for every factor permits transitional evaluations of participation in them, which implies each set could have components that live mostly to it; the level of having a place is called enrollment functions extending from 0 to1. If X is the Universe of talk and its components are de-noted as X , interestingly with fresh set, at that point the fuzzy-based set An of X has attributes work related to it. The fuzzy-based set is communicated by a participation work, de-fined as seek af

□□□□X□□□□□□□□□□□ □ if x is not in A

0 □□□ □ □X□□□□ 1 if x is partly added in A.

□□□□X□□ represent to which the integer value X included in the fuzzy set A. The data-value 0 coincide to the infinite non-set membership and the value 1 belongs to the total infinite membership. Therefore, a fuzzy set membership function □□□□X□□ shows the association-degree to some value element X of the domain of discourse X under consideration. This maps each value of X to a data-membership scale between 0 and 1 in various functions like Triangular, Trapezoidal, curvaceous and Gaussian. Triangu-lar fuzzy-membership function that is extensively used is selected in this study of research. Triangular fuzzy-membership value function is computes by the equations as below:

$$\mu_A(X)=\begin{cases}0 & if\ x\le a\\ \dfrac{x-a}{c-a} & if\ x\in[a,c]\\ \dfrac{b-x}{c-b} & if\ x\in[b,c]\\ 0 & if\ x\ge c\end{cases}$$

where a, b, and c have been defined by experts doctors.

3.1 Fuzzy Expert System

Many fuzzy expert systems have been developed but the efficiency is depending basically upon the decision of the domain scientists on different problems related to the work under consideration. This system is evaluated with the help of medical practitioners and specialist. The developed system, christened has an structural design conferred in following figure 1. The development of system involves many components like fuzzification, deduction (inference) engine and de-fuzzification. It is a rule based system that uses fuzzy logic rather that Boolean logic. The system is designed and developed solely based on the knowledge-base, fuzzy logic rules and dataset.

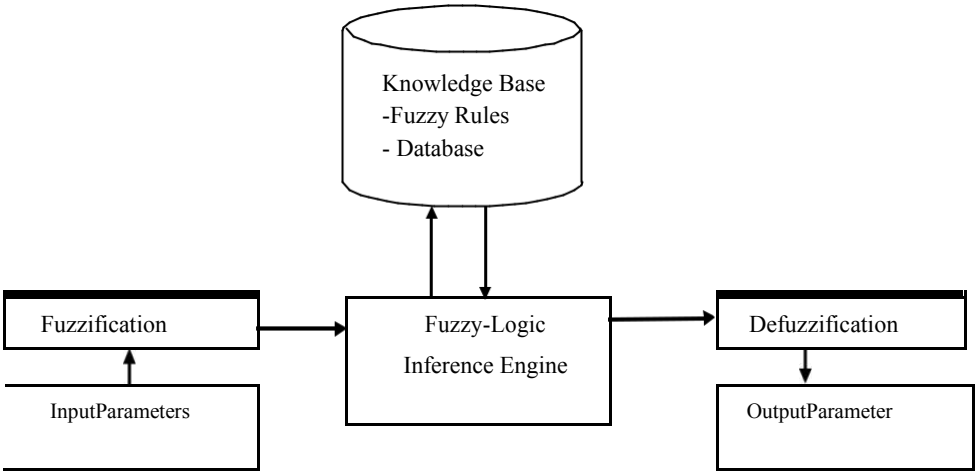

Fig. 1: Architecture of Proposed System

Procedure for Fuzzy logic based Malaria Diagnosis

The algorithm designed for the fuzzy rules based diagnostic process of malaria :

1: First give m signs and observed symptoms of patient as an input the classification.

where m = numeral of signs and syndrome.

2: Look for the knowledge-base for the disease d, which has the syndrome identified.

3: Then find the weighing factors (wf) (it is the degree of intensity of symptoms associated)

wf = 1, 2, 3, 4

Where 1 = Mild, 2 = Moderate, 3 = Severe, 4 = Very Severe.

4: Use fuzzy logic rules on the input.

5: Correlate the fuzzy data as inputs into their particular weighing factors to find out their degree of relationship.

6: Calculate the fuzzy rule base evaluating.

7: Find out the firing strength of the rules R.

8: Compute the quantity of truth R, of each rules by evaluating the nonzero minimum data value.

9: Identify the level/depth of the disease.

10: Declare the fuzzy system investigation for decision making

The Knowledge-Base of the System

Information (knowledge repository) is a key factor in the presentation of canny frameworks. The information base of the proposed framework is made out of an or-ganized and compact portrayal of the information on space specialists of tropical pre-scriptions. The unpredictable information is worried about sureness, rule, and pres-ence of tropical sicknesses, which were as often as possible settled upon by specialists in the field of tropical prescription. For the assurance of this exploration, intestinal sickness as a realized central malady is dealt with.

Fuzzification

Fuzzification process is the dispose of identifying and changing a absolute scalar value into a fuzzy set. This is accomplished with various sorts of fuzzifiers. There are commonly four kinds of fuzzifiers, which are utilized for the fuzzification procedure. They are: Trapezoidal fuzzifier, Triangular fuzzifiers, Singleton fuzzifier, and Gaus-sian fuzzifier [17]. Traingular fuzzifier which is broadly utilized will be utilized in this examination.

Fuzzification of information is completed by choosing input parameters into the flat pivot and anticipating vertically to the overhead limit of participation capacity to de-cide the level of enrollment.

The initial phase in the improvement of fluffy rationale based master framework is to develop fluffy sets for the parameters. This is appeared in conditions underneath. Based on do-principle specialists' information, both information and yield parameters chose for this exploration were portrayed with four semantic factors (mild i.e. gentle, moderate, severe :serious and very severe: extreme). The detail range of fuzzy value for all variables is given in following table 1:

FuzzyLinguistic Variables	Fuzzy RangeValues
Mild- gentle	□□□□□□□x □ 0.3
Moderate-	□□□□□□□□x □ 0.6
Severe-serious	0.6 □□□x □ 0.8
Very Severe-extreme	0.8 □ x □ 1.0

Table 1: Range of Fuzzy Set Values

Fuzzification starts with the upset of the crude information utilizing the capacities that are communicated in conditions beneath. During the activity, phonetic factors are look at utilizing triangular enrollment work and are go-to by consolidating level of participation running from 0 to 1 as appeared in conditions underneath. These recipes are unfaltering by the help of one and the other master specialists in the field of tropi-cal prescription and writing. The following stage in the fuzzification procedure is the advancement of fluffy (fuzzy) standards. The fuzzylogic principles for this examination were created with the help of area specialists. The knowledge-base of this system has so many fuzzy rules designed with the aid of consolidation theory but only the valid rules (20 in number) selected those are suggested by the field experts. Following are the some of the sample fuzzy rules for malaria.

Some of the rules (Rules 1, Rules 2, 18 and Rule 20) can be interpreted as fol-lows:

Rule1: IF fever = mild and headache = mild and nausea = mild and vomiting = mild and jaundice = mild and enlarge liver = mild and joint pain = mild and body weakness= mild, and dizziness = severe, and loss of appetite = mild and MP = mild THEN malaria = mild.

Rule 2: IF fever = moderate and headache = mild and nausea = mild and vomiting = mild and jaundice = mild and enlarge liver = mild and joint pain = moderate and body weakness = severe and dizziness = very severe, and loss of appetite = severe and MP = moderate THEN malaria = moderate.

Rule 18: IF fever = moderate and headache = Very Severe and nausea = Very Severe and vomiting = mild and jaundice = Severe and enlarge liver = Severe and joint pain = moderate and body weakness = severe and dizziness = very severe, and loss of appetite = very severe and MP = severe THEN malaria = very severe.

Rule 20: IF fever = very severe and headache = severe and nausea = severe and vomiting = moderate and jaundice = severe and enlarge liver = severe and joint pain = severe and body weakness = severe and dizziness = severe and loss of appetite = se-vere and MP = moderate THEN malaria = very severe.

Equations for fuzzification process:

$$\mu_{Mild}(X)=\begin{cases}0 & if \quad x\le 0.1\\ \frac{x-0.1}{0.2} & if \quad 0.1\le x\le 0.3\\ \frac{0.2-x}{0.1} & if \quad 0.2\le x\le 0.3\\ 0 & if \quad x\ge .0.2\end{cases}$$

$$\mu_{Moderate}(X)=\begin{cases}0 & if \quad x\le 0.3\\ \frac{x-0.3}{0.3} & if \quad 0.3\le x\le 0.6\\ \frac{0.45-x}{0.15} & if \quad 0.45\le x\le 0.6\\ 0 & if \quad x\ge .0.45\end{cases}$$

$$\mu_{Severe}(X)=\begin{cases}0 & if \quad x\le 0.5\\ \frac{x-0.6}{0.2} & if \quad 0.6\le x\le 0.8\\ \frac{0.7-x}{0.1} & if \quad 0.7\le x\le 0.8\\ 0 & if \quad x\ge .0.7\end{cases}$$

$$\mu_{Very\ Severe}(X)=\begin{cases}0 & if \quad x\le 0.8\\ \frac{x-0.1}{0.2} & if \quad 0.8\le x\le 1.0\\ \frac{0.2-x}{0.1} & if \quad 0.9\le x\le 1.0\\ 0 & if \quad x\le 1.0\end{cases}$$

4 Experimental Results

In the experimental analysis total 30 patient's data is validated. It is observed that all the 20 rules are fired according to the input values of symptoms narrated by the pa-tient. According to the result analysis the output of this expert system is on the same line with the domain medical expert with +_ 5% differences as shown in the graph figure 2. For further understanding one sample analysis is given here: seventeenth (17) rules were fired out for patient number 30. i.e. 17 rules generated non-zero min-imum values from the fuzzy rule base for malaria. For all of the linguistic variables: mild, moderate, severe and very severe, the respective output membership function strength (range: 0-1) from the possible rules (R1 to R20) are computed using RSS inference technique as shown in equations below:

Mild $\sqrt{R6^2 \; R10^2}$

$\sqrt{0.25^{\,2} \; 0.25^2}$

0.3536

Moderate $\sqrt{R2^2 \; R5^2 \; R8^2 \; R9^2 \; R13^2 \; R19^2}$

$\sqrt{0.25^2 \square 0.25^2 \square 0.25^2 \square 0.25^2 \square 0.25^2 \square 0.25^2}$

0 .6124

Severe $\sqrt{R3^2 \square R7^2 \square R12^2 \square R14^2 \square R15^2}$

$\sqrt{0.5^2 \square 0.25^2 \square 0.25^2 \square 0.5^2 \square 0.25^2}$

0 .8291

Very Severe $\sqrt{R11^2 \square R16^2 \square R17^2 \square R20^2}$

$\sqrt{0.5^2 \square 0.25^2 \square 0.25^2 \square 0.25^2}$ 0 .6614

The output from the fuzzylogic set calculated using the RSS later on defuzzified to get the crisp result for decision making. Then for defuzzification it uses the discrete center of gravity technique, the sample calculation is as shown in equation below:

$$= \frac{0.5 * 0.2 + 0.75 * 0.4 + (0.79 * 0.62) + (1.22 * 0.98)}{(0.5 + 0.78 + 0.795 + 1.3)}$$

$= 0.62, \quad = 62\%$

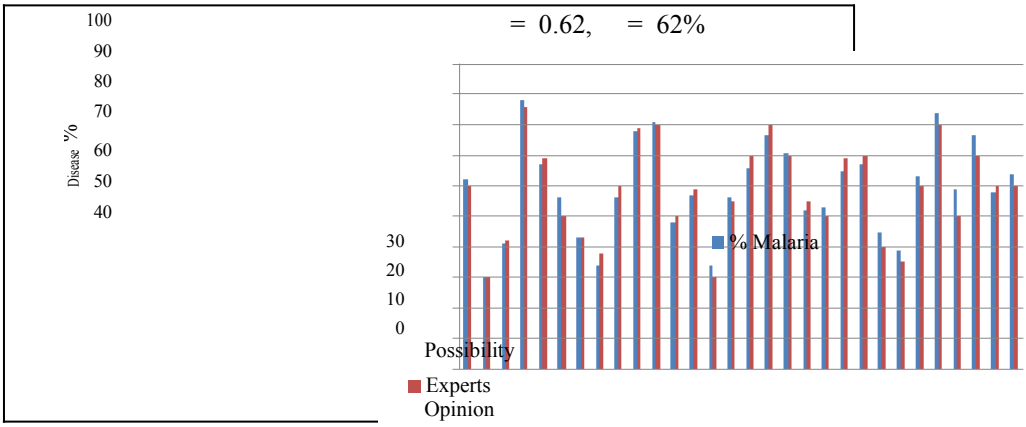

Fig2. Comparison of Fuzzy Expert systems output with Medical experts opinion

5 Conclusion

In the research work presented, the fuzzy expert system is developed for malaria dis-ease predication. The result analysis indicates that the fuzzy logic based systems can be used for direct medical diagnosis. The function of fuzzy logic for healthcare diag-nosis contributes an very helpful methodology to aid unsophisticated physicians to take a decision of malaria-disease higherside instantaneously as well as precisely. This developed system is evaluated with the domain expert's opinion and it is found that the system resembles 95.9% with the expert's decision. Hence the proposed tech-nique developed in this study, if used reasonably, could be an efficient approach for diagnosing malaria. Furthermore, this work can be scaled up as multi-disease diagno-sis system for detection other diseases showing similar kind of symptoms in patients

Ratnagiri, India ,
priyanka.bandagale@famt.ac.in,vinayak.bharadi@famt.ac.in

Abstract—**Traditional approaches to data warehousing have significant drawbacks in terms of effectively delivering a solution to various businesses requirements. They were also designed primarily for Online Transaction Processing (OLTP), making them unsuited for the growing need for analytics and ad hoc queries. Significant other drawbacks include high licensing and storage cost, slow query performance against large data volumes, and difficulty in providing access to all of the data stored in multiple databases. Columnar databases can be very helpful in your big data project We have described and implemented the Column Oriented approaches for OLTP and shown how it is efficient when compared to row oriented databases.**

Keywords— OLTP, Columnar Orientation, Infobright, ICE, DPN, PHP

I. INTRODUCTION

Over the past decade, business intelligence has emerged as one of the highest priority items on Chief Information Officer (CIO) agendas. Businesses and government agencies know that mining information from the increasingly large volumes of data they collect is critical to their business or mission. Traditional database technologies were not designed to handle massive amounts of data and hence their performance degrades significantly as volumes increase. Some of the reasons for this are:

- Disk I/O is the primary limiting factor. While the cost of disk has decreased, data transfer rates have not changed. Therefore accessing large structures such as tables or indexes is slow.
- A row oriented design forces the database to retrieve all column data regardless of whether or not is it required to resolve the query.
- Load speed degrades since indexes need to be recreated as data is added; this cause huge sorts (another very slow operation). The ideal architecture to solve this problem must minimize disk I/O, access only the data required for a query, and be able to operate on the data at a much higher level to eliminate as much data as possible, as soon as possible.

A. Columnar Versus Row Databases

Column databases stores data in columns instead of rows. So when we query data the row store has to go through the whole row, whereas in column store we can just work with the specific column(s) we are interested in. This enables massive performance benefits in scaling of the database [1], [2]. Figure 1 displays organization of data on disk in column and row stores.

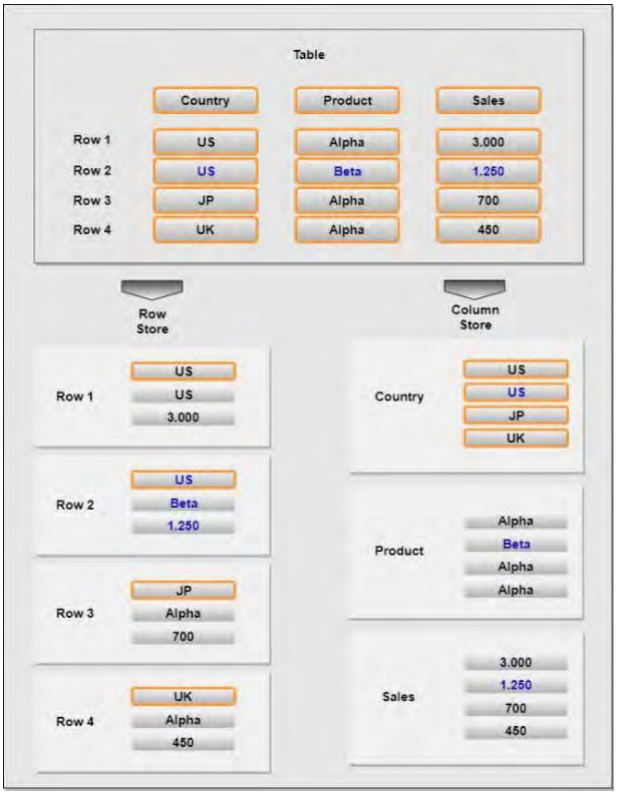

Figure 1. Actual storage on hard disk

B. Advantages Of Columnar Databases[3]

Better analytic performance: Column oriented approach allows better performance in running a large number of simultaneous queries.

b. Rapid joins and aggregation: data access streaming along column oriented data allows for incrementally computing the results of aggregate functions, which is critical for data warehouse applications.

c. Suitability for compression: Eliminates storage of multiple indexes, views and aggregations and facilitates fast improvement in compression.

d. Rapid data loading: In columnar arrangement the system effectively allows to segregate storage by columns. This means each column is build in one pass and stored separately, allowing the database system to load columns in parallel using multiple threads. Finally since the

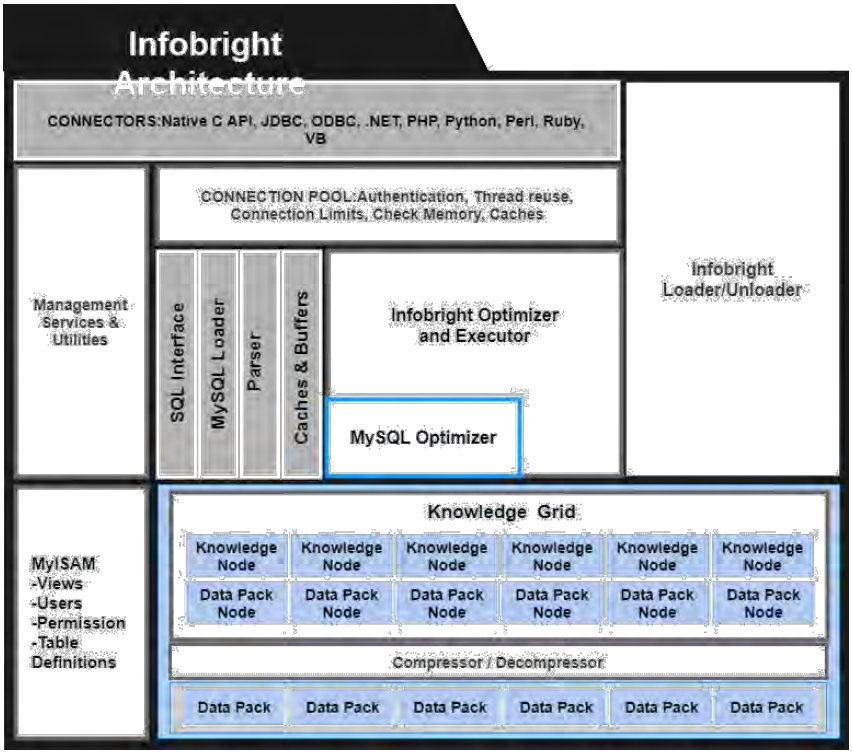

Figure 2. Architecture of Infobright

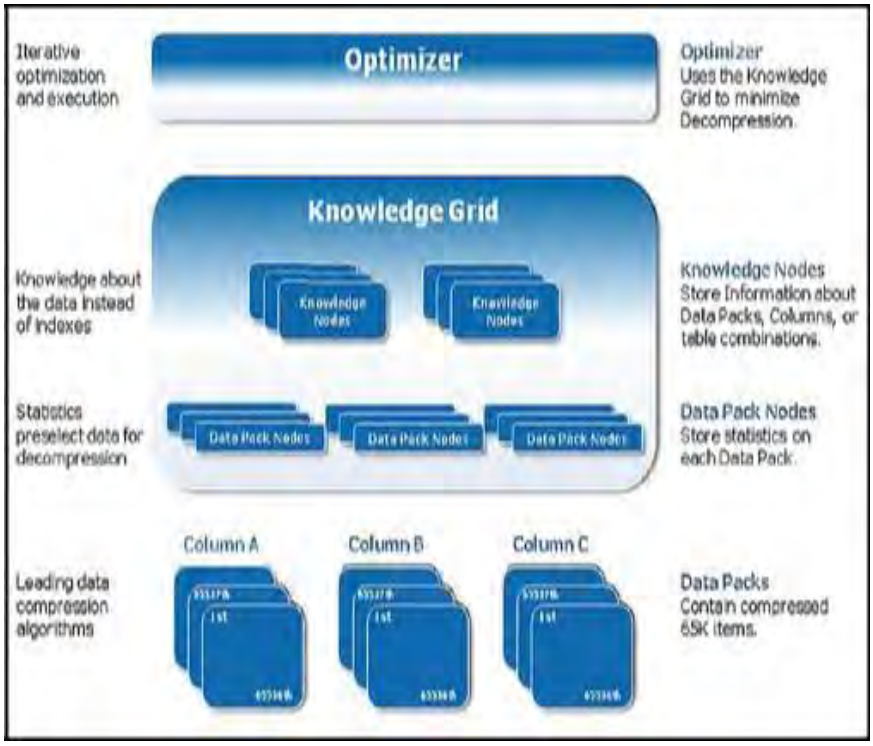

Figure 3. Data Organization

columns are stored separately entire table columns can be added or dropped without downing the system and without the need to re-tuning the system following the change.

The paper is organized in four sections followed by references. Section 2 describes the open source software which we have used to implement the system. Section 3 describes the implementation showing comparison of row and column databases. Section 4 summarizes the paper.

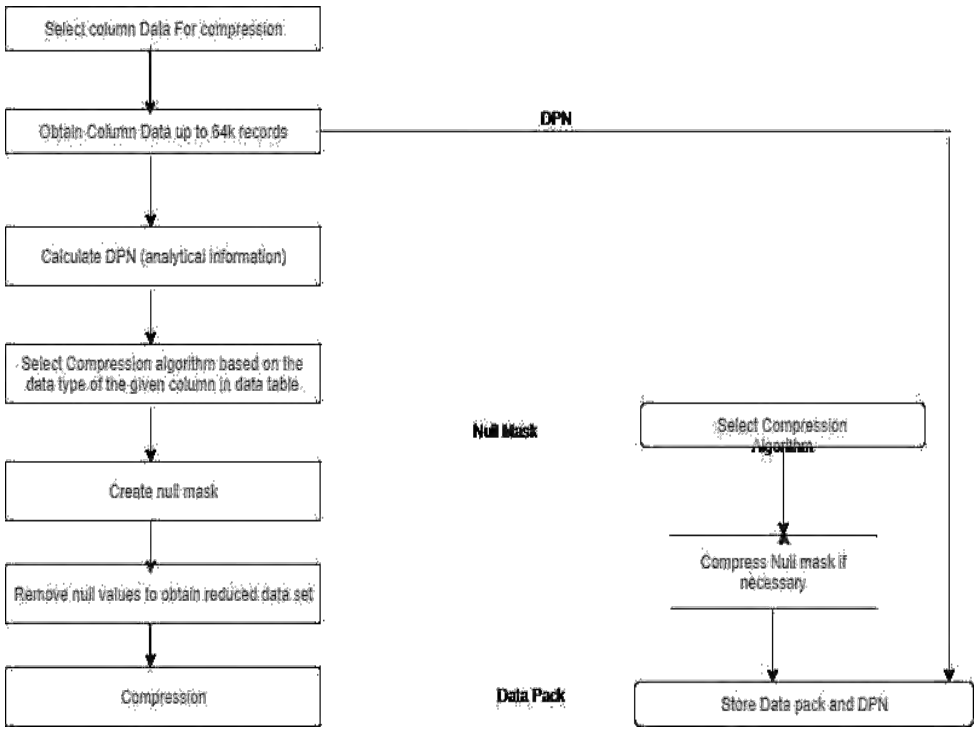

Figure 4. Data Storing and Compression

II. INFOBRIGHT COMMUNITY EDITION (ICE)

ICE is an open source software solution designed to deliver a scalable data warehouse optimized for analytic queries [4], [5].

A. *Key Benefits*

Ideal for data volumes up to 30TB

Market-leading data compression (from 10:1 to over 40:1), which drastically reduces I/O (improving query performance) and results in significantly less storage than alternative solutions

No licensing fees

Fast response times for complex analytic queries

Query and load performance remains constant as the size of the database grows

No requirement for specific schemas, e.g. Star schema

No requirement for materialized views, complex data partitioning strategies, or indexing

Simple to implement and manage, requiring little administration

Reduction in data warehouse capital and operational expenses by reducing the number of servers, the amount of storage needed and their associated maintenance costs, and a significant reduction in administrative costs

Runs on low cost, off-the-shelf hardware

Is compatible with major Business Intelligence tools such as Pentaho, JasperSoft, Cognos, Business Objects, and others.

B. *Infobright's Architecture*

It is based on the following concepts:

Column Orientation

Data Packs and Data Pack Nodes

Knowledge Nodes and the Knowledge Grid The Optimizer

Data Compression

The architecture is shown in Figure 2 .

1) Column Orientation

Infobright at its core is a highly compressed column-oriented data store. There are many advantages to column-orientation, including the ability to do more efficient data compression because each column stores a single data type (as opposed to rows that typically contain several data types), and allows compression to be optimized for each particular data type, significantly reducing disk I/O.

2) Data Organization and the Knowledge Grid

Infobright organizes the data into 3 layers:

a) Data Packs

The data itself within the columns is stored in 65,536 item groupings called Data Packs. The use of Data Packs improves data compression since they are smaller subsets of the column data (hence less variability) and the compression algorithm can be applied based on data type as shown in Figure 3.

b) Data Pack Nodes (DPNs)

Data Pack Nodes contain a set of statistics about the data that is stored and compressed in each of the Data Packs. There is always a 1 to 1 relationship between Data Packs and DPNs. DPN's always exist, so Infobright has some information about all the data in the database, unlike traditional databases where indexes are created for only a subset of columns.

c) Knowledge Nodes

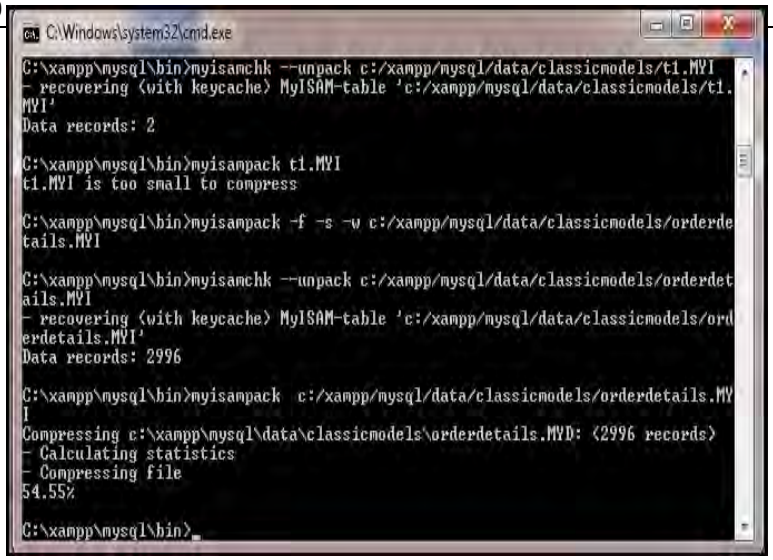

Figure 5. Compression command in MYSQL

These are a further set of metadata related to Data Packs or column relationships. They can be more introspective on the data, describing ranges of value occurrences, or can be retrospective, describing how they relate to other data in the database. Most KN's are created at load time, but others are created in response to queries in order to optimize performance.

3) The Infobright Optimizer

The Optimizer is the highest level of intelligence in the architecture. It uses the Knowledge Grid to determine the minimum set of Data Packs, which need to be decompressed in order to satisfy a given query in the fastest possible time.

4) Data Loading and Compression

The mechanism of creating and storing Data Packs and their DPNs is illustrated in Figure 4. One of Infobright's benefits is its industry-leading compression. Unlike traditional row-based data warehouses, data is stored by column, allowing compression algorithms to be finely tuned to the column data type. Moreover, for each column, the data is split into Data Packs with each storing up to 65,536 values of a given column. Infobright then applies a set of patent-pending compression algorithms that are optimized by automatically self-adjusting various parameters of the algorithm for each data pack. Within Infobright, the compression ratio may differ depending on data types and content. Additionally, some data may turn out to be more repetitive than others and hence compression ratios can be as high as 40:1. An average compression ratio of 10:1 is achieved in Infobright.

III. Implementation and Results

The PHP Hypertext Preprocessor (PHP) is a programming language that allows to create dynamic content that interacts with databases. This server-side scripting language designed for web development is used as a general-purpose programming language [6]. Since it provides easy connectivity to databases and its ease to understand it is chosen for implementation. XAMPP is used which provides Apache server to run the scripts and MYSQL which is a row oriented database [7].

A. Database used for Implementation

Once Infobright is downloaded and installed, you are ready to establish a connection to the Infobright columnar database. It's simply a matter of executing the following PHP code as you would with MySQL. In the rudimentary example we will use root for the user and 'password' as blank. [8].

B. Loading data in database:

Infobright includes a dedicated high performance loader that differs from the standard MySQL Loader. The Infobright Loader is designed for speed, but supports less LOAD syntax than the MySQL Loader, and only supports variable length text formatted load files [9].

a) Infobright Loader Syntax

MY SQL Loader: Loads from a flat file that includes text and field delimiters. Supports more features for escaping embedded characters, error handling, and transforming data using functions at the time of load then the Infobright Loader. This loader is set using an environment variable (@bh_dataformat='mysql').

Import your data into an Infobright table by using the following load syntax (all other MySQL Loader syntax is not supported):

```
LOAD DATA INFILE
'/full_path/file_name' INTO TABLE
tbl_name [FIELDS
[TERMINATED BY 'char']
[ENCLOSED BY 'char']
[ESCAPED BY 'char']
];
```

Example: Loading data in OrderDetails Table in the database:

```
LOAD DATA LOCAL INFILE
'e:/datafiles/orderdetails.txt' INTO TABLE OrderDetails
```

	173	233	328	362	447	452	489
Execution Time - IB	43	46	42	39	47	46	43
Execution Time - MSQL	44	48	42	41	50	47	45

Figure 6. InfoBright and MySQL Query Execution Performance

FIELDS TERMINATED BY ',' ENCLOSED BY '"'
LINES TERMINATED BY '\r\n';
To load data in the database a form is provided to enter the name of the table.
Considering we have entered Orderdetails in the form above. In MYSQL the query executes in 0.211844 seconds. In Infobright the same query executes in 0.43 seconds. Note: The performance is affected in Infobright due to limitations of ICE (single threaded). In ICE due to multithreaded operation it is faster than MYSQL.

C. Compression:

One of the major advantages of a column-based approach is its effect on compression. Since data is stored by column, and each column consists of a single data type, it is possible to apply optimal compression algorithms for each column. This may seem like a small change but the difference in database size can be very significant when compared to other approaches. The compression information is stored in information schema database[10].
Compression in Infobright takes place automatically whereas in MYSQL we need to use pack command to compress and unpack to uncompress. Once compressed in mysql the data becomes readable only. Hence for every update we need to uncompress it.
Considering orderdetails table which has 2996 rows the compression is as shown in Fig. 6.

a) Syntax for mysql compression is:

Myisampack
c:/xampp/mysql/data/classicmodel/orderdetails.MYI

The compression is 54.55%. Hence the file size becomes 43.55KB. This can be shown from the information stored in information schema database. The query to show the size of the data file stored after compression is given by the query .
SELECT table_name AS "Table",round(((data_length+index_length)/1024), 2) "Size in KB" FROM information_schema. TABLES WHERE table_schema = "classicmodels" AND table_name = "orderdetails";

In Infobright compression takes place during loading and the compression is nearly 80%. Hence file size becomes 15.39 Kb. The same query above can be used to get the file size of the compressed file.

D. Data Analysis

Column oriented databases are better suited for analytics, where only portions of each record are required. By grouping the data together like this, the database only needs to retrieve columns that are relevant to the query, greatly reducing the overall I/O needed. Infobright is an example of an open source column oriented database built for high-speed reporting and analytical queries, especially against large volumes of data. How query is executed to retrieve data and display in graphical form.

Query showing the sum of all products ordered is given as:
SELECT sum(quantityordered) from orderdetails
Query execution time in MYSQL is 0.006655 seconds.

Whereas same query when executed in Infobright takes 0.002024 seconds.

Displaying Data Analyzed in Graphical Format

JpGraph is an Object Oriented graph drawing library for PHP 5.1 and above. Highlights of the available features are: multiple scale types; anti-aliasing of lines; color-gradient fills; support for GIF, JPEG, and PNG formats; and support for multiple Y axes. JpGraph can dynamically generate various types of graphs based on data you feed it from a database/array.

JpGraph makes it easy to draw both "quick and dirty" graphs with a minimum of code and complex professional graphs which requires a very fine grain control. JpGraph is equally well suited for both scientific and business type of graphs.

Query :

"SELECT sum(creditlimit),customernumber from customers group by customer number having sum(creditlimit) between 40000 and 50000"; In Infobright the execution time and bar chart for the same query is shown in Figure 6, InfoBright has less execution timing as compared toMySQL.

IV. CONCLUSION

The working of columnar databases for OLTP operations are better is presented in this paper on loading compression and data analysis speed. This is implemented using ICE as backend and PHP as frontend. The columnar databases for large volume of data are analyzed. Infobight database is having better performance 10% faster as compared to MySQL.

Abstract

Data collection and data analysis models changed business trends over the past few years. By using BigData analytics we can predict the effects of drugs and how drugs develop disease on mankind. Many machine learning algorithms like Cluster computing environment, Classification etc. analyze the content of Health care. The proposed framework developed C-means clustering algorithm in developing Biomedical Engineering applications. The data is collected from machine learning repository. Big data framework dbmongo database is used to analyze the data. Here we have modules like Doctor, Administrator and analyst. By using machine learning and Bigdata, the analyst module identifies the chronic disease and help in reducing the medical expenses. Doctor by observing the predicted data symptoms and predicts related disease. Administrator's role is to add or remove the users in the database.

Keywords: mongoDB, BigData, C-means clustering, K-means clustering, Supervised Learning

I.INTRODUCTION

BigData is widely used in Biomedical engineering domain in the recent trends. The Research studies have been carried out in BigData analysis so, as to work on the domains like BioMedical Engineering. Before discussing all this it has to be discussed about the reason we are choosing BigData [1][2] [3] [4].

This paper highlights supervised learning techniques where there is a need of training data that is acquired with training examples. Supervised learning is a machine learning techniques which always maps the input with the output basing on the examples that were provided to it. Supervised learning always works with supervisor or trainer that we provide to it. Supervised learning builds model and later it evaluates it with predictions as base. It trains the input data with the given examples using the stated algorithm and make reasonable predictions. So, as to solve problem of supervised learning, the following steps are performed:

Step1. Initially we have to decide the type of training examples.

Step2.Secondly there is need for collecting a training set.

Step3: Determine the learned function for the input representation.

Step4 Learned function structure is determined with corresponding learning algorithm.

The above mentioned research paper Researcher Framework using MongoDB & FCM clustering for Prediction of the Future of Patients from EHR is said to help the patients .

II. OBJECTIVES

The main objective of this masters degree project

1. Is to examine different clustering algorithms in order to detect groups in a real-world, high-dimensional EHR data set.
2. The goal of the work is to find algorithms that detect high-quality clusters Accuracy within a reasonable computational time.
3. In order for the chosen algorithms to scale with an increasing size of the patient sample size and/or features, it is desirable.
4. To find an algorithm that achieves high-qualityAccuracywithminimal preliminary processing of the data

The choice of methods for the identification of groups in the data set imposes challenges due to several aspects:

• High-dimensionality: The data set originally has about 1200 features, which constrains the choice of algorithms and evaluation measures.

• Missing data: The set contains missing values that are not missing at random.

• Accuracy: Data are collected through health questionnaires and the accuracy of this self-reported data is unknown

III. EXISTING SYSTEM

Indeed hierarchical clustering algorithms generally seems to perform better than partitioned methods in creating high-quality clusters. As opposed to partitioned methods, they are also able to discover non spherical clusters. Hierarchical clustering algorithms also offer a good visualization in the form of a dendogram, which is suitable for interpretation. The hierarchical methods has the main drawback that the time complexity is quadratic O(n2).Because of the popularity in literature and widespread use of the two traditional methods, hierarchical clustering and C-means clustering will be of interest in this study. Although our high-dimensional data set might implicate lengthy running times for the hierarchical method, leading to lengthy experiments, it compensates this drawback through producing high-quality clusters, which is of main interest for this work.

IV. PROBLEM DEFINITION

Effective prediction of clinical risks of ACS patients via their heterogeneous EHR data is still an intricate problem and remains a major challenge for health care management, mainly due to high clinical complexity and the natural heterogeneity in EHR data. Therefore, one of the most important tasks in clinical risk prediction is to develop robust prediction models that can effectively handle high dimensional heterogeneous EHR data and accurately classify different clinical risks levels based on the acquired EHR data. It has particular advantages such as rapid inference and the ability to reconstruct features (a.k.a. clinical risk factors) yielding good classification accuracy. In order to ensure that features reconstructed by FCM are useful to the HER in problem for each patient, two regularization constraints are added on FCM to capture characteristics of patients at similar risk levels to make the reconstructed features of patients within the same risk level as close as possible, and preserve the discriminating information across different risk levels to make the reconstructed features of patients as separated as possible. After this we append FCM Clustering layer on the top of the resulting reconstructed feature representation layer, which is tailored to the EHR problem. Our proposed model learns more discriminative patient feature representations and thus improves the performance of EHR Data set.

V. ROLE OF BIGDATA AND MACHINE LEARNING IN BIOMEDICAL ENGINEERING

BigData and Machine Learning helped BioMedical Engineering in many aspects [1][2][3][4][5][6][7].

[1].Artificial Intelligence came into existence from the study pattern recognition and computational learning theory.

[2].Machine learning creates algorithms that learn from many examples and it makes predictions on the data

[3].Machine learning algorithms were trained to Identify the disease basing on symptoms. It helps to Diagnose Parkinson's Disease based on Dysphonia Measures. It also provide a review of recent researches on brain tumor etc

[4].Machine-learning techniques used for identifying Retinal image analysis.

[5].Machine learning algorithms supported in finding Obstructive Sleep Apnoea Detection using neural network with the help of deep learning framework.

[6].Machine learning algorithms help in detecting cell damage and tumors.

[7].Researches not only detects the disease they also try to provide remedies to the concerned disease.

VI. PRAPOSED SYSTEM

The proposed framework contains modules like Administrator, Doctor(Clinician) and Analyst / Researcher. The Administrator role is to add or remove users i.e. update user information. The Doctor's module role is to name the disease and their symptoms. All the disease regarded information is stored in database. Analyst module role is to provide the parameter values for the analysis and it has to apply relevant C-means algorithm to the provided data. The parameters can be like names, dates, gender or age.

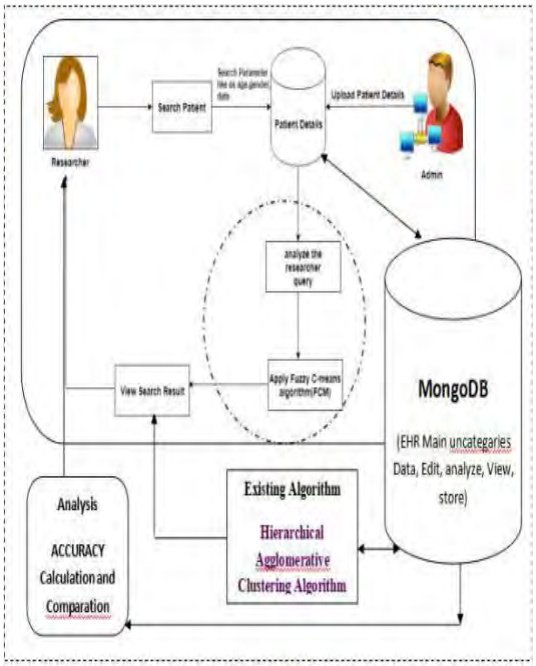

Figure No: 1- SYSTEM ARCHITECTURE

Figure No-1 shows the framework flow which explain the working of the system.

Analyst after choosing required parameter, he/she can select the required representation method to get the desired output. Proposed Frame Work where the Bigdata trained with machine learning using Fuzzy. C-Means algorithm. Hierarchical clustering iteratively joins the two nearest clusters beginning from singleton clusters or with the complete set. After joining of two clusters distance between all the other clusters and a new cluster that is joined are recalculated.

a) PATIENT DATA

The hospital dataset used in this study contains real-life hospital data, and the data are stored in the data center. To protect the patient's privacy and security, we created a security access mechanism. The data provided by the hospital include EHR, medical image data and gene data. The inpatient department data is mainly composed of structured and unstructured text data. The structured data includes laboratory data and the patient's basic information such as the patient's age, gender and date, etc. While the unstructured text data includes the patient's narration of his/her illness, the doctor's interrogation records and diagnosis, etc. In order to give out the main disease which affects this region, we have made a statistics on the number of patients, the sex ratio of patients and the major disease in this region every year from the structured and unstructured text data.

b) PATIENT DETAILS PREDICTION

We obtain the main cancer disease in this region. The goal of this study is to predict whether a patient is amongst the cerebral infarction high-risk population according to their medical history. More formally, we regard the risk prediction model for cerebral infarction as the supervised learning methods of machine learning, i.e., the input value is the attribute value of the patient, A = (a1, a2, · , an) which includes the patient's personal information such as age, gender, the prevalence of symptoms, and other structured data and unstructured data.

c) ALGORITHM ACCURACY

The accuracy determines and predicts the measure of how machine learning classification algorithm is working correctly. It finds the number of true positives and true negatives and is also used to divide by the number of true positives and negatives, false positives and negatives. True positive /true negative is a data which determine that algorithm is designed. False positive / False negative determine that algorithm is incorrect it is not classified properly. It we get correct result it is true positive.

d) MACHINE LEARNING

Machine learning (ML) algorithms help software applications to predict outcomes accurately. Machine learning follows the same strategies of data mining and predictive modeling. Machine learning is widely used in many domains like fraud detection, network security threat detection etc.

Fuzzy C-means clustering algorithms steps are:

1. Intially Choose C cluster centers in a random. (matrix V).
2. Make Computation for the membership matrix U.
3. Make modification by Updating the cluster Centers vi.
4. Objective function J is to be computed.
5. We have to repeat steps 2 to 4 until we get Convergence (|| var (J) ≤ €||).

6.After execution of all steps are completed w we Exit.

VII. SOFTWARE DETAILS

In this section, drugs for the patients are chosen basing on K-means clustering. We used software like [1][2][3][4].

[1] Operating System used for the research is Windows 8.

[2] Application Server used is Tomcat 6.0/8.0

.[3] Front End used is HTML, Java,Jsp.

[4] Script used is JavaScript. Database used is MongoDB. Database Connectivity used is Robomongo-0.8.5-i386.

Why we are Using MongoDB?

1. The storage pattern in MongoDB is Document Oriented Storage. Here the Data is stored in the form of JSON(JavaScript Object Notation (JSON) pattern style documents.

2. MongoDB uses multikey indexes . The indexing of multikey index is used to store the content in arrays. Field is indexed that holds an array value.

3. MongoDB creates variable index entries for each and every element of the array. Multikey indexes allow queries to select the documents which contain arrays by matching .A replica set in MongoDB is a group of mongodb processes that can maintain the same data set.

Replica sets in MongoDB provides redundancy and high availability.

4. Sharding feature of MongoDB is the process of distributing data across multiple servers for storage purpose. MongoDB software uses sharding to manage huge massive data growth. Sharding feature in MongoDB allows to add many servers to our database to support the data growth. MongoDB automatically balances data and load across its various servers.

Advantages of MongoDB over RDBMS

MongoDB database is a document based schema less in which database where there is collection that holds variety of documents. The Number of fields, the content and size of document differ from one another.

Structure of object in MongoDB is very clear.

MongoDB database have no complex joins to work with.

MongoDB supports dynamic queries when we are working with documents. This is called document-based query language which is as powerful as that of Structured Query Language.

MongoDB is much easier to scale.

No need of Object to database mapping in MongoDB.

MongoDB uses internal memory for storing the working setand that help in fast access of data.

VIII. ALGORITHM

Fuzzy C means algorithm

In cluster populations or data points are divided into different groups. Data points of same group are similar and data points of dissimilar group are not similar. C-means clustering algorithm works by assigning membership to each data point. The member ship to data point is given basing on data point distance with cluster centre. If the data point is nearest to cluster centre its membership is more. We can conclude the data point nearest to cluster centre serve as prototype of cluster

Fuzzy C-means clustering algorithms steps are:

1. Chose C cluster centers randomly (matrix V)
2. Compute the membership matrix U
3. Update the cluster centers vi
4. Compute the objective function J
5. Repeat steps 2 to 4 until convergence (|| var (J) ≤ €||)
6. Exit.

Data Base with MongoDB

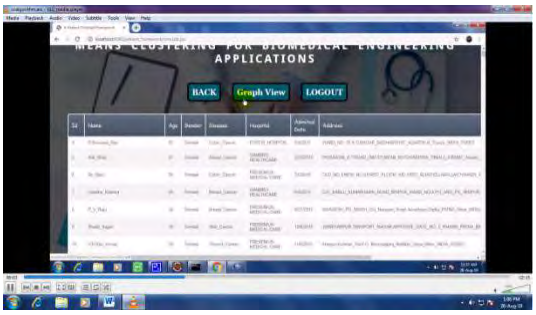

Figure No-2 : Mongodb Scinerio-1

Figure No-3 : Mongodb Scinerio-2

IX. RESULT ANALYSIS

1) This C-means algorithm gives best results for overlapped datasets when compared with k-means algorithm.

2) In k-means algorithm data points are assigned to single cluster center. In c-means algorithm data points are assigned its membership to more than one cluster

Accuracy of C-means clustering algorithm

Calculation Formula

Accuracy can be calculated as below

Acc = (Pc / Ds)

(Accuracy=predicted class/dataset)

Acc – Stands for accuracy

Pc - Stands for correctly predicted

class Ds - Stands for Dataset

NM-Not match User variable

MMngMU

Where $X_i=X_1+X_2+X_3\ldots+X_n$

Where xi represents a measurement and n is the number of measurements.

Modified Fuzzy C-Means Clustering

$$J(U,V)=\sum_{i=1}^{c}\sum_{j=1}^{N}U\binom{m}{ij}||x_{j-}v_i||^2$$

Where

- U: membership matrix
- V: cluster centers matrix
- N: number of data points
- C: number of clusters
- Xj: is the jth measured data point
- vi: is the center of cluster i

Dunn was the first to implement fuzzy C-means clustering algorithm in 1973, later Bezdek improved this algorithm in 1981. For fuzzy C-means, the membership function is represented by matrix (U) having values between 0 and 1 that represent the membership of data points to every cluster, while hard C-means uses only 0 and 1 values for membership function. Fuzzy C-means algorithm is based on an objective function.

The search result of gender parameter using FCM are shown below

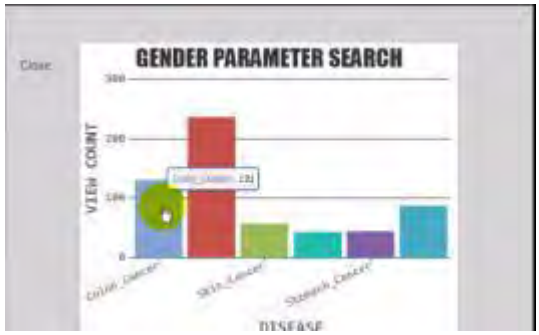

Figure No-4 : analysis with gender parameter

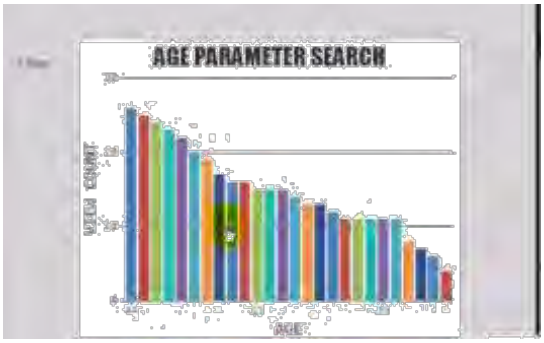

Figure No-5 : Analysis with age parameter

X. CONCLUSION

The aim of this paper was to propose a framework using Bigdata and K-means clustering method to select drugs for patients. Biomedical engineering applications are trained with k-means clustering algorithm. This is a deep learning approach. Machine learning and BigData Analytics together helps in developing a new era in Biomedical engineering. From Identifying Diseases and Diagnosis to Machine Crowd sourced Data Collection the machine learning plays a major role. Both Bigdata science and the approach of machine learning together build Biomedical engineering domains. They are dependent upon one another and they are mutuality. Bigdata analytics makes analysis on huge volumes of data and machine learning helps to give input and get output patterns. Hadoop and Mapreduce are used for distributed processing of large datasets. MongoDB is a NoSQL database used for high volume data storage and it is document oriented. The database used here is MongoDB. Here in this research C-means algorithm is taken for training purpose as it works faster. C-means algorithm assigns its values to multiple clusters. In the proposed framework the work has been done on C -means clustering algorithm. So, selecting C-means made the programming part simple. In future this above said framework will be developing
Healthcare data solutions, Healthcare Intelligence and data accuracy etc.

Vidya.s@xavier.ac.in,amogh.chaudhari@gmail.com,frfabiansj@xavier.ac.in

Abstract—**Human society is faced with the increasing global burden of cancer as we enter the new decade. According to the Globocan 2018 report, in India alone, breast cancer has the largest number of new cases (27.7 %) as compared to the world incidence rate of 24.7 %. Breast cancer detection after clinical examination includes two tests, namely Breast Imaging and Breast Histopathology. Breast cancer has different stages or spread, aggressiveness, and genetic makeup. An end to end system that helps in early detection and prevention would increase the survival rates. Traditionally, Machine Learning techniques have been used to detect malignancy in breast cancer images. However Machine Learning is limited in its ability to process natural data in its raw form. The limitation is due to the need of domain expert who can carefully handcraft features to feed a classifier. Deep Learning, a subfield of Machine Learning, however automatically learns multiple levels of representation and abstraction that help to understand breast cancer images at a greater depth. Deep Convolutional Neural Networks have achieved remarkable breakthroughs in processing images. In our paper we review the Deep Learning techniques that have given extraordinary performance for both Breast Cancer Image and Breast Cancer Histopathology Image Classification and thus helped in early detection of Breast Cancer.**

Index Terms—Breast Cancer Image Classification, Convolutional Neural Networks, Deep Learning, Machine Learning

I. INTRODUCTION

As we begin a new decade, we are faced with the increasing global burden of cancer. It remains an unresolved cause for increased morbidity and mortality of human beings. This in turn impacts societal life and economy. The GLOBO-CAN database, compiled by the International Agency for Research on Cancer (IARC), provides estimates on national cancer incidence and mortality [1]. In India, according to the GLOBOCAN 2018 report, breast cancer has the largest number of new cases (27.7 %) as against the world incidence rate of 24.7 %.

The last decade has seen an intensified research efforts in the field of prevention and early detection of this disease. As the wave of rapid urbanization sweeps India, one observes drastic changes in dietary habits and life style, causing at times high stress levels. Studies in high-income countries have indicated that from one-third to two-fifths of new cancer cases could be avoided by eliminating or reducing exposure to known lifestyle and environmental risk factors [2].

The risk factor for most cases of breast cancer is due to a combination of genetic and environmental factors. The breast cancer detection process, after physical examination includes two tests, namely Breast Imaging and Histopathology. Early detection, true diagnosis and prompt treatment are crucial for a better prognosis [3]. This is made possible by effective and efficient screening programs. Early diagnosis of cancer in the natural progression of disease, before it spreads to local regions or to distant organs can result in higher 5-year survival rates.

Imaging modalities may be classified as primary or simple and secondary or complex. In regular screening of patients and as a first line of diagnostic tools only the primary imaging modalities are preferred because they are cheap and provide reliable and repeatable results under a variety of conditions. One of the commonly used imaging modalities for regular screening of patients for breast cancer is mammography. Here any anomaly is categorized as regular or irregular, and capsulated (benign - not cancerous) or non-capsulated (malignant). Mammography techniques may be a screen-film mammography (SFM) or a full-field digital mammography (FFDM). SFM may not detect benign cancer properly. FFDM performs better in case of misdiagnosed cancer samples as the images are processed using Image processing techniques.

Screening mammography reduces breast cancer mortality by about 20% to 35% in women aged 50 to 69 years and slightly less in women aged 40 to 49 years [4]. Some of the other primary imaging modalities include Ultrasound, Thermogra-phy and Electrical Impedance. For further examination and confirmation of dier screening has potential limitations and drawbacks which include false-positive, false-negative test results and overdiagnosis.

Presently, full-field digital mammography (FFDM) is rapidly being replaced by digital breast tomosynthesis (DBT, also called 3D mammography). An independent risk factor for breast cancer is the breast tissue density. It results in reduced mammographic accuracy because of masking and superimposition of dense tissue. Hence the need for supplemental imaging to improve the sensitivity of screening in women with significant mammography breast density [5].

Mammographic breast density is visually assessed by radiologists in routine mammogram image reading, using four qualitative Breast Imaging and Reporting Data System (BI-RADS) breast density categories. However it is difficult for radiologists to consistently distinguish the two most common and most variably assigned BIRADS categories, i.e., "scattered density" and "heterogeneously dense" [6].

II. MACHINE LEARNING AND DEEP LEARNING

A. Machine Learning

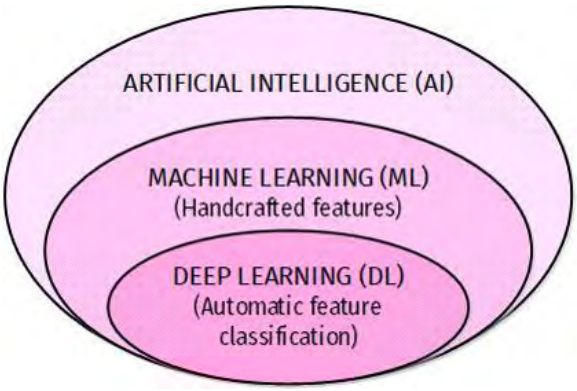

Fig. 1. Difference between ML and DL

The pioneer of Machine Learning (ML), Arthur Samuel, defined ML as a "field of study that gives computers the ability to learn without being explicitly programmed." ML primarily focuses on classification and uses regression analysis on known features previously learned from the training data. ML helps to understand the structures and patterns within large datasets. It is used for classification, clustering and prediction. Classification is putting something into one or more categories. Clustering is dividing a large set of data points into a few clusters, with points within a cluster having common properties. Prediction uses historical data and builds models that are used to forecast a future value.

Conventional ML techniques are limited in their ability to process natural data in their raw form. The limitation is because of the need of domain expert and carefully hand feature extraction method as shown in Figure 1. The low-level features can be hand crafted with great success for certain data and tasks, but designing effective features for new data and tasks usually requires new domain knowledge as most hand-crafted features cannot simply be adapted to new conditions [7]. ML algorithms uses Support Vector Machines (SVMs) with different kernel functions like Gaussian Radial Basis Function (RBF) or a polynomial function. SVMs are "non-parametric" models where the parameters are not predefined and their number depends on the training data used. An SVM classifier performs binary classification. Multiple classifiers may be combined using the bagging and boosting techniques to improve performance.

The other ML techniques that have been used are k-Nearest Neighbors (k-NN), Random Forest (RF) and Bayesian Networks (BNs) [8]. k-NN captures the idea of similarity (distance or closeness) and votes for the most frequent label in case of classification. RF combines many decision trees to ensemble a forest of trees. This gives a better stability and is also insensitive to the noise of the input data. BN is a subfield of probabilistic graphical models (directed acyclic graph - DAG) that are used for prediction and knowledge representation of uncertain domains. In ML the classification is done in two stages, namely, training and testing. During training the image is acquired, preprocessed and features are extracted and selected. Similar steps are followed during testing. The preprocessing step helps to remove the noise and thus improve the quality of the image. Finally in the classification stage different classifiers are applied for diagnosis and prognosis.

B. Deep Learning

Deep Learning (DL) uses Deep Neural Network (DNN) architectures as shown in Figure 2, to learn multiple lev-els of representation and abstraction. DL techniques are representation-learning methods that help to understand data such as text, images and sound. The features are learned automatically by the DNN and are obtained by composing simple but non-linear modules that each transform the representation at one level (beginning with the raw input) into a representation at a higher, slightly more abstract level. These transformations can help to learn very complex intricate functions. A deep-learning architecture is thus a multilayer stack of simple modules, which learn features and many of which compute non-linear input–output mappings.

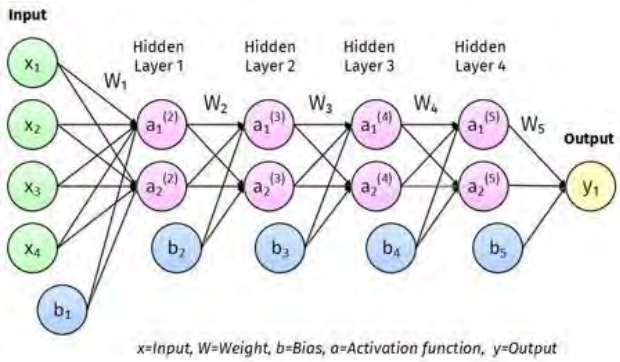

Fig. 2. Deep Neural Network (DNN) architecture

The power of DNNs is due to the highly optimized hardware, that is the Graphics Processing Units (GPUs) which can handle lots of parallel computations using thousands of cores and possess a large memory bandwidth to deal with the data for these large computations. They work on the massive training data and learn its multi-level feature representation. Li Deng [9] categorizes DL architectures into thre

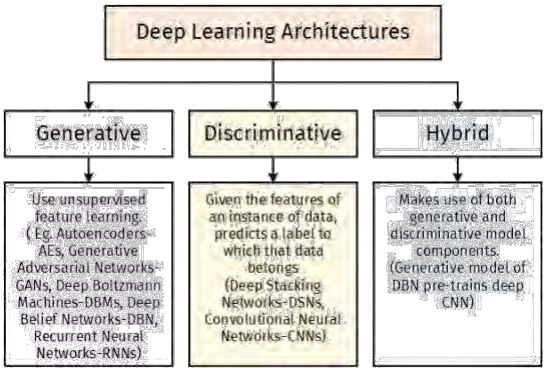

Fig. 3. Deep Learning Architectures

III. DATASETS

In the past three decades several image databases have been created for breast cancer research, some of which are public and others private. Public databases provide a common reference for researchers to test and compare their methods. The image database is crucial to the type of study that one wishes to undertake. Often the collected datasets are class imbalanced. There is a large class where the patients do not have cancer and a small class of patients with cancer. Necessary precautions need to be taken while conducting research by choosing the proper research design.

Datasets are available both for Breast Imaging and Breast Histopathology. Based on the imaging results, a doctor may suspect that a person has breast cancer. A biopsy is then performed to diagnose if cancer is really present. Among the different biopsy techniques, the most common ones are fine needle aspiration (FNA), core needle biopsy, vacuum-assisted, and incisional or excisional surgical biopsy [10]. The surgical biopsy, though reliable, is invasive and costly.

The designed classifying system needs an adequately large and preferably public database. In case of Deep learning this database has to be large to get meaningful classification results. The author in [11] give the details of the requirements for mammographic databases. These include the case selection, ground truth, patient's associated information and importantly the organization and distribution of the database. In [12] a case is made for Computer Aided Detection (CADe) as against a human person interpreting screening mammograms because it is a highly repetitive task and also highly subjective, resulting in large intra- and inter-interpreter variability.

Breast Cancer Wisconsin (Diagnostic) Data Set [13] which was made public in 1992, has been widely used especially for creating good machine learning classifiers [14]. It has 32 attributes, 569 instances and two classes. Another database is the mini-MIAS (Mammographic Image Analysis Society) database of mammograms [15]. The dataset contains 322 images, with each image falling into one of seven categories: calcification, circumscribed masses, spiculated masses, architectural distortion, asymmetry, other ill-defined masses and normal. The size of each image is 1024x1024 pixels.

A publicly available database, is the Digital Database for Screening Mammography (DDSM) [16] which is available from the University of South Florida was released in 1997. The authors in [17] have developed a new dataset called INbreast. It has total of 115 cases (410 images) from which 90 cases are from women with both breasts affected (four images per case) and 25 cases are from mastectomy patients (two images per case).

The Breast Cancer Histopathological Image Classification (BreakHis) is composed of 9,109 microscopic images of breast tumor tissue collected the through a clinical study from Jan-uary 2014 to December 2014. It is collected from 82 patients using different magnifying factors (40X, 100X, 200X, and 400X). It contains 2,480 benign and 5,429 malignant samples which are 700X460 pixels, 3-channel RGB, 8-bit depth in each channel in the PNG format [18].

IV. DEEP LEARNING MODELS

AlexNet [19] is a deep convolutional neural network that classified 1.2 million high-resolution images in the ImageNet LSVRC-2010 contest into the 1000 different classes. The neu-ral network has 60 million parameters and 650,000 neurons. It consists of five convolutional layers, two of which are followed by max-pooling layers, and at the end are three fully-connected layers with a final softmax layer as shown in Figure 4.

The authors in [6] used a improved version of the AlexNet model. They used the two-class CNN model to classify the two BI-RADS breast density categories: "scattered density" vs. "heterogeneously dense". They have suggested future work in the area of identifying more likely to be misclassified images, comparing other CNNs model structures to the AlexNet, developing other approaches to deal with noisy or potentially inaccurately labeled data and testing by using larger multi-center datasets. They also used transfer learning from nonmed-ical images to medical imaging-based applications. They used the AlexNet model pretrained on ImageNet and fine-tuned it with their mammogram data.

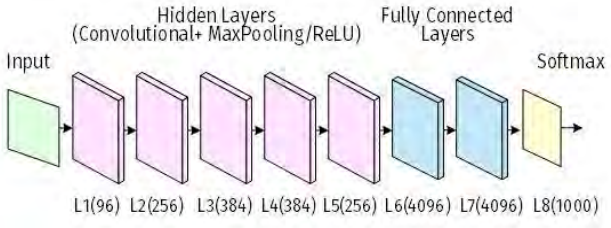

Fig. 4. AlexNet Architecture

concatenations). The authors in [21] have developed a deep learning model called Grouped-Resaunet (GRA U-Net) which

U-Net [20] describes a Convolutional Neural Network (CNN) that was developed for biomedical image segmenta-tion at the Computer Science Department of the University of Freiburg, Germany. The architecture works with fewer training images and yields more precise segmentations. The name comes from the U-shaped architecture consisting of a contracting (Convolution + Maxpooling + Rectified Linear Unit-ReLU) and an expanding path (up-convolutions and

segments the nipple region with very high accuracy from other similar looking non-nipple regions such as tumour.

The authors in [22] have developed an efficient deep learning framework. It identifies, segments, and classifies cell membranes and nuclei from human epidermal growth factor receptor-2 (HER2)-stained breast cancer images with minimal user intervention. The also used Long Short-Term Memory (LSTM) so as to use pixel information from the multiple frames in making the semantic segmentation and classification cases. Their model achieved 96.64% precision, 96.79% recall, 96.71% F-score, 93.08% negative predictive value, 98.33% accuracy, and a 6.84% falsepositive rate. Their framework was run for almost 7 days (24 7 = 168 hours) for training that was done on a parallel computing platform. It took on average, 1.06 seconds for cell membrane and nucleus segmentation, classification and HER2 scoring on test data.

V. CONCLUSION

As researchers fight against time to discover the holy grail to cure cancer one has to accept the fact that great progress has been achieved to increase the survival rate. Deep Learning-based CNN models have given extraordinary performance for both Breast Cancer Image and Breast Cancer Histopathology Image Classification. As Deep Learning progresses, we look forward to an end to end system, which along with other mul-tidisciplinary approaches, will not only help in early detection but also help prevent cancer in the first place.

Clinical Risk Prediction of Acute Coronary Syndrome Using Deep Learning Approach

Ms. Swati Suchak, Dr. Uttara Gogate
PG Scholar, Associate Professor
Alamuri Ratnamala Institute Of Engineering & Technology, Shivajirao S. Jondhale College Of Engineering,
Mumbai, India,
swatisuchak0702@gmail.com,uttara.gogate16@Gmail.Com

Abstract: **Acute coronary syndrome (ACS) is a severe cardiovascular disease which is leading to death and it is serious long-term disability globally. Prediction of ACS is important for diagnosing earlier to treat it. Previous ACS models based on small set of risk factors and predictive variables used to simplify the score calculation are numbered. This study developed stacked and regularized un noising auto-encoder (SDAE) model to find clinical risks of ACS patients from huge collections of electronic health records (EHR). It Determine patients at similar risk levels characteristics, low risk, high risk and medium risk and preserve the results. This approach is validated with more than 2000 real clinical dataset consisting of patient samples. The Approach followed by us remains robust and gives more than 0.8 accurate results for predicting AUC.**

Index Terms—Acute coronary syndrome, Clinical risk Deep learning, Electronic Health Records

I. INTRODUCTION

Acute coronary syndrome (ACS) includes unstable angina and myocardial infarction (MI) are the common types of coronary heart diseases (CHD).This disease occurs if the heart muscle does not receive sufficient oxygen in blood. Due to this patient may face problems like morality, ACS became an important health issue its treatment cost and the prolonged chronic course mortality rates increased.[4]. Every year ACS is estimated to affect millions of people in china and U.S.A.[5]. Approximately 1/3 rd population are at risk of ACS disease.[6] In United States of America more than50, 000 to 60,000 people are dying before taking them to hospital because of ACS attack. All the above stated adverse affects have to be ended by diagnosing patients and prevent this disease.[7] Prevention of ACS may help both the patients and society. These are mentioned in points. [8] Clinical risk prediction has been done with tool so, that patient takes care of his disease and he can undergo proper disease treatment steps. [9]. Clinical risk prediction helps clinicians to predict the chance of cardiac disfunctions (such as myocardial infarction, death). This proposed tool help in taking timely and appropriate intervention strategies to those at high risk of cardiac arrests and to motivate patients to remain alert following these strategies the patients can reduce high mortality. Extensive research work carried on clinical risk estimation of ACS. Earlier ACS risk-scoring tools like GRACE and TIM have been developed for monitoring population samples over long period. In proposed model patient's information is extracted from admission records of Hospital for clinical risk prediction models of ACS patients.

II. RELATED WORK

W are using SVM for the following reasons as in points [1][2][3][4[5]][6][7].[1].SVMs need less memory. SVM are less prone to errors. They perform text classification in HER systems and pattern recognition in echo-cardiograph imaging. [2].They help to stratify CV risk and physicians make decisions. SVM is feasible for large and complex data which is nonlinear, such as "omic" data. [3].SVM accuracy and enhance processing time. The wrong choice in kernel functions may lead to errors .SVM works even with small data sets. [4].The Decision Tree algorithm encounters over fitting because of the small datasets. It is used with a series of yes/no questions. SVM classify data into categories. [5].In addition it can be used in clinical decision-making. Random Forest algorithm is an extension to Decision Tree algorithm. In this algorithm Decision Trees are combined together
and every Decision Tree is trained independently.[6]. Random Forest algorithms compute angiography, readmission, HF risk and survival prediction models.

[7].The Naive Bayes classifier is probabilistic classifier obtained from Bayes theorem. It executes small training datasets which is be used in text classification problems in CV risk factor identification and decision-making systems. Fuzzy logic used in areas such as prediction of early coronary artery disease and mortality. K-nearest neighbor is nonparametric methods. It works on small training datasets. Fuzzy is used a in ECG interpretation problems. K-nearest neighbor takes more space and time when using large datasets.

III. EXISTING SYSTEM

There are many data mining algorithms like decision trees, fuzzy inference systems and Bayesian networks, etc., have been said to explore the uses of EHR data for clinical risk prediction. When considering an example Tay et al. gave an neural inspired deep learning ANN algorithm for risk prediction by using EHR data. There exists a Bayesian analyses which predict human clinical adverse events which very well helped in drug development programs. In existing work, a genetic fuzzy system designed for risk prediction in unstable angina. It also evaluated on a dataset which is collected from a Chinese hospital in EHR patients. We previously developed a probabilistic topic modeling. The said model finds risk stratification by exploring the potential of Electronic Health Recording unsupervised fashion.

IV. PROBLEM DEFINITION

Acute coronary syndrome (ACS), as a common and severe cardiovascular disease, is a leading cause of death and the principal cause of serious long-term disability globally. Deep learning architectures with a greater number of layers, can potentially extract abstract and invariant features for better performance of patient classification. The ability of inference on a large volume of heterogeneous EHR data is particularly suitable for our aim. Therefore, this paper proposes a novel approach for clinical risk prediction of ACS based on deep learning. Among various deep learning models, the Stacked Denoising Auto-encoder (SDAE) has particular advantages
such as rapid inference and the ability to reconstruct features. After considering all reconstruction learning phases, i appended a softmax regression layer on the top of the resulting reconstructed feature representation layer. This can help in solving clinical risk prediction .Our proposed model can learn more patient feature representations and improve the performance of clinical risk prediction.
The main objective of this research as stated below [1][2][3][4]. [1]Is to examine different deep learning algorithms in order to detect risk factors of coronary heart disease in a real-world, high dimensional Electronic Health Record data sets with heterogeneous data.[2]. The goal of the work is to find different algorithms and find algorithm that is suited for large data sets working.[3].In order for the chosen algorithms to scale different levels of risk factors in ACS with an increasing size of the patient sample size.[4].To find an algorithm that achieves Accuracy with less preliminary processing of the data.

V. IMPORTANT TERMS

This section briefly describes the background that is closely related to the proposed research paper. We discuss three issues here namely One is deep learning and its applications in biomedicine and the second one is clinical risk.

1. Deep learning

Deep learning is an Artificial Intelligence concept applying set of algorithms in machine learning that model very high-level abstractions in the data by using architectures which is
composed of multiple non-linear transformations.[1]. Stacking the nonlinear transformations is the basic idea used for deep learning algorithms.[2]. The more layers the data goes through within the deep learning architecture, the more tough to use nonlinear transformations construction. [3]. Stacked denoising auto-encoder (SDAE), is most investigated deep learning architectures. SDAE is a symmetrical neural network, which is used for learning the features from dataset in unsupervised fashion [4]. Auto-encoder in SDAE is trained to reconstruct input that is clean "repaired" from the version that is corrupted. [5]. Chen et al. proposed a deep learning Model for phenotyping from Electronic Health Records and the model is predictive modeling of chronic
diseases. [6], Tran et al. proposed a computational framework to harness EHR with a type of deep neural network. Many deep learning models promise results in learning good representations in an unsupervised manner. This model performs supervised tasks, such as clinical risk prediction etc. On the contrary, in proposed paper Deep learning

models using classes, it can reconstruct more discriminative features by using supervised task. Thus in the proposed model a regularized SDAE for clinical risk prediction of ACS has been developed in our research.

2. Clinical risk prediction

Clinical risk prediction models are used in healthcare for variety of applications as described in[1] to [3]..[1]. Mostly they are targeted to identify patients with higher risk of ACS disease. With levels like high, average and low. [2]. A model called GRACE risk scoring model, is a popular and well-accepted risk scores of ACS disease which was developed to predict clinical risk score on an individual patient each.

[3]. However, models along with this line have been estimated using a small set of especially of patient features from highly-stratified cohorts. [4] Bayesian networks and fuzzy inference systems have been proposed to find the potential of EHR data for risk prediction.[5] Karaolis et al., used C4.5 decision tree algorithm to retrieve essential risk factors of heart events from Electronic Health Records.[6] Hybrid model was developed to identify risk factors of heart disease in patients. My proposed model will adapt dynamic treatment information in EHR data to improve the performance of prediction for ACS model. It, and help in the clinical prediction of coronary heart diseases, from a large volume of EHR data.

3. CHALLENGES

Machine learning techniques using deep learning methods is new technology. They require properly organize data sets to provide correct answers to the questions we shoot them. A business depending on machine learning application needs to give time, resources, and take risks. Artificial neural network can take millions of parameters. A training set usually consists of thousands of records.ANN is capable of remembering the training set and it also gives answers with 100 percent accuracy.

Though it is giving answers to many questions it may prove useless when new data is given. This problem is known as over fitting (or overtraining). This limits deep learning algorithms usage.

VI. PROPOSED FRAMEWORK

The proposed framework contains modules like Administrator, Clinician and Researcher. The Administrator role is to make registration that is to add or remove users. The Clinician's module role is to find risk factors related to acute coronary syndrome symptoms. Disease regarded information is collected from samples of various patients and it is stored in MongoDB database. Researcher module role is to provide the parameters for the analysis and it has to find risk levels basing on predictions by applying Softmax regression algorithm to the provided data. Process flow of proposed framework can be seen verified in the below diagram which is given in proposed framework.

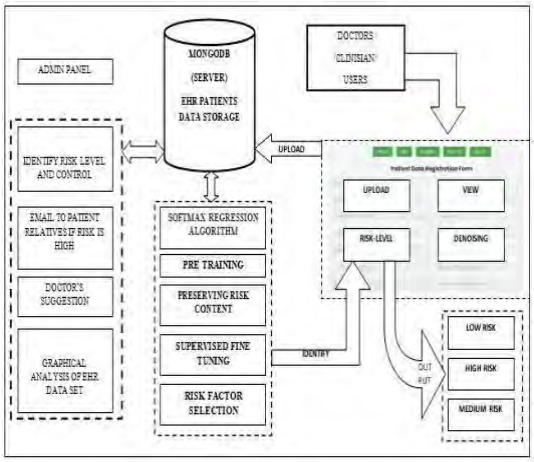

Figure No-1: System Architecture

Module Description

1. Pre training using SDAE

In this module we discuss the training and validation of ACS clinical risk prediction model by using our proposed approach. In SDAE model is a symmetrical neural network which is mainly used for learning all the features of a dataset by using techniques of unsupervised learning. So, as to build a deep learning architecture by using K hidden layers SDAE is trained using greedy layer-wise learning in unsupervised mode.

2. Preserving risk content into SDAE

SDAE has been used for classification problems the features reconstructed by SDAE are in unsupervised manner. While taking other side, risk information is contained in the training dataset. This dataset is included into learning so, as to make the reconstructed features that are beneficial for the future tasks of clinical risk prediction. We add two specific constraints like intra-risk-level affinity & inter-risk-level repulsion. These two constraints helps SDAE to preserve clinical risk information of training on patient samples. These two constraints

use the reconstructed feature representations of patients with the same risk level and also on different risk levels.

3. Supervised fine tuning

After the completion of pre training we added a Softmax regression layer. We placed it on the top of the reconstructed layer to construct a deep artificial neural network which is named as stacked denoising auto-encoder using Softmax regression model. RSDAE-S perform clinical risk prediction task. Here we fine tuned the RSDAE-SM using algorithm techniques of back propagation . This back propagation minimizes the cross entropy loss by taking help of Softmax regression layer.

4. Risk factor selection

In our proposed model risk factor selection strategy identify risk factors of ACS patients with different risk levels. We assume that patient features with less reconstruction errors are more re-constructible. Patient with more re-constructible features are likely to bear the below characteristics. When patient sample within a specific risk level there is small reconstruction error between the original and reconstructed data as it learn regularized SDAE model. We can also argue that different risk-level patient behave differently according to their risk factors, and produce a big reconstructed error. We expect a big reconstruction error in the discriminative learning. This happens as there is mismatch of input patient sample and the testing model used for implementation.

VII. ALGORITHM

Algorithum-1: Deep Learning Algorithms

Deep learning algorithms run its data using many "layers" of artificial neural network algorithms. Every layer passes its specified representation of the data to the other adjacent layers. All machine learning algorithms perform its tasks properly on datasets which have up to a few hundred columns or given features. However when taking an example of unstructured dataset,

like an image which include features that this process becomes completely unfeasible. An image with800-by-1000-pixel which supports RGB color has more than 2.4 million features. All these mentioned features are handled by several machine learning algorithms.

Algorithum-2:Support Vector Machine Algorithm

Support vector machine (SVM) is used to classify the patient in different categories. SVM is the algorithm that can assign two different problems like problem of classification and problem of regression. It is supervised learning algorithm. In this algorithm we have plotted each data item as a separate point in n dimension plane. Where n is the number of features, in our case we have taken twelve major features who are considered as cause of ACS.SVM areconsidering co-ordinates of individual observation from the report of patient. In our system we have considered three hyper planes to classify patient in three different categories. we have kept maximum possible distance in each hyperplane so that the category of each patient should get accurately classified. If we select less distance between two hyper planes then there is high chance of miss classification between the patient. Many methods are available for classification of data but our analysis shown that SVM is giving best accuracy i.e. more than 90% accuracy in classification.

VIII. SOFTWARE DETAILS

Used software and algorithms in this research are [1][2][3][4][5][6].[1].Operating System used in research is Windows -7. [2]. Application Server used in research is Tomcat Server 8.0 [3]. Front End details are JSP, Java. [4].Database that is used is MongoDB. Database Connectivity used is Robomongo-0.8.5-i386. MongoDB is used because, MongoDB uses its storage pattern in the

MongoDB provides redundancy and high availability. Data can be distributed across multiple servers. MongoDB is used for this research work as it is supporting NOSQL. It can deal with BIGDATA analytics. As the Electronic Health records are huge volumes of data and related with machine learning technique.[5] Javais used for front end design as the data is more secure and robust. Since GUI design is possible in java it is opted for my research work.

IX. EXPERIMENTAL DATA

Several experiments that were conducted to compare the performance of the proposed model by using "Start-of-the-art" methods on the clinical risk prediction task.

A. DIAGONOSIS OF ACS

The study sample consisted of more than 2000 patients admitted to the General Hospital with a diagnosis of ACS. ACS was said as symptoms of Ischemia along with positive cardiac enzymes, new

coronary Artery disease or previous existence of Cardiac Artery Disease. In an early stage of hospitalizations of ACS patients, we gathered the 1experimental dataset from admission patient's record sets of the EHR system as shown in figure -2

Figure No-2: Different field of EHR Data set Preprocessing was done on the datasets. Patient features mapped with binary values into 0 and 1. Feature "Gender" can be mapped as 0 assigned to "male"& 1 Assigned to "female". Patient's features with multiple categories were split into multiple categories of variables. Cardiac function is given 1, 11 and 111 level rating basing on severity. Patients Features were stacked into datasets with minimum and maximum value. Top 20 patients feature of ACS were recorded. Basing on high, low, medium patients risk levels of ACS records were stratified.

B. AUC

Accuracy is used as a method for the prediction performance. Medical data-sets when used the accuracy can be high, when classifying the Minority samples with that of majority sample class. Patients at low-risk levels are much greater when compared with that of high that of high-risk levels. Receiver operator characteristic curve (AUC) is used. The receiver operatorcharacteristic curve plots true positive rate against the false positive rate (specificity). A good method produces Higher AUC values for ACS risk prediction. A typical measure of prediction accuracy was plotted to find high-risk cases varied with the number of low risk patient cases in the sample.

C. Experimental Study

We have taken the generalized data set of 2000 patient record of all different fields. Every field of HER data set is very important for processing the records. Approval and suggestion was taken from cancer specialist doctors and institutional review department to carry this research work.

D. Comparison with state-of-the-art supervised learning algorithms

We compared the performance of the proposed RSDAE-SM model with the regular SDAE adding a softmax layer (SDAE-SM). We also

used five state-of-the-art classification algorithms, i.e., Support Vector Machine (SVM), Logistic Regression (LR), Random Forest (RF), Multi-layer perceptron neural networks (MLP), and naive Bayes (NB), as benchmark methods.

E. Informative risk factor selection

The proposed model is used to find informative risk factors from Electronic Health Data Records data. Top 10 risk factors for the patient group with same risk. Level were taken and confirm their validity with the clinical experts, patient features were divided into two classes 0 or 1 (saying patient case has this particular mentioned feature or not) in the model learning process. Creatinine, smoking status, etc validated inside the clinical cohort study. To apply this proposed model in clinical practice, we should consider the

simpler model implementation which investigates the simplicity and accuracy. Clinicians are interested to know risk factors that collect to obtain a predictive performance. We apply our risk factor selection strategy to find risk factors with regard to each risk level. We use top 20 in the union of these risk factors to proposed model for our ACS risk prediction model.

X. RESULT ANALYSIS

We have analysis this work on the basis of low, high, medium risk category. How many numberof patient in each category which shown in graphical format.

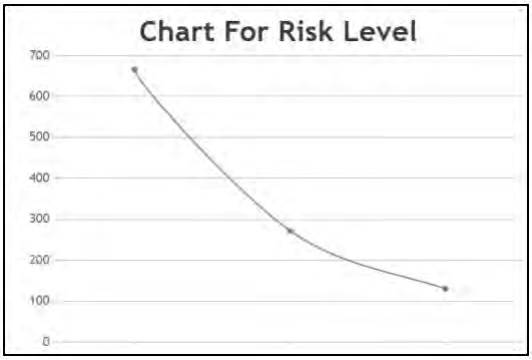

Figure No-3: Spline Chart Analysis

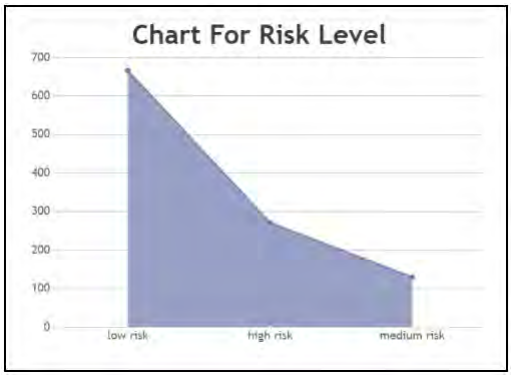

Figure No-4: Area Chart Analysis

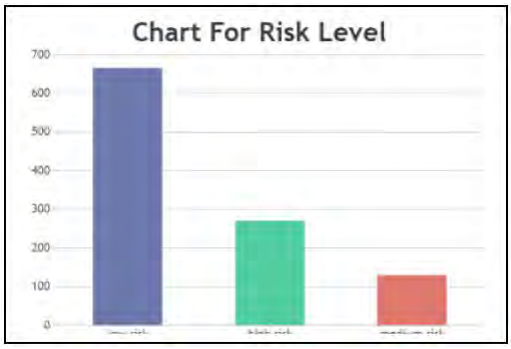

Figure No-5: Bar Chart Analysis

Above chart shows number of risk patients categorized in different risk levels. Depending upon the input values of patients different test records, system assigned various risk levels. Maximum patients who gets admitted as uneasy or restless feeling are coming in low risk category. Some patients who are not having any complaints initially, but their various test shown that they are at high risk and need to be treated quicky.

XI. CONCLUSIONS

This work proposes learning approach to discuss the clinical risk identification problem of ACS from Electronic Health Record data. [1].In Existing ACS risk methodologies relied on asmall set of known risk factors, in this proposed approach we are able to utilize a large volume of heterogeneous Electronic Health Records.[2]. Our Model is an accurate and robust clinical risk prediction model which gives the 90% accuracy to predict the level of cancer patients using the different data set. In this work we have used SVM algorithm which achieved the best result also our model directly informed to patient relatives for caring of patients if the risk is too high and they got good suggestion from expert doctors. The experiments in the research were conducted on a clinical dataset and the results shows that the proposed model is able to achieve good performance in clinical risk prediction, when compared with the algorithms like state-of-the-art classification algorithms.

Mumbai (M.S.)
saroj.shambharkar@gmail.com

Abstract. **The diagnosis of complex genetic diseases such as cancer, cardiovas-cular, respiratory diseases, human disease resistant genes(R-Genes) in Homo sapiens at early stage is a need is a challenging task in the today's biomedical and other research field. In this paper the analysis of gene expression dataset of is done and discussed. The gene expression dataset is considered because of it high dimensional data and gives more scope for analysis of diseases. The gene expression dataset E-GEOD-6575 using heatmap and tumor gene expression dataset using classification technique is analyzed. The classification of gene ex-pression dataset of 801 samples of RNA-seq tumor (cancer) is discussed. Each sample is associated with set of gene expression values. And based on these gene expression values the samples are distributed among the 5 different types of classes of tumors. The main objective of paper is to understand the gene ex-pression dataset of diseases and purpose of analyzing it. The change in gene ex-pression values considered as differentially Expressed Genes. The identification of differentially Expressed Genes will be helpful for good and poor prognosis of disease.**

Keywords: Classification, Differentially Expressed Genes, GEO dataset, gene expression, Heat map, National Centre for Biotechnology Information, NCBI.

I. INTRODUCTION

There are two technologies, microarray and RNA-seq technology used to generate the gene expression data. The paper objective is to understand the importance of anal-ysis of gene expression dataset. There are various techniques and methods used to visualize, interpret and understand the gene expression data. The objective behind the visualization, interpretation and understanding gene expression data is to get the knowledge about the condition of a human being. The analysis is helpful for the phy-sician for proper diagnosis of the disease.

The National Centre for Biotechnology Information, NCBI website provides us the gene expression dataset .The required gene expression datasets can be searched through Gene Expression Omnibus (GEO).From NCBI, the Gene Expression Omni-bus, GEO dataset E-GEOD-6575, gene expression dataset is a imported from NCBI. The domain experts have uploaded their data after conducting experiments on various diseases cases, and they are freely downloaded by the user. These dataset are authentic and regularly updated.

1.1 Gene Expression dataset

The gene expression tumor dataset downloaded from UCI Machine Learning Re-pository. This dataset consisting of 801 samples of 5 different types of tumor with 20531 attributes. These attributes associated with gene expression values. Before the analysis of gene expression dataset the dataset has to go through the preprocessing depending of dataset considered by us. The gene expression dataset sometimes may get affected by the certain environment conditions. And because of change in envi-ronment conditions the noise, missing values and inconsistency found in the dataset, such dataset requires the preprocessing.

As we mentioned, the analysis is performed on the datasets of tumor and E-GEOD-6575 of gene expression in blood of children with autism. The dataset of gene expres-sions fetch from the website National Centre for Biotechnology Information, NCBI and UCI is used. The gene expression dataset of cancer (tumor) and gene expression dataset with accession number E-GEOD-6575 is considered and studied. The paper focused on analysis of change in gene expression attribute values associated with each sample.

II. LITERATURE SURVEY

Earlier in past decades,linkage analysis was carried out for the purpose of identification of novel disease genes.The problem or disadvantage of linkage analysis is it is time consuming and expensive method.In the research papers it is mentioned the diagnosis of Autism Spectrum Disease is costly and time Consuming Process using linkage analysis,so to overcome this problems the machine learning approach can be used.In the literature the authors used a Random Forest Classifier ,and they achieved

80% accuracy for predicting new Autism Spectrum Disorder(ASD) genes and their results are better than previous work.In this paper for identification of biological markers the machine learning methods were used,and they used Gene Ontology to improve the identification of biological markers in complex diseases like ASD.The training performed by machine learning classifier done using Gene Ontology.And performance can further be improved by incoorporating functional similarities.There are algorithms like Random Walk Restart(RWR) which are widely used for prediction of disease genes.The gene expression helps the physician to know the disease transition in human body due to change in Gene expression profile.

In paper "Prediction of gene function by genome-Scale Expression Analysis: Prostate cancer-Associated genes" the authors objective was identifying the diseases associated with genes and discovered for cancer using the Guilt By Association method. In this paper they worked on the expression pattern consist of 40,000 human genes taken from 522 cDNA libraries.From the survey papers it is understood that the disease similarity network can be extracted from a disease similarity matrix,using text mining techniques performed by taking OMIM records**.**But the accuracy of this approach is less and it is improved if the we use phenotype ontology Database and also improves prediction performance.

The network of protein–protein interactions also help and provides us the valuable insights into the inner workings of cells. Accordingly, it is crucially important to develop an automated method or high-throughput tool that can efficiently predict the PPIs. The authors of paper has introduced a predictor, called iPPI-PseAAC(CGR), was developed by incorporating the information of "chaos game representation" into the PseAAC (Pseudo Amino Acid Composition). The predictor has used the machine learning algorithm ,Random forest.

The advantage of this predictor mentioned by them is the key sequence-order or sequence-pattern information obtained can be more effectively incorporated during the treatment of the protein pair samples. It has been observed by them using the cross-validations applied on their datasets given the remarkably higher success rate than the existing.

The following challenges identified after going through literature survey and study:

(i) In post-genomic scenario, the challenge is to identify and predict "disease genes" from the large amount of genetic related information

(ii) Identify biological marker from complex diseases is difficult as these diseases presents highly heterogeneous genotype

(iii) Identify and predict human disease Resistant-genes from large genomic data

(iv) Identify and predict disease and non-disease genes from genomic dataset or

predict true disease genes and essential genes from genetic dataset.To solve the above mentioned challenges there is a need of some techniques,computational methods,approaches or tools.The question comes from the study for complex diseases how we can analyze and identify the gene expressoins are changed or not.And what is the purpose of analyzing gene expression datasets.From the literature it is observed that the researchers employed varoius techniques to study and analyze the genes related information,some of them used machine learning approach and deep learning approaches and concluded they are effective, powerful computational technique to understand and analyze the genomic datasets.

2.1 Visualization and Interpretation of Gene Expression dataset

The gene expression dataset E-GEOD-6575 is analyzed using heat map which is combined with clustering. The most common method to visualize the gene expression dataset is heatmap. The heat map is a grid like structure containing rows and columns, the rows indicating genes and columns indicating samples. The color and intensity of each grid indicates the state of gene expression. From the color and intensity we can analyze that there is change in gene expression.

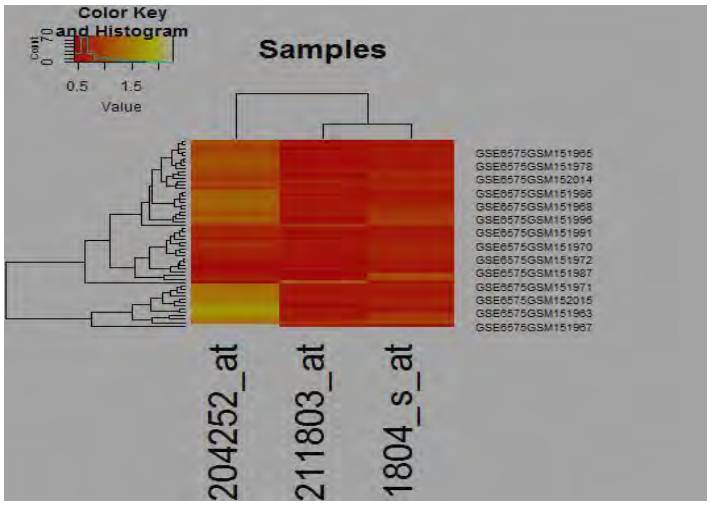

Fig.1. A figure showing the visualization of gene expression dataset GEOD-6575 using heat map

The heat map of E-GEOD-6575 gene expression dataset is obtained using R-programming shown in the figure. The heatmap shown is containing the group of gene expressions patterns based on the similarity. Therefore the most similar gene expression patterns were grouped together.

The figure 1 showing values using different colors in each sample. The colors yel-low and red used to analyze the attribute values of E-GEOD-6575 gene expression. In the fig 1 there are 3 samples (represented using 3 columns) containing probe sets 204252_at, 211803_at, 1804_s_at as attributes or considered as samples. The rows of heatmap consist of gene expression values of genomic series GSE6575 dataset. In middle column (sample specified by probe set 211803_at) we can observe the similar-ity is more and they used same color. There is less change in gene expression values more are in red color and less values in yellow colors. It means less change in gene expression values in middle sample. But if we observe the sample specified by probe set 204252_at and 1804_s_at, there is more variation in values for same set of values (values specified by rows) and less variation in sample 1804_s_at as compared to 204252_at.If the change in expression values is more we conclude them as differen-tially expressed. So, among 3 samples we conclude more changes or differentially expressed genes in first leftmost sample (204252_at).

In this way heatmap are giving good visualization and analysis of values stored E-GEOD-6575 gene expression dataset.

2.2 Classification of RNA Seq. Gene Expression Dataset of cancer

The Gene expression dataset for cancer RNA-Seq dataset is fetched from the UCI repository (Machine Learning).The the size of the dataset is 201.354 MB. The 801 samples were taken and each sample containing the change in gene expression value. Each sample consists of numerical values of gene expressions. There are total 20531 attributes from gene_0 to gene_20530. This dataset also giving us different way to analyze the classification of each sample based on values of associated with each sample.

The figure 2 is showing the classification of 801 patient samples RNA-Seq PANCAN dataset. The dataset referred by us is used by the authors Weintenstein, John N. et al. in their paper 'The cancer genome atlas pan-cancer project 'published in Nature genetics 45.10 (2013).

The patients are classified into 5 classes of different types of tumors. The patient is classified into different categories of tumors and found more cases under category of BRCA in the dataset of 801 samples of tumor patients. The classification tells us the 801 samples containing 300 patients suffered from BRCA, 146 with KIRC, 141 of LAUD, 136 with PRAD and only 78 with COAD tumor. This helps a physician to analyze the patients with BRCA tumor, what makes changes in gene expression and how it can be reduced. From the samples of 801 patients we conclude from the classi-fication more changes in gene expression values in samples of BRCA and conclude more differentially expressed genes in it.

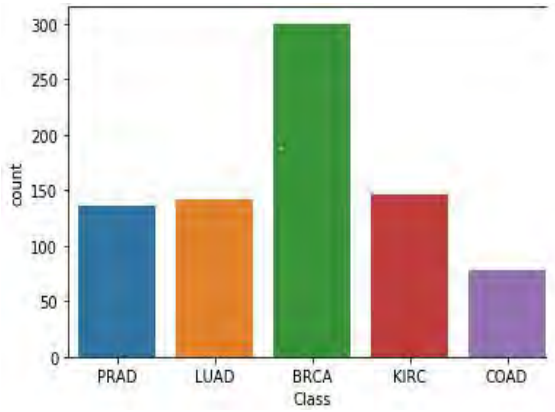

Fig.2. A figure showing the classification of RNA-seq gene expression dataset of cancer.

This classification done for the patients whose changed expression values changed and the change in gene expression shows the patients are suffered by cancer. From the classification results we say the gene expression dataset analysis gives us proper deci-sion on the available sample of a patient.

III. CONCLUSION AND FUTURE WORK

In this paper the main focus is on understanding the gene expression dataset and change in values of gene expression. And change in gene expression makes them differentially expressed. It is studied from the literature too that the identification of differentially expressed genes will help in analyzing the state of a patient.

The analysis of gene expression dataset, we can identify the differentially ex-pressed genes. From the literature also it has been observed that the identification of the differentially expressed genes requires the comparison of gene expression levels or read counts at different conditions of an organism say human. The difference be-tween gene expression level at normal condition and abnormal condition has to be calculated to diagnose the disease. If the difference is found then we conclude the gene expression levels have been changed and the patient condition is not normal. In future work we will work out the analysis of gene expression dataset using different Machine Learning algorithms to identify differentially expressed genes. The analysis can also be done using python programming language on gene expression dataset of diseases to identify differentially expressed genes.

Review Paper on E-Commerce and Recommendation System

Dr. Nita Thakre,Vedant Santoshwar,Aditya Upadhye,Prashant Roy,Aakash Shende, Pratik Paraye
Department of Computer Technology
Priyadarshini College of Engineering, Nagpur
bfbiznet@gmail.com, bfbiznet@gmail.com, bfbiznet@gmail.com

Abstarct **- In today's world, AI is getting better and better in predicting people's behaviour more efficiently and accurately. E-commerce is no exception. Right from finding the shortest path possible to deliver the product, to providing more relatable suggestions to the user, AI is integral to e-commerce business model. Recommendation system of the e- commerce websites/applications is the best example of AI at work. Recommendation system processes the user data and provides the results that the user is searching for. It has made the search engine of the e-commerce websites/applications more powerful and to the point, filtering out the results that the user may not be interested in.**

Keywords - BFBiz.net,E-commerce, website, Online shopping within the city, Delivery, Electronic

I. INTRODUCTION

E-commerce is all about selling and buying of goods and services over the internet. Before e-commerce, it was done without internet physically in the markets but after the arrival of e-commerce in India our life has become more comfortable because of its number of advantages. The services offered by e-commerce are online shopping of anything 24x7 and at any place, customers can find the products on e-commerce websites which is not available in physical markets, it reduces cost and time, without stepping out of home we can get our product at home. But, due to e-commerce the revenue generated by local vendors is decreasing day by day. People prefer to the offers provided by the online stores to save money by comparing different stores. The latest report says that India has approximately $16.8 billion Mobile Commerce market size and mobile commerce is set to become the primary way to shop online in India. It is already used for 46% of transactions, one of the highest rates in our report series. Mobile commerce will expand at a compound annual growth rate of 31.2%, to reach a value of $49.8 billion by 2021. To deal with the problems of local stores we are making an E-commerce website “BFBiz.net” where the required products will be shown from the nearest store within the city from the user’s location by comparing the prices of different stores within the selected distance. This will make the goods sell and the delivery can be done very fast within the same day.

II. LITERATURE SURVEY

The concept of recommendation systems emerged in mid- 90s. In past 15 years there has been a tremendous boom in the development of recommendation sites. The people using the recommendation systems is increasing exponentially making it crucial for these systems to generate recommendations that are close to the items of user’s interest. Micheal Pazzani [1] proposes recommending data sources for news articles or web sites after learning the taste of the user by learning his profile data. This paper mentions information that can be considered to learn the profile of a user. Based on ratings given by a user to different sites, ratings that other users have given to those sites and demographic information about users the recommendations can be made. This paper describes how all the processed information
can be combined to provide recommendations to the users.

Balabanovic, M. and Shoham[2] discuss that 'personalized recommendation systems' are widely used in e-commerce websites to provide users with recommendations. It suggests that Hybrid approach is the best possible way for recommendation to user rather than using only content-based filtering or only collaborative based filtering.

Satya Prakash Sahu, Anand Nautiyal, Mahendra Prasad [3] presented a best possible precision and have presented a comprehensive comparative analysis by selecting Content Based Filtering, Collaborative Based Filtering, Hybrid Content-Collaborative Based Filtering, k- mean clustering and Naive Bayes classifier among various machine learning techniques which can be used to conclude the recommendation system.

III. PROS & CONS

- Highly relevant: As the system uses the preferences of the user, it is able to show only the relevant data which the user may may find interesting. It is very helpful in narrowing down the search results for that user.

- Transparency: Transparency is another important aspect of Content- Based filtering. As the user can know the reasons for which the products are recommended, it makes the system more trustworthy. As oppose to the Collaborative-Based filtering in which products are recommended by preference of other users. The process of recommending the products is open to the user.

- User Friendly: While the system waits for some initial inputs, it is relatively faster in recommending the items. Gradually over the time, after hundreds or thousands of search results it recommends the products more precisely and accurately to the user.

- New items can be recommended more quickly: In Collaborative-Based filtering new items may not be recommended immediately as the users may not have look for that item. As oppose to this, in Content-Based filtering items can be recommended more quickly. Content-Based filtering does not require the users to interact with the object in order to recommend them as it is based on individual preferences.

IV. PROPOSED SYSTEMPHP, SQL, Bootstrap, HTML, CSS, JavaScript, jQuery, Ajax, Machine Learning

–Proposed Methodology

In this the user will be shown the products from its nearest locations within the same city. The products will be recommended according to the search history of the user. The products will be given discounts by the seller on his personal choice based on profits of both seller and customer. Here are languages that we have used and underlying reasons:

- PHP – Open Source, ML libraries easily available also it is probably the most widely adopted programming language. It's a highly scalable, functional, and object oriented language.

- SQL – Communication with Database, SQL is a lightweight, declarative language that does a lot of heavy lifting for the relational database, acting like a database's version of a server-side script. One particular advantage of SQL is its simple-yet-powerful JOIN clause, which allows developers to retrieve related data stored across multiple tables with a single command.

- Bootstrap – Lightweight and customizable. Responsive structures and styles hence we have mobile ready website

- HTML – For document design and display on web page

- CSS – for Designing Web pages and make them user friendly

- JavaScript/jQuery – for Client-side interaction that works on almost every web browser. It also makes websites launch super-fast and provides the end users with enhanced user experience (UX).

- Machine Learning – It is used for recommending products to the users based on their search history and one's interest.

- Ajax- It is used to create dynamic webpages where only part of whole web page is updated, if needed, without reloading entire webpage.

V. CONCLUSION

The other recommendation systems use historic data of the current user and user data of other users with same preferences, while our current system requires less historic data and operates on real time using the inputs of current user. The delivery system is also faster, as it delivers the package within few hours.

VI. FUTURE PLAN

To implement the system in different cities of India for the facilitation of the local shops and to enhance the delivery system using Honeycomb Structure where each cell will represent an area and will have its own delivery person to hand over the parcel to another cell to reach the final destination.

Deep Learning Techniques for Detecting Deepfake: A Review

Abstract: **Deepfake algorithms can make forged pictures and videos that people can't differentiate them from true ones. The suggestion of technology that locate and prove the truth of virtual visual media is as a result essential. This paper offers a survey of tools and algorithms used to make deepfakes and, additional significantly, methods to locate deepfakes. We present large discussions on challenges, studies developments and guidelines related to deepfake technologies. By reviewing the history of deepfakes and cutting-edge deepfake detection strategies, this gives a comprehensive assessment of deepfake techniques and helps the development of latest and more robust strategies to deal with an increasing number of tough deepfakes.**

Keywords: deepfakes, deep learning, autoencoders, genereative adversarial networks (GAN).

I. INTRODUCTION

Deepfake (stemming from "deep learning" and "fake") is a technology which creates fake images or videos of targeted humans by swapping their faces another character saying or doing things that aren't absolutely done by them and humans start believing in such fake, as it isn't always recognizable with the everyday human eye. Deep learning models such as autoencoders and generative adversarial networks have been applied widely in the computer graphics vision to solve various issues [1,2]. These models have been used by deepfake algorithms to examine facial languages and actions of a person and synthesize facial images of another person making equivalent expressions and movements [3]. Deepfake algorithms usually require a large dataset to train models to make realistic images and videos. As public figures such as legislator or celebrities may have a large number of videos and images available online, they are probable targets of deepfake. Deepfakes were used to superimpose faces of legislator or celebrities to bodies in porn images and videos.

The first deepfake video found in 2017 where face of a celebrity was superimposed to that of a porn actor. It is threat to world security when deepfake procedures can be employed to make videos of world leaders with forged speeches for false purposes. Deepfakes therefore can be abused to cause political or religious misunderstanding between countries, to fool public and affect results in election campaigns, or create confusion in financial

markets by creating fake news. It can be even used to

create forged satellite broadcasting images of the Earth to hold items that do not really exist to create chaos in military**.**

There is also advantages of deepfakes such as creating voices of those who have lost theirs voice or updating episodes of web series without reshooting them . However, the number of venomous uses of deepfakes largely dominates that of the positive ones. The growth of advanced deep learning networks and the accessibility of big amount of data have completed the forged images and videos almost unique to people and even to algorithms. The method of creating those forged images and videos is also much easy today as it wants as little as a self-photo or a small video of a targeted individual. Less effort is required to produce an impressively substantial tempered footage. Recent advances can even create a deepfake with just a motionless image. Deepfakes therefore can be a threat affecting not only community figures but also ordinary people.

Finding the fact in digital domain therefore has become gradually critical. It is even more interesting when dealing with deepfakes as they are majorly used to help venomous drives and almost anyone can create deepfakes these days used with present deepfake tools.

Therefore, here have been abundant methods proposed to detect deepfakes. Most of them are also based on deep learning, and thus a battle between malicious and optimistic uses of deep learning methods has been rising.

In Section 2, we present the ideologies of deepfake algorithms and how deep learning has been used to enable such riotous technologies. Section 3 reviews different methods for detecting deepfakes as well as their advantages and disadvantages. We discuss challenges, investigation movements and directions on deepfake recognition as well as interactive program and forensics issues along with research gap in Section 4. Section 5 concludes the paper.

II. DEEPFAKE CREATION

Deepfakes have become popular due to the quality of tampered videos and the easy-to-use skill of their applications to a wide range of users with various computer skills from expert to beginner. These applications are typically developed based on deep learning practices. Deep learning is well known for its ability of instead of complicated and high dimensional data. The first attempt of deepfake creation was Fake App, developed by a Reddit user using autoencoder-decoder blending structure. In that method, the autoencoder extracts hidden features of face images and the decoder is used to reconstruct the face images. To swap faces between source images and target images, there is a need of two encoder decoder sets where each pair is used to

train on an image set, and the encoder's parameters are joint sandwiched between two network sets.

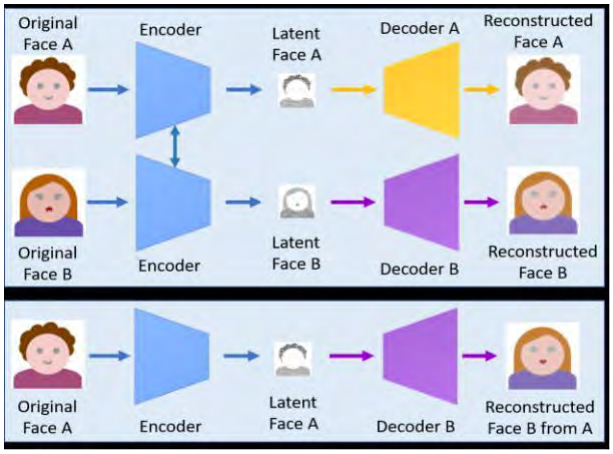

Fig. 1: A deepfake creation model.

This approach enables the common encoder to find and learn the comparison between two sets of face images, which are comparatively unchallenging because faces normally have similar structures such as eyes, nose, mouth places. Fig. 1 demonstrations a deepfake making procedure where the feature set of face A is linked with the decoder B to rebuild face B from the original face A. Table 1 shows some tools for deepfake creation along with its algorithm used and key features

Table 1: Summary of notable deepfake tools

Tools	Algorithm used	Key features,
DFaker	GAN with DSSIM	Reconstruction of face is done by DSSIM loss function. Keras library-based implementation
Faceswap-GAN	GAN v2.2 with MTCNN	the auto-encoder architecture is provided with adversarial loss and perceptual loss (VGGface) are added to.
Faceswap	GAN with MTCNN and DFL-H128	Parameters of the encoder are shared and pairs of encoder-decoder.
DeepFaceLab	GAN-er with MTS3FD	Expand from the Faceswap model with new models, Uses multiple face
DeepFake-tf	GAN with DSSIM	Like DFaker but tensor-flow is used for implementation.

This segment gives a review of deepfake detection methods where we categorize them into two major classes: fake image detection approaches and fake video detection approaches as shown in Fig. 2. The latter is distinguished further: visual artifacts within video frame-based methods and temporal features across frames- based ones. Whereas most of the approaches based on temporal features use deep learning recurrent classification models, the methods use visual artifacts within video frame can be executed by either deep or shallow classifiers.

III. DEEPFAKE DETECTION

Deepfake finding is normally deemed a binary arrangement problem where classifiers are used between reliable videos and interfered ones. This kind of method requires a large database of real and fake videos to train classification models. The number of fake videos is progressively available, but it is still limited in terms of setting a level for validating many discovery methods.

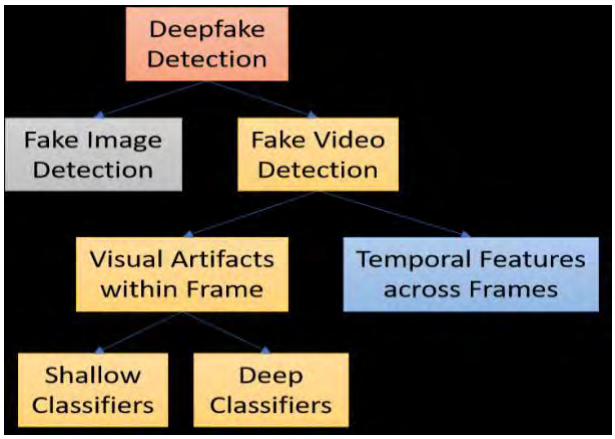

Fig. 2: Classification of deepfake detection.

.

To report this matter, Korshunov and Marcel [6] produced a distinguished deepfake data set containing of 598 videos based on the GAN with the open source code Face swap-GAN. Videos from the openly available VidTIMIT database were used to produce low and high quality deepfake videos, which can efficiently emit the facial features, mouth actions, and eye blinking. These are then used to test various deepfakes. Test outcomes show that the general face recognition systems supported VGG and Facenet [6] are incapable to detect deepfakes successfully. Additional approaches such as lip-syncing and image quality metrics with SVM makes very high error rate when allied to detect deepfake videos from this newly shaped dataset. This increases fears about the serious need of upcoming development of more strong systems that can detect deepfakes from the original.

3.1 Fake Image Detection

Face swap has a few convincing applications in video compositing, transformation in portraits, and specially in individuality safety as it can swap faces in photos by ones from a group of typical images. However, it is one of the approaches that fake attackers enter authentication structures to gain access. The usage of deep learning such as CNN, GAN, SVM, Random forest and multi-layer perceptron has exchanged face images more challenging for forensics as it can reserve pose, facial appearance and light of the photos. Among deep learning produced images, those produced by GAN are possibly most tough to notice as they are genuine and good quality based on GAN's ability to learn supply of the input data and gives novel outcomes with same input distribution.

Maximum works on recognition of GAN produced images do not consider the capability of the recognition models although the development of GAN is continuing, and
several new extensions of GAN are often introduced. Xuan et al. [7] used an image preprocessing phase. This rises the pixel level statistical comparison between actual image and false image and needs the forensic classifier to study additional essential and meaningful features, which has better simplification competence than preceding image forensics methods or image stag analysis networks.
Additionally, Agarwal and Varshney [8] company the GAN-based deepfake recognition as a hypothesis challenging issue where a statistical outline was presented by means of the information theoretical study of verification. The least distance among deliveries of genuine images and images produced by a specific GAN is defined, explicitly the vision fault. The logical outcomes demonstrate that this distance rises when the GAN is fewer correct, and in this situation, it is easier to distinguish deepfakes. In case of high-resolution image, a very accurate GAN is required to produce fake images that remain tough to detect.

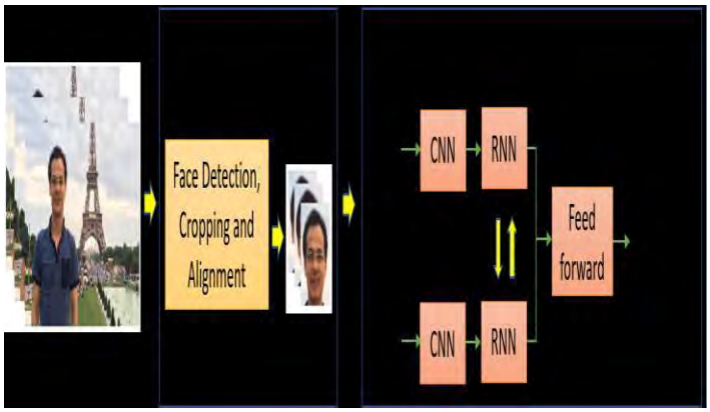

Fig. 3: A two-step process for face manipulation detection.

3.2 Fake Video Detection

Maximum image based deepfake recognition approaches cannot be used for videos because of the robust deprivation of the frame data after audiovisual compression. Also, videos have chronological features that are diverse amongst sets of frames and thus challenging for approaches intended to sense individual fake images. This subcategory emphases on deepfake video recognition approaches and classifies them into two clusters: approaches that uses chronological features and those that explore visual artifacts inside frames.

3.2.1 Temporal Features across Video Frames Based on the opinion that temporal coherence is not imposed efficiently in the procedure of deepfakes, Sabir et al. [10] use of spatio-temporal features of audiovisual streams to sense deepfakes. Video manipulates to carry out on a frame-by-frame basis so that low level objects formed by face manipulations are supposed to further clear themselves as temporal artifacts with irregularities among frames.

A recurrent convolutional model (RCN) was projected based on the combination of the convolutional
network Dense Net and the gated recurrent unit cells to exploit temporal inconsistencies across frames see Fig. 3. The proposed technique is verified on the Face Forensics++ data set, which contains 1,000 videos , and displays promising outcomes.
Guera and Delp [11] detailed that deepfake videos comprise intra-frame conflicts and temporal conflicts among frames. Then they proposed the temporal-aware pipeline technique that uses CNN and long short term memory (LSTM) to detect deepfake videos. CNN is employed to extract frame- level features, which are then fed into the LSTM to create a temporal sequence descriptor.
A fully-connected network is used afterwards for classifying doctored videos from real ones based on the sequence descriptor (Fig. 4).

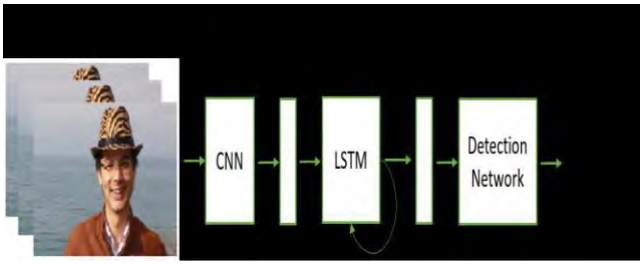

Fig. 4: A deepfake detection using CNN and LSTM.

Similarly, the use of a physical signal, eye blinking, to notice deepfakes was planned in [9] based on the opinion that a individual in deepfakes has a lot fewer frequent blinking than that in original video. A fit adult human would usually blink somewhere between 2 to 10 seconds, and every open and close the eye would take 0.1 to 0.4 seconds. Deepfake procedures, however, frequently use face images existing online for training, which usually demonstrate persons with open eyes. Therefore, without blinking images of persons, deepfake algorithms do not have the ability to produce fake faces that can blink typically. To distinguish actual and false videos, Li et al.
[9] initially decompose the videos into frames where face areas and then eye region are mined based on six eye signs. After some stages of pre-processing such as aligning faces, extraction and scaling the bounding boxes of eye sign points to generate new arrangements of frames, these cropped eye area arrangements are distributed into long-term recurrent convolutional networks (LRCN) for dynamic state prediction. The LRCN contains of a feature extractor built on CNN, a sequence learning built on long short-term memory (LSTM), and a state prediction built on a fully connected layer to forecast probability of eye open and close state. The eye blinking illustrates robust temporal dependencies and therefore the application of LSTM helps to capture these time-based patterns efficiently. The blinking rate is calculated built on the predicted outcomes where a blink is defined as a highest above the threshold of 0.5 with interval less than 7 frames. This technique is assessed on a dataset collected from the internet containing of 49 videos and their matching fake videos produced by the deepfake algorithms.

3.2.2 Visual Artifacts within Video Frame

As observed in the preceding subsection, the approaches using temporal patterns across video frames are typically based on deep recurrent network models to sense deepfake videos. This subsection inspects the additional

method that usually decomposes videos into frames and explores visual artifacts within single frames to get distinguished features. These features are then dispersed into either a deep or shallow classifier to discriminate between false and true videos. We thus assemble approaches in this subsection based on the categories of classifiers, i.e. either deep shallow.

3.2.2.1 Deep classifiers

Deepfake videos are usually formed with few resolutions, which need a face warping method (i.e., rotation and shear) to matches the original ones. Because of the resolution contradiction between the warped face part and the nearby context, this procedure leaves objects that can be noticed by CNN methods such as VGG16, ResNet50, ResNet101 and ResNet152. A deep learning technique to spot deepfakes based on the objects observed throughout the face warping step of the deepfake generation algorithms was proposed in [12]. The proposed structure is assessed on two deepfake datasets, i.e. the UADFV and Deepfake TIMIT. The UADFV dataset [15] contains 49 actual videos and 49 forged videos with 32752 frames in total. The Deepfake TIMIT dataset contains bad quality videos of size 64*64 and another good quality videos of 128 x 128 with 10537 unique images and 34,023 forged images mined from 320 videos for each set. Performance of this technique is associated with other predominant approaches such as the face tampering recognition technique two-stream NN, Head Pose [15], and two deepfake recognition MesoNet methods, i.e. Meso-4 and MesoInception-4 [13]. Advantage of the proposed technique is that it need not to produce deepfake videos as forged examples before training the detection methods. As an alternative, the false examples are produced dynamically by mining the face area of the unique image and aligning it into several scales before applying Gaussian blur to a scaled image of chance choice and warping back to the unique image. This decreases a huge time and computational resources associated to other approaches, which need deepfakes are produced in advance. Recently, Nguyen et al. [14] proposed the usage of capsule networks for distinguishing doctored images and videos. The deepfake face swap dataset created by Afchar et al. [13].

IV. RESEARCH ISSUES

Deepfakes are gradually damaging to confidentiality, society safety and democracy. Diverse approaches for detecting deepfakes are proposed by many researchers as soon as this menace was familiarized. Initial efforts were based on handcrafted features gained from objects and irregularities of the fake video synthesis procedure. Current methods, additionally, uses deep learning to automatically mine prominent and discriminative features to spot deepfakes. Using recognition approaches to spot deepfakes is critical but considering the actual intent of persons reproducing deepfakes is even more important. This needs the decision of users built on social context in which deepfake is revealed. This is serious as deepfakes are getting more photorealistic and it is extremely projected that recognition software will be lagging behind deepfake creation techniques.

4.1 Limitations of Existing system

In the technique where the recognition is done by eye blinking technique [9] the dataset used was very small thus system accuracy will be reduced. The experimental outcomes show great performance of the planned technique in detecting false videos, which can be further enhanced by seeing dynamic pattern of blinking. Detection is done by frame by frame basis so there might be chances of inconsistency [10]. RNN gives better result than CNN [11][12][13].

4.2 Effects of Deepfake

Misinformation: Folks are more probable to have a response to misinformation in the form of forged image, audio, and video content, which allows the doctored media to spread more rapidly than purely written fake data. Additional, images and video have been recommended to generate a Mandela effect, the formation of memories that never happened.

Exhaustion of serious thinking: It will take more effort for people to determine whether data is true, specially when it does not originate from reliable actors. Uncertainty around content reliability might also put off an distinct from sharing correct content, dropping the distribution of true information.

The deceiver's dividend: The presence of entirely artificial content offers an avenue for actors to deflect charges of impropriety based on footages and video, by appealing the source material has been faked.

These results are troubling and will be most persistent in the future, as deepfake excellence increases and social alertness lags

V. CONCLUSION

Deepfakes have started to wear down trust of people in media contents as seeing them is no longer corresponding with believing in them. This is critical nowadays as the technologies for creating deepfakes are progressively approachable and social media platforms can spread those fake contents rapidly. This paper has revised the state-of-the-art methods and a summary of typical approaches are provided. It is noticeable that a fight between those who use progressive machine learning to create deepfakes with those who make effort to detect deepfakes is rising. Deepfakes' good quality has been increasing and the

performance of discovery methods needs to be enhanced consequently. Detection methods are still in their early stage and various methods have been suggested and evaluated but using fragmented data sets. An approach to progress performance of detection methods is to create a rising updated standard data set of deepfakes to authorize the ongoing development of discovery methods. This will simplify the training process of discovery models, particularly those based on deep learning, which involves a large training set. The current detection methods mostly focus on disadvantages of the deepfake generation pipelines, i.e. finding weakness of the participants to attack them. This kind of information and knowledge is not always available in adversarial surroundings where attackers usually attempt not to reveal such deepfake creation technologies. This is a real challenge for detection method development and a future research needs to focus on introducing more robust, scalable and generalizable methods.

harshalidesai28@gmail.com, anand.khandare1983@gmail.com

Abstract- **Clustering is an unsupervised learning technique in which similar datapoints are grouped together into groups called clusters. Each cluster contain datapoints that are similar to each other and dissimilar to datapoints in other groups. Clustering is achieved by various algorithms like K-means, DBSCAN, PAM, Hierarchical clustering etc. Every algorithm has its own drawbacks which has to be overcome. The most common drawback of algorithms is that they do not work well for large datasets. Accuracy of algorithms is degraded for large datasets. Also, this type of dataset increases processing time of algorithm. This paper compared different clustering algorithms on various standard datasets and analyzed their performance with respect to various performance parameters such as time complexity, accuracy and various cluster quality measures. From this analysis it is found that there is a scope to enhance the performance of these algorithms.**

Keywords- clustering, quality measures, performance parameters,accuracy

I. LITERATURE REVIEW

Clustering algorithm uses distance metric or similarity metric in order to compute similarity between the datapoints. Choosing any appropriate clustering algorithm totally depends on the type of application or datasets we are working with. It is very easy and efficient to work with numerical dataset. But when it comes with working with the other datasets like categorical, time series data it becomes very difficult to handle problems with these datasets.[1]

When a cluster belongs to an only single and distinct cluster then such clustering is called hard clustering, whereas a cluster belonging to different cluster is called soft clustering.

The author(s) have highlighted various merits and demerits of K-means, KNN clustering algorithm. Number of the clusters to be formed is the major factor while selecting correct clustering algorithm.[2]

Clustering is also referred as cluster analysis. The author aims to give basic understanding of clustering by explaining the type of clusters and various clustering methods. In well separated clusters the dissimilar datapoints lies far away from each other.[3] In clustering technique large dataset is divided into small groups called as clusters. In other words, clusters are group of similar data. These clusters have following properties:

- Each cluster is homogeneous, which states that the datapoints in same cluster are similar to each other.
- Every cluster must be different from every other clusters, which states that the datapoints in different clusters are dissimilar to each other.[4]

K-Means algorithm is one of the simplest and most widely used partitioning based clustering algorithm. The goal of K-mean algorithm is to partition datapoints into ‘k’ clusters based on their similarities. The similarity between the datapoints is calculated with help the of random or mean value called cluster centroid. In most of the cases Euclidean distance is used as dissimilarity measures for k-means algorithm. Calculating the similarity between clusters is dependent on the implementation of the model. All the clustering algorithm has its own measures to calculate the similarity or dissimilarity.

The major drawback of K-Means is prediction of accurate ‘k’ value, as different ‘k’ gives different clusters. DBSCAN algorithm is used to discover clusters of arbitrary shape, unlike K-means which discovers spherical clusters. Also, DBSCAN algorithm does not require number of clusters as initial parameter.[5]

Weka tool is an open source software which is a collection of machine learning algorithms mainly used for data mining tasks. The author(s) has compared the clustering algorithms namely K-means, Density based algorithm, Hierarchical algorithm using Weka tool in terms of efficiency and accuracy. K-Means algorithm yields more accuracy and consumes less time with comparison to Hierarchical, Density clustering algorithm.[6]

II. INTRODUCTION

In machine learning, the learning is divided into mainly 3 categories- Supervised, Unsupervised and Reinforcement. In supervised the machine or model will be trained using labelled data (i.e. data

which is already tagged with correct output). But in case of unsupervised learning the model is not trained usinglabelled data. The model in such scenario have to find the hidden patterns or structures or groups from input data based on similarity. One such technique of unsupervised learning is clustering.

Clustering is a process of dividing the datapoints or population into groups of similar datapoints. So, the output of clustering will be groups having datapoints which are similar to the datapoints in the same group and are dissimilar to the datapoints of other groups.

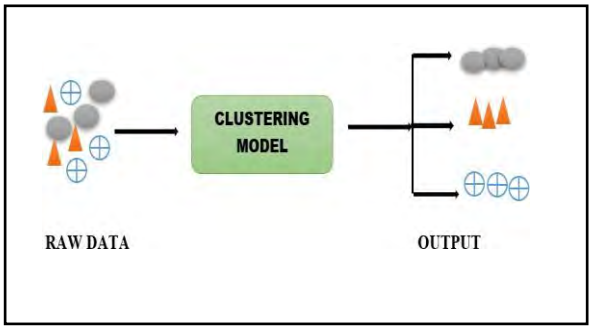

Figure 1. Overview of Clustering process.

The Figure 1. depicts the working of clustering process. In above figure, the raw data is passed as an input to the clustering algorithm or model and the resultant clusters are formed based on the similarity between the objects or datapoints.

There are various clustering algorithms. In this paper, we have studied and analysed five most common clustering algorithms
– Hierarchical, K-means, PAM, Mini batch K-means, DBSCAN.

1. K-Means

K-means algorithm is a type of unsupervised partitioning based clustering algorithm. The goal of this algorithm is to divide the datapoint into 'k' clusters using centroid. The k-means clustering algorithm assigns datapoints to the cluster by finding the minimum distance between the datapoints and centroids. It then iterates through this technique in order to perform more accurate clustering over a time.

In this method the minimum distance between datapoint and centroid are calculated by Euclidean distance formula.

Euclidean distance formula is given by:

$$\text{Distance}(p, q) = \text{Sqrt}\left(\sum (qi - pi)2\right).$$

Algorithm for K-means is as follows:

Step 1. Randomly Select 'k' centroids C1 to Cn.
Step 2. Calculate distance between each data point and centroid using Euclidean distance formula.
Step 3. Assign datapoint to the respective cluster having minimum distance.
Step 4. Recalculate the new centroids.
Step 5. Repeat Step (2) to (4) till same clusters are obtained.

After applying K-means on iris dataset for sepal length and sepal width the resultant three clusters formed are represented below and the black dot represents the centroids.

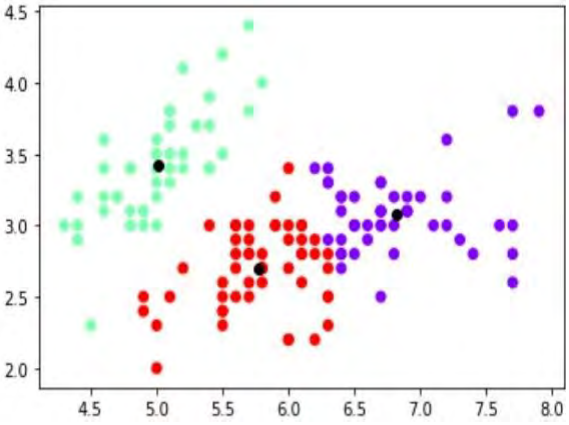

Figure 2. K-Means clusters for Iris dataset

Advantages:

1) When centroids are recalculated object can change the cluster i.e. can move into another cluster.
2) Only work well for spherical clusters.
3) It is very easily implemented for numeric datasets.
4) Tighter clusters are produced.

Disadvantages:

1) Difficult to predict initial 'k' value i.e. number of clusters.
2) Random selection of centroids can also yield less accurate results.
3) Does not work well for categorical values.
4) This algorithm can discover spherical clusters. Thus, it is prone to outliners.

2. HIERARCHICAL CLUSTERING

This technique is also referred as hierarchical cluster analysis (HCA). Similar clusters are merged or dissimilar clusters are splitted depending on the type of hierarchical algorithm used. This technique is broadly classified as – Agglomerative and Divisive Hierarchical clustering.

Agglomerative Hierarchical clustering - It starts

with treating each datapoint as an individual cluster and then go on merging similar clusters to form a final clusters. Therefore, this method corresponds to bottom-up approach.

Divisive Hierarchical clustering- All the datapoints are consider as a single cluster and then in each iteration, we

separate datapoints from the cluster which are dissimilar. Therefore, this method corresponds to top-down approach.

The following linkage criterion are used which determines what distance to use between sets of datapoints. This algorithm then merges the clusters that minimize this criterion.

- Single Linkage: In this method, the distance between two clusters is defined as the shortest distance between two points in each cluster.
- Complete Linkage: The distance between two clusters is defined as the longest distance between two points in each cluster.
- Average Linkage: In average linkage hierarchical clustering, the distance between two clusters is defined as the average distance between each point in one cluster to every point in the other cluster
- Ward Linkage: It minimizes the variance of the clusters being merged.

The agglomerative clustering is performed as follows:

Step 1. Consider each datapoint as a separate cluster. Given a dataset (d1, d2, d3…dn) of size 'n', treat each datapoint in dataset as a separate cluster (c1, c2, c3… cn).
Step 2. Compute the distance matrix.
Step 3. Then perform below steps until similar clusters are merged.
   a. Identify the two clusters that are closest to each other.
   b. Merge the two similar clusters and update the distance matrix.

Hierarchical clustering is implemented on shopping dataset where the attributes for forming clusters are annual income and spending score.

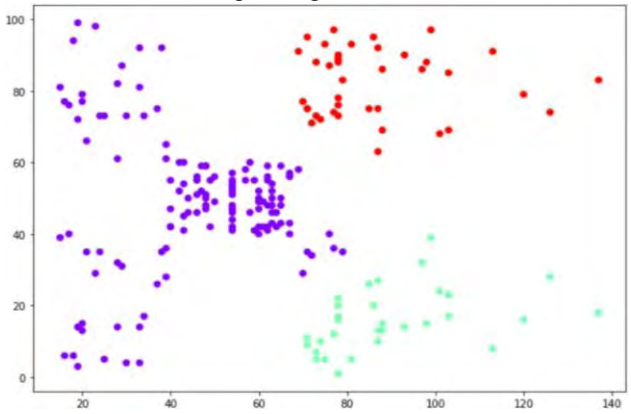

Figure 3. Hierarchical clustering on Shopping dataset

Advantages:

1) No priori information about the number of clusters required.

Disadvantages:

1) Not suitable for huge dataset due to high time complexity.
2) Loose clusters are formed as compared to K-Means.
3) Algorithm cannot undo previous step once merging or splitting is done.

3. DBSCAN

Partitioning and hierarchical clustering are suitable for only compact, spherical and well separated clusters. Moreover, they are also severely affected by the presence of noise and outliners in the dataset. This drawback is overcome by DBSCAN, which discovers arbitrary shapes based on density.

The idea behind this algorithm is that for each point of a cluster its radius has to contain at least minimum number of points. In simple words, DBSCAN works by identifying dense region, which are measured by the number of datapoints close to a given point.

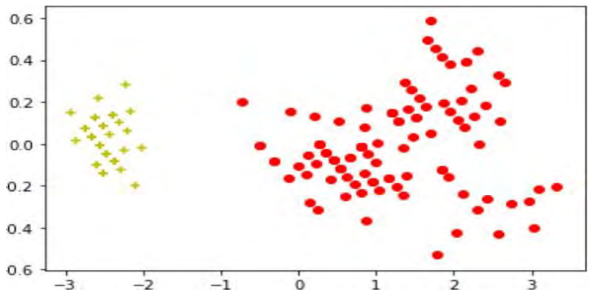
The algorithm works on two fundamentals:

- eps (epsilon): Radius of neighbourhood around the point.
- MinPts: It determines minimum number of neighbours within the 'eps.

DBSCAN algorithm is as follows:

Step 1. Pick random point 'p' and mark is as visited.
Step 2. Get all the points which falls in neighbourhood (upto eps distance) of point 'p' and store it in set S.
Step 3. If S >= minPts, then
   a. Consider point 'p' as first point of a new cluster.
   b. Consider all points (which are member of set S) as other points in this cluster.
   c. Repeat the above step b for all points of S.
Step 4. Else mark p as outliner or noise.
Step 5. Repeat step 1-5 till clustering is completed and all points are visited.

Two clusters are formed when DBSCAN is applied on iris dataset.



Advantages:

1) Does not require to specify the number of clusters to be generated.
2) It can discover arbitrary sized and arbitrary shape clusters very well.
3) Outliers or noise are easily identified.

Disadvantages:

1) Doesn't perform well when clusters are of varying densities.
2) Selection of DBSCAN parameters (eps and MinPts) is very tricky.

4. K-Medoid

K-Medoid also called as Partitioning Around Medoid (PAM) was proposed by Kaufman and Rousseeuw. A medoid is a point in a cluster which has minimum dissimilarity with all other points in the cluster. Clusters are formed based on the randomly selected medoids from dataset. Then the other non-medoid datapoints are grouped with that medoid to which it is most similar.

The basic algorithm for K-medoid is:

Step 1. Randomly select k from 'n' datapoints as the medoids.
Step 2. Assign each datapoint to the closest medoid.
Step 3. For every medoid 'm' and every data point which is associated to m swap m and o and compute the total cost (i.e. the average dissimilarity of a datapoint to all the data points associated to m). Then select the medoid which has lowest cost.
Step 4. Repeat the steps 2 and 3 until there same clusters are obtained.

Advantages:

1) Less sensitive to outliner compared to K-Means.

Disadvantages:

1) Not suitable for clustering arbitrary shape clusters.
2) It is expensive than K-Means, as it compares each medoid with entire dataset in every iteration.

5. Mini Batch K-Means

It is similar to K-means with only difference that here the computation is only done on random batch of observation.
This algorithm works by taking small random batches of fixed sized data. This is done so as to reduce the memory storage. Therefore, this approach significantly reduces the total time required by the algorithm to fit the data.

Mini Batch K-Means algorithm is as follows:

Step 1. Random samples(batches) are chosen from the dataset.
Step 2. Assign these batches to nearest centroids.
Step 3. Update the centroids.
Step 4. Perform above Steps until it reaches pre- determined number of iterations.

Advantages:

1) Reduces the computational time as compared to K- Means.

Disadvantages:

1) Still requires random selection of centroids.
2) Need to specify number of clusters in advance.

III. CLUSTERING PERFORMANCE MEASUREMENT PARAMETERS

Evaluating the clustering algorithm is helpful in determining how accurate the algorithm is running. Evaluating a clustering model is not very easy therefore many evaluation parameters has been proposed which are used to evaluate the clustering algorithms.
Some of these evaluation parameters are discussed with an example:

1. Within Sum Square Error (SSE)

It is defined as the sum of the squared differences between each datapoint and cluster centroid within cluster.

Formula is given by,
Within SSE = $\sum (Ci - Xi)^2$.

2. Between Sum Square Error (SSE)

It is defined as the sum of squared differences between two clusters.

It is given by formula,
Between SSE = $\sum$ (Global Mean - Ci)^2 * number of datapoint in the cluster.

3. Total Sum Square Error (SSE)

It is given by formula,
Total SSE = Total Within SSE + Between SSE

4. Accuracy

It defined as a measure to determine the quality of

clustering. It is calculated as,
Accuracy = (Between SSE/Total SSE) * 100

5. Time Complexity

Time taken by clustering algorithm to form k specified clusters. Time complexity of a clustering algorithm depends upto the number of clusters, number of iterations etc.

For below K-Means example we have calculate the above performance parameters.

Example 1: Consider the dataset {2,3,10,12,15,21,22,23,24} and number of clusters (k) = 3.

Randomly select initial centroids: C1 = 2, C2 = 15, C3 = 23

Calculate the Euclidean distance between each datapoint and centroid and assign the datapoint to cluster having minimum distance.

Table 1. K-Means 1st iteration table

Data Point (X)	Dist|C1-X|	Dist|C2-X|	Dist|C3-X|	Cluster
2	**0**	13	21	Cluster1
3	**1**	12	20	Cluster1
10	8	**5**	13	Cluster2
12	10	**3**	11	Cluster2
15	13	**0**	8	Cluster2
21	19	6	**2**	Cluster3
22	20	7	**1**	Cluster3
23	21	8	**0**	Cluster3
24	22	9	**1**	Cluster3

After calculating Euclidean distance between each datapoint and centroid and assigning the datapoint to cluster having minimum distance the clusters formed are:

Cluster1= {2, 3}

Cluster2 = {10, 12, 15}

Cluster3 = {21, 22, 23, 24}

Now, recalculate the centroid by taking mean of the clusters. Therefore, the new centroids are:

C1` = (2 + 3) / 2 = 2.5
C2`= (15 + 12 + 10) / 3 = 12.33
C3` = (21 + 22 + 23 + 24) / 4 = 22.5

Again, calculate the Euclidean distance between each datapoint and centroid and assigning the datapoint to cluster having minimum distance.

Table 2. K-Means 2nd iteration table

Data Point (X)	Dist|C1`-X|	Dist|C2`-X|	Dist|C3`-X|	Cluster
2	0.5	10.33	20.5	Cluster1
3	0.5	9.33	19.5	Cluster1
10	7.5	2.33	12.5	Cluster2
12	9.5	0.33	10.5	Cluster2
15	12.5	2.67	7.5	Cluster2
21	18.5	8.67	1.5	Cluster3
22	19.5	9.67	0.5	Cluster3
23	20.5	10.67	0.5	Cluster3
24	21.5	11.67	1.5	Cluster3

Therefore, the clusters formed are:

Cluster1= {2, 3}

Cluster2 = {10, 12, 15}

Cluster3 = {21, 22, 23, 24}

Since, the clusters obtained after recalculating the centroid are same, we can say than the clusters formed are correct and final and then we can terminate the algorithm.

For above example (Example 1) the performance parameters are defined and calculated as:

1. Within Sum square error (SSE)

Within SSE for Cluster1= $(2.5-2)^2 + (2.5-3)^2$ = 0.25 Within SSE for Cluster2= $(12.33-10)^2$ + $(12.33-12)^2$ + $(12.33-15)^2$ = 12.66
Within SSE for Cluster3= $(22.5-21)^2 + (22.5-22)^2+(22.5-23)^2+(22.5-24)^2$ = 5

Total Within SSE = Within SSE for Cluster1+ Within SSE for Cluster2+ Within SSE for Cluster3.

Therefore, Total Within SSE = 0.5 + 12.66 + 5 = 18.16

2. Between Sum square error (SSE)

Global Mean = (2+3+10+12+15+21+22+23+24) / 9 = 14.66

Therefore,

Between SSE = $[(14.66-2.5)^2 * 2 + (14.66-12.33)^2 * 3 + (14.66 -22.5)^2 * 4] =$ **557.8803**

3. Total Sum Square Error (SSE)

Total SSE = Total Within SSE + Between SSE
= 18.16 + 557.8803 = 576.0403

4. Accuracy

It is calculated as,
Accuracy = (Between SSE/Total SSE) * 100

Therefore,
Accuracy = (557.8803 / 576.0403) * 100 = **96.84**

IV. CONCLUSION

Clustering is a technique of dividing the entire population into small groups. There are many clustering algorithms, but each algorithm faces some drawbacks. These algorithms are analysed using various clustering evaluation parameters. There are many ways to determine the quality of clusters. Large number of dataset degrades the quality of clusters and also slow downs the performance of the clustering algorithm.

Abstract: **The increasing population around the world, development , growth and urbanization and also the increase in the standard of living has lead to the increase vehicular usage by the people since the people are moving more towards the private vehicles than the use of public transport vehicles. Due to this our traffic system is facing load of the increased vehicular traffic and it is leading to the crowded roads and cities and our traditional traffic control system is clearly inefficient in proper traffic control and management. However few such model or design exists which actually consider the flow of the vehicle at the node and consider the factors which include vehicle deviation, vehicle density, number of emergency vehicles present ,number of pedestrians crossing and also accidents. Here in this article we have reviewed the various systems available and used around the world and also tried to find out the possible improvements which are needed and tried to develop an algorithm which focuses and uses machine learning strategy to provide solutions which can be implemented in order to achieve the necessary needed improvements.**

Keywords: Intelligent Traffic System, Traffic light, Congestion, Vehicle Density.

I. INTRODUCTION

The ever-increasing population and urban development has lead to the problem of road congestion and heavy traffic jams and hence leading to various problems concerned with the environment and economy. Emergence of such scenario make it difficult for the traditional traffic monitoring system to provide efficient management of traffic . Also since the traffic is a matter of critical concern as it includes various constraints like vehicular density, number of pedestrians, number of emergency vehicles on the road, vehicle deviation and other during finding a approach for traffic management. The traffic light system used are also just designed in a way to show a particular signal light for a specific duration of time. Though there exists other systems through which we can change the duration for a traffic light based on the situation like peak hours and free hours. However they can't themselves take into account the factors of density of traffic on the road. All together this traffic congestion problems result in unexpected delays and makes it difficult to reach the required destination on time especially in case of emergency services like ambulance, fire brigade vehicles. Hence taking into consideration there was need of the intelligent monitoring system which must incorporate the algorithms and techniques which should be able to meet these requirements. Hence here we study the various algorithms and technologies so developed for better and effective traffic management and monitoring.

II. LITERATURE SURVEY

[1] This system focuses on Congestion Control, Emergency Vehicle Clearance and also Stolen Vehicle Detection. The system would be designed in a way such that it will be detecting the number of vehicles entering into the system using Infrared Sensors (IR Sensors). These IR Sensors are connected to a microcontroller. The System proposes that this microcontroller would be able to detect the vehicle density and will be automatically able to control traffic. This is done by controlling the traffic signal lights in a four road junction. Here for the experiment purpose suggests the use of RFID tags with a RFID reader with frequency 125kHz. RFID tag of vehicle comes in the range of the receiver will transmit that unique RFID to the reader. This RFID reader is connected to the microcontroller which counts the RFID tags. This RFID tags and reader work using IR sensors. Also for Stolen vehicle Detection the stolen vehicle RFIDs will be kept in a list and this vehicle will come in a contact of a RFID reader and it will compare the tag with the list of tags present in the list and it will detect the stolen vehicle. For Emergency vehicle clearance system working will be done with the combination of

ZigBee transmitter and receiver. The vehicles which are used for emergency purposes consists of ZigBee transmitter which will be switched on during the emergency use. The signal transmitted by such vehicles will be detected by ZigBee receiver. Detecting such signal will automatically make the system to give preference to that lane consisting of emergency vehicle.

[2] This system basically focuses on Vehicle Detection and recognition for Traffic Surveillance System. It manages vehicle detection and its recognition on the basis of static images using image processing. The images are read by a classifier which has functions based on the machine learning algorithms such as Ada Boost algorithm and Haar .This allows recognition of the region of interest. Further the additional training is carried out for analysing the different types of vehicle samples.

[3] This proposed system basically focuses on customizing the duration of green signal based on the current traffic conditions and it aims of this system is to determine the best possible cycle duration and best possible phase depending upon the current situation i.e. the incoming traffic from each of the four lanes .It also make sure that duration of each phase should be flexible so that it must not result into traffic congestion in any of the remaining lane. The vehicle density of each road is calculated and depending upon the results traffic signals will be programmed such that more crowded road will get green signal for greater duration of time.

III. PROPOSED SYSTEM

The main disadvantage of the traditional system is that it doesn't understand important factors like peak hours of traffic or sudden factors like a procession on the road. Hence, there are times when vehicles have to wait for too long before the signal releases. In worse situations, a platoon (a term coined by traffic engineers), which is a group of vehicles cannot make it all through the traffic without any kind of interruptions, thereby, a particular platoon breaks into two and the latter half of the platoon might have to stay on the same signal twice. The proposed system ensures that no particular platoon breaks. It also ensures that there are no pileups during peak hours. Moreover, this system also ensures that no drivers are induced to jump signals during lean hours.

IV. THE DETECTOR

This system requires the installation of an economically-friendly detector, which will measure the maximum traffic upto a specifically calculated distance.

The detector is a wideband spread-spectrum radar. It is very inexpensive and it has extremely accurate range discrimination. It can also penetrate many types of materials, including concrete. It has a range of about 20 feet, so it may be useful as an inexpensive, single-lane vehicle detector. It is predicted that the sensor, when made in production quantities, would cost much less than $10 per sensor. Because of their accurate range discrimination, they have a very well defined field of detection. They could become a cheap alternative to magnetometer probes. Their ability to detect range provides additional information for future traffic control systems.

We will develop a broadband transmitter/receiver pair to be used with these sensors. This would eliminate the need for communication lines between the sensor and the controller.

V. METHODOLOGY

Our model works on the simple logic of "freeing the congestion first" during peak hours. And "freeing the easy transit" during lean hours. If the situation it's a mix of both then, our algorithm alternatively executed its task.This method defines traffic as still movement of vehicles for 200 meters of a 4-lane passage. The mentioned range was chosen after a careful consideration of traffic in different locations of the city of Mumbai.

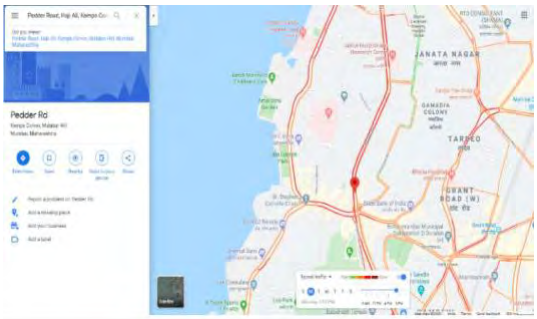

Fig.1: Showing the traffic of one of the busiest roads of Mumbai-Peddar Road.

In the above diagram, it is very clearly depicted that how all the roads are jam packed. The shockwave theory

The second consideration of this method is that each row of vehicle in a traffic is taken as 5 metres. This calculation is an average of a vehicle as small as a rickshaw and a vehicle as large as a bus. With the help of the spread-spectrum wideband radar, the system would analyse the situation of the traffic and categorize it in either of the three option viz., i] High ii] Low iii] Optimal.

For this analysis the setup would require a maximum of 40 hops from the start of the signal to 200 metres away from it. This calculation is given by:

Thus, the time complexity of our counter would be O(n). Several other factors are taken into consideration, such as the width of the road. Therefore, the road is divided into particularly three halves, i]4 laned passage ii]3 laned passage iii] 2 laned passage(due to the barriers of the roads such as sudden accidents leading to road rage, procession on the road or coherent construction of roads). In all the above scenarios, the waiting time and the release time would be different. These different values would be already pre-set by the traffic engineers based on the local factors and environment of a particular intersection.

Another consideration proposed by this approach is the modification based on the movement of the traffic. At each approach to the intersection there are three direction the vehicles can go movements. These movements are namely, left, through and right. Right and through are typically grouped as a single movement. So an intersection has 8 vehicular and 4 pedestrian movements.

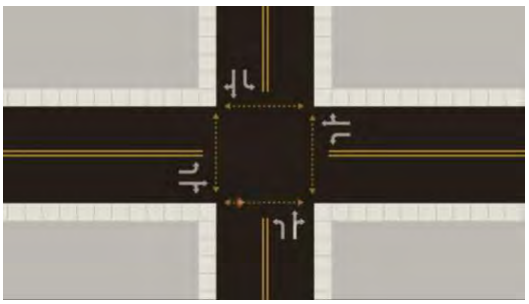

Fig.2 The diagram depicts an 8 way vehicular movement

In such a case, the movements can be phased into phases. For example, right turn movements of opposite intersection can be grouped into a single phase. Because they both can move at the same time without any kinds of interruptions or conflicts.Such a method decreases the overall waiting time of the particular intersection. Because instead of waiting for three other signals before your turn come, one only has to wait for 1 signal. However, the disadvantage of such a method is that the movement gets restricted. As the vehicles get prohibited from taking one of the turns.

The second situation is when no turns are restricted and one path has to wait for the other three to complete their cycles before releasing its traffic again.

The fifth consideration is to decrease the noise levels of the road. Our model not only aims at controlling the flow of the traffic but it aims to minimize congestion. Hence, there is a need to control the average decibels on the road.

For the same reason,

A sensor will be installed which will sense the noise . It basically work as when the red light will come to an end and will shortly turn into green light and if before its end if noise (horn) will be made by the travellers and if that noise level with cross the set value the red light automatically will increase by 90 sec or more. This mechanism will help to control the noise level , for smooth functioning of the system and many more..

VI. WORKING

To explain the working our our proposed solution we have take the following considerations:

1. The pivot is considered to be the south-most intersection. This means that the default scanning of the traffic will start from the above intersection. And then go in the anti-clockwise direction.

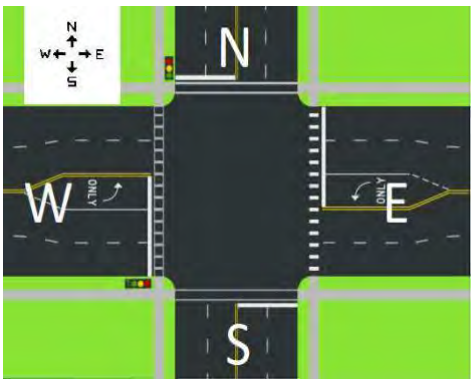

Fig. 3 depicts the naming of the direction of road**s**

2. The default time of the signal will be taken as 35s, 70s, 135s and 0s (0s is taken because in a crossroad three roads would be waiting while only one can be released)
This time will not be displayed on the screen. The purpose of this time is to act as a default after the which the four signal will have to mandatorily swap.
3. 200 meters is the situation with heavy traffic while 20 meters is the situation with light traffic

CASE 0: OPTIMAL TRAFFIC

This scenario would occur when then the jam is less than 200 meters but more than 20 meters. Such a system would word similar to the traditional system Since the pivot is decided to be south, the start would be considered from south and then the traffic will move in this way:

	Pass 1	Pass 2	Pass 3	Pass 4
South	35s	0s	135s	70s
West	70s	35s	0s	135s
North	135s	70s	35s	0s
East	0s	135s	70s	35s

Fig. 4 depicts the waiting time of each road in each particular pass.
Signal 1 gets free, after waiting for 35 seconds. It is released for 32 seconds and the buffer time is 3 seconds.
After (35+32+3) seconds, considered from time 0, the second signal will get released for 32 seconds and the buffer time is 3 seconds.
After (35+35+32+3) seconds, considered from time 0, the third signal will get released for 32 seconds and the buffer time is 3 seconds.
After (35+35+35+32+3) seconds, considered from time 0, the fourth signal will get released for 32 seconds and the buffer time is 3 seconds.

VII. CASE 1: HEAVY TRAFFIC

PART A: ONLY ON THE SOUTH ROAD

In this situation, the timer which is supposed to be 35s as default automatically, becomes a countdown of just 10 seconds. Such a situation occurs when the other three roads have optimal traffic.
Signal 1 gets free, after waiting for 5 seconds. It is released for 36 seconds and the buffer time is 2 seconds.
After (5+36+2=43) seconds, considered from time 0, the second signal will get released for 32 seconds and the buffer time is 3 seconds.
After (35+43) seconds, considered from time 0, the third signal will get released for 32 seconds and the buffer time is 3 seconds.
After (35+35+43) seconds, considered from time 0, the fourth signal will get released for 32 seconds and the buffer time is 3 seconds.

In this situation, the release time is considered to be more for the region with high traffic as compared to the region of low traffic. It is calculated by estimating an average speed of a car in traffic as 10 kmph. Then, Distance/Speed=Time, which is calculated to be 36 sec. The above consideration is an important factor, as our goal is to make sure that a platoon doesn't break into 2 equal or unequal halves.

After the 4th signal is released of 1 cycle, the time calculated turns out to be 113s. While with the traditional method it was 135 seconds. Hence, 22 seconds per cycle is saved this way.

PART B: ON ANY OTHER ROAD

This situation is a simple alteration of Part a. If any other road, except south, have heavy traffic, then the pivot is temporarily changed to that particular road and then it proceeds in the same anti-clockwise manner.

CASE 2: HEAVY TRAFFIC ON MORE THAN 1 ROADS

Case 2 is nothing but a combination of part a and part b of case 1. In the circumstance, the priority would be given to the hroads with heavy traffic first. For example. if West and East have heavy traffic, then the flow of the traffic as per the anti-clockwise rule (with the pivot being West) would be: West East South North.
Note that the above algorithm was designed keeping in mind the priority of the flow of traffic.

CASE 3: LIGHT TRAFFIC

PART A: ONLY ON 1 OF THE CROSSROADS.

If the jam is under 20 meters from the traffic light then it is considered as light traffic. Light traffic is as dangerous as heavy traffics are because usually the riders are tempted to jump the signal due to the easy accessibility and also due to impatience.

Hence, the waiting time would be 5 seconds and the release time would be 12 seconds.

Signal 1 gets free, after waiting for 5 seconds. It is released for 10 seconds and the buffer time is 2 seconds.

After (5+10+2=17) seconds, considered from time 0, the second signal will get released for 32 seconds and the buffer time is 3 seconds.

After (35+17) seconds, considered from time 0, the third signal will get released for 32 seconds and the buffer time is 3 seconds.

After (35+35+17) seconds, considered from time 0, the fourth signal will get released for 32 seconds and the buffer time is 3 seconds.

After the 4th signal is released of 1 cycle, the time calculated turns out to be 87 seconds. While with the traditional method it was 135 seconds. Hence, 48 seconds per cycle is saved this way.

PART B: ON MORE THAN 1 ROADS

In this case, if there are two crossroads with light traffic and the 2 others with heavy traffic then alternatively light and then heavy traffic would be released. For instance: if South and West have heavy traffic while North and East have Light traffic then, the pivot would be North and the flow would be as follows:

North South East West

The above flow ensures the alternate release of light and heavy traffic turn-by-turn.

ALGORITHM

For making the algorithm, a datatype called timecount is used. timecount allows the program to increment or decrement the value of an variable by 1 every second.

Function car:

1. boolean p
2. count=5 meters
3. while (count =200)
4. if (p=true)
5. Count+=5
6. Return count.

The above function will run in correspondence to the wideband spread-spectrum radar and return how much length of the road is occupied to another function HLO.

Function HLO:

1. If count=200 Return h
2. If count<=20 Return l
3. If count<200 but count >=20 Return 0

This function categorizes the traffic different roads of an intersection into either of the three parts viz., H, L or O. H stands for high, L stands for low and O stands for optimal.

Main Function:

1. Storing values of H, L or O for 4 roads viz. in an array check [s, n, e, w]. Generate three arrays of datatype timecount namely, green, red and yellow
2. for i=1 to 4 if (i=4) i=0

if(check[i]==check[i+1])then

red[i]=red[i]+35 red[4]=0
if(red[i]=0)then yellow[i]=3

if(yellow[i]=0) then green[i]=32

if (green[i]=0) then restart the timecount variable
else if(check[i]='h')

red[i]=5
if(red[i]=0) then
yellow[i]=2

if (yellow[i]=0) then
green[i]=36

if(green=0) then
restart the timecount variable

else(check[i]=='l')
red[i]=5
if(red[i]=0) then
yellow[i]=2

if (yellow[i]=0) then
green[i]=10

if(green=0) then
restart the timecount variable

VIII. CONCLUSION

The main motive of this intelligent traffic model is to reduce the level of not only traffic congestion but also noise levels in a smarter way. It is a process which analyses the amount of traffic congestion at any given point of time and changes its methodology of working based on different situations. Since, the system is not

static or standardized a buffer period of 5 second is always present so the traveller gets alerted before the signal turns green or red as the case may be.

IX. FUTURE SCOPE

In dense urban areas, traffic congestion is often very self-limiting. It is estimated, that during peak times for every one person on the road there are many others at their home or work waiting for the congestion to clear up before heading out. This theory therefore predicts that any free up of traffic will be quickly filled up with more traffic bringing the congestion back to the same level from where it began. Hence, we can definitely, consider this factor in future to decrease congestion levels.

anam.mail4u@gmail.com,megharani.patil@thakureducation.org

Abstract— ***Soft Computing is a branch of science and engineering that allows us for reasoning, thinking, analyzing, and detecting, and correlating the real-world problems to the biologically inspired methods. Soft Computing is the big motivation behind the idea of machines working on conceptual intelligence. As such, it's an extension of heuristics for solving complex problems that are too difficult to model mathematically. Soft Computing is tolerant of imprecision, uncertainty, and approximation and is different from hard computing. Soft Computing has a collection of techniques like ANN, Evolutionary computing, Fuzzy Logic, and Statistics. Though they are advantageous and separately applied techniques but when hybridized, solve complex problems very easily. Also, Big Data is paving its way to enter into the area of Soft Computing and build more intelligent and computationally accurate systems. Various soft computing techniques and emerging fields of soft computing where they are successfully applied are highlighted in this paper.***

Keywords— Soft Computing, Fuzzy Logic, Artificial Neural Network, Genetic Algorithm.

I. INTRODUCTION

Engineering is a task of solving complex real-world problems. For obtaining the low cost and feasible solution to these problems, numerous tools and technology are already available. Among them, Soft Computing is one of the powerful problem-solving technique for the problems which have no known method to find an exact solution.

The idea of soft computing came into light in the year 1981 when professor Lotfi A. Zadeh published his first paper on soft data analysis titled "What is Soft Computing". Professor Zadeh defined soft computing as "it is an innovative approach to design a system which parallels the extraordinary ability of the human mind and is computationally intelligent to learn and reason in an environment of imprecision and uncertainty". It is a multi- disciplinary system that is a combination of the fields of Fuzzy Logic, Artificial Neural Networks, Genetic Algorithms, Probabilistic Reasoning, and Neuro Computing. Soft Computing is the fusion of methodologies effectively designed and modeled to provide a solution to the real word problems, which are however too difficult to model mathematically. The primary goal of soft computing is to follow and match the human mind and its reasoning and thinking behavior as much as possible. It supports low solution cost and better rapport with reality. The final aim is to develop a computer or a machine which will work exactly similar to human-being thereby replicating the wisdom of human being into the computers in an artificial manner.

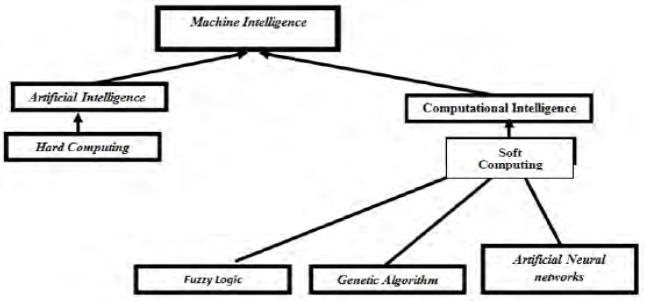

Figure 1: An Overview of Branches of Machine Intelligence

Soft Computing is probably going to play an especially important role in science and engineering, and eventually, its influence is extending farther. Building human-centered systems is an important task for scientists and engineers within the new millennium.

Fuzzy Logic (FL)

Fuzzy Logic is predicted on pure mathematics and provides methods for modeling and reasoning under uncertainty, a characteristic present in many problems, which makes FL a valuable approach. It allows data to be represented in intuitive linguistic categories instead of using precise(crisp) numbers which could not be known, necessary or in general, could also be too restrictive.

A practical way for designing nonlinear control systems is provided by Fuzzy Logic It achieves non-linearity through piece wise linear approximation.

The basic building blocks of a fuzzy logic control system are fuzzy rule-based models (sets of if-else) that approximate a functional mapping.

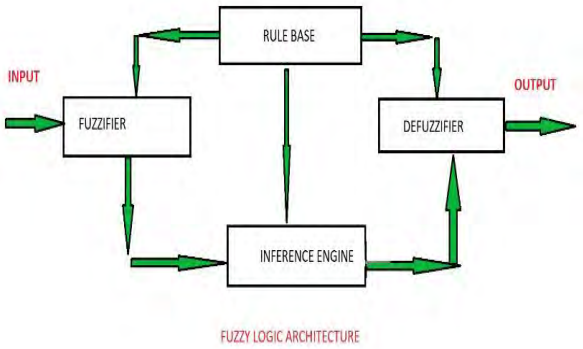

Figure 2: Components and Architecture of Fuzzy Logic

Artificial Neural Network (ANN)

ANN is a computational structure designed to mimic or copy the biological neural network. It is comprised of neurons which are connected by interconnected weights. ANN has three types of neuron namely- input nodes, hidden nodes & output nodes.

Mostly two types of ANN are used:

Feed_ Forward Neural Network

Feed_ Backward Neural Network

Feed Forward Neural Network

Feed-Forward Neural Network was the arguably simple and first neural network. In this, information flow is uni- directed i.e. forward direction. In this type of network, no loops and cycles are formed.

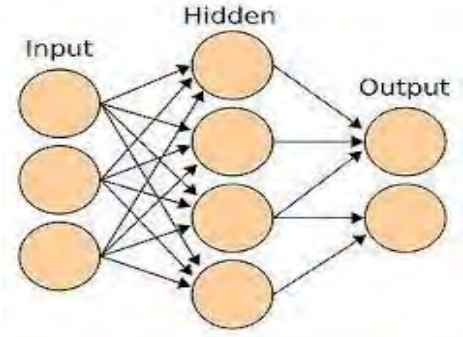

Figure 3: Feed Forward Neural Network

Feed Backward Neural Network

Feed-Backward Neural Network is also known as the recurrent neural network. Feedback connections are contained by these neural networks. In this, data flow is in both the directions. Possible of loop formation is there in this network.

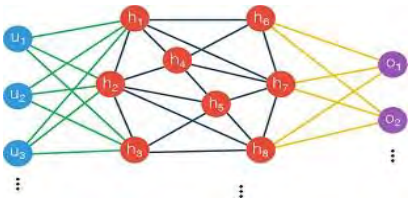

Figure 4:Feed Backward Neural Network

Problem analysis by ANNs

This fish-bone structure represents the important factors to be considered while analyzing NN model problems. An essential way of understanding the objectives sub- problems, to train the network for improving its learning by iteration.

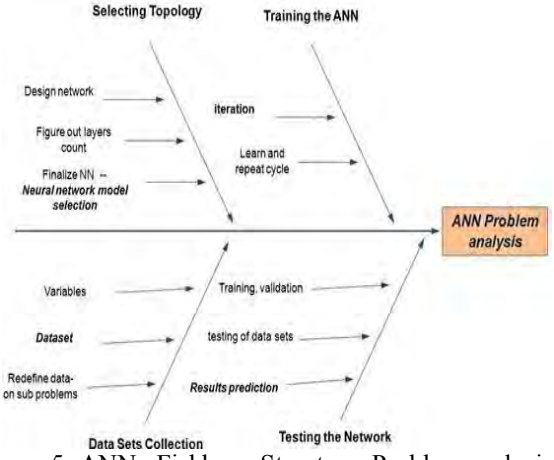

Figure 5: ANN –Fishbone Structure: Problem analysis

Genetic Algorithm (GA)

In terms of nature, evolution refers to competition among different individuals for resources in the environment or generally a natural selection. Those individuals who can survive and propagate genetic material are considered better. The diversity in the population is calculated by mutation operation.

Usually found grouped under term evolutionary computation or evolutionary algorithms, are domains of genetic algorithms (GA), evolution strategies evolutionary programming & genetic programming.

Possible better solutions are generated on the basis of common concept by simulating the evolution of individual structures through processes of selection, recombination & mutual reproduction. [11].

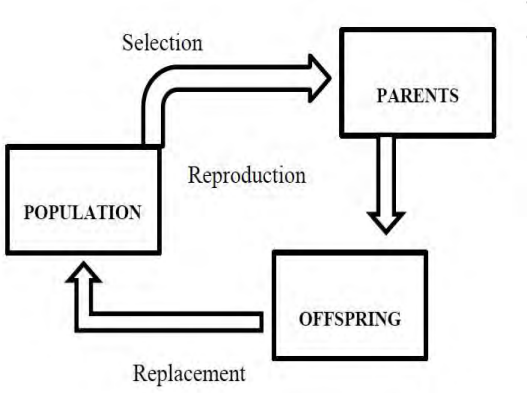

Figure 6: Flowchart for Genetic Algorithm

II. LITERATURE SURVEY

Soft computing has tremendous advancement in the engineering fields such as Aircraft, mobile, robot, cooling, and heating, power electronics etc. One of the emerging and striking examples of soft computing techniques is the "neuro-fuzzy"[1] system – a combination of neural network and fuzzy logic. These systems are becoming increasingly famous among customers, ranging from air conditioners, washing machines, photocopiers, and camcorders.

It is not easy to control the growing complexity of modern machinery by making use of traditional control systems techniques. Plants with large time delays such as nonlinear and time-variant plants cannot easily be controlled and stabilized using traditional techniques. The lack of an accurate model that describes the plant is one of the reasons for this difficulty. Soft computing is proving to be an efficient way of controlling such complex plants[2].

It has been discovered that Soft Computing could prove to be one of the efficient methods to reduce power consumption in the cloud. An N-P complete problem can be efficiently solved by using Soft Computing approach. As compared to Hard Computing, better results in this scenario are achieved using Soft Computing. Therefore, it will be preferable to use advanced techniques to follow Hybrid Soft Computing[3] approach for energy efficiency in cloud computing.

Effectiveness of Soft computing methods to detect the fault in A.C. Motor[4]. Feed Forward Back Propagation (FFBP) and Radial Basis Function (RBF), Neural Network controller are being used as a soft computing method and Three Phase Induction motor is used as an AC Motor. The healthy and unhealthy condition of the motor is tested and classified using both the neural network controllers. Both controllers give good results for the above purpose but the RBF neural network shows very encouraging results for multi-class classification problems. thereby proving the effectiveness of the controller for setting up a base in incipient fault detection of Induction Motor.

There are a number of discussions and explanations regarding the evolvement of Big Data Challenges[5], and many complexities involved in Big data mainly format and unstructured nature. These have to be organized and extracted using computational intelligence and soft computing.

III. RECENT TRENDS IN FUZZY LOGIC

Some of the recent real-world examples are stated below where Fuzzy Logic is taken into consideration and the results are highly effective.

Machine Learning and Pattern Recognition:
Several tasks are supported by machine learning techniques, such as clustering, classification, optimization, rule development and many more[6]. In these processes, data is needed to be evaluated and similar patterns are extracted and captured from raw data. Therefore, it becomes suitable for tasks like image recognition and text classification.

Medical Science:
Fuzzy set theory and fuzzy logic are a highly appropriate and relevant source for evolving knowledge-based structures in medicine for accountabilities such as the elucidation, explanation of sets of medical discoveries and outcomes, diagnosis of diseases, mixed diagnosis, the optimal selection of medical treatments, and for real-time observing of patient data [7].

Transportation Industry:
In the transport industry, the fuzzy-based system has a variety of applications ranging from traffic scheduling, braking to signaling and many more [8].

Green Energy:
Fuzzy controllers are being implemented in the system along with power electronic interfacing units to stabilize the output voltage at the load side for achieving a constant- voltage irrespective of the change in supply voltage and load in a solar photovoltaic cell-based application[9].

Data Mining and Clustering:

In order to provide useful information to the user for decision making, data mining extracts information from large databases. Dependencies between the data are discovered by fuzzy sets.
Business customer market share and telecommunication customer data mining are effectively done using Fuzzy Clustering[10] algorithms.

Psychology:
It has been analyzed that Fuzzy Logic has numerous applications in the field of Psychology[11] namely- emotion, perception, motivation, anxiety, frustration, stress, etc.

In Psychology, fuzzy logic is used in the following areas

- Fuzzy logic-based analysis of human behaviour
- Criminal investigation and prevention based on fuzzy logic reasoning and many more.

Cyber Security:
Advanced Cyber Security System (ACSS) [12] are being modelled and implemented using Fuzzy Logic, consisting of rule depository and mechanism for accessing and executing those rules. Where the depository is usually a collection of the set of Fuzzy rules

IV. RECENT TRENDS IN ARTIFICIAL NEURAL NETWORK

E-Learning through ANNs:
ANN supports application scope to implement and utilize the neural model for the personalization level. Smart e-Learning applications [13] must require neural system design features for learning behaviour analysis to utilize for betterments of academic teaching and learning processes.

Forecasting:
Everyday business decisions (e.g. sales, the financial allocation between products, capacity utilization), require forecasting extensively in economic and monetary policy, in the finance and the stock market. Forecasting problems are complex, more often. Predicting stock prices is a complex problem with a lot of underlying unknown and unseen factors. There are limitations in traditional forecasting systems in terms of taking into account these complex, non- linear relationships. A robust alternative can be provided if ANNs are applied in the right way, giving it ability to model and extract unseen features and relationships. Also, ANN doesn't impose any restriction on input and residual distributions unlike the traditional models.

Signature Verification Application:
The primary approach is extracting the feature or the geometrical feature set that represent the signature.Using these feature sets,train the neural networks by making use of an efficient neural network algorithm. Classify the signature by this trained neural network as being genuine or forged under the verification stage.

Human Face Recognition:
All the input images need to be preprocessed, at first. Then, the dimensions of that image needed to be reduced. And, at last, classification is done using a neural network training algorithm. Following are the neural networks used for training purposes with preprocessed image −

Fully-connected multilayer feed-forward neural network is trained with the help of the back- propagation algorithm.

Principal Component Analysis (PCA) technique is used, for dimensionality reduction.

V. RECENT TRENDS IN GENETIC ALGORITHM

Application domains in Genetic Algorithm
New applications where GAs prove to be well-suited tools are continuously found. Bioinformatics, image analysis, signal processing, telecommunication, hardware optimization, and artificial music and art represent recent application domains [14].

Genetic Programming
Since beginning of the early 90s, much progress has been witnessed with respect to genetic programming. This class belongs to genetic algorithms, uses programs in the form of tree-structures as required solutions. It has the ability to automatically produce results that are competitive to be patented or human inventions that can be patented[13].Such successful applications are analyzed and reported for the design of electronic circuits for analog filters and controllers, and for the development of quantum algorithms, and certain problems in bioinformatics.

Extended hybrid architectures:

For solving discrete optimization problems, classical simple EAs are found to be typically less efficient compared to other state-of-the-art algorithms that are specifically tailored to the problems. As a result, EAs are often combined with problem-specific algorithms. The hybridised form of EAs and other algorithms such as local search, simulated annealing, guided local search, variable neighbourhood search, and variable depth search are widely used in recent time, and for several hard-combinatorics optimization problems, such techniques are today's topmost algorithms for computing superior solutions to large problem instances within limited time. Such combinations are also known as memetic algorithms. Typically, the EA's primary responsibility is to need care of diversification and coverage of all major areas of the search space, while the embedded other metaheuristic is particularly responsiblefor the intensification of the search, thus, the fine-tuning of the foremost promising candidate solutions.

Estimation of distribution algorithms (EDAs):
In this relatively new class of EAs, a probabilistic model is used to represent desired solutions. A new generation of candidate solution is calculated by taking samples of the probabilistic model. These solutions are evaluated, and a subset is selected which later is used to update and refine the probabilistic model. *Univariate marginal distribution algorithm* (UMDA) is the simplest form of an EDA. In it, the variables which represent a solution are regarded as independent and the probabilistic model is a vector of associated probabilities. More sophisticated EDAs also consider Dependencies among the variables is also considered by more sophisticated EDAs, Bayesian networks as probabilistic models is one of the examples.

Neural Networks: Neural networks, in particular recurrent neural networks are trained using GAs.

VI. CONCLUSION

The evolvement of soft computing techniques is remarkable in every field of physics, material sciences, computer, chemistry, statistics, etc. Outline of various soft computing techniques and their different applications and techniques have been represented in this paper. The robustness, cost-effectiveness, simplicity are some of unique and remarkable features of soft computing. Fuzzy logic is very suitable for tracking imprecision and uncertainty and has wide variety of applications. Whereas ANN offers good prediction capabilities thanks to its generalization and learning features. On the other hand, Evolutionary computing techniques are very much applicable in optimization problems and for estimation of different distribution algorithms. As the development of soft computing flourish day by day, the application areas will also be felt increasingly in the coming years. Day by day Soft Computing based products are increasing. Majority of such products uses any of the soft computing technique inside the sub-systems which aren't known to end-user. The gist is that soft computing techniques will become common to various applications and can deal with imprecise problems.

Abstract— **the amount of water required by a plant depends upon number of factors, which include plant's species, soil type, weather and various other micro parameters. In general, best way to water most plants is by applying enough to moisten the plant's entire root system, and then letting the soil dry out slightly before watering again. A soil moisture sensor can be used to check the soil near plant roots and water them accordingly. But, plants can receive water naturally through rain and as we know, too much water can be as harmful as too little water to the plants. In this project we are planning to build an automatic watering system which not only measure soil moisture but also check the weather depending on which it makes decision to water the plant. To check the weather we will be using a web based API which will communicate with our Adriano microcontroller. If, in near future there is chance of rainfall the system will refrain from watering the plants regardless of soil moisture status. This project will help reduce the human effort required and also decrease water consumption, while maintaining the health of the plants.**

I. INTRODUCTION

Nowadays there is scarcity of water all over the world, especially in India due to low groundwater table and irregular rainfall most of the water gets wasted in drainage. Thus there is a need of more efficient and cheap alternative to traditional form of watering the plants.

Automated plant watering system estimate and measure the existing plant and then supplies desired amount of water needed by that plant. It is minimizing the excess water use as well as keeping plants healthy. This system

Saves time and is accurate. At places like societies and Building gardens we can implement an automatic watering system which is easy and accurate for the growth of plants. This will minimize the human intervention and will also save time.

To demonstrate building and enhancing of existing automatic plant watering systems, we exploit available technologies we have such as a free web hosting and

Free cloud to develop such a system. We believe that our

Proposed system can be applied to different types of plants.

II. BACKGROUND

Fuzzy logic Natural language (like most other activities in life and indeed the universe) is not easily translated

Into the absolute terms of 0 and 1. (Whether everything is ultimately describable in binary terms is a philosophical

Question worth pursuing, but in practice much data we might want to feed a computer is in some state in

Between and so, frequently, are the results of computing.)

It may help to see fuzzy logic as the way reasoning really works and binary or Boolean logic is simply a special case of it.

Internet of Things (IoT) is a system of interrelated computing devices, mechanical and digital machines, objects, animals or people that are provided with unique identifiers (UIDs) and the ability to transfer data over a network without requiring human-to-human or human- to-computer interaction

Embedded System is combination of computer hardware and software which is designed for a specific function. Industrial machines, agricultural and process industry devices, automobiles, medical equipment, cameras, household appliances, airplanes, vending machines and toys as well as mobile devices are all possible locations for an embedded system. Embedded system technology reduces the cost and size of electronic circuit for project developments.

III. PROPOSED IDEA

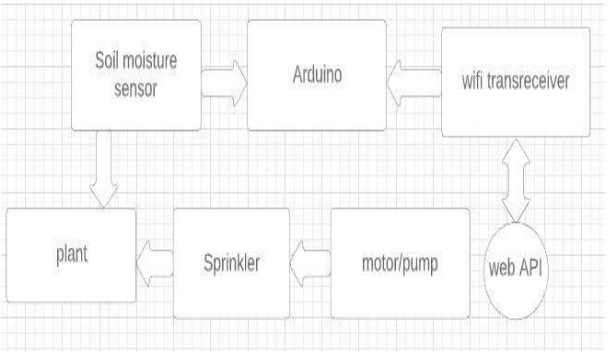

Figure 1: Block diagram

Our project is based on three functional model. First function is to measure the moisture content in soil. Second is to keep track of weather conditions by the use of real time data from open source Weather API. Lastly analyses both the data, compare to pre-set values for the given plant and decide whether to start the motor for water supply. The complete system is controlled by Adriano board which is programmed using Adriano IDE software.

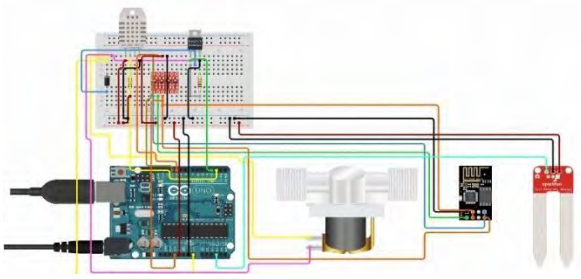

Figure 2: Pictorial Representation of System

A. Detecting soil moisture content:
The measurement of water content in the soil is achieved by usage of soil moisture sensor which sends an alert to the microcontroller when the soil moisture drops below
Threshold level.

B. Gathering Weather data
To track the weather conditions of near future we use open weather map API which is an open source weather
API that provides data in JSON format to the microcontroller in every ten minutes using Wi-Fi Transceiver. This data includes mean temperature, probability of shower, air humidity and wind speed.

Automatic watering and recording data
Based on the analysis and comparison of collected data with certain preset requirements and fuzzy logic
Algorithm the system determines the appropriate conditions to start the motor and water the plants

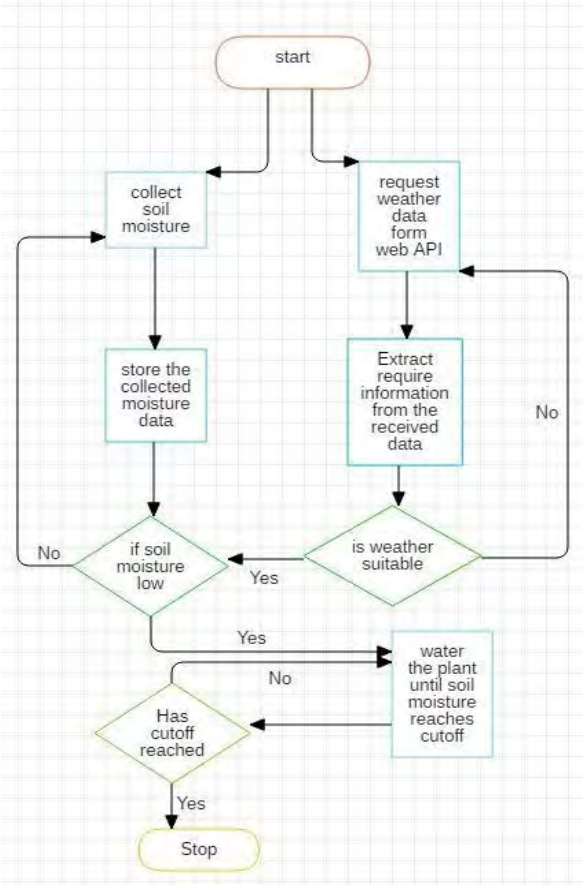

Figure 3: Flowchart of Automatic Watering System

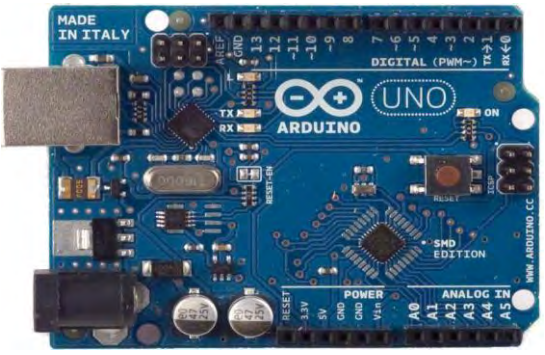
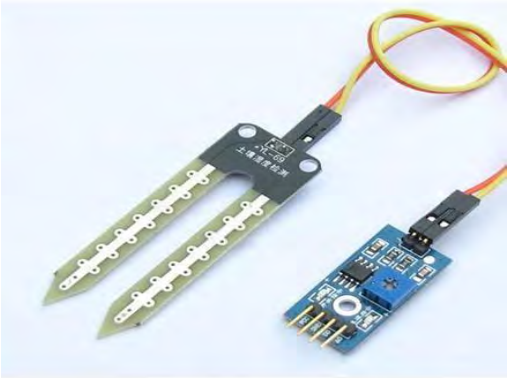
IV. COMPONENTS USED FOR SYSTEM

1. Adriano Uno: This microprocessor is used to gather collected data from adjoining modules and takes decision to start watering.



2. Soil Moisture Sensor: Soil moisture sensor will be used to measure moisture content in the soil.



3. ESP8266-01 (Wi-Fi Transreciever): Tran's receiver will be used to collect data from openweathermap.org API to get real-time weather reports.

4. Relay: The main operation of this device is to make or break contact with the help of a signal without any human involvement in order To switch it ON or OFF. We will be using this to Control the motor to pump water.

5. Water pump: DC powered pumps use direct current from motor, battery, or solar power to move fluid in a variety of ways.

6. SD card module: This module will be used to collect data in the SD card for future analysis.

V.RESULT AND ANALYSIS

During the process of testing we have achieved positive results from this project. It was found that our plants were able to grow without dehydration whilst using limited water. Although, further optimization can be Done to our fuzzy rule set. The data stored by SD module can be used to further analyses the pattern using data analysis algorithms like linear regression, K-mean clustering etc. We can also add a mini camera module available with esp32 Wi-Fi module to store growth process in the SD card which can be converted to a time-lapse to further your understanding of the gardening.

V.CONCLUSION

Design and develop a smart system that can sense the content of water in the soil. And by analyzing the results irrigation becomes easy, accurate and practical. The Volumes, volumetric water contents play an important role in producing the output.

The primary application of this project is to provide plants with adequate water without wasteful use of water and manual labor. This project is making the use of fuzzy inference system to decide the plant

Watering process. This project can further be extended to larger scale combining with the principles of rain water harvesting; it could be instrumental in areas with severe shortage of rainfall.

The principle can be extended to create fully automated gardens and farmlands. Combined with the principle of rain water harvesting, it could lead to huge water savings if applied in the right manner. In agricultural lands with severe shortage of rainfall, this model can be successfully applied to achieve great results with most types of soil.

This Smart irrigation proves to be the system automates for irrigation system and regulates water for irrigation is done without manual Using this system, solenoid valves and relay board can be controlled remotely which opens the opportunities to control the water flow as well as the electrical flow. Irrigation system is automated with depends on sensor Report the pump is operated by the weather condition by soil, rain and temperature conditions the water pump will work and by wireless trans receiver the data is communicate and the sensor readings are uploaded in

to cloud network by Wi-Fi___33 technology

.

Deep Learning Using Boltzmann Machines & Belief Network

Tarunima Mukherjee , Ganguly,Prof.Veena Kulkarni
Thakur College of Engineering & Technology
Kandivli East – Mumbai, India

Abstract: **- In recent times, the field of deep learning has achieved great importance and success in fields like natural language processing and computer vision. Deep Learning with its strong ability to learn by making use of datasets for feature selection is gaining more importance than traditional machine learning. Deep learning is becoming popular amongst researchers due to its practicability. In this paper we discuss about some of the advanced neural networks with its applications. We also, discuss about the limitation and advantages of deep learning with Deep Boltzmann Machine (DBM) & Deep Belief Networks (DBN) being the area of study.**

Keywords – Deep Learning, DBM, DBN, Neural Network, Dataset

I. INTRODUCTION

Deep learning is a machine learning technique which helps the computers to learn by example. Images, text, or sound helps the computer model to perform classification tasks directly. High degrees of accuracy, sometimes exceeding human-level performance is achieved by Deep Learning. The deep learning models are trained by using a large set of labeled data and neural network architectures that contain many layers.

Discovering high-level representations from high dimensional data is the basic idea of resolving multiple AI related tasks, which includes object recognition, speech perception and language understanding. To create such systems, we require deep architectures which includes many layers of nonlinear processing.

The Greedy algorithm suffers from various disadvantages such as
1) It is based on a very approximate inference procedure, limited to a single bottom-up pass. 2) The model can fail to effectively account for uncertainty while interpreting ambiguous sensory inputs. 3) The existing greedy procedure is suboptimal as it learns one layer of features at one time and never re-adjusts its lower- level parameters. 4) While global fine-tuning has been done by using the contrastive wake-sleep algorithm of Hinton et al. (2006) still it turns out to be very slow and inefficient.

Deep Boltzmann Machine (DBM) is a new kind of learning algorithm that was introduced by Hilton & Salakhutdinov for hierarchical probabilistic model. DBM is a type of Markov random field, with undirected connections between layers. The concept of Deep Boltzmann Machines are exciting for several reasons. Firstly, it retains much of the desired data as found in Deep Belief Networks. Secondly it also discovers several layers of increasingly complex representations of the input data and comes with an efficient layer-by-layer pretraining procedure. Thirdly it can also be trained on unlabeled data and can be tweaked for a specific task using the labeled data. For DBN's and deep convolutional neural networks, the approximate inference procedure for DBM's incorporates a top-down feedback in addition to the usual bottom-up pass, thereby enabling Deep Boltzmann Machines to better incorporate uncertainty about ambiguous inputs. Also, the parameters of all layers can be optimized jointly by following the approximate gradient of a variation lower- bound on the likelihood function. Greatly facilitates learning thereby providing better generative models

II. MODELS OF DEEP ARCHITECTURE

Deep Architecture learning algorithms are the one that learn to represent functions with many levels of composition. It is made up of many layers of Non-Linear Operations like neural nets with multiple hidden layers. The building blocks of deep architectures such as DBN and DBM are the RBMs.
Now we will look at some of the deep learning models: -

A) Deep Boltzmann Machine (DBM)
DBM is a network of stochastic binary units coupled symmetrically. It contains a set of visible units $v \in \{0, 1\}$, and a sequence of layers of hidden units $h1 \in \{0, 1\}F1$, $h2 \in \{0, 1\}F2$,..., $hL \in \{0, 1\}FL$. There are connections only between hidden units in adjacent layers, as well as between the visible units and the hidden units in the first hidden layer [1]. This is represented in Figure 1[2].
The various advantages include the following points: -

Advantages:
Firstly, it retains much of the requisites found in Deep Belief Networks. Secondly, it discovers several layers of increasingly complex representations of the input, and it comes with an efficient layer-by-layer pre-training procedure. Also, it can be trained on unlabeled data and can be modified for a specific task using the labeled data.

Also, the approximate inference procedure for DBM's incorporates a feedback which is top down in nature in addition to the bottom-up pass, which allows Deep Boltzmann Machines to include uncertainty of ambiguous inputs. Additionally, all the parameters of all layers can be jointly optimized by following the approximate gradient of a variation lower-bound on the likelihood function which in turn enables better learning generative models.

2) Disadvantages: -

One of the disadvantages is described as below: -

The approximate inference is based on the mean-field approach, which is considerably slow when compared to a single bottom-up pass of Deep Belief Networks. Due to this disadvantage the joint optimization of DBM parameters becomes unfeasible for large datasets. Secondly, this also reduces the appeal for using DBM's in extracting useful feature representations as the expensive mean-field inference has to perform for every new test input.

3) Characteristics of DBM

- The various features of Deep Boltzmann Machine are as below:-These are unsupervised, generative & probabilistic model with completely undirected connections between various layers
- Similar to RBM, no intralayer connection exists in DBM.
- In DBM connections exists only between units of the neighbouring layers
- This contains visible & multiple layers of hidden units.
- DBM is made up of binary units which are symmetrically connected and are stochastic
- DBM can be seen as bipartite graph with odd layers as one set of vertices and even layers as another set

.

- In DBM the units within the layers are dependent on neighbouring layers but are independent of each other.
- Efficient learning is ensured by pre training of all the layers one at a time. However, it is to be noted that Greedy layer wise pre training is different than DBM pretraining.
- By using back propagation, the DBM layers can be fine-tuned.

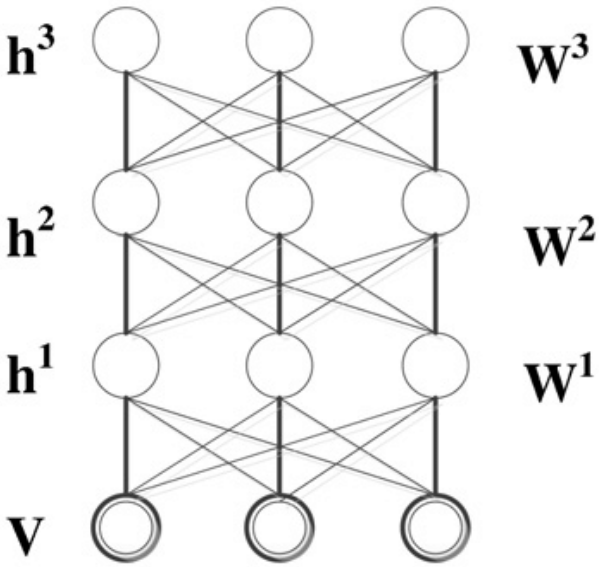


Fig. 1 Graphical Representation of DBM

B. Deep Belief Network (DBN)

The second model which will be discussed is the Deep Belief

Net (DBN) by Hinton [3].

DBN is obtained by training and stacking several layers of Restricted Boltzmann Machines (RBM) in a greedy manner. In this the stack of RBMs is trained at first and then it is used to initialize classification of multi-layer neural network.[4].

DBN is a multi-layer generative model with layer variables as h0 (the input or visible layer), h1, h2, h3 etc. The top two layers have a joint distribution which is an RBM, where P(hk|hk−1) is parametrized in the same way as it is done for RBM. Therefore, we sat that a 2-layer DBN is an RBM, and a stack of RBMs share parametrization with a corresponding DBN as in Fig 2. [5]

Thus, we see that Deep belief nets are probabilistic generative models and is made up of multiple layers of latent variables having binary values and are termed as feature detectors or hidden units. Also, we see that the undirected and symmetric connections of top two layers forms an associative memory. To initialize each layer of a DBN as an RBM, the contrastive divergence update direction is used as below: -

- The first layer of the DBN is trained as an RBM P1 with visible layer v1 and hidden layer h1.
- The second layer RBM P2 is trained such that the models with its visible layer v1 is sampled from the training data set and the sample h2 from P1(h1|v1).

It has been shown in [6] that this maximizes a lower bound on the log-likelihood of the DBN. With the newly added top layer trained as an RBM to model the samples produced by chaining the posteriors P(hk|hk−1) of the lower layers

(starting from h0 from the training data set) the number of layers are increased greedily, [6].

1) Greedy layer wise training

Greedy layer wise training is accomplished by first training the lower layer with an unsupervised learning algorithm, thereby giving rise to an initial set of parameter values for the first layer of a neural network. Then the output of the first layer is used as an input for another layer, and similarly initialize that layer with an unsupervised learning algorithm. After having thus initialized a number of layers, the whole neural network is fine-tuned with respect to a supervised training criterion. [4].

2) Advantages

Firstly, one of the advantages of the greedy layer-by layer learning algorithm is that it can quickly find a find a good set of model parameter, even if the models contains huge number of parameters. Secondly, the learning algorithm efficiently use large sets of unlabeled data. Thirdly, the model can be pre-trained in a completely unsupervised fashion. Lastly, there is an efficient way of performing approximate inference to compute the values of the latent variables in the deepest layer with some given input [7].

3) Disadvantages

One of the main disadvantages of the greedy algorithm is that the approximate inference procedure is limited to a single bottom-up pass. The model fails to adequately account for uncertainty when interpreting ambiguous sensory inputs because of ignoring top- down influences on the inference process. Also, as the greedy procedure learns one layer of features at a time and never re-adjusts its lower-level parameters thereby resulting in the making the greedy procedure as sub optimal. Despite global fine- tuning using the contrastive wake-sleep algorithm has been used by Hinton, still the greedy algorithm it is very slow and inefficient [7].

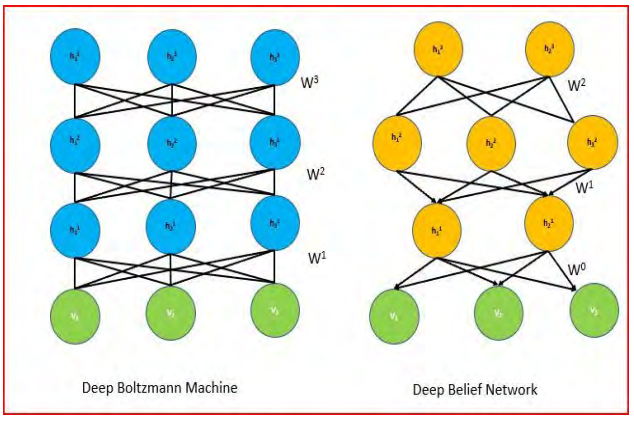

Fig. 2 Graphical Representation of DBN

C Deep Belief networks (DBN) vs Deep Boltzmann Machine (DBM)

- For Deep Belief Network (DBN) the top two layers are having undirected connections while directed connections exists for the lower layers. On the other hand /.the Deep Boltzmann Machine (DBM) are having entirely undirected connections.
- A top-down feedback along with the bottom-up pass is used for approximate inference procedure for DBM, thereby allowing Deep Boltzmann Machines to have better control over uncertainty about ambiguous inputs.
- The approximate inference based on mean field approach as used in DBN is slower as compared to a single bottom-up pass as used in Deep Belief Networks. This is because for every new input, the Mean field inference needs to be performed again and again thereby reducing its efficiency. The differences are shown in Fig 3 [8]

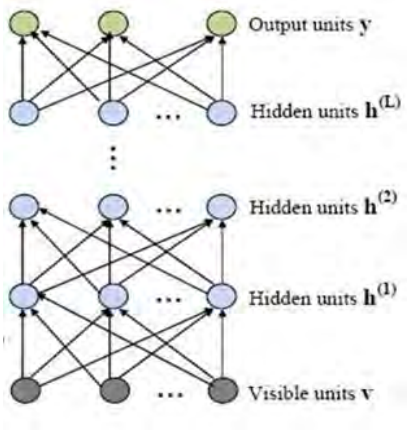

Fig. 3 Graphical Difference between DBM & DBN

The table below lists down the major differences between DBM & DBN Table I. Comparison of DBN with DBM

S.No	Deep Boltzman Machine	Deep Belief Network
1	DBM are undirected	Belief Networks are directed
2	Each layers forms an RBM because the connection between all layers are undirected	The first 2 layers forms a RBM then subsequent layers form a directed
3	These are Markoff Random Fields	These are sigmoid belief networks
4	Computing P (v | h) is infeasible	Computing P (v | h) is easy
5	Intractable Function makes P infeasible	No Intractable Partition Function

6	DBM gives lesser error rate as compared to DBN on various	DBN has higher error rate as compared to DBM.

D. Applications of the Model

In this section we will be discussing about various applications of Deep Boltzmann Machine and Deep Belief Network.

Deep Boltzmann Machine:-

1) Shape Completion: - It is an important task in the field of image processing. DBM with its strong ability to deal with distribution of shapes, it is easy to achieve the result by sampling from the model. Here hidden activation of the DBM is used and incorporated with the convolutional shape features to fit a regression model and then the output of the regression model is compared with the incomplete shape feature in order to set a mask for sampling from the DBM.

2) Deep Feature Selection - The structure of a Deep Boltzmann Machine enables it to learn very complex relationships between features and facilitates advanced performance in learning of high- level representation of features. Deep Feature Selection (Deep- FS), is used to remove irrelevant features from large datasets in order to reduce the number of inputs which are modelled during the learning process. Deep-FS algorithm uses a Deep Boltzmann Machine, to remove features at the initiation of the learning process.

3) Object Recognition:- Object Recognition means to detect and classify objects in an image or video into generic categories DBM uses binary hidden and visible units, which is applicable to quasi- binary images (e.g., handwritten digits). The extension of DBMs are more suitable to the continuous data. The characterization of object recognition using DBM has been a recent focus in the computer vision community.

4) DBMs are extensively used in solving combinatorial optimization problems.

5) DBMs are also used for detecting Parkinson Disease using signal decomposition.

Deep Belief Network:-

1) Generating and recognizing images-In this the input will be a picture and the output will be a category. It has a wide range of application varying from simple photo organization to critical functions like medical diagnoses. For example, smart microspores which can do image recognition could be used to classify pathogens.

2)Video sequences -It works similarly to vision, in which it finds Meaning in the video data. For example, it can be used to detect an object or a gesture of a person. It can also be used in many different fields such as home automation, security and healthcare.

3) Motion-capture data - Motion capture data involves tracking the movement of objects or people by using deep belief networks. Motion capture can easily lose track and depends on what an object or person appearance velocity and distance. It is used in video game development and in filmmaking

4) Natural language understanding problem- It is done by using an efficient learning algorithm called contrastive divergence (CD). CD enables DBNs to learn a multi-layer generative model from unlabeled data and the features discovered are then used to initialize a feed-forward neural network which is fine-tuned with backpropagation

5) Precision Mechanism Quality Inspection- Precision mechanism is widely used for various industry applications. Quality inspection for precision mechanism is important for manufacturers to ensure that the product dispatched is of good quality.This is achieved by a detection method, based on a Deep Belief Network (DBN) auto-encoder known as Tilear.It is structured in two parts: training and decision-making. Tilear is trained by using the signals only from good samples, which in turn enables it to reconstruct signals of good sample only. If the signal from the sample part matches the Tilear reconstructed signal, then the part is of expected quality and facilitates decision making.

6) Image compression and extraction -This application powers the capacity of deep belief network for classification of raw data from their features and increases their ability to handle large number of parameters.

III. CONCLUSION

When it comes to representation learning techniques, we find that Deep learning is one of the most powerful tool. In this paper, it has been represented as to how the ability of one deep learning architecture i.e. the deep belief network varies from the Deep Boltzmann machines.

Deep Belief Networks (DBNs) and Deep Boltzmann Machines (DBMs) look very similar diagrammatically, however they are actually very different qualitatively. Also, both the techniques are probabilistic graphical models composed of stacked layers of RBMs with the difference being in the manner these layers are connected with each other.

For both the models the learning tasks are enabled by using greedy layer-by-layer training procedure. The greedy layer-by-layer learning algorithm very quickly finds a good set of model parameters, even if the models contains many

parameters and layers of non-linearities. Also, the model can be pre-trained in a completely unsupervised manner. A grave disadvantage of this greedy algorithm is that it is based on an approximate inference procedure which is restricted to a single bottom-up pass. Compared to DBNs, DBMs are found to be more effective. Unlike existing models with deep architectures, including DBNs and deep convolutional neural networks, the approximate inference procedure for DBMs incorporates a top-down feedback along with bottom-up pass, enabling DBMs to include uncertainty about ambiguous inputs, also the easy implementation enables its usage in various data set as compared to the intricate models of deep convolutional neural networks Third, and perhaps more importantly, parameters of all layers can be improved jointly by

.

following the approximate gradient of a variational lower-bound on the likelihood function. This greatly facilitates learning better generative models. However, a critical weakness of DBMs is that approximate inference, which is based on the mean-field approach, is considerably (between 25 and 50 times) slow as compared to a single bottom-up pass as in Deep Belief Networks. Due to this for large datasets the joint optimization of DBM parameters becomes impractical

Study of Predictive Analysis in Fin Tech

Pooja sharma, Dr. Sheetal Rathi
Dept. of Computer Engineering
Thakur College of Engineering Technology
pooja12sharma.1997@gmail.com, sheetal.rathi@thakureducation.org

Abstract-***One of the leading trend among investors is FinTech related venture. For discussion, people will always take an issue on financial and banking on the phones and many customers want to resolve the matter without directly going to the banks. Thousands of customer calls done for queries will make use of call center receive each day which will increase the growth of online banking and all the things now switching towards online system which will reduce cost, human error etc. and it will change the way of consumer markets and our societies. Based on predictive analytics businesses are identifying the patterns and trends to increase the efficiency of Data Mining (DM) which we proposed by using an Artificial Neural Network (ANN)approach for predicting the success of telemarketing calls in selling long term deposits of bank which will perform other conventional classifier and confirms its valuable for campaign on telemarketing. Its goal is to predict if the client will subscribe a term deposit.***

Keyword- Bank Telemarketing, Decision making, Prediction, Input parameters, machine learning techniques.

I. INTRODUCTION

Telemarketing is a interactive and personalized method of marketing the product through various medium like phone or a subsequent face to face or web conferencing appointments scheduled during the call. In banking sector telemarketing has gained an importance as an effective tool for promotion. [1]

Telemarketing having a process for making use of sophisticated communication network for promoting the banks. This includes promoting through various mediums like television, telephone, radio and nowadays very largely through cell phones. Now a today Banks have started using 'SMS' and many other services for their customers supported by cell phones to provide benefits and thus have tried to increase their sales. In today's competitive and modern scenario it very important that banks makes use of telemarketing techniques very efficiently to have desirable results [2]. Marketing selling is to promote through various mediums like TV, online, radio, media etc. done a campaigns constitute to enhance business.

Customers by meeting and contact them for a specific goal. Marketing put into operation through a contact Center is called telemarketing due to the remoteness characteristic. To predict a non-linear nature of stock there are several methods are applied. For prediction a very powerful tool is ANNs and one of the type of ANNs is Multi-Layer Perceptron (MLP). It will used to explain and predict one or more observable and effectively measured phenomena. For all variables the analysis is done on database using a supervised learning. From hidden information we explore a new information, in this case there is a target variable to be predicted. There is available data for research and was collected from a Portuguese retail bank.

II. LITERATURE REVIEW

For stock market prediction selection of input features is important task. Technical indicator were used as an input for machine learning techniques. Here further we see some of the techniques used by researchers used some input features for prediction.

Yan LeCunn is said to be one of the fathers of deep learning, mostly due to his work with a pioneering 7-Level CNN known as LeNet-5 in the year 1998 [3]. His work was applied by various banks in order to recognise hand written digits on cheques. Whilst still using the CNN Since the introduction of ANNs, other techniques such as SVM have been given more importance and have achieved a better results in a short time period.[4] In bank telemarketing Using CNNs whereby its aim is to predict whether a customer will take up a particular marketing campaign based on a number of numeric and nominal features per customer. Amongst all accuracy an impressive 76.70%, is the highest from among all 7 classifiers [5].

Y. Kawasaki & M. Ueki have examined predictive modelling with several sparse regression methods for bank telemarketing

Success they have concluded that an effective predictive model may help in reducing costs for marketing in companies. [6]

H. A.Elsalamony has estimated performance on three statistical measures: specificity, classification accuracy, sensitivity. He has used a Multilayer perceptron neural network (MLPNN) and Ross Quinlan new decision tree model (C5.0) using a database of bank to increase the campaign effectiveness by identifying the main characteristics that affect a success [7].

III. THE PROPOSED APPROACH

The direct marketing campaign of "Portuguese bank dataset" is used in this paper. [8]

A. Dataset

The data is related with direct marketing campaigns of a Portuguese banking institution. The marketing campaigns were based on phone calls. Often, more than one contact to the same client was required, in order to access if the product (bank term deposit) would be ('yes') or not ('no') subscribe. This research focus on targeting through telemarketing phone calls to sell long-term deposits.

Within a campaign, the human agents execute phone calls to a list of clients to sell the deposit (outbound) or, if meanwhile the client calls the contact- center for any other reason, he is asked to subscribe the deposit (inbound).[9] Thus, the result is a binary unsuccessful or successful contact. For evaluation purposes, a time ordered split was initially performed, where the records were divided into training (four years) and test data (one year). The training data is used for feature and model selection and includes all contacts executed up to June 2012, in a total of 51,651 examples. The test data is used for measuring the prediction capabilities of the selected data-driven model, including the most recent 1293 contacts, from July 2012 to June 2013.Each record included the output target, the contact outcome ({"failure", "success"}), and candidate input features. These include telemarketing attributes (e.g., call direction), product details (e.g., interest rate offered) and client information (e.g., age). These records were enriched with social and economic influence features (e.g. Unemployment variation rate), by gathering external data from the central bank of the Portuguese. Republic statistical web site. The merging of the two data sources led to a large set of potentially useful features [10].

Table 1: client attribute's information

Sr.No	Attribute's	Description
1	Age	numeric
2	Job	type of job (categorical: 'admin.', 'blue collar', 'entrepreneur', 'housemaid', 'management', 'retired', 'self employed','services','student','technician','unemployed','unknown')
3	Martial	marital status (categorical: 'divorced', 'married', 'single', 'unknown'; note: 'divorced' means divorced or widowed)
4	Education	(categorical:'basic.4y','basic.6y','basic.9y','high.school','illiterate','professional course','university degree', 'unknown')
5	Default	has credit in default? (categorical: 'no', 'yes', 'unknown')
6	Balance	categorical: 'no','yes', 'unknown'
7	Housing	has housing loan? (categorical: 'no', 'yes', 'unknown')
8	Loan	has personal loan? (categorical: 'no','yes', 'unknown')
9	Contact	contact communication type (categorical: 'cellular', 'telephone')
10	Day	last contact day of the week (categorical: 'mon', 'tue', 'wed', 'thu', 'fri')
11	Month	last contact month of year (categorical: 'jan', 'feb', 'mar', ..., 'nov', 'dec')
12	Duration	last contact duration, in seconds (numeric).
13	Campaign	number of contacts performed during this campaign and for this client (numeric, includes last contact)
14	Pdays	number of days that passed by after the client was last contacted from a previous campaign (numeric; 999 means client was not previously contacted)
15	Previous	number of contacts performed before this campaign and for this client (numeric)
16	Poutcome	outcome of the previous marketing campaign (categorical: 'failure', 'non-existent','success')
17	Y/N	has the client subscribed a term deposit? (binary: 'yes', 'no')

B. Dataset Balancing, Training, and Test Split

We will be utilizing data from 2003 till 2013 (11 years) as our training set and 2014 till 2016 (3 years) as our test set. This ensures a substantial amount of data for training, whereby 11 years of stock movements should cover a wide range of long and short term trends. The remaining three years will be used for testing, this approach will ensure that we are forecasting and calculating our evaluation metrics on unseen, out-of-sample data [11].

C. MLP

MLP means Multilayer Perceptron's. It is the classical type of neural network. It is the set of interconnected neurons. It comprised of one or more layers of neurons. In input layer Data is fed, more than one hidden layers providing levels of abstraction, and predictions are the output layer, also called the visible layer. The activation functions used in such networks are mainly threshold or sigmoid functions.

$$\sigma(y) = \frac{e^y}{e^y+1} = \frac{1}{1+e^{-y}}$$

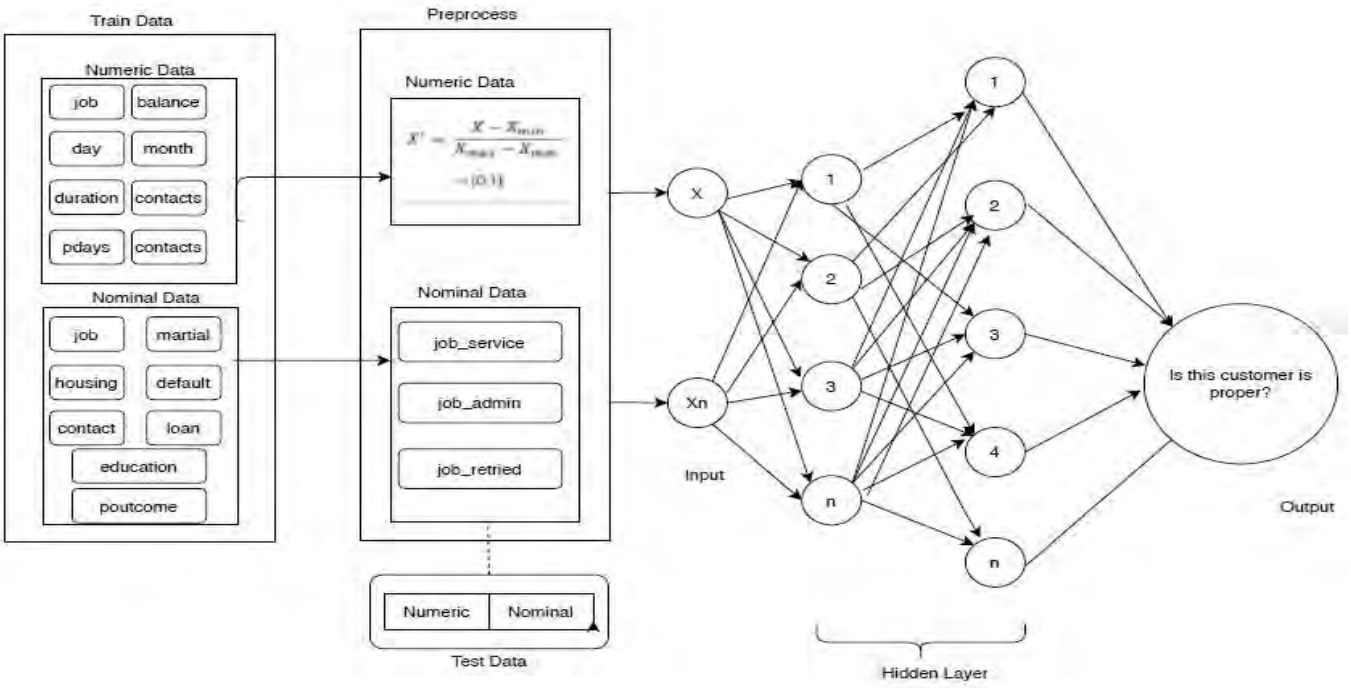

Figure 1: System analysis of bank telemarking using MLP

There are several uses of MLP are:

- Tabular datasets
- Classification prediction problems
- Regression prediction problems[12]

- The input layer: First layer of the network where no calculation is made. The input cell only receives in input the values of attributes: X,… , Xn

- The output layer: Last layer of the network that contains one or more decision cells.[13]

For numerical data: (Ref. Table 1)

- For each numerical feature we calculate directly statistic parameters (mean, max, min, variance, standard deviation).

For categorical data:

- It is distinguish into 3 subtypes features are scaled features, binomial features and nominal features.[14]

For scaled values (Month, days of week):

- For calculating a statistics parameters for numerical values we substitute items by their ordinal number.

For Boolean features:

- For the Boolean features we have two possibilities either yes or no (1/0); else success or failure (1/0).

For Nominal features:

- For each value of the feature Vj for the
- i is replaced by his occurrence frequency which is calculated by:

$$Vij \leftarrow fij = mN \quad (1)$$

Where m is the frequency of the class, and N is the total number of instances.

Having a class which highest in similarity measure (Average of all features) is allocated. [15]

IV. CONCLUSION

In this paper we have proposed a type of ANN which is MLP technology used to predict the direct marketing campaign which is in the main strategy of many banks and insurance companies for interacting with their customers and making new business. We have a technique computes a specific similarity for each type of features. This technique fostered most significant features and predicts the client class more accurately. This paper evaluating the DM technique on the bank direct marketing dataset to classify for bank deposit subscription and increasing the campaign effectiveness by identifying the main characteristics that affect the success

V. ACKNOWLEDGEMENT

We would like to thank “Portuguese bank dataset” for their helpful suggestions.

Comparative Analysis of Different NLP Techniques for Detecting Sarcasm on Various Applications

Priyanka Bolinjkar
M.E. Second Year in
Computer Engineering
Thakur College of Engineering and Technology
Mumbai, India
Priyankabolinjkar33@gmail.com

Abstract— **sarcasm is a sophisticated form of irony widely used in social networks and microblogging websites. It is usually used to convey implicit information within the message a person transmits. Sarcasm might be used for different purposes, such as criticism or mockery. However, it is hard even for humans to recognize. Therefore, recognizing sarcastic statements can be very useful to improve automatic sentiment analysis of data collected from microblogging websites or social networks. Sentiment analysis refers to the identification and aggregation of attitudes and opinions expressed by internet users toward a specific topic. We also study the importance of each of the proposed sets of features and evaluate its added value to the classification. In particular, we emphasize the importance of pattern-based features for the detection of sarcastic statements.**

Keywords: pos (part of speech), ner (named entity relation), twitter, sentiment analysis, polarity

I. INTRODUCTION

Sentiment Analysis is a Natural Language Processing (NLP) and data extraction process that helps to acquire user‘s sentiments written in positive, negative, neutral remarks, questions and demands by doing research on large quantities of documents. As a rule, sentiment analysis expects to decide the perception of a speaker or an author as for some point or the general tonality of a report. Sentiments of people can be analyzed as Positive, Negative and Neutral. The sentiment analysis is vital to the business fields. By analyzing, the negative sentiment from the twitter can be used to improve the business and can benefit to the customers. Sarcasm is a kind of sentiment derived from the French word ―Sarkasmos‖ which means ―tear flesh‖ or ―grind the teeth. The meaning is different than what the
speaker intends to say through sarcasm. Sarcasm can also be defined as a ―contrast between a positive sentiment and negative situation‖ and vice versa. Twitter became one of the biggest web destinations for people to express their opinions, share their thoughts and report real-time events, etc. Throughout the previous years, Twitter content continued to increase, thus constituting a typical example of the so-called big data. Today, according to its official website, Twitter has more than 288 million active users, and more than 500 million tweets are sent every day. Many companies and organizations have been interested in these data for the purpose of studying the opinion of people towards political events, popular products or movies . However, due to the informal language used in Twitter and the limitation in terms of characters (i.e., 140 characters per tweet), understanding the opinions of users and performing such analysis is quite difficult. Furthermore, presence of sarcasm makes the task even more challenging: sarcasm is when a person says something different from what he means. Some people are more sarcastic t h a n others, however, in general, sarcasm is very common, though, difficult to recognize. In general, people employ sarcasm in their daily life not only to make jokes and be humorous but also to criticize or make remarks about ideas, persons or events. Therefore, it tends to be widely used in social networks, in particular microblogging websites such as Twitter. The area of Sentiment Analysis intends to comprehend these opinions and distribute them into the categories like positive, negative, neutral. Most sentiment analysis work has been done on review sites . Review sites provide with the sentiments of products or movies, thus, restricting the domain of application to solely business. Sentiment analysis on Twitter posts is the next step in the field of sentiment analysis, as tweets give us a richer and more varied resource of opinions and sentiments that can be about anything from the latest phone they bought, movie they watched, political issues, religious views or the individuals state of mind.

II. II. LITERATURE REVIEW

In the last few years, more attention has been given to Twitter sentiment analysis by researchers, and a number of recent papers have been addressed to the classification of tweets. However, the nature of the classification and the features used vary depending on the aim. Sriram et al. used non-context-related features such as the presence of slangs, time-event phrases, opinioned words, and the Twitter user information to classify tweets into a predefined set of generic classes including events, opinions, deals, and private messages. Akcora et al. proposed a method to identify the emotional pattern and the word pattern in Twitter data to determine the changes in public opinion over the time. They implemented a dynamic scoring function based on Jaccard‘s similarity of two successive intervals of words and

used it to identify the news that led to breakpoints in public opinion.

However, most of the works focused on the content of tweets and were conducted to classify tweets based on the sentiment polarity of the users towards specific topics. A variety of features was proposed. Not only they include the frequency and presence of unigrams, bigrams, adjectives, etc, but they also include non-textual features such as emoticons (i.e., facial expressions such as smile or frown that are formed by typing a sequence of keyboard symbols, and that are usually used to convey the writer‘s sentiment, emotion or intended tone) and slangs . Dong et al. proposed a target-dependent classification framework which learns to propagate the sentiments of words towards the target depending on context and syntactic structure.

Sarcasm, on the other hand, and irony in general have been used by people in their daily conversations for a long time. Therefore, sarcasm has been subject to deep studies form psychological and even neurobiological perspectives. Nevertheless, it has been studied as a linguistic behavior characterizing the human being . In this context, 5478
VOLUME 4, 2016 researchers have recently been interested in sarcasm, trying to find ways to automatically detect it when it is present in a statement. Although some studies such as highlighted that, unlike irony, sarcasm _is not a discrete logical or linguistic phenomenon‘‘, many works
have been proposed and present high accuracy and precision.

Burfoot and Baldwin introduced the task of filtering satirical news articles from true newswire documents. They introduced a set of features including the use of profanity and slangs and what they qualified of _semantic validity‘‘; and used Support Vector Machine (SVM) classifier to recognize satire
articles. Campbell and Katz studied the contextual components utilized to convey sarcastic verbal irony and proposed that sarcasm requires the presence of four entities: allusion to failed expectation, pragmatic insincerity, negative tension and presence of a victim, as well as stylistic components.

III. SCOPE OF NLP

The tweets are differentiated among positive, negative and neutral based on the detection engine. The tweets that are classified as positive, negative and neutral are further classified as Actual positive, Actual negative and Sarcastic sentiment. Actual positive tweets contain the tweets that are actually positive, Actual negative tweets are the tweets that are actually negative and sarcastic tweets are those in which it is difficult to determine whether tweets are actually positive or negative.

Removal of Stop Words:-

The stop words are removed using python programming. The stop words corpus distributed with NLTK have been used. The stop words corpus consist of 2400 stop words for
11 different languages. Example: –This is a long bar sentence‖. After stop words removal we get `long‘ `bar‘sentence‘.
`

Tokenization:

Tokenization is process of breaking texts into words, phrases and symbols called tokens. The tokens generated helps in parsing and performing other mining tasks. Tokenization is done using TextBlob package installed in NLTK. Example: –Beautiful is better than ugly‖. After tokenization using TextBlob we get every word separated
such as `Beautiful‘, `is‘, `better‘, `than‘, `ugly‘.

Part of Speech Tagging :

Part of Speech Tagging divides sentences into words and assign part of speech for each word. In this paper TextBlob is used for Part of Speech Tagging. Example: –Sarcasm detection using twitter data‖. Part of Speech tagging for the example is Sarcasm-NNP, detection-NN, using-VBG, twitter-NN, data- NNS. Here NNP stands for proper noun singular, NN stands for noun singular, VBG stands for verb present participle and NNS stands for noun plural.

III. APPROACHES AND COMPONENTS OF SARCASM DETECTION

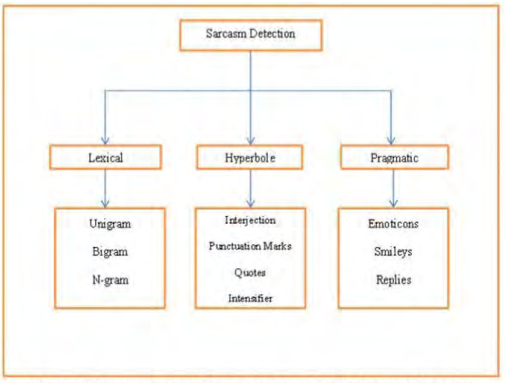

Figure [1] Approaches and Components used in the Sarcasm Detection

Lexical analysis: It the process of analyzing a stream of individual characters, into a sequence of lexical tokens to feed into the parser. Performs reading of input characters, removal of white spaces and comments. Roughly the equivalent of splitting ordinary text written in a natural language (e.g. English) into a sequence of words and punctuation symbols. Strictly speaking, tokenization may be handled by the parser. The reason why we tend to bother with tokenising in practice is that it makes the parser simpler, and decouples it from the character encoding used for the source code.

Hyperbole: It is a device that we employ in our day-to- day speech. For instance, when you meet a friend after a long time, you say, –It‘s been ages

since I last saw you.‖ You may not have met him for three or four hours, or a day, but the use of the word –ages‖ exaggerates this statement to add emphasis to your wait.

Examples of hyperbole:

1. The blacksmith‘s hand was harder than the rock.
2. The old man was older than the Himalayas.

Pragmatic: Pragmatics is a subfield of linguistics and semiotics that studies the ways in which context contributes to meaning. Pragmatics encompasses speech act theory, conversational implicative, talk in interaction and other approaches to language behavior in philosophy, sociology, linguistics and anthropology.
Various Approaches used in Sarcasm detection

1. Rule Based Approach: Rule-based system is used to store and manipulate knowledge to interpret information in a useful way. It is often used in artificial intelligence applications and research. A classic example of a rule-based system is the domain-specific expert system that uses rules to make deductions or choices. For example, an expert system might help a doctor choose the correct diagnosis based on a cluster of symptoms, or select tactical moves to play a game. Rule- based systems can be used to perform lexical analysis in natural language programming.
2. Supervised Approach : Supervised learning is the machine learning task of learning a function that maps an input to an output based on example input-output pairs. It infers a function from *labeled training data* consisting of a set of *training examples*. In supervised learning, each example is a *pair* consisting of an input object (typically a vector) and a desired output value (also called the *supervisory signal*). A supervised learning algorithm analyzes the training data and produces an inferred function, which can be used for mapping new examples

.

Following are some key characteristics of various applications:

1. Message Length: The maximum length of a Twitter message is 140 characters. This is different from previous sentiment classification research that focused on classifying longer texts, such as product and movie reviews.

2. Writing technique: The occurrence of incorrect spellings and cyber slang in tweets is more often in comparison with other domains. As the messages are quick and short, people use acronyms, misspell, and use emoticons and other characters that convey special meanings.

3. Availability: The amount of data available is immense. More people tweet in the public domain as compared to Facebook (as Facebook has many privacy settings) thus making data more readily available. The Twitter API facilitates collection of tweets for training.

V. DESIGN AND ANALYSIS

Tools used

1. Python and visual studio code
2. Libraries

- Textblob :To perform Sentiment Analysis
- Tweepy: To fetch twitter data
- Tweeter Developer: It is an API used to fetch keys

• Def clean_tweet: Used for cleaning of tweets
• Ptweets: positive tweets

• Ntweets: negative tweets

V. METHODOLOGY

The tweets are differentiated among positive, negative and neutral based on the detection engine. The tweets that are classified as positive, negative and neutral are further classified as Actual positive, Actual negative and Sarcastic sentiment. Actual positive tweets contain the tweets that are actually positive, Actual negative tweets are the tweets that are actually negative and Sarcastic tweets are those in which it is difficult to determine whether tweets are actually positive or negative.

Removal of Stop Words:-
The stop words are removed using python programming. The stop words corpus distributed with NLTK have been used. The stop words corpus consist of 2400 stop words for
11 different languages. Example: –This is a long bar sentence‖. After stop words removal we get `long‘ `bar‘ `sentence‘.

Tokenization
Tokenization is process of breaking texts into words, phrases and symbols called tokens. The tokens generated helps in parsing and performing other mining tasks. Tokenization is done using TextBlob package installed in NLTK. Example: –Beautiful is better than ugly‖. After tokenization using TextBlob we get every word separated such as `Beautiful‘, `is‘, `better‘, `than‘, `ugly‘.

Part of Speech Tagging
Part of Speech Tagging divides sentences into words and assign part of speech for each word. In this paper TextBlob is used for Part of Speech Tagging. Example: –Sarcasm detection using twitter data‖. Part of Speech tagging for the example is Sarcasm-NNP, detection-NN, using-VBG, twitter-NN, data-NNS. Here NNP stands for proper noun singular, NN stands for noun singular, VBG stands for verb present participle and NNS stands for noun plural.

Parsing
Parsing is process of analyzing the symbols based on natural

language. When a sentence is passed through parser, the parser divides the whole sentence into words and finds Indian Journal of Science and Technology Vol 10 (25) | July 2017 | www.indjst.org 5 Shubhodip Saha, Jainath Yadav and Prabhat Ranjan Part of Speech (POS) tags.POS and syntactic relations are used to form units such as subject, verb and object. In this paper python based package named TextBlob is used for parsing. Example: ‒Sarcasm detection using twitter data‖ is parsed giving result as Sarcasm/NN/B- NP/O, detection/ NN/I-NP/O, using/VBG/BVP/O,twitter/NNP/B-NP/O, data/NNS/I-NP/O. Here O represents out

Sentiment Related Features.

A very popular type of sarcasm that is widely used in both regular conversations as well as short messages such as tweets, is when an emotionally positive expression is used in a negative context. A similar way to express sarcasm is to use expressions having contradictory sentiments. This type of sarcasm we qualified as ‗whimper‘‘ is very common in social networks and microblogging websites. Riloff et al. show that this type of sarcasm can be identified and detected when a positive statement, usually a verb or a phrasal verb, is collocated with a negative situation (e.g., ‗I love being ignored all the time‘‘). They built a lexicon-based approach that learns the possible positive expressions and negative situations and used it to detect such contrast in unknown tweets. Therefore, to identify and quantify such inconsistency, we extract sentimental components of the tweet and count them. For this purpose, we maintain two lists of words qualified as ‗positive words‘‘ and ‗negative words‘‘. The two lists contain respectively words that have positive emotional content (e.g., ‗love‘‘, ‗happy‘‘, etc.) and negative emotional content (e.g., ‗hate‘‘, ‗sad‘‘, etc.). The two lists of words are created using SentiStrength6 database. This database contains a list of emotional words, where negative words have scores varying from −1 (almost negative) to −5 (extremely negative) and positive words have score varying from 1 (almost positive) to 5 (extremely positive). Using these two lists, we extract two features we

denote respectively pw and nw by counting the number of positive and negative words in the tweet.

IV. COMPARISON OF DIFFERENT NLP TECHNIQUES

SVM	Hybrid	NER	Text Summarization
Support machine is a kind of large machine classifier: here the goal I is to find a decision boundary between 2 classes	It is used for text clustering which is the combination of active feature selection genetic algorithm and bisecting k- Gram	It is subtask of information extraction that seeks to locate and classify name entity mentioned in unstructured text into predefined categories like name,person,v	It is a process of shortening a set of data computantion ally,to create a subset of that represents the must important or relevant information within the original
Many NLP problems can be formulated as classification Eg.Word sense disabmiguation,spam Filtering,Etc	Improving NLP Application. If We are developing grammar correction system, Rule based module that identifies wrong pattern and generate tight pattern.	Most research on NER system has been as taking an unnoted block text Eg. Jim Bought 300 shares of Acme corp. organization in 2006 [Jim] –Person [Acme Corp]- [2006]-time	In addition to text, images and videos can also be summarized. Eg. key pharses that can be used to ‒tagllor index a text document
More effective in wgh dimension spaces	Much better suited to classification with complex non-distributed classes.	It provides different models for pulling out name entities.	Works in any language, improves productivitty

V. CONCLUSION

Using the senti-strength tool we get the polarity of each word as well as the overall sentence. For the sentence, a polarity score of -1 to -5 is considered to be negative polarity sentence, 0 is taken to be neutral while a score of +1 to +5 is taken to be of positive polarity.

VI. ACKNOWLEDGEMENT

We hereby take the privileged to present our paper on NLP Techniques for detecting Scram on Twitter . We are very grateful to our paper guide Dean Dr.R.R.Sedamkar for contributing and valuable time in the paper from their busy and hectic schedule. Thank you for being after us like a true mentor and great academic parents.

We are very thankful to Dean Dr.R.R.Sedamkar whose guidance and support was an immense motivation for us to carry on with our paper. Also suggestions have greatly contributed for the betterment of our paper.

Abstract— **As a rule, House value record speaks to the condensed value changes of private lodging. While at a solitary family house cost expectation, it needs increasingly exact technique dependent on area, house type, size, form year, nearby civilities, and some different components which could influence house request and supply. With restricted dataset and information includes, a pragmatic and composite information pre-handling, innovative element building strategy is inspected right now.**

Keywords: Regression, Lasso, Ridge, Ada-boost, city, comfort, investments, house price, estate agent, property

I. INTRODUCTION

Land Property isn't just the essential need of a man yet today it additionally speaks to the wealth and notoriety of an individual. Interest in land by and large is by all accounts productive in light of the fact that their property estimations don't decrease quickly. Changes in the land cost can influence different family unit financial specialists, brokers, approach creators and many. Interest in land segment is by all accounts an alluring decision for the ventures. Accordingly, foreseeing the land esteem is a significant monetary record. India positions second on the planet in number of family units as indicated by 2011 evaluation with various 24.67 crore. India is additionally the quickest developing significant economy in front of China with previous' development rate as 7% this year and anticipated to be 7.2% in the following year.

According to the 2017 version of Emerging Trends in Real Estate Asia Pacific, Mumbai and Bangalore are the topranked cities for investment and development. These cities have supplanted Tokyo and Sydney. The house prices of 22 cities out of 26 dropped in the quarter from April to June when compared to the quarter January to March according to National Housing Bank's Residex(residential index). With the introduction of Real Estate Regulation Development Act (RERA) and Benami property Act throughout the country India, more number of investors are attracted to invest into real estate in India. The strengthening and modernizing of the Indian economy has made India as attractive Investment destination. However, past recessions show that real estate prices cannot necessarily grow. Prices of the real estate property are related to the economic conditions of the state [1]. Despite this, we are not having proper standardized ways to measure the real estate property values.

Generally the property values rise with respect to time and its appraised value need to be calculated. This appraised value is required during the sale of property or while applying for the loan and for the marketability of the property. These appraised values are determined by the professional appraisers. However, drawback of this practice is that these appraisers could be biased due to bestowed interests from buyers, sellers or mortgages. Thus, we require an automated prediction model that can help to predict the property values without any bias. This automated model can help the first time buyers and less experienced customers to understand whether the property rates are overrated or underrated.

Now, Property prices depend on various parameters in the economy and society. However, previous analyses show that house prices are strongly dependent on the size of the house and its geographical location [2], [3]. We have also considered various intrinsic parameters (such as number of bedrooms, living area and construction material) and also external parameters (such as location, proximity, upcoming projects, etc.) [4], [5]. Then we have applied these parameter values to two different machine learning algorithms.

II. Literature Review

In most recent two decades anticipating the property estimation has become a significant field. Ascend in the interest for property and unusual conduct of economy urge analysts to discover a way that anticipate the land costs with no inclinations. Therefore, it is a test for scientists to discover all the moment factors that can influence the expense of property and make a prescient model by thinking about all the variables. Building a prescient model for land value valuation requires a careful information regarding the matter. Numerous

specialists have dealt with this issue and imparted their examination work.

The majority of this exploration work is enlivened from [6]. The creator has scratched the lodging informational index from Centris.ca and duProprio.com. Their dataset comprises of around 25,000 models and 130 components. Around 70 highlights were scratched from the above sites and land offices, for example, RE/MAX, Century 21, and Sutton, and so forth. Other 60 highlights were sociodemographic dependent on where the property is found. Afterward, creator actualized Principal Component Analysis to diminish the dimensionality. The creator utilized four relapse strategies to anticipate the value estimation of the property. The four

procedures are Linear Regression, Support Vector Machine, KNearest Neighbors (KNN) and Random Forest Regression and an outfit approach by consolidating KNN and Random Forest Technique. The gathering approach anticipated the costs with least blunder of 0.0985. Notwithstanding, applying PCA didn't improve the forecast mistake.

A lot of researches have been done on Artificial Neural Networks. This has helped many researchers focusing on real estate problem to solve using neural networks. In [7], the author has compared hedonic price model and ANN model that predict the house prices. Hedonic price models are basically used to calculate the price of any commodity that are dependent on internal characteristics as well as external characteristics. The hedonic model basically involves regression technique that considers various parameters such as area of the property, age, number of bedrooms and so on. The Neural Network is trained initially and the weights and biases of the edges and nodes respectively are considered using trial and error method. Training the Neural Network model is a black box method. However, the RSquared value for Neural Network model was greater compared to hedonic model and the RMSE value of Neural Network model was relatively lower. Hence it is concluded that Artificial Neural Network performs superior than Hedonic model.

Some researchers like that in [8] have used classifiers to predict the property values. The author in research article [8] has collected the data from Multiple Listing Service (MLS), historical mortgages rates and public school ratings. Real Estate Data was obtained from Metropolitan Regional Information Systems (MRIS) database. The author extracted approximately 15,000 records from these three sources which included 76 variables. Subsequently, t-test was used to select 49 variables as a preliminary screening.

Their research question was to determine whether the closing price was higher or lower than the listing price [8]. Thus to address this classification problem, the author used four machine learning models. C4.5, RIPPER, Naive Bayesian, and AdaBoost are the four algorithms used by author. However, they found that RIPPER outperforms other house prediction models. However the drawback is that performance evaluation is based only on classifiers. Performance comparison of other machine learning algorithms should also be considered.

In article [9], the authors have predicted the stock market prices using linear regression technique. They have collected stock market data from TCS stock Database. The author have also used RBF and polynomial regression technique along with linear regression and found that latter is superior to the remaining techniques.

In [11], the author has considered the most macroeconomic parameters that affect the house prices variation. In this, the author has used back propagation neural network (BPN) and radial basis function neural network (RBF) to establish the nonlinear model for real estates price variation prediction. The dataset have been taken from Taipei, Taiwan based on leading and simultaneous economic indices. The author has considered 11 parameters. The prediction results obtained from them are compared to public Cathay House Price Index or the Sinyi Home Price Index. The two error metrics used were Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE). When the prediction results were compared to Cathay House Price Index, RBF Neural Network showed better prediction results than BPN Neural Network. Similarly, for Sinyi Home Price Index BPN Neural Network showed better prediction results than RBF Neural Network.

Some examination articles portray the inside and out strategies and methods to gather the land information and their preprocessing procedures. The writer in article [12] portrays programming that is utilized in land value assessment. The product examines different land servers and site pages of land organizations, and records their present connects to land buy or rental into their product database. He has accumulated information from Czech Republic. The information is accumulated each month to record the progressions occurring in land. The product assembles 110,000 sections each month. These passages incorporate different writings, notices and pictures of the property. The creator has gathered information from the year 2007 to 2015.This unstructured information that is gathered is traded into an organized structure. Diverse property types have various parameters. In this manner it makes the informational collection increasingly clear. This informational index is then

assessed. New passages made every month are contrasted with the more seasoned sections and checked for their culmination. In the last period of the product, this accessible clean informational collection is then assessed and delivers different perceptions as per the necessity of the client. In this manner the yield got might be utilized as justification for fitting speculations as well as lodging choices for both normal people and organizations.

Some researchers have focused on feature selection and feature extraction procedure. The author in article [14] uses a open source data set of the housing sales in King County, USA. There are about 20 explanatory variables. The author has compared various feature selection and feature extraction algorithms combined with Support Vector Regression. The author has collected approximately 21,000 observations in a time period of one year. The paper shows various data analysis performed on the data set. Feature Selection is the process of selecting a subset of variables from a given set of parameters either based on their importance or their frequency. However, feature extraction is the process of reducing the dimensionality of the data. Initial set of data is transformed into derived values which are equally informative and non-redundant. The three feature selection algorithms used are Recursive Feature Elimination (RFE), Lasso and Ridge and Random Forest Selector and the mean from each algorithm is calculated. Using feature selection, the author selects fifteen features out of twenty. The feature extraction algorithm used is Principal Component Analysis (PCA) and reduces the parameters from twenty to sixteen. However, the author found that both the techniques work equally well with the R squared value of 0.86.

III. COMPARATIVE ANALYSIS

Algorithm	Hyperparameters
AdaBoost (AB)	**n-estimators:** Number of decision trees in the ensemble. **Learning rate :** Shrinks the contribution of each successive decision tree in the ensemble.
Gradient Tree Boosting(GTB)	**n-estimators** - Number of decision trees in the ensemble. **Learning rate :** Shrinks the contribution of each successive decision tree in the ensemble. **Loss:** Loss function to be optimized via gradient boosting. **Max_dept**: Maximum dept of the dept of the decision trees. Controls the complexity of decision tree **Max_features:** Number of features to consider when computing the best node split.
Random Forest (RF)	**n-estimators** - Number of decision trees in the ensemble. **Max_features:** Number of features to consider when computing the best node split. **Criterion:** Function used to measure the quality of a split. **Min_weight-fraction_leaf:** Number of features to consider when computing the best node split.
Decision Tree (DT)	**Max_features:** Number of features to consider when computing the best node split. **Criterion:** Function used to measure the quality of a split. **Min_weight-fraction_leaf:** Number of features to consider when computing the best node split.
K-Nearest neighbour (KNN)	**n_neighbours** – Number of neighbours to use. **weights**: Function to weight the neighbour votes.
Support Vector Classifier (SVC)	**kernel**: 'linear', 'poly', 'sigmoid', or 'rbf' **C :** Penalty parameter for regularization. **Gamma:** Kernel coefficient for 'rbf', 'poly' and 'sigmoid' kernels **Degree:** degree for the 'poly' kernel.
Logistic Regression (LR)	**C:** Regularization of strength. **Penalty**: whether to use lasso or ridge regularization. **Fit_intercept** : whether or not the intercept of the linear classifier should be computed.
Linear Regression	The basic form where the model is penalized for its choices of weights. That means, during the training stage, if the model feels like one particular feature is particularly important, the model may place a large weight to the feature. This sometimes leads to overfitting in small datasets. Hence, following methods are invented.
Lasso	Lasso is a modification of linear regression, where the model is penalized for the sum of absolute values of the weights. During training, the objective function become: $\frac{1}{2m}\sum_{i=1}^{n}(y_i - Xw_i)^2 + alpha\sum_{i=1}^{n}\lvert w_i\rvert$ Lasso introduced a new hyperparameter, alpha, the coefficient to penalize weights.
Ridge	Ridge takes a step further and penalize the model for the sum of squared value of the weights. Thus, the weights not only tend to have smaller absolute values and more evenly distributed, but also tend to be close to zeros. The objective function becomes: $\sum_{i=1}^{n}(y_i - Xw_i)^2 + alpha\sum_{i=1}^{n}w_i^2$
ElasticNet	ElasticNet is a hybrid of Lasso and Ridge, where both the absolute value penalization and squared penalization are included, being regulated with another coefficient l1_ratio:

Fig 2 : Comparative Analysis of Regression Algorithms

IV. CONCLUSION

In this research paper, we have used machine learning algorithms to predict the house prices. We have mentioned the step by step procedure to analyze the dataset and finding the correlation between the parameters. Thus we can select the parameters which are not correlated to each other and are independent in nature. These feature set were then given as an input to four algorithms and a csv file was generated consisting of predicted house prices. Hence we calculated

the performance of each model using different performance metrics and compared them based on these metrics.

For future work, we recommend that working on large dataset would yield a better and real picture about the model. We have undertaken only few Machine Learning algorithms that are actually classifiers but we need to train many other classifiers and understand their predicting behavior for continuous values too. By improving the error values this research work can be useful for development of applications for various respective cities.

Diabetic Retinopathy: A General Survey

Nidhi Kamothi, Rashmi Thakur
Thakur College of Engineering & Technology
University Of Mumbai
Mumbai, India
nidhikamothi95@gmail.com, thakurrashmik@gmail.com

Abstract— **Diabetic retinopathy (DR) is one of the leading causes of vision loss and can be effectively avoided by screening, early diagnosis and treatment. The retina is the only part of the human body where the blood circulation can be observed directly. Diabetic retinopathy is caused by the retinal micro vasculature which may be formed as a result of diabetes mellitus. Blindness may appear as a result of unchecked and severe cases of diabetic retinopathy.**

Manual inspection of fundus images to check morphological changes in micro aneurysms, exudates, blood vessels, hemorrhages, and macula is a very time-consuming and tedious work. It can be made easily with the help of computer-aided system and intervariability for the observer. In this paper, we provide overview of a computer-based approach for the detection of diabetic retinopathy using retinal images. There are many features present in retina but the exudates feature which is one of the primary signs of diabetic retinopathy and which is a main cause of blindness that could be prevented with the help of this automatic detection process technique.

The automatic detection process reduces examination time, and increase accuracy. In this paper provide review on many techniques and algorithms that helps to diagnose Diabetic Retinopathy in retinal fundus images.

Keywords— Diabetic Retinopathy, Fundus images, Exudates, Retinal blood vessels, macula, microaneurysms.

I. INTRODUCTION

Diabetes is a very common disease worldwide. It serves as a most common cause of blindness for people having age less than 50 years. Diabetes is the chronic state caused by an abnormal increase in the glucose level in the blood and which causes the damage to the blood vessels. The tiny blood vessels that nourish the retina are damaged by the increased glucose level. It is a systemic disease which is affecting up to 80 percent of people for more than 10 years. Many researchers acknowledged that 90 percent of diabetic patients could be saved from this disease through an early diagnose. A person having diabetes is more prone to the risk of diabetic retinopathy (DR) [1].

Diabetic retinopathy (DR) occurs when diabetes damages the tiny blood vessels inside the retina, the light- sensitive tissue at the back of the eye [2]. This tiny blood vessel will leak blood and fluid on the retina, forming features such as microaneurysms (MAs), haemorrhages (HMs), hard exudates (EXs). Microaneurysms are an earlier sign of DR. DR can be broadly classified as non-proliferative diabetic retinopathy (NPDR) and proliferative diabetic retinopathy (PDR) [3]. Depending on the presence of features on the retina, the stages of DR can be identified [3]. DR has four stages [3, 4].

1. Mild non-proliferative retinopathy. At least one micro aneurysm with or without the presence of retinal haemorrhages, hard exudates, cotton wool spots, or venous loops will be present. Approximately 40 per cent of people with diabetes has at least mild signs of DR [5].
2. Moderate non-proliferative retinopathy. Numerous microaneurysms and retinal haemorrhages will be present. Cotton wool spots and a limited amount of venous beading can also be seen. 16 per cent of the patients with moderate NPDR will develop PDR within 1 year [6].

3. Severe non-proliferative retinopathy. This is characterized by any one of the following characteristics:

(a) numerous haemorrhages and microaneurysms in four quadrants of the retina;
(b) venous beading in two or more quadrants;
(c) intraregional micro vascular abnormalities in at least one quadrant;

4. Proliferative retinopathy. This is the advanced the signals sent by the retina for nourishment trigger the growth of new blood vessels. These new blood vessels are abnormal and fragile.

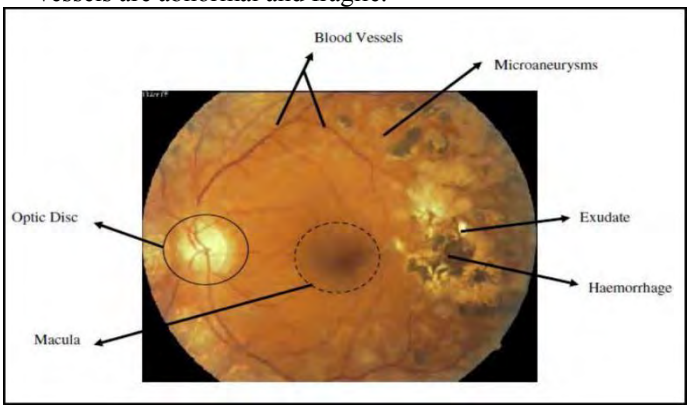

Figure 1: Features in DR image

II. LITERATURE SURVEY

Survey of various research papers are done in this section.

Sr	Title	Author & year of publication	Key findings	Research Gap
01	A brief review of the Detection of Diabetic Retinopathy in Human Eyes Using Pre-Processing & Segmentation Techniques	Yogesh Kumaran, Chandrashekar M. Patil , December 2018	Gives a brief insight into the detection of DR in human eyes It uses different types of preprocessing & segmentation techniques.	processing time is not taken into the account
02	A Survey Paper on Diabetes Retinopathy	Dr. Ruksar Fatima, Laxmi Math, Sept 2017	presents a fast, effective and robust way of detecting diabetic features in the fundus images. Various classification schemes have been applied for retinopathy	the processing time can be decreased in future.
03	Detection of Diabetic Retinopathy: A Survey	Nisha A. Panchal, Dr. Darshak G. Thakore, April 2018	presents a fast, effective and robust way of detecting diabetic features in the fundus images.	processing time is not taken into the account.
04	A Survey on methods of automatic detection of Diabetic Retinopathy	Swati Gupta, A.M. Karandikar, January 2015	Provides overview of a computer-based approach for the detection of diabetic retinopathy using retinal images. The automatic detection process reduces examination time, and increase accuracy.	performance of the proposed model is satisfactory.
05	Automatic detection and classification of diabetic retinopathy stages using CNN	Ratul Ghosh, Kuntal Ghosh, Sanjit Maitra, 2017	A model is presented for classification of DR stages based on the severity using color fundus images.	Proper accuracy is not achieved.

III. PROBLEM DEFINITION

Diabetic Retinopathy is a condition that occurs as a result of damage to the blood vessels of the retina in people who have diabetes. Diabetic retinopathy can develop if you have type 1 or 2 diabetes and a long history of uncontrolled high blood sugar levels. While you may start out with only mild vision problems, you can eventually lose your sight. Untreated diabetic retinopathy is one of the most common causes of blindness in the United States, according to the National Eye Institute. It's also the most common eye disease in people with diabetes. There are various factors affecting the disease like age of diabetes, poor control, pregnancy but Researches shows that progression to vision impairment can be slowed or averted if DR is detected in early stage of the disease. There is a need to detect DR at early levels, so that the damage to the retina can be minimized as it is a common persistent problem faced up to date.

IV. DESCRIPTION OF CNN

Convolutional networks (ConvNets) have recently enjoyed a great success in large-scale image and video recognition which has become possible due to the large public image repositories, such as ImageNet (Deng et al., 2009), and high-performance computing systems, such as GPUs or large-scale distributed clusters

A Convolutional Neural Network (CNN) is comprised of one or more convolutional layers (often with sub-sampling step) and then followed by one or more fully connected layers as in a standard multilayer neural network. The architecture of a CNN is designed to take advantage of the 2D hierarchical structure of an input image (or other 2D input such as a speech signal).

Another benefit of CNNs is that they are easier to train and have many fewer parameters than fully connected networks with the same number of hidden units. CNNs also consider the hierarchical representation of images while training by stacking multiple trainable stages on each other.

V. METHODOLOGY AND STRATEGY

There are various methods used in process of detection of DR.
Divide the process into three steps pre-processing, the feature of DR detection and classification.

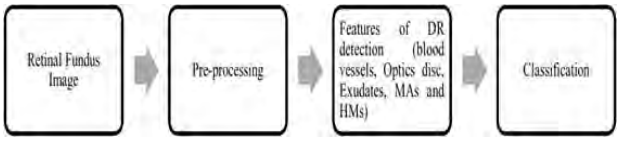

Figure 2: Flowchart of Diabetic Retinopathy

A. Retinal Fundus ImagePre-processing

Pre-processing is an important step in process of detecting DR. Pre-processing is required to ensure that the dataset is consistent and displays only relevant features. Next, the images are segmented to differentiate between the normal and abnormal substances.

B. Feature Extraction

In this step, various features of DR retinopathy are extracted.

Blood Vessels detection: MAs, HMs, and EXs are the main reason for blood vessel damage. So the blood vessels detection is an important factor for detection of DR.

Optic disc detection: The Optic disc is a bright yellow portion and approximately circular in shape. To detect EXs, we need to detect a portion of the optic disc in retinal fundus image because Optic disc and EXs both have same intensity.

EXs Detection: Exudates are bright yellow objects in retinal fundus image which have less than 100 pixels in fundus image. The main objective of exudate detection is the removal of the optic disc before the onset of the process.

MAs and HMs Detection: Microaneurysms and Haemorrhages are first DR symptoms. If we detect the earlier stage then we can reduce the blindness causes from DR. Two methods are used for detecting MAs and HMs. The first method is Semi-automated DR detection using Eigenvalue of Hessian matrix Analysis. The second method is automatic DR detection using Eigenvalue of hessian matrix analysis, image processing techniques, and SVM classifier.

C. Classification

The data is taken from Messidor and then preprocessed using the process of image segmentation. Once that is done, the image is then selected and classified using SVM classifier.

VI. DATASET

We have taken the dataset from the KAGGLE coding website.

VII. EXPECTED OUTCOME

Our proposed model expects the following outcomes:

a. Diabetic retinopathy is best diagnosed with a comprehensive dilated eye exam.
b. Visual loss from diabetic retinopathy is both preventable and treatable.
c. Detection of early, pre-symptomatic disease allows timely treatment with laser photocoagulation to prevent visual loss.
d. The trained CNN makes a quick diagnosis and instant response to a patient possible.

VIII. CONCLUSION

Different types of classifier and its performance are analysed for the automated diagnosis of diabetic retinopathy from the features extracted. There are several detection algorithms that have already been developed and proposed which perform satisfactorily.

Our study has shown that the five-class problem for national screening of DR can be approached using a CNN method. Our network has shown promising signs of being able to learn the features required to classify the fundus images, accurately classifying the majority of proliferative cases and cases with no DR. Our method produces comparable results to these previous methods without any feature-specific detection and using a much more general dataset.

The potential benefit of using our trained CNN is that it can classify thousands of images every minute allowing it to be used in real-time whenever a new image is acquired. The trained CNN makes a quick diagnosis and instant response to a patient possible. This survey paper can act as a resource for the future researchers interested in automated detection of abnormal signs of diabetic retinopathy and help them to get an overview of this field in order to develop more efficient algorithms.

Design of Intruder Detection System using Convolutional Neural Network and Raspberry Pi

Yadnesh Mohan Zagade, Mrs. Shiwani Gupta
Computer Enginnering
Thakur College of Engineering and Technology
Mumbai,India
zagade.yadnesh9@gmail.com

Abstract— **Security is an important part of our day to day life. It can be of your bank account, your home, your children etc. but the main thing is to check if your belongings are in safe zone. It is important to take prevention so that such crimes are avoided, rather than solving them after they take place. Thus, we propose a system using Raspberry Pi which shall be trained using Convolutional Neural Network (CNN) and deliver output using Rpi camera module and Bluetooth Speaker. Several researchers have worked in the area with respect to object detection and text to speech conversion, but many of them fail in their ability to identify the object. Thus, the proposed system detects unauthorized person, unwanted object, identifies it and speaks its class via Bluetooth speaker. The training shall be done using online coco dataset. The trained model shall be deployed onto Raspberry pi with camera module connected. Training shall be done with CNN the identified object class should be read out on Bluetooth speaker. The System is intended to be deployed for applications that require security with respect to the access into specific premises during day as well as night.**

Keywords: Neural Networks, Text to Speech Conversion, Image Processing, Features.

I. INTRODUCTION

J.

The field of Artificial Intelligence is essentially when machines can do tasks that typically require human intelligence. It encompasses Machine Learning, where machines can learn by experience and acquire skills without human involvement. Deep learning is a subset of Machine Learning where Artificial Neural Networks, inspired by the human brain, learn from large amounts of data. Similarly, to how we learn from experience, the deep learning algorithm performs a task repeatedly each time tweaking it a little to improve the outcome. We refer to 'deep learning' because the neural networks have various (deep) layers that enable learning. Just about any problem that requires "thought" to figure out is a problem deep learning can learn to solve.

The amount of data we generate every day is staggering currently estimated at 2.6 quintillion bytes and it's the resource that makes deep learning possible. Since deep-learning algorithms require a ton of data to learn from, this increase in data creation is one reason that deep learning capabilities have grown in recent years. In addition to more data creation, deep learning algorithms benefit from the stronger computing power that's available today as well as the proliferation of Artificial Intelligence (AI) as a Service. Organizations access to artificial intelligence technology and specifically the AI algorithms required for Deep Learning without a large initial investment. Deep Learning allows machines to solve complex problems even when using a data set that is very diverse, unstructured and inter-connected. The deeper learning algorithms learn, the better they perform.

Deep Learning architectures such as deep neural networks, deep belief networks and recurrent neural networks have been applied to fields including Computer Vision, Speech Recognition, Natural Language Processing, audio recognition, social network filtering, machine translation, bioinformatics, drug design, medical image analysis, material inspection and board game programs, where they have produced results comparable to and in some cases superior to human experts. Deep learning models are vaguely inspired by information processing and communication patterns in biological nervous systems yet have various differences from the structural and functional properties of biological brains (especially human brains), which make them incompatible with neuroscience evidences. Deep learning (also known as deep structured learning or hierarchical learning) is part of a broader family of machine learning methods based on learning data representations, as opposed to task-specific algorithms. Learning can be supervised, semi-supervised or unsupervised. Deep learning models tend to perform well with amount of data whereas old machine learning models stops improving after a saturation point.

II. Literature Review

K. Laubhan, et. al. [1], presented a system that consists of five ultrasonic sensors which continuously trigger serially and are positioned as left, right and front. The ultrasonic sensors are detecting objects and compares with the minimum value. If the value received is greater than threshold value then the user gets to know about the position of the obstacle via the Bluetooth headset. It successfully contributes in elimination of the walking sticks and detects if any object is present in surrounding of the blind person using the ultrasonic sensors positioned at five different directions hence the direction of object is also known. It detects position of the object, But it cant identify object.

Zhong-Qiu Zhao[2], presented a system on CNN which helps to determine where objects are located in a given image and which category each object belongs to (object classification). In this object detection models can be mainly divided into three stages: informative region selection, feature extraction and classification. They have deeper architectures with the capacity to learn more complex features than the normal ones. Also, this training algorithms allow to learn informative object representations without designing features manually.

Rithika.H1 , B. Nithya santhoshi[3] presents the system which basically can be used by people who do not know English and want it to be translated to their native language. The new thing of this research work is the speech output which is available in 53 different languages translated from English. This paper is based on a prototype which helps user to hear the contents of the text images in the desired language. This is done with Raspberry Pi and a camera module by using the concepts of Tesseract optical character recognition (OCR) engine, Google Speech API [application program interface] which is the Text to speech engine and the Microsoft translator.

Yeong-Hwa Chang[4] have used open source robotic middleware, it is applied to identify objects with a Raspberry Pi based mobile robot. Faster R-CNN algorithm very popular dataset for building and evaluating algorithms for image classification, object detection, and segmentation. COCO is a large-scale object detection, segmentation, and captioning dataset. The advantages about Microsoft COCO dataset provided for object segmentation, Recognition in context, multiple objects per image, more than 300000 images, more than 2 million instances and so on.

P. Patil, et. al. [5], presents a system that is easily wearable, user-friendly, and portable and can be used in their day to day life. This system consists of the belt along with modernized cane which duplicates the real sensation provided by the traditional white cane. It contains Raspberry pi 3, Ultrasonic sensors, PIR sensors, and Lithium battery. The ultrasonic sensor is used for distance measurement. It

the ultrasonic sound which is not audible to humans but can get reflected by obstacles and received by the sensor.

Muthukrishnan Ramprasath [6], presents system for Image Classification using Convolutional Neural Networks. This consist of uses deep learning algorithm to achieve the expected results in the area like computer visions. This system presents Convolutional Neural Network (CNN), a machine learning algorithm being used for automatic classification the images. By training the images using CNN network we obtain the 98% accuracy result in the experimental part it shows that this model achieves the high accuracy in classification of images.

Tiagrajah V. Janagiraman [7] presents research on “Traffic Light Detection Using Tensorflow Object Detection Framework”. They presents research on object detection for auto driving cars, where they have used CNN for object detection along with flexibility of Tensorflow Object Detection framework to solve real time problems. Its working on combination of CNN, faster RCNN with Tensorflow. They are working on giving more safe automated driving vehicle system. So they have presented automated driving system which will detect color of signal and will Start, Stop cars accordingly. This feature is not there in other driverless cars.

K.S.Shilpashree1 , Lokesha.H2 [8] presents paper about Implementation of Image Processing on Raspberry Pi. input is an image, like a photograph or video frame, the output of an image processing may be either an image or a video frame or a set of characteristics or parameters related to the image. Image processing concepts are implemented in Raspberry pi in the application of MAV. The system provides Debian Linux operating system Raspbian image for download. Python is used as main programming language for raspberry pi.

S. Venkateswarlu1 [9] in this paper has presented a robust approach for text extraction and converting it to speech Optical character Recognition (OCR) is a process that converts scanned or printed text images, handwritten text into editable text for further processing. Testing of device was done on raspberry pi platform. Picture is taken and processed by Raspy to hear the spoken words of the text through the earphone or speaker plugged into Raspy through its audio jack.

Yu Han LIU [10] presents recent studies about providing a technical solution for image recognition, by applying a algorithm called Convolutional Neural Network (CNN) which is inspired by animal visual system. Being highly-hierarchical networks, This paper talks about the basic understanding of CNN, including its structure, different layers, and working process. Feature extraction and redundancy reduction occur. The simple features gradually gather in an efficient way. Afterwards, all the features are combined partially and the resulting features each count for a part of configuration of the labelled class. Eventually, these top features are sent into the fully-connected layer and we get estimate of the classification.

ANALYSIS

Paper Title	Obstacle Detection	Object Identification	Wireless Screen Visual	Audio Output Wirelessly
A wearable portable electronic travel aid for blind[1]	Yes	No	No	No
Object detection using deep learning: A Review [2]	Yes	Yes	Yes	No

III.DESIGN OF PROPOSED SYSTEM.

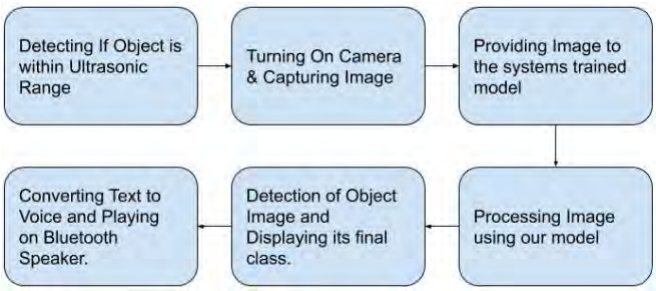

Figure 1: Block Diagram of the Proposed System.

If any intruder intersects within threshold range of ultrasonic system, then our camera will get turned on. It will capture all the things coming in its view and will send the images to our systems trained model that will process the image using trained model deployed onto Raspberry pi which is trained using CNN. Our system will identify the object and display its final Class on screen with accuracy. Accuracy is confidence of machine, that how much our system thinks that this is particular object.

Then text to speech will be done by doing extraction of text output, and it will speak out with the voice output on our Bluetooth speaker. The object identification will be done using CNN algo, by referring trained model on COCO dataset.

IV.METHODOLOGY

1. Data Collection

System totally works on neural networks that's on CNN, so our system need training dataset. In our system data will be in the form of images. Which we have to train to create a model, which we can use further when we are doing real time testing. We are going to use COCO dataset, for our object detection part of the system. It is a large-scale object detection, and captioning dataset. COCO has several Features. It has Object segmentation, Recognition in context, it also consist Super pixel stuff segmentation, total number of images used in this are around 330K (>200K labeled), have used approximately 1.5 million object instances, it consist of 80 object categories, 91 stuff categories, 5 captions per image. This dataset have different variants as well, which has different number of images for training. The dataset used in this project was an open source dataset.

2. Data Preprocessing

It is a process of transforming the raw, complex data into systematic understandable knowledge. It involves the process of finding out missing and redundant data in the dataset. On the basis of that the dataset is taken.

3. Building Model

Neural Networks is one of the most popular machine learning algorithms at present. It has been decisively proven over time that neural networks outperform other algorithms in accuracy and speed. With various variants like CNN (Convolutional Neural Networks), RNN(Recurrent Neural Networks), Auto Encoders, Deep Learning etc. neural networks are slowly becoming for data scientists or machine learning practitioners what linear regression was one for statisticians. It is thus imperative to have a fundamental understanding of what a Neural Network is, how it is made up and what is its reach and limitations. This paper is an attempt to explain a neural network starting from its most basic building block a neuron, and later delving into its most popular variations like CNN, RNN etc.

Increases with an increase in the number of layers and thus stagnates the learning of a neural network at a certain level.

In convolution layer the input is matrix form of image. In this the filter having particular weight multiplies matrix of image, and then creates output However, a sigmoid function also suffers from a problem of vanishing gradients. Sigmoid function squashes it's input into a very small output range

[0,1] and has very steep gradients. Thus, there remain large regions of input space, where even a large change produces a very small change in the output. This is referred to as the problem of vanishing gradient. This problem

The Convolutional Neural Network (CNN) is a class of deep learning neural network. CNNs represent a huge breakthrough in image recognition. They're most commonly used to analyze visual imagery and are frequently working behind the scenes in image classification. They can be found at the core of everything from Facebook's photo tagging to self-driving cars. They're working hard behind the scenes in everything from healthcare to security. Image classification is the process of taking an input (like a picture) and outputting a class (like "cat") or a probability that the input is a particular class ("there's a 90% probability that this input is a cat").

A CNN convolves learned features with input data and uses 2D convolutional layers. This means that this type of network is ideal for processing 2D images. Compared to other image classification algorithms, CNNs actually use very little preprocessing. This means that they can learn the filters that have to be hand-made in other algorithms. CNNs can be used in tons of applications from image and video recognition, image classification, and recommender systems to natural language processing and medical image analysis. It is important to select proper features to get desired output. Our machine learning algorithm is made for detecting different objects, in simple words for classifying the object it got in input, and giving its voice output. Machine learning fits mathematical notations to the data in order to derive some insights. CNNs have an input layer, and output layer, and hidden layers. The hidden layers usually consist of convolutional layers, ReLU layers, pooling layers, and fully connected layers. Convolutional layers apply a convolution operation to the input. This passes the information on to the next layer. Pooling combines the outputs of clusters of neurons into a single neuron in the next layer. Fully connected layers connect every neuron in one layer to every neuron in the next layer. CNN works by extracting features from images. This eliminates the need for manual feature extraction. The features are not trained! They're learned while the network trains on a set of images. This makes deep learning models extremely accurate for computer vision tasks. CNNs learn feature detection through tens or hundreds of hidden layers. Each layer increases the complexity of the learned features.

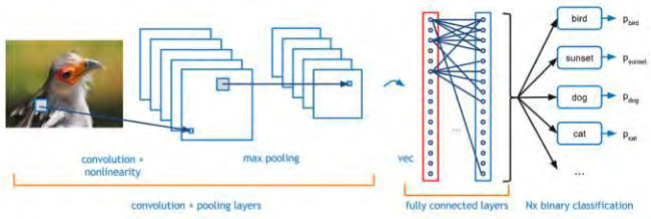

Figure 2: CNN Working

The depth of the filter has to be the same as the depth of the input, so if we were looking at a color image, the depth would be 3. That makes the dimensions of this filter 5x5x3. In each position, the filter multiplies the values in the filter with the original values in the pixel. This is element wise multiplication. The multiplications are summed up, creating a single number. If you started at the top left corner of your bubble wrap, this number is representative of the top left corner. Now you move your filter to the next position and repeat the process all around the bubble wrap. The array you end up with is called a feature map or an activation map! You can use more than one filter, which will do a better job of preserving spatial relationships.

5. Hardware requirements

Method is very necessary to get desired output, but along with software it also depends on hardware part of it. The hardware need was such that it should be compatible with CNN. Our coding for the same will be done in python, so the hardware is selected accordingly. Along with that we also used many different components and sensors compatible with above. The main aim of this paper is to propose system that helps the authorized person to get alert when something wrong is happens in his absence, or without his acknowledgement. So we will use method to convert text form of output into voice form. For that purpose we will be using processor compatible with Bluetooth, so that we can connect it to Bluetooth speaker. So our main hardware components will be Raspberry Pi 3b,RPi camera Module, Bluetooth Speaker, Power cord, Ultrasonic sensor.

V. CONCLUSION

Proposed system can be used for improving security of the Important places around us, such as home, office, building premises. This will help us to decrease crime rates. Above system will provide us hardware structure which can be installed easily at any required premises.

In future this system can be optimized to add few more features like monitoring and output through internet that is you can hear voice output from wherever you are. We can also put some notification to the user if something is identified using our system.

Image Classification Of Fasion-Mnist Dataset Using Cnn

Dhiiraj Yadav, Mrs Veena Kulkarni
Department of Computer Engineering
Thakur College of Engineering & Technology
Mumbai, India
erdhiraj1992@gmail.com, veena.kulkarni@thakureducation.org

Abstract— **Image classification is used in several applications, ranging from recognizing life-threatening illnesses in medical scans to detecting hotdogs in selfies. For humans, identifying numbers or items in a picture is extremely simple, but how do you train the machine to recognize these different things in images? Convolutional Neural Networks (CNN) can solve this problem. In this report, a convolutional neural network has been trained by identifying pictures in MNIST handwritten digital database to predict exactly what the numbers in the picture are. Obviously, human beings can perceive that there is a hierarchy or conceptual structure in the image, but the machine does not, for example the trained neural network is inconvenient to deal with special changes in a position of numbers in digital pictures. Exactly put, no matter what the environment of the image (image background) is, it is unchallenging for human beings to judge whether there is such a figure in the image and it is unnecessary to repeat the learning training. This dataset is publicly available for the research community to further advance handwritten digit recognition algorithms. Researchers at Zalando (the e-commerce company) have developed a new image classification dataset called Fashion MNIST in hopes of replacing MNIST. This new dataset contains images of various articles of clothing and accessories — such as shirts, bags, shoes, and other fashion items. The Fashion MNIST training set contains 55,000 examples, and the test set contains 10,000examples.**

Each example is a 28x28 grayscale image (just like the images in the original MNIST), associated with a label from 10 classes (t-shirts, trousers, pullovers, dresses, coats, sandals, shirts, sneakers, bags, and ankle boots).

Keywords— **Machine learning, CNN, Fashion, Image Annotation, E-ecommerce ,Image data, clothing, multiclass classification, shopping, object identification**

I. INTRODUCTION

Recently, digitization of handwritten documents has become significantly important to protect and store data more efficiently. The growth of digitized handwritten documents highlights new types of challenges and problems which lead to development of many automated and computerized analysis systems. Images are a special class of data that exhibit some interesting properties in respect to their

Structure. For example do the dimensions of an image (i.e. the pixel) exhibit a spatial relationship to each other Images are a special class of data that exhibit some interesting properties in respect to their structure. For example do the dimensions of an image (i.e. the pixel) exhibit a spatial relationship to each other?

The general idea is the following: if we want our model to generalize well, then we should design the learning process in such a way as to bias the model into learning such transformation-equivariant properties. One way to do this is via the design of the model itself, which for example was idea behind convolutional neural networks.

The MNIST data set is a classic handwritten digit recognition data set. This report shows how one can use conventional neural network to get a classification accuracy of 98%.

MNIST database is also widely used for training and testing in the field of machine learning.

The MNIST database (Modified National Institute of Standards and Technology database) is a large database of handwritten digits that is commonly used for training various image processing systems. The database is also widely used for training and testing in the field of machine learning. It was created by "re-mixing" the samples from NIST's original datasets. The creators felt that since NIST's training dataset was taken from American Census Bureau employees, while the testing dataset was taken from American high school students, it was not well-suited for machine learning experiments. Furthermore, the black and white images from NIST were normalized to fit into a 28x28 pixel bounding box and anti-aliased, which introduced grayscale levels.

II. BACKGROUND

The neocognitron was introduced by Kunihiko Fukushima in 1980. It was inspired by the above-mentioned work of Hubel and Wiesel. The neocognitron introduced the two basic types of layers in CNNs: convolutional layers, and downsampling layers. A convolutional layer

contains units whose receptive fields cover a patch of the previous layer. The weight vector (the set of adaptive parameters) of such a unit is often called a filter. Units can share filters. Downsampling layers contain units whose receptive fields cover patches of previous

In a variant of the neocognitron called the cresceptron, instead of using Fukushima's spatial averaging, J. Weng et al. introduced a method called max-pooling where a downsampling unit computes the maximum of the activations of the units in its patch. Max-pooling is often used in modern CNNs.

Several supervised and unsupervised learning algorithms have been proposed over the decades to train the weights of a neocognitron. Today, however, the CNN architecture is usually trained through backpropagation.

The neocognitron is the first CNN which requires units located at multiple network positions to have shared weights. Neocognitrons were adapted in 1988 to analyze time-varying signals

The name “convolutional neural network” indicates that the network employs a mathematical operation called convolution. Convolution is a specialized kind of linear operation. Convolutional networks are simply neural networks that use convolution in place of general matrix multiplication in at least one of their layers

A convolutional neural network consists of an input and an output layer, as well as multiple hidden layers. The hidden layers of a CNN typically consist of a series of convolutional layers that convolve with a multiplication or other dot product. The activation function is commonly a RELU layer, and is subsequently followed by additional convolutions such as pooling layers, fully connected layers and normalization layers, referred to as hidden layers because their inputs and outputs are masked by the activation function and final convolution.

Though the layers are colloquially referred to as convolutions, this is only by convention. Mathematically, it is technically a sliding dot product or cross-correlation. This

Has significance for the indices in the matrix, in that it affects how weight is determined at a specific index point

When programming a CNN, the input is a tensor with shape (number of images) x (image width) x (image height) x (image depth). Then after passing through a convolutional layer, the image becomes abstracted to a feature map, with shape (number of images) x (feature map width) x (feature map height) x (feature map channels). A convolutional layer within a neural network should have the following attributes: Convolutional kernels defined by a width and height (hyper-parameters).

convolutional layers. Such a unit typically computes the average of the activations of the units in its patch. This downsampling helps to correctly classify objects in visual scenes even when the objects are shifted.

The number of input channels and output channels (hyper- parameter). The depth of the Convolution filter (the input channels) must be equal to the number channels (depth) of the input feature map.

Convolutional layers convolve the input and pass its result to the next layer. This is similar to the response of a neuron in the visual cortex to a specific stimulus. Each convolutional neuron processes data only for its receptive field. Although fully connected feed forward neural networks can be used to learn features as well as classify data, it is not practical to apply this architecture to images. A very high number of neurons would be necessary, even in a shallow (opposite of deep) architecture, due to the very large input sizes associated with images, where each pixel is a relevant variable. For instance, a fully connected layer for a (small) image of size 100 x 100 has 10,000 weights for

Each neuron in the second layer. The convolution operation brings a solution to this problem as it reduces the number of free parameters, allowing the network to be deeper with fewer parameters. For instance, regardless of image size, tiling regions of size 5 x 5, each with the same shared weights, requires only 25 learnable parameters. In this way, it resolves the vanishing or exploding gradients problem in training traditional multi-layer neural networks with many layers by using back propagation Convolutional networks may include local or global pooling layers to streamline the underlying computation. Pooling layers reduce the dimensions of the data by combining the outputs of neuron clusters at one layer into a single neuron in the next layer. Local pooling combines small clusters, typically 2 x 2. Global pooling acts on all the neurons of the convolutional layer. In addition, pooling may compute a max or an average. Max pooling uses the maximum value from each of a cluster of neurons at the prior layer. Average pooling uses the average value from each of a cluster of neurons at the prior layer.

III. MOTIVATION

Recently, digitization of handwritten documents has become significantly important to protect and store data more efficiently. The growth of digitized handwritten documents highlights new types of challenges and problems which lead to development of many automated and computerized analysis systems. Images are a

special class of data that exhibit some interesting properties in respect to their structure. For example do the dimensions of an image (i.e. the pixel) exhibit a spatial relationship to each other Images are a special class of data that exhibit some interesting properties in respect to their structure. For example do the dimensions of an image (i.e. the pixel) exhibit a spatial relationship to each other? The general idea is the following: if we want our model to generalize well, then we should design the learning process in such a way as to bias the model into learning such transformation-equivariant properties. One way to do this is via the design of the model itself, which for example was idea behind convolutional neural networks.

The MNIST data set is a classic handwritten digit recognition data set. This report shows how one can use conventional neural network to get a classification accuracy of 98%.

MNIST database is also widely used for training and testing in the field of machine learning.

IV. CNN

CNNs are regularized versions of multilayer perceptron's. Multilayer perceptron's usually mean fully connected networks, that is, each neuron in one layer is connected to all neurons in the next layer. The "fully-connectedness" of these networks makes them prone to over fitting data. Typical ways of regularization include adding some form of Magnitude measurement of weights to the loss function. CNNs take a different approach towards regularization: they take advantage of the hierarchical pattern in data and assemble more complex patterns using smaller and simpler patterns. Therefore, on the scale of connectedness and complexity, CNNs are on the lower extreme.

Convolutional networks were inspired by biological processes in that the connectivity pattern between neurons resembles the organization of the animal visual cortex. Individual cortical neurons respond to stimuli only in a restricted region of the visual field known as the receptive field. The receptive fields of different neurons partially overlap such that they cover the entire visual field.

CNNs use relatively little pre-processing compared to other image classification algorithms. This means that the network learns the filters that in traditional algorithms were hand- engineered. This independence from prior knowledge and human effort in feature design is a major advantage

When programming a CNN, the input is a tensor with shape (number of images) x (image width) x (image height) x (image depth). Then after passing through a convolutional layer, the image becomes abstracted to a feature map, with shape (number of images) x (feature map width) x (feature map height) x (feature map channels). A convolutional layer within a neural network should have the following attributes:

- Convolutional kernels defined by a width and height (hyper-parameters).
- The number of input channels and output channels

(hyper-parameter).

- The depth of the Convolution filter (the input channels) must be equal to the number channels (depth) of the input feature map.

Convolutional layers convolve the input and pass its result to the next layer. This is similar to the response of a neuron in the visual cortex to a specific stimulus.Each convolutional neuron processes data only for its receptive field. Although fully connected feed forward neural networks can be used to learn features as well as classify data, it is not practical to apply this

Image recognition with CNNs

A system to recognize hand-written ZIP Code number involved convolutions in which the kernel coefficients had been laboriously hand designed.Yann LeCun et al. (1989) used back-propagation to learn the convolution kernel coefficients directly from images of hand-written numbers. Learning was thus fully automatic, performed better than manual coefficient design, and was suited to a broader range of image recognition problems and image types.

This approach became a foundation of modern computer vision. LeNet-5, a pioneering 7-level convolutional network by LeCun et al. in 1998, that classifies digits, was applied by several banks to recognize hand-written numbers on checks (British English: cheques) digitized in 32x32 pixel images. The ability to process higher resolution images requires larger and more layers of convolutional neural networks, so this technique is constrained by the availability of

computing resources.

Shift-invariant neural network

Similarly, a shift invariant neural network was proposed by W. Zhang et al. for image character recognition in 1988. The architecture and training algorithm were modified in

1991and applied for medical image processingand automatic detection of breast

cancer in mammograms .A different convolution-based design was proposed in 1988 for application to decomposition of one-dimensional electromyography convolved signals via de-convolution. This design was modified in 1989 to other de-convolution- based designs.

Neural abstraction pyramid

for each neuron in the second layer. The convolution operation brings a solution to this problem as it reduces the number of free parameters, allowing the network to be deeper with fewer parameters For instance, regardless of image size, tiling regions of size 5 x 5, each with the same shared weights, requires only 25 learnable parameters. In this way, it resolves the vanishing or exploding gradients problem in training traditional multi-layer neural networks with many layers by using back propagation architecture to images. A very high number of neurons would be necessary, even in a shallow (opposite of deep) architecture, due to the very large input sizes associated with images, where each pixel is a relevant variable. For instance, a fully connected layer for a (small) image of size 100 x 100 has 10,000 weights

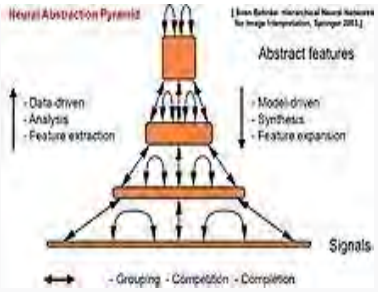

Fig: Neural Abstraction Pyramid

The feed-forward architecture of convolutional neural networks was extended in the neural abstraction pyramid by lateral and feedback connections. The resulting recurrent convolutional network allows for the flexible incorporation of contextual information to iteratively resolve local ambiguities. In contrast to previous models, image-like outputs at the highest resolution were generated, e.g., for semantic segmentation, image reconstruction, and object localization tasks.

GPU implementations

Although CNNs were invented in the 1980s, their breakthrough in the 2000s required fast implementations on graphics processing units (GPUs). In 2004, it was shown by K. S. Oh and K. Jung that standard neural networks can be greatly accelerated on GPUs. Their implementation was 20 times faster than an equivalent implementation on CPU. In 2005, another paper also emphasised the value of GPGPU for machine learning.

The first GPU-implementation of a CNN was described in 2006 by K. Chellapilla et al. Their implementation was 4 times faster than an equivalent implementation on CPU. Subsequent work also used GPUs, initially for other types of neural networks (different from CNNs), especially unsupervised neural networks.

In 2010, Dan Ciresan et al. at IDSIA showed that even deep standard neural networks with many layers can be quickly trained on GPU by supervised learning through the old method known as backpropagation. Their network outperformed previous machine learning methods on the MNIST handwritten digits benchmark. In 2011, they extended this GPU approach to CNNs, achieving an acceleration factor of 60, with impressive results In 2011, they used such CNNs on GPU to win an image recognition contest where they achieved superhuman performance for the first time Between May 15, 2011 and September 30, 2012, their CNNs won no less than four image competitions. In 2012, they also significantly improved on the best performance in the literature for multiple image databases, including the MNIST database, the NORB database, the HWDB1.0 dataset (Chinese characters) and the CIFAR10 dataset (dataset of 60000 32x32 labeled RGB images).

Subsequently, a similar GPU-based CNN by Alex Krizhevsky et al. won the ImageNet Large Scale Visual Recognition Challenge 2012. A very deep CNN with over 100 layers by Microsoft won the ImageNet 2015 contest.

V. APPLICATION

First, we need prepare out dataset. In this example, it will be the MNIST dataset. We need One-hot encode the labels of MNIST dataset. Each file has 1000 training examples. Each training example is of size 28x28 pixels. The pixels are stored as unsigned chars (1 byte) and take values from 0 to 255. The first 28x28 bytes of the file correspond to the first training example, the next 28x28 bytes correspond to the next example and so on. The example below loads the MNIST dataset using the Keras API and creates a plot of the first nine images in the training dataset.

According to the model given above, the final accuracy is stable at more than 90%. In fact, for many tasks, the model is prone to over-training. If over-training occurs during training, the error caused by training will decrease with the increase of training times.

The more data, the more data in the training set, the smaller the impact of training error and test error, and ultimately the accuracy can be improved. We can find the larger training set can develop the performance of LeNet5. After

improving this problem, our accuracy can reach 94%. If we increase the number of training, this accuracy will be improved to some extent.

This report is a completely new study for me. I chose the most famous handwritten digit recognition in the CNN model, which is also the earliest prototype of the convolution model. The datasets and reference papers were all from LeCun et al. This model is also the most classic model for image information processing. It also encountered some problems during the construction of LeNet-5 neural network. But those high-level interfaces for building neural networks in Python gave me a lot of convenience and came up with the training results mentioned in the references. But no doubt there is still much room for improvement in my identification of neural networks.

The digits patterns used in this training are all black and white images, so this model may be difficult to deal with common color patterns. The training set of color images may lead to an increase in the degree of ambiguity in the image, which in turn affects the accuracy of the prediction. Moreover, in this paper, I only studied the pictures in the MNIST data set. In actual problems, the specification and definition of the pictures are undoubtedly important factors affecting the accuracy of the model. Therefore, how to preprocess is very important, but in order to simplify the research process, I omitted this step. And in real life, most of the pictures we touch are very complicated and colorful

An Efficient Privacy Preserving Technique And System For Data Publishing On Social Media

Snehal Tukaram Patil, Dr. Aand Khandare

Thakur College of Engineering & Technology ,

Kandivali(E),Mumbai ,Maharashtra ,India

snehal321.patil@gmail.com, anand.khandare1983@gmail.com

Abstract—**In the era of technology and network, big data and huge amount of data is produced over the world-wide. The use and sharing of enormous amounts of data has become possible. Once the information and data accumulated, it will become the wealth of information. The existing traditional data processing techniques and algorithms directly operated on the initial data set, which is able to cause the leakage of privacy data. At the same time, huge amounts of information implicate the sensitive knowledge that their disclosure cannot be ignored to the competitiveness of enterprise. So as to beat these problems, Privacy Preserving Data Mining and Data Publishing techniques are developed. Traditional PPDP techniques suffer from differing types of attacks and loss of data.**

In this paper new method is proposed that improves the performance of the present & traditional PPDM techniques. The comparison of existing techniques and proposed technique is additionally discussed in the paper and results shows the time taken by the proposed system is very less than the existing techniques. The proposed method provide less information loss and more privacy.

Keywords— Information Filtering, Social Computing, Social Network, Topic Identification, Topic Ranking, leakage of privacy, key based encryption.

I. INTRODUCTION

Due to World Wide Web, there is vast amount of information available over the network. This information could be accessed through data mining. Data mining is concerned with the extraction of nontrivial, novel and potentially useful knowledge from large databases. In order to extract the knowledge various data mining techniques are used as per the application domains like health care, Cyber security, banking, e-commerce etc. [1]. These domains contain confidential data which should not be disclosed to all users which lead to the development of privacy preserving techniques in data mining [2]. PPDM is a new research in data mining where data mining functionalities are analysed with respect to privacy in data.

One of the central problems of managing privacy within the Internet lies in the simultaneous management of both public and personal data. So as to receive services like recommendations, users often willing release some data about themselves, like their movie watching history. However users even have other data they consider private, such as income level, political affiliation, or medical conditions.

In this work, we focus on a technique in which a user can release her public data, but is able to prevent against inference attacks. With the currently growing interest in the Semantic Web, it is reasonable to expect that increasingly more metadata describing domain information about resources on the Web will become available. The idea presented here is to enrich the search process for hypermedia applications with information extracted from the semantic model of the application domain. One of the major problems of traditional search engines is that they typically are based in keyword processing.

In this paper, the key based encryption algorithm is proposed which protect user activity data, like the privacy leakage of user-specified private data is minimized. The system achieves better privacy protection and less leakage of private data.

II. LITERATURE SURVEY

Today many organizations publish their data. This information contains private data of individual, organization, industry, and person. Public information should not be released without preserving the privacy of each record. It should ensure that no individual information is identified from the anonymized data. Anonymization approaches has been utilized in numerous application domains. Social networks have always existed in society in varying forms. People are unaware of the privacy issues. The published data in the social network can be anonymized and do not infer to any single individual.

Large organizations in different sectors viz. medical, social networking, banking, and business, insurance collect, store and use personal information of their customers. This collected data are used for the research and analysis purposes [2]. To do the same, data mining techniques have been used for the analysis and research work. The collected data might contain person specific private information. Therefore, analyzing such collected person specific private data can disclose the private information of an individual. Protecting the private information of an individual becomes a prime research issue in privacy preserving data publishing. The user data is very important and need the strong privacy. By considering the factors there are many privacy models in the privacy preserving data publishing. Privacy models which gives different algorithms and different techniques for achieving privacy like Anonymization which contains the techniques such as generalization, bucketization, slicing. K-anonymity and L-diversity.

In this section we will be going to discuss about the above mention existing techniques, and the proposed key based privacy preserving hash function technique.

A. K-Anonymity

If the identifiable attributes of any database record are undistinguishable from at least other k-1 records, then the dataset is known as k-anonymous [7]. In k-anonymity

attributes are suppressed or general awaiting every line is the same through at slightest k-1 extra rows. At this point the record is supposed to be k-anonymous. It can separate access details and non-access details of Data set. It'll include slicing approach of Column separation method.

B. L-diversity

The L- diversity can be described as Say if you have a group of k different records that all share a particular quasi-identifier. That's good, therein an attacker person cannot identify the individual based on the quasi-identifier. But if the worth they are fascinated by, (e.g. the individuals' medical diagnosis) is that the same for each value within the group. The distribution of target values within a bunch is referred to as l-diversity. At present, there exist two categories of l-diversity techniques: generalization and permutation-based. The current generalization method would partition the data into disjoint groups of transactions, specified each group contains sufficient records with l-distinct, well represented sensitive items. It preserves both record and attributes linkage.

The Table 1 shows the k anonymity =6 and L-diversity =4, it means only six rows be able to be position in one slice table view with L-diversity have apply on disease attribute. The four unique values has place in diversity attributes.

Table 1: K-anonymity and L-diversity

Name	Address	Zip code	Age	Disease
****	Nairobi	452***	[0-25]	cancer
****	Melbourne	145***	[26-50]	cancer
****	Sidney	365***	[26-50]	cancer
*****	Jakarta	356***	[51-75]	diabetes
*****	Mumbai	458***	[26-5]	angina
*****	Delhi	564***	[51-75]	cancer

C. SHA 256 Hash Function

Large organizations in numerous sectors viz. medical, social networking, The SHA (Secure Hash Algorithm) relations be a set of connected cryptographic hash function designed by the algorithm creates a hash value from any kind of data, such as a file, password, or in this case, a praise certificate number. This value is virtually unique to the input data, so even a small change in the data will bring about a totally extraordinary hash because of the torrential slide impact. Additionally, there is no down to earth approach to compute a specific information input that will bring about a greatly desired hash esteem and it is very difficult to utilize the hash an incentive to recuperate the first information. The most generally utilized capacity in the family is SHA-1 and it is utilized in a vast assortment of prevalent security applications and conventions. Things being what they are, the reason is it still safe to utilize SHA-1 to encode your Master card numbers? Since the odds of two charge card numbers having a similar hash esteem are so little, it's far-fetched you'll discover a circumstance where the hash of a decent card number matches the hash of a terrible card number, accordingly discounting the likelihood of a false positive. The Table 2 shows SHA-256 results of plain data.

Table 2: SHA 256 view

Name	Address	Zip code	Age	Symptoms	Disease
John	Nairobi	452****	[0-25]	398ed52a42b0fd22abb8252393a73e29	cancer
Ram	Goa	145****	[26-50]	bcf82b421a0beb03c7d682fada277afa	cancer
Jhon	Sidney	365****	[26-50]	c7e36c2e7d63e53228831b18a61a092f	cough
Khan	Jakarta	356****	[51-75]	e4b87007c431335a0f27b0cd1c1597bc	diabetes
RJ	Delhi	145****	[26-50]	bcf82b421a0beb03c7d682fada277afa	cancer
Shah	Pune	365****	[26-50]	c7e36c2e7d63e53228831b18a61a092f	cough

Similarly, the assault is an impact assault, not a pre-picture assault. As I beforehand said, an impact assault discovers two bits of information with a similar hash, however the aggressor can't pick what the hash will be and thusly can't break the instruments that utilization SHA-1 to check for changes in a hashed information. Then additionally, a pre-picture terribly empowers somebody to locate a terrible Visa number that causes a hash capacity to deliver a hash estimation of a substantial card number. Nonetheless, in light of the fact that you are utilizing a boycott, the aggressor can't exploit this, on the grounds that the examination procedure would locate the awful card number on the reject list. On the other hand there is less chance that you are as yet concerned, you could consider utilizing SHA-224, SHA-256, SHA-384 or SHA-512, here and there all things considered referring in indirect way to as SHA-2. This would require additional storage room, notwithstanding, in light of the fact that SHA-1 makes a hash value size of 160 bits and SHA-224, for example, makes an estimation of 224 bits. Likewise, the correlation procedure would be a little slower.

III. System Design

In the proposed research work to design and implement a system than work as classify and re-rank all kind of query events along with the present events further as news. The Google API will provide the third party interface for communicate with search engine to classify the all data using machine learning approach and re-rank with page rank and click through algorithms. We are collect the information from Google API, YouTube as well as twitter and rank all the news base on current user query

A. Project Overview

The proposed system consolidates and rank the foremost prevalent topics discussed in both journalism and social media during a selected period of time. To gain its goal, the system must undergo four main stages.

Pre-process and features extraction: In this module system extract all the information shared by user and apply similarity base weight calculation using private and public

training rules. For each attribute we will generate the specific weight according to training policies.
Classification using privacy framework: This module will classify all data as private or public according to current similarity weight, the data which is classified by classification algorithm as public or private those attributes which is shared by end user.
Re-Ranking: Here system choose to measure the pair wise ranking loss using a widely known metric, created two private and public vectors to different users using Kendall-T distance algorithm.
Analysis: System provide the comparative analysis using different parameters for accuracy time complexity using different graphs.

B. Development Methodology

The above figure 1 shows a proposed system architecture with execution process, in first phase user uploads the his own information on social media, it contains some private as well as some public information. The proposed work also carried out to identify the potential of private data and provide auto security using proposed given algorithms. Natural Language Processing (NLP) extract the features from user's shared data and apply the weight clustering using cosine similarity algorithm. Once clustering has done it will generate the three different clusters viz public, private and activity etc.

The second phase in system implementation of ranking algorithm according to their weights and apply the privacy policies on those private data attributes. In whole process system automatically maintain the privacy on vulnerable data which is shared by data owner.

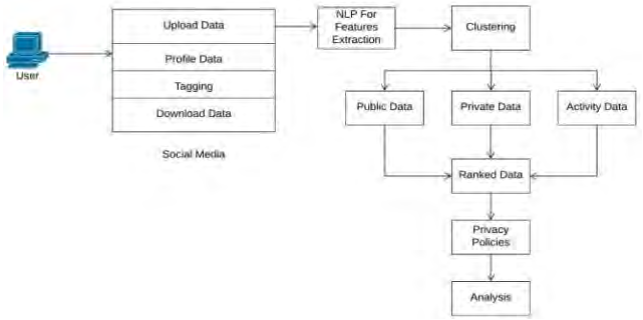

Figure 1: Proposed System Architecture

IV. PROPOSED TECHNIQUE

In a system that not only records but also encrypts the video, before storing it for later use. The idea is that while the officer is on duty, the camera will always be recording. The video, however, is broken up into smaller segments for efficiency. After a certain time period passes, the video that was recorded is then encrypted using an encryption key so as to automatically generate. Certain metadata, including the date as well as time of the video, the name of the video, the encryption key, and the name of the client is saved for later use. This procedure be repetitive used for as long as the officer is on duty. At the ending of their shift, the officer archives the videos to the backend server. The backend server will execute classification algorithms which receives the encrypted videos, decrypts them, and classifies them based on their content and the metadata that was previously saved. Classification criteria include whether the video was recorded inside a safe position, whether the video captured a crime and the type of crime recorded, and whether the video contains sensitive content. This classification is then used to perform additional encryption for access control. When an officer wishes to access the videos, he will log into the retrieval program, which will assign the appropriate decryption keys base on the request. If the officer has the appropriate keys, he will might be get back and decrypt the necessary videos. The below Table 3 shows the key base encrypted view.

Table 3: Key based encrypted view

Name	Address	Zip code	Age	Symptoms	Disease
John	Nairobi	452***	[0-25]	06F6620636F726F6E6172792	cancer
Ram	Goa	145***	[26-50]	646F6D697A6174696F6E20737	cancer
Jhon	Sidney	365***	[26-50]	656C20363030206D6720666	cough
Khan	Jakarta	356***	[51-75]	7374656E6F7369730A2020202045	diabetes
RJ	Delhi	145***	[26-50]	41726D2920696D706C616E	cancer
Shah	Pune	365***	[26-50]	E742053797374656D0A20	cough

In key base hash function it generates very much long encrypted text, which is related to privacy approaches like, but the main different in key base hash encryption is it generate probable cipher data up to 256 bytes.

A. Key base hash privacy algorithm

Input: Generate Key, data d
Output: Generated hash H according to given data
Step 1: Input data as d
Step 2: Generate secure random key from byte[].
Step 3: Apply Secure Hash from Hash family
Step 4: CurrentHash= SecureHash (d,key)
Step 5 : RetrunCurrentHash

Observations:

- It provides secure data broadcasting without any secure multiparty computation, so it reduces the execution cost.
- It doesn't support for secure data extraction from privacy view, it means there is no possibility for any kind attacks like collusion, bruited forces attack etc.
- It is applicable on structured as well as semi structured dataset respectively.

V. COMPARATIVE ANALYSIS

Algorithms Name	Proposed	Observations
K-Anonimity, L-Diversity, Anonimization, Generalization, Random Permutation, Generalization, Specialization, Slicing, Bucketization etc	Existing	Very high time complexity for multi-party computation, and generate secure view It work only data distribution time. Original data can be leaked by attacker , because its privacy provide sufficient Background Knowledge (BK) to attacker.
PrivRank base privacy framework using obfuscate	Base Paper	Cluster generation follow long process, and generate very high time complexity, According base system privacy parameter has extracted based on mutual information between released public and private data, it can be leaked sensitive inform during the data broadcasting. It is too much hard to apply on different kind sensitive as well as private parameters values like health care privacy data etc.
Key base hash function	Proposed (Key Contribution)	It provides secure data broadcasting without any secure multi party computation, so it reduces the execution cost. It doesn't support for secure data extraction from privacy view, it means there is no possibility for any kind attacks like collusion, bruited forces attack etc. It is applicable on structured as well as semi structured dataset respectively.

VI. RESULTS AND DISCUSSIONS

This section discuss the dataset used and result obtained from the modified algorithm. It also compares it with the existing algorithm. Result obtained from the algorithm have been checked on different types of the datasets. The dataset used in system text format dataset.

fig 1: Sample Dataset

This section discuss the dataset used and result obtained from the modified algorithm. We focus on ranking stage that considered as the fundamental commitment of this paper. New positioning calculation is delivered to rank comparative significant information in the wake of ordering stage. Notwithstanding, information recovery process turn out to be quicker, less demanding and more exact. The execution accomplished with 99 percent applicable outcomes in greatest time 60 ms and 1 percent just for immaterial outcomes. The proposed structure and positioning calculation can be additionally produced for later use in distinguishing more exact semantic data from interpersonal organizations in a brief timeframe. The point of the semantic web index has pulled in substantial interests both from industry and research with coming about assortment arrangements in various errands. There is no institutionalized structure that screens and fortify the advance in this field. In this paper, Four standard undertakings of semantic web crawler are talked about including creeping, ordering, positioning lastly recovering assignment. This survey paper demonstrates that utilizing PrivRank produces an altogether different positioned rundown of news themes, which may imply that depending just on high-recurrence news points gave by the media does not really give understanding into what clients are intrigued on or think about essential. Contemplating all outcomes underlines the point that MF alone is a substandard estimator of what clients find fascinating or think about imperative, and ought to thusly not be utilized as a part of along these lines. PrivRank, then again, turns out to be more equipped for playing out this, thus we infer that the data gave by PrivRank can demonstrate imperative in business based territories where the enthusiasm of clients is paramount.

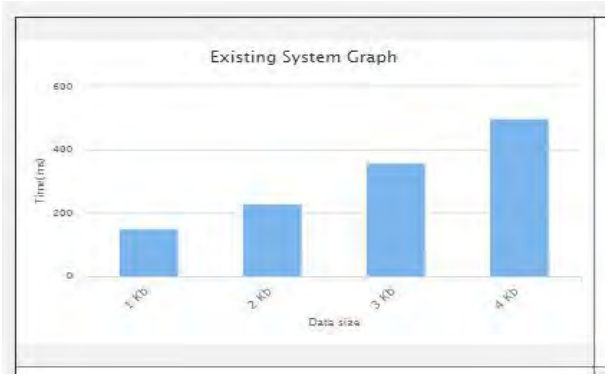

fig 2 (a)

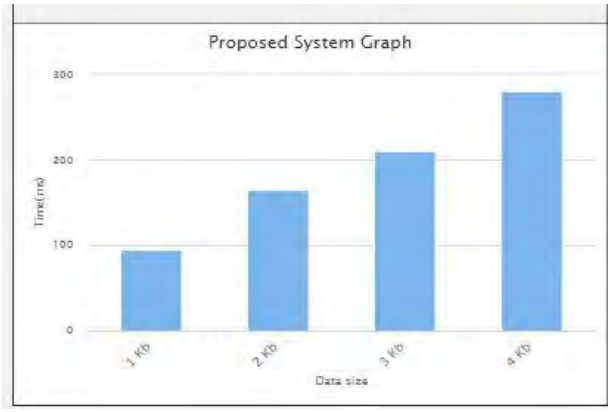

fig 2 (b)

fig 2: Execution time comparison between proposed vs. existing approach

Figure 2 shows the comparison between the existing technique or methods for privacy preserving and the proposed key based hash algorithm. From the Fig 2(a) & Fig 2(b) it is observed that the time require to compute the privacy function on data is reduced by the proposed technique.

As well the privacy gain has been better within the proposed method compared to the traditional method.

CONCULSION

Privacy-preserving distributed information/data mining could be a siblings to the research topic of privacy-preserving data publishing (PPDP). PPDDM assumes a scenario that more than one data holders want to collaboratively perform information processing on the union of their data without disclosing their sensitive information. PPDDM usually employs cryptographic solutions. Sharing of information has become part of the routine activity of the numerous individuals, companies, organizations, and government agencies. Privacy-preserving data publishing is a approach to data sharing, while preserving individuals' personal and protecting sensitive information. Information sharing has become a part of the routine activity of the many individuals, companies, organizations, and government agencies. Privacy-preserving data publishing is a promising approach to data sharing, while preserving individual personal data and protecting sensitive information.

System proposed an unsupervised technique Automatic privacy preservation on public additionally private data. The privacy function which is able to filter all user data and apply anonymity base privacy. Automatic Role Base Access Control to non-public parameters for user data. It also provide ranked data in line with to user's perspective for each new session.

In this paper, we assesses the traditional methods in the field. The goal is to convert the original data into some anonymous form to prevent from inferring its record owners' sensitive information. Most previous privacy-preserving techniques were proposed for data publishers, but individual record owners should also have the right and responsibility to protect their own private information.

Distributed Data Mining

Deepali Joshi

Assistant Professor

Thakur College of Engineering & Technology

deepali88.dj@gmail.com

Abstract:

Human beings are surrounded by numerous devices and is almost impossible to complete work without these devices. In this process the devices perform various operations and utilize, create numerous data. Devices are present at numerous locations that is they are distributed. The data generated and utilized by these devices should be analyzed. All the data that is generated by the devices may not be useful, So Data mining technique to help to extract essential data. The data may be located at different locations and due to this Data mining should be done with respect to distributed devices. This process is known as Distributed Data Mining (DDM).

Keywords
Data Mining, Distributed Data Mining

I. INTRODUCTION

In the recent years there is a boom in data generation. Number of devices are utilized by users. The devices can be wired or wireless. The enhancement in data mining leads to distributed data mining (DDM) that will mine data from different sources available at different locations. The best suitable example is internet, sensor which is commonly used and spread across large geographical area. Distributed Data Mining (DDM) can be described as extraction of essential data, information, knowledge, patterns from large amount of distributed databases.

II. Architecture

2.1 Data Mining Architecture

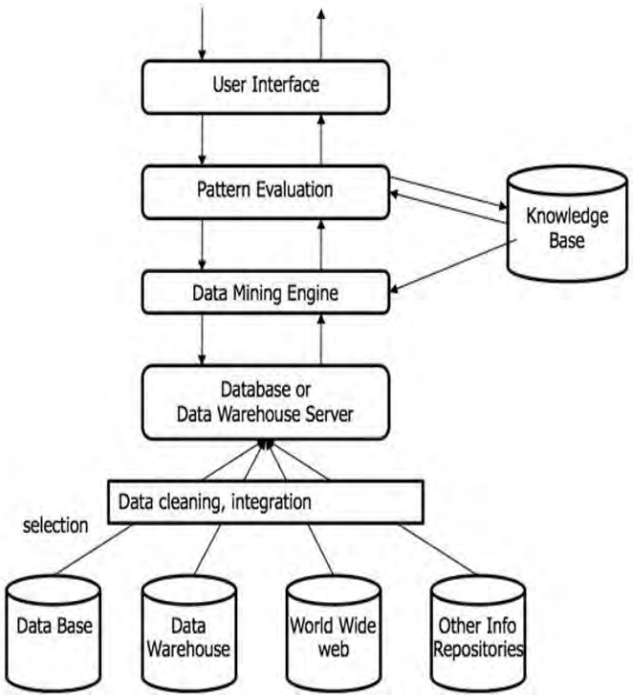

Fig 1: Data Mining Architecture

1. Database, data warehouse, www, other information repository

These are repositories where the data can be stored. The data which is required will be searched in repositories. Once the data is selected number of steps are to be completed. The data may have some missing values or may have incorrect data so Data cleaning is to be performed. The data may be gathered from different sources and will be known as Integration.

2. Database or data warehouse server

It is responsible for fetching essential data, based on user's data mining request.

3. Data Mining Engine

The data mining engine is responsible for performing data mining operations on the data. Depending upon the application appropriate data mining algorithm will be selected. It consists of set of functional modules for tasks like classification, prediction, etc.

4. Knowledge base

This is domain knowledge that guides the search or evaluate interestingness of resulting patterns. Such knowledge can be used to organize attributes into different levels (hierarchies).

5. Pattern Evaluation Module

It interacts with the data mining module so as to focus the search toward interesting patterns. It can be integrated with data mining module.

6. User Interface

It communicates between users and the data mining system, allowing the user to interact with system by specifying a data mining query or task. It allows the user to browse database and data warehouse schemas or data structures and visualize the patterns in different forms.

2.1 Distributed Data Mining Architecture

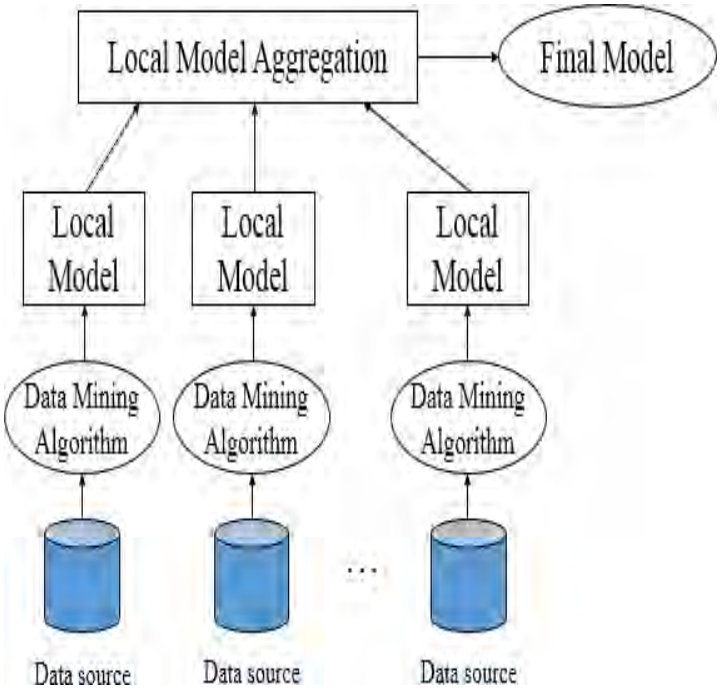

Fig 2: Distributed Data Mining Architecture

In distributed data mining, there are local data sources at every location. On this data source required data mining algorithms are applied. The result that is generated is aggregated together and then the final result is evaluated. The data may be downloaded to single site and then data mining operations may be performed. In order to perform the operations it is very essential to know how exactly the data is distributed. The data can be in different forms, so the first step is to identify it. Distributed data mining is executed in parallel manner. The same algorithm is applied to data that is available at different locations.

III. ISSUES IN DISTRIBUTED DATA MINING

3.1Replication of Data: Local databases are available at each location and similar data may be available.

3.2. Fragmentation of Data:

Local tables are present in each location. Tables are divided into rows and columns. Fragmentation can be horizontal or vertical.

3.1. Communication Cost:

In distributed environment, the devices which are situated in different locations have to communicate with each other for transferring data, command.

3.2. Integration of results:

The results of distributed data mining systems are collated from various sources and this operation may be difficult. The result is combination of outputs generated by different models.

IV. APPLICATIONS OF DISTRIBUTED DATA MINING

- Credit card fraud detection
- Intrusion detection
- Information retrieval from Internet
- Ad hoc sensor networks

V. CHALLENGES OF DISTRIBUTED DATA MINING

- Real-time distributed data mining
- Adaptive to changing environment, new data, new pattern

VI. CONCLUSION

Distributed Data Mining gathers data from various sources and then it is integrated into one component. So it can be said that the operations are carried out on different local machines simultaneously and then combined to generate a result. The data mining architecture is of centralized form where operations are carried out on local data whereas in case of distributed data mining, the operations are carried out on local data and then the patterns are evaluated by combining data from different sources. The main advantage is that even though data is available on different machines, it can be integrated.

Power Of Visualization In Data Analysis

Anupriya Babbar
Assistant Professor
Thakur College of Engineering and Technology
Mumbai 400101 India
anupriyababbar.86@gmail.com

Abstract— **Data Visualization is a powerful tool, it turns monotonous information into a visual that our brains can actually relate and understand. Because our brains process visuals up to 60,000 times faster than text. Visualization provides deep insight about data. There are many powerful libraries like pyplot.Matplotlib, Seaborn, bokeh of python**

Which build interactive graphs, visualization involves producing images that communicate relationships among the represented data to viewers of the images. It helps in decision making and gives deep insight about the data and its relation with the other attributes.

Keywords— Data Visualization, Data Analytics

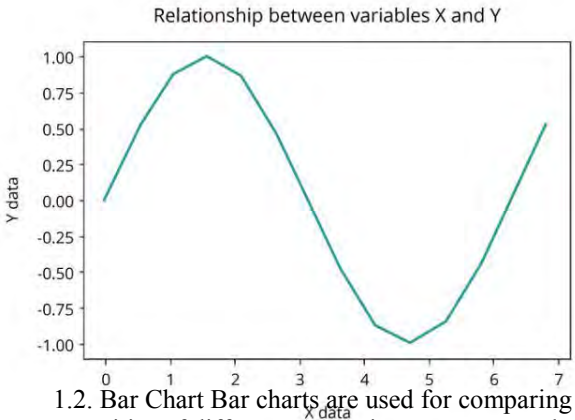
I. VISUALIZATON TECHNIQUE

Data visualization is applied in practically every field of knowledge. Scientists in various disciplines use computer techniques to model complex events and visualize phenomena that cannot be observed directly, such as weather patterns, medical conditions or mathematical relationships.

Data visualization provides an important suite of tools and techniques for gaining a qualitative understanding. The basic techniques are the following plots:

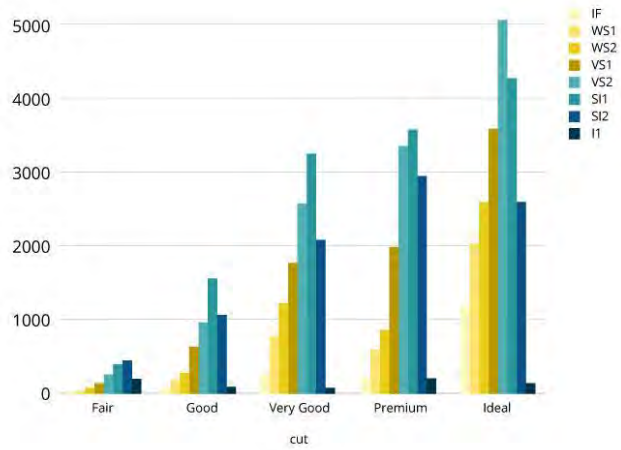
1.1. Line Plot

The simplest technique, a line plot is used to plot the relationship or dependence of one variable on another. To plot the relationship between the two variables, we can simply call the plot function.



1.2. Bar Chart Bar charts are used for comparing the quantities of different categories or groups. Values of a category are represented

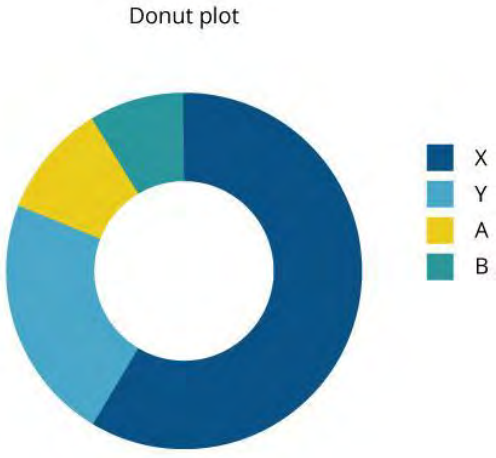
With the help of bars and they can be configured with vertical or horizontal bars, with the length or height of each



Bar representing the value.

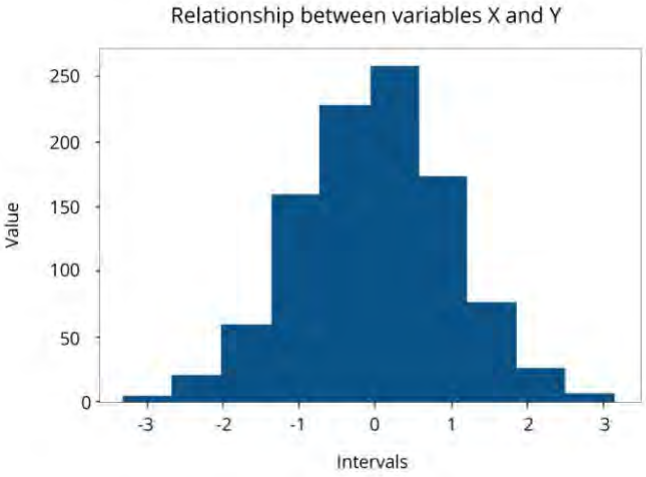
1.3 Pie and Donut Charts

There is much debate around the value of pie and donut charts. As a rule, they are used to compare the parts of a whole and are most effective when there are limited components and when text and percentages are included to describe the content. However, they can be difficult to interpret because the human eye has a hard time estimating areas and comparing visual angles.



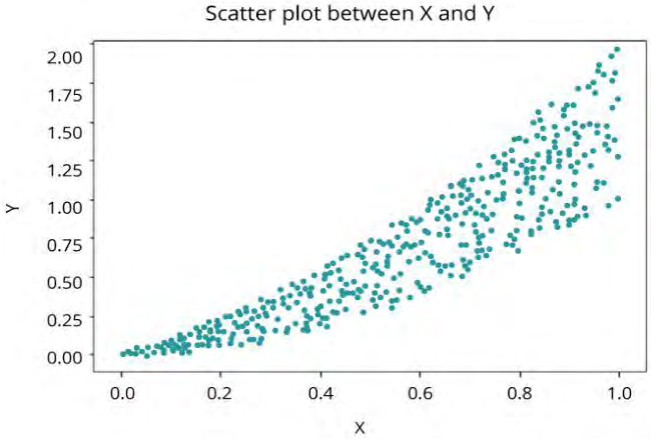
1.4 Histogram Plot

A histogram, representing the distribution of a continuous variable over a given interval or period of time, is one of the most frequently used data visualization techniques in machine learning. It plots the data by chunking it into intervals called 'bins'. It is used to inspect the underlying frequency distribution, outliers, skewness, and so on.



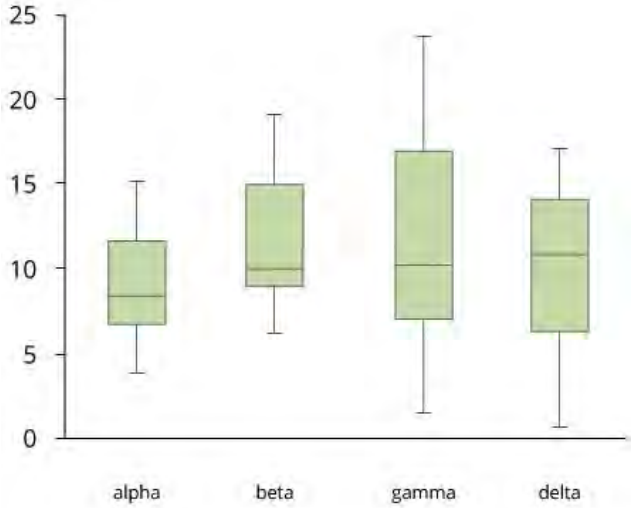
1.5 Scatter Plot

Another common visualization techniques is a scatter plot that is a two-dimensional plot representing the joint variation of two data items. Each marker (symbols such as dots, squares and plus signs) represents an observation. The marker position indicates the value for each observation. When you assign more than two measures, a scatter plot matrix is produced that is a series of scatter plots displaying every possible pairing of the measures that are assigned to the visualization. Scatter plots are used for examining the relationship, or correlations, between X and Y variables.



1.6 Box and Whisker Plot for Large Data

A binned box plot with whiskers shows the distribution of large data and easily see outliers. In its essence, it is a graphical display of five statistics (the minimum, lower quartile, median, upper quartile and maximum) that summarizes the distribution of a set of data. The lower quartile (25th percentile) is represented by the lower edge of the box, and the upper quartile (75th percentile) is represented by the upper edge of the box. The median (50th percentile) is represented by a central line that divides the box into sections. Extreme values are represented by whiskers that extend out from the edges of the box. Box plots are often used to understand the outliers in the data.



1.7 Word Clouds and Network Diagrams for Unstructured Data

The variety of big data brings challenges because semi structured and unstructured data require new visualization techniques. A word cloud visual represents the frequency of a word within a body of text with its relative size in the cloud. This technique is used on unstructured data as a way to display high- or low-frequency words.

Another visualization technique that can be used for semi structured or unstructured data is the network diagram. Network diagrams represent relationships as nodes (individual actors within the network) and ties (relationships between the individuals). They are used in many applications, for example for analysis of social networks or mapping product sales across geographic areas.

II. APPLICATION IN DATA ANALYTICS

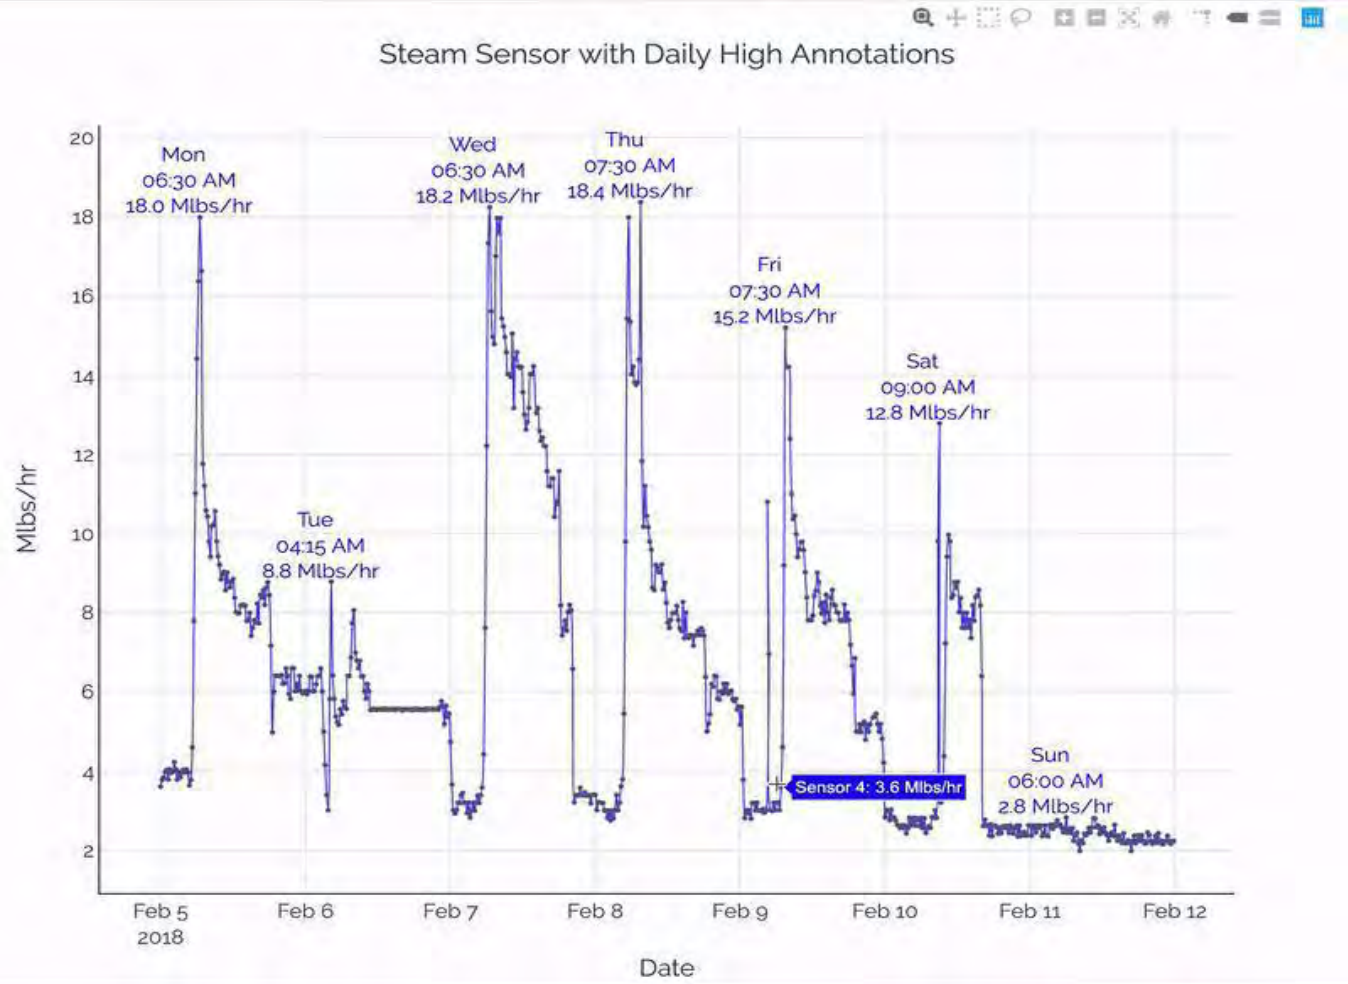
Data visualization is a general term that describes any effort to help people understand the significance of data by placing it in a visual context. Patterns, trends and correlations that

Might go undetected in text-based data closed and recognized easier with data visualization software.

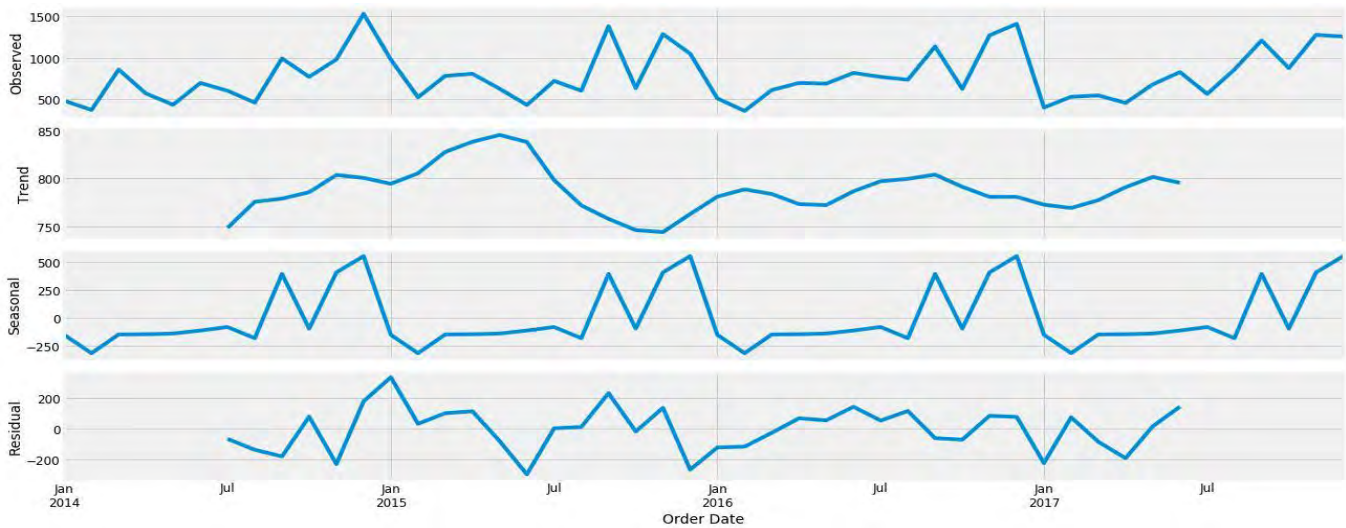
2.1 Forecasting

Data visualization play vital role in time series data where Graphs enable you to visualize many features of the data, including patterns, unusual observations, changes over time, and relationships between variables. Just as the type of data determines which forecasting method to use, it also determines which graphs are appropriate.

This type of interactive plots give deep insight about observations, trends, and seasonality and residual values



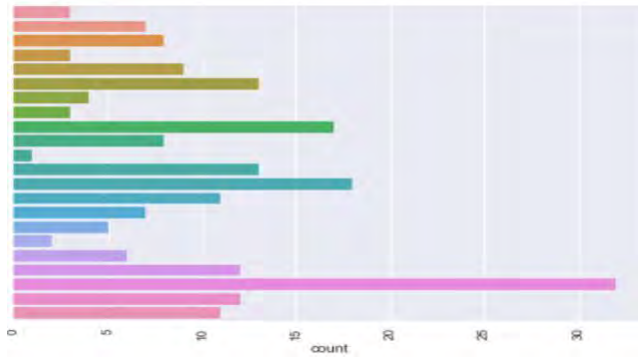
2.2 Public Health:



The ability to analyze and present data in an understandable manner is critical to the
Success of public health surveillance. Health researchers need useful and intelligent tools to aid their
Work [4]. Security is important in cloud-based medical data visualizations. Open any medical or health
Magazine today, and you will see all kinds of graphical representations.

2.3 Healthcare

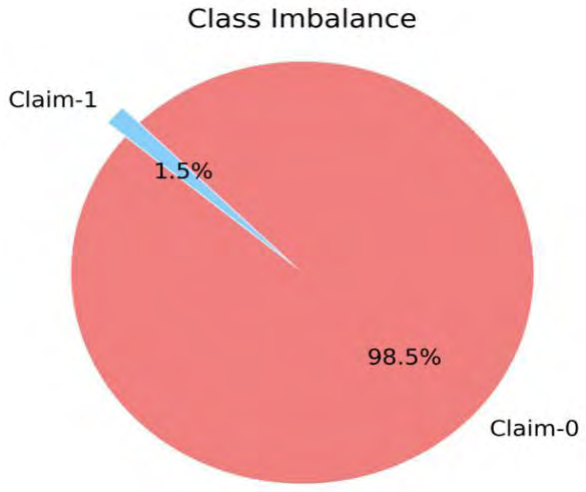
Visualization tools sometimes help in avoiding diagnosing error by eliminating human error in a higher risky environment and set a protective layer for patient safety. It creates a dashboard, i.e., e-health records and e-medical records for tracking and monitoring patient health records. Its computer-based recording system facilitates a better understanding of on-going medical operations.



Number of people effected in various area of country

2.4 Fraud Detection

We might come across the problem of class imbalance while solving classification problems like Anomaly Detection, fraud detection, disease diagnosis, etc. which can be easily viewed by various charts.



CHALLENGES

- Visual noise: Most of the objects in dataset are too relative to each other. Users cannot divide them as separate objects on the screen.
- Information loss: Reduction of visible data sets can be used, but leads to information loss.
- Large image perception: Data visualization methods are not only limited by aspect ratio and resolution of device, but also by physical perception limits.
- High rate of image change: Users observe data and cannot react to the number of data change or its intensity on display.
- High performance requirements: It can be hardly noticed in static visualization because of lower visualization speed requirements--high performance requirement.

IV. CONCLUSION

Visualizations can be static or dynamic. Interactive visualizations often lead to discovery and do a better job than static data tools. Interactive visualizations can help gain great insight from big data. Interactive brushing and linking between visualization approaches and networks or Web-based tools can facilitate the scientific process. Web-based visualization helps get dynamic data timely and keep visualizations up to date.

The extension of some conventional visualization approaches for data analysis is far from enough in functions. More new methods and tools of Data visualization should be developed for different Data analysis. Immersive virtual reality (VR) is a new and powerful method in handling high dimensionality and abstraction. It will facilitate Data visualization greatly.

Genetic Algorithm for feature selection and parameter optimization to enhance learning on healthcare data

Abstract. **Classification algorithms as Support Vector Machine (SVM), and Neu-ral Network (NN) have provided considerably good results in diagnosis of critical care diseases. These Machine Learning algorithms have hyperparameters whose values if chosen optimally can provide enhanced learning. Operating on entire set of features is computationally expensive and requires more number of instances. Hence utilizing important features will reduce computation time. Both these objec-tives can simultaneously be obtained through nature inspired algorithms as Genetic Algorithm (GA). In the proposed work, GA has been utilized for feature selection as well as tuning the hyperparameters of SVM and NN. Optimal value of SVM Radial Basis Function (RBF) kernel parameters C and ɣ has been obtained. Simi-larly the novelty lies in identifying optimal no. of hidden layers, no. of hidden nodes, learning rate, momentum and optimizer for Multi Layer Perceptron (MLP) NN classifier. Results have been found better compared to utilizing Grid Search for the same. Further when reduced set of features are used for learning; sensitivity and precision score have found to be promising. Sensitivity is of more importance when healthcare is talked about and F1 score gives better accuracy since it is unbiased to data imbalance. Thus we have dealt with Multi objective optimization problem uti-lizing meta heuristics with improvement in diagnostic performance.**

Keywords: genetic algorithm, hyperparameter optimization, feature selection, sensitiv-ity.

I. INTRODUCTION

1.1 Support Vector Machine

In order to save sufficient computation time and build models that generalize well, penalty parameter C and kernel function parameter ɣ needs to be optimized. Though Grid algorithm can identify these optimal values through exhaustive search but cannot perform feature selection task. Support Vector Machine identifies the hyperplane D(x)=wx+b with maximum margin for linear separability as shown in Fig 1. For non-linear separable problem, kernel trick is applied as shown in Fig 2.

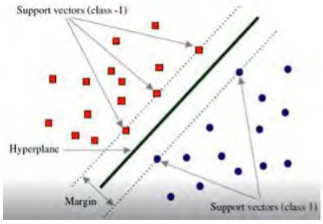

Fig. 1. Support Vector Machine

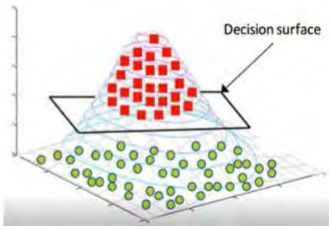

Fig. 2. Kernel Trick

1.2 Neural Network

Neural Network is modeled after the human brain and is capable of capturing complex non linear models. Activation functions operate in hidden nodes to transform net input to output. To avoid overfitting, bias is introduced. The activation function may be Lo-gistic / Sigmoid, ReLU (Rectified Linear Unit) etc. For a classification problem, output is the probability of belonging to a certain class. The model is retrained w.r.t. the error backpropagated until convergence. Thus we get optimal weights following Stochastic Gradient Descent (S.G.D.) algorithm shown in Fig. 3. An extension to S.G.D. is adam (adaptive moment estimation) optimization algorithm realizing the benefits of AdaGrad and RMSProp.

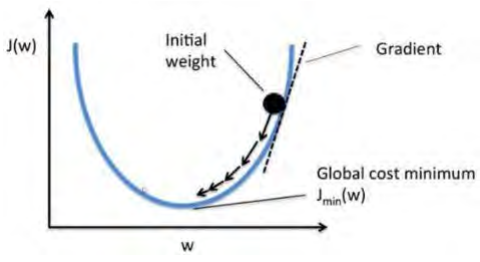

Fig. 3. Stochastic Gradient Descent

1.3 Genetic Algorithm

Genetic Algorithm are Evolutionary Algorithm inspired by natural selection, reproduc-tion and survival of fittest utilizing genetic operators – selection, crossover and muta-tion. Encoding is termed as a chromosome, a single bit being called Allele. It utilizes population of solutions in each iteration. It randomly selects solution to produce other solution and evaluates each potential solution. Two parents are chosen, genetic opera-tors are applied and moved to next generation until convergence.

Crossover is performed over random cutoff points. Mutation is bit flip with certain probability usually low. Elitism is to take best fitness value to next generation by re-placing the worst one. Fitness value is the value of objective function. Selection is through Roulette wheel where size is proportional to individual's fitness or Tournament Selection where several tournaments among few chromosomes are selected at random. Winner of these tournaments is selected for crossover.

II. LITERATURE SURVEY

Gupta S. et. al. have proposed that simultaneous optimization of hyperparameters of NN or SVM RBF kernel and feature subset selection through GA can yield high diag-nostic accuracy. Further they claim in another paper that feature selection is essential for simpler, faster, robust and more reliable ML models.

Huang et. al. has simultaneously optimized parameters and feature subset without compromising accuracy of SVM utilizing GA and compared performance with Grid search. Steps taken for GA based Feature selection are:

- Scaling to avoid attributes in greater numeric range dominate those in smaller nu-meric ranges
- Evaluate the fitness of each chromosome
- Look for better solutions by selection, crossover and mutation

The data is partitioned into training and independent test sets via kfold cross validation (CV). Fei et. al. searches best penalty and kernel function parameter and finally a less complex SVM model with fewer support vectors is proposed.

Bhatia et. al. has tried experimenting onto Cleveland multiclass using 'one against one' and binary class problem utilizing integer coded GA in order to avoid curse of dimensionality. The fitness value chosen is the classification accuracy achieved by fea-ture subset with 25 generation, 50 population, 0.8 crossover probability and 0.2 muta-tion probability. Similarly Arrythmia dataset with 17 classes received sensitivity of 91.40%, accuracy 98.99% and specificity 99.46% with genetic ensemble of classifiers by Plawiak et. al.

ANN is one of the most promising computational intelligence technique though the design requires setting of the structure and tuning complex parameter. Thus GA has been used by Ahmad et. al. to select significant features and identify optimal no. of hidden nodes along with Levenberg Marquardt (LM) backpropagation algorithm, the chromosome is shown in Fig. 4. Fitness function is calculated based on Mean Square Error (MSE) as shown in Eq. 1 and 2 below. MSE is converted to rank and chromosome with smaller MSE has better chance of selection. The author further utilized GA to fine tune weight of ANN. The chromosome being shown in Fig. 5.

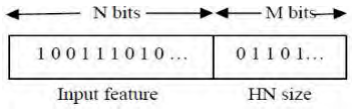

Fig. 4. Optimize features and hidden nodes [Ahmad et.al.]

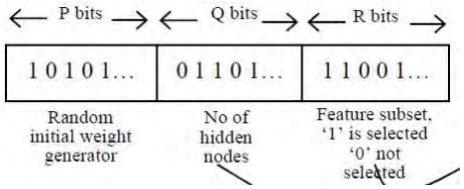

Fig. 5. Optimize initial weight, Hidden nodes, feature subset [Ahmad et.al.]

$$\text{MSE} \quad \frac{1}{0} \times \sum \sum (\quad - \quad)^2 \qquad (1)$$

$$= \quad \underline{0}$$

$$=1$$
$$=1$$

(2) $$fitness(i) = \frac{100 \times rank(i)}{\sum_{i=1}^{population\ size} rank(j)}$$

For RBF N/W, GA solves subset selection problem. Lacerda et. al. utilized holdout k fold CV and bootstrap function to accomplish the same. Zhao et. al. has also analyzed that inappropriate parameter settings lead to lower classification accuracy. Better per-formance may be achieved by discarding noisy, irrelevant and redundant features. The objective achieved was highest classification accuracy, least no. of selected features and least average processing time. Amin et. al. has utilized the global optimization ad-vantage of genetic algorithm for initialization of NN weights with faster, stable and accurate learning than Backpropagation (BP). The initialization of NN weights in BP algorithm is a blind process and there is slow convergence. LM optimization is fastest BP algorithm though requires more memory. Testing was done on 20 chromosomes in 100 generations with 12, 10 and 2 neurons in input, hidden and output layer respec-tively. The fitness function is based on MSE.

Jabbar et. al. identified the value of hyperparameter k in kNN with crossover prob=0.6 and mutation prob=0.033 for 20 chromosomes in 20 generation each resulted in enhanced accuracy for several diseased datasets. Pima Indian Diabetes dataset lies under normal distribution hence feature selection utilizing GA SVM enhanced accuracy and identified critical attributes by Santhanam et al. GA is used to select optimal set of features from 22 features of Parkinson's disease to 7 by adaboost and 10 by bagging ensemble utilizing fitness function as classification rate with 96.55% and 98.28% ac-curacy respectively by Fayyazifar et. al.

GA wrapper with embedded regularization achieved train and test accuracy of 98.83% and 93.61% respectively on Lung Cancer dataset by Liu et al. Increase in per-formance of NN by 10% through enhancing initial weights utilizing GA was obtained by Abrasadi et. al. Optimal feature subset with min. MSE and max. R^2 chosen with 22, 5 and 1 neuron in input, hidden and output layer respectively. Future work states opti-mizing learning rate and momentum factor. Gokulnath et. al. utilized Roulette wheel selection and SVM for classification with single point crossover followed by mutation to preserve genetic diversity and elitism. The data is preprocessed based on:

$$\text{Z-score normalisation} = \frac{(\ -\ )}{\quad} \quad \text{where } \mu\text{=mean and } \sigma = \text{s.d.} \qquad (3)$$

The fitness function f is based on classification accuracy f1 and no. of selected genes f2 as shown in Eq. 4-6 below. Comparison with other feature selection algorithms improved the classification accuracy by 4.64% onto Cleveland Heart Disease dataset.

$$\text{Classification accuracy of SVM } {}_1(\ ) = \frac{\quad +}{\quad + \ + \ +} \qquad (4)$$

$$\text{Number of selected genes } (\ ) = (1 - \frac{\quad}{2}\ ) \qquad (5)$$

$$\text{Fitness Function } (\ ) = {}_1(\ ) + (1 - \ ) {}_2(\ ) \qquad (6)$$

Similarly GA is able to optimize no. of base classifiers in an ensemble with signifi-cantly lower classification error and produce a model that is robust to outliers by both Fletcher et. al and Oh et. al. GA is also used to impute missing values when there is high rate of missing data with info gain as fitness function by Shahzad et. al.

III. EXPERIMENTATION AND RESULTS

Current work involves utilizing GA for parameter optimization of SVM and NN.
Genetic Algorithm is based on randomness. The methodology involved is as follows.
The same is reflected in the flowchart in Fig 6.

1. Set No. of iterations/generations (M), No. of individuals/chromosomes in initial population (N), crossover probability (p_c), mutation probability (p_m)
2. Create N population randomly of string size l
3. m=1, n=1
4. Select 2 parents through selection
5. Crossover the parents to get children at p_c
6. Mutate children at p_m
7. Calculate fitness of mutated children, save fitness value
8. Repeat 4-7 n/2 times (increment n)
9. Get a new generation of mutated children
10. Increment m
11. Repeat 4-10 M times
12. Chose best fitness value from last generation

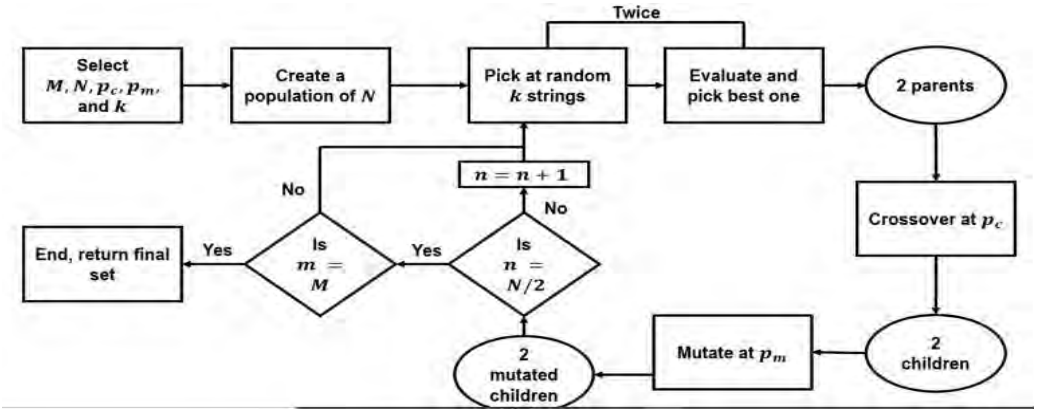

Fig. 6. Flowchart for applying GA

3.1 Dataset

According to yourtotalhealth website; WHO estimates 11.1 million deaths from Cardi-ovascular Artery Disease (CAD) in 2020. Further there are several datasets available on Kaggle.com on heart diseases. Cleveland and Stalog have less no. of instances whereas Hungarian and Switzerland have large missing values. Framingham Heart Dis-ease dataset predicting Ten Year Coronary Heart Disease (CHD) with 14428 instances and 15 features is preferred for experimentation due to availability of more data and less percentage of missing values. Any disease dataset has been found to be imbalanced since number of instances in healthy class will be less compared to diseased class.

Feature Engineering showed categorical features as gender, education level, cur-rently smoking, taking BP medication and whether stroke, hypertension, diabetes are prevalent. These features were transformed by creating dummy features and then de-leting redundant ones. Framingham heart disease dataset was containing unequal binary class distribution with 3596 and 644 instances respectively for patients suffering from TenYearCHD and healthy patients. Thus dataset was balanced through Synthetic mi-nority oversampling technique (SMOTE) which enhanced all parameters specially

Sen-sitivity results which are of more importance in medical diagnosis. Exploratory Data Analysis is done to reveal missing value in features BPMeds, education, glucose and totchol. Since the missing percentage was less, kNN imputation with Manhattan dis-tance for continuous and hamming for categorical was used for k=30. EDA also demon-strates features in differing scale. Standard Scaler is applied so that features in greater ranges do not overpower those in smaller ranges. Train:Test ratio kept is 60:40 as com-pared to 75:25. The table below reveals good sensitivity and F1 score for NN and SVM.

Accuracy=(TP+TN)/(P+N) (7)

Sensitivity or Recall = TP/P (8)

Specificity = TN/N (9)

Precision = TP/(TP+FP) (10)

F1 score = 2*Precision*Recall/(Precision+Recall) (11)

where TP=True Positive, TN=True negative, FP=False Positive, FN=False Negative P = TP+FN and N = FP + TN

Table 1. Comparison of base classifiers

Classifier	Accuracy (CV)	Sensitivity	Specificity	Precision	F1 score
Decision Tree	85 %	82 %	30 %	87 %	84 %
K Nearest Neighbor	85 %	71 %	49 %	88 %	79 %
MLP Neural Network	82 %	**84** %	28 %	87 %	**85** %
Support Vector Machine	83 %	**82** %	32 %	87 %	**84** %

3.2 GA for hyperparameter tuning SVM

The experimentation is performed for initial population of 100 chromosomes iterated over 50 generations for convergence. The validation set is chosen of 3 folds. The pa-rameters for GA are p_c=1, p_m=0.2, pop=50, gen=50, kfold=3. A stack of random chromosomes is created each time a new set of solution belongs to the population. Pre-cision is used to compute feature vector for binary chromosome. Then chromosome is decoded with respect to the range in which C and ɣ is allowable as shown in Eq. 7-8 below:

$$\text{Precision} = \frac{-}{2^{} - 1} \text{ where range (a,b), chromosome length=l} \quad (12)$$

$$\text{Decoding} = (\quad * 2) * + \quad (13)$$

The initial chromosome chosen is binary comprising of 1st 15 bits for ɣ and last 15 for C regularization hyperparameter of SVM RBF kernel respectively. The sample is shown in Fig. 7. Upper and Lower bound default ranges are b=1000, a=10 for C and b=0.99, a=0.05 for ɣ. This lower and upper bound has been provided through knowledge from published literature.

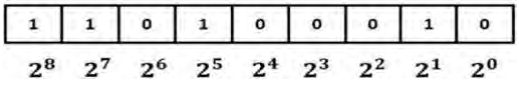

Fig. 7. Sample Chromosome of 9 bits

Decoding the chromosome/genotype to a value of C or ɣ is called phenotype. 3 contestants are chosen for tournament selection as per the knowledge gained from online sources. The basis is MSE with SVM classifier. Again this is the default number as stated in courses undergone. Diversity is created through unique random numbers.

Thus the minimization objective function = 1-Accuracy (14)

We find that the Accuracy for SVM w/o GA is **83**% and with is **84**%. Hyperparam-eter tuning with GA retrieved hyperparameter values as C=903.83 and ɣ=0.055. De-fault kernel parameters are C=1 and ɣ=0.1. Similar experimentation utilizing Grid search gave 80% accuracy with SVM linear kernel and C=1.

3.3 GA for hyperparameter tuning NN

Similar experimentation was performed with Multi Layer Perceptron (MLP) classi-fier to optimize weights used in training NN. The data has been shuffled for generali-zation. The no. of neurons range 6-10 and no. of hidden layers 3-8 based on similar experimentations done by other researchers. The chromosome is now 32 bit with 1^{st} 2 being combinatorial/discrete for no. of hidden layer and no. of neuron and next 30 being continuous for momentum γ and learning rate η respectively. A population of 50 chro-mosomes is generated for 50 generations. NN improves training speed and accuracy. Training finds appropriate value for weights and bias, utilizing BPNN keeping track of mutated child per generation and updating the weights computing increment by Eq 9-10 below:

Weight increment Δ = (∗)

$$\Delta = (* \_\_\_) + (* \Delta^{-1})$$

where η is the learning rate, γ is the momentum factor, Δ^{-1} is weight increment in previous iteration, and is weight gradient

The solver used is adam which gives better results than S.G.D. in terms of stability and speed. Upper and Lower bound default ranges are a=0.01, b=0.3 for momentum and a=0.01 and b=0.99 for learning rate based on literature reviewed. Two point cross-over has been chosen. The optimal value of hyperparameters obtained by GA is # of neurons=6, # of hidden layers=4, Momentum=0.086, Learning rate=0.060. Training accuracy achieved is **84** % with GA as compared to 82% w/o GA . Similar experimen-tation utilizing Grid search gave 80% accuracy with MLP NN utilizing activation=tanh, alpha=0.05, hidden_layer_sizes=(50, 50, 50), learning_rate being constant and solver as sgd.

3.4 GA for Feature Selection

The feature selection task when performed through NN with binary chromosome of size = # of features i.e. 15 reduces no. of features to 9 selecting male, age, education, currentSmoker, BPMeds, sysBP, diaBP, heartrate, glucose as high risk factors whereas feature selection task when performed through SVM returns 12 features i.e. male, age, education, cigsperday, BPMeds, prevStroke, diab, sysBP, diaBP, BMI, heartrate, glu-cose as high risk factors. Initial level of Feature Engineering through profiling showed correlation in features SysBP and DiaBP with Hypertension. Also correlation in Cur-rentSmoke and CigPerDay features was found through Spearman and Pearson Correla-tion. Results of feature selection through GA verify statistical findings. The experimen-tation is done for population of 80 chromosomes for 30 generations. 5 fold CV is per-formed for generalization based on courses undergone. Crossover is always performed whereas mutation is performed 20% of the time.

Table 2. Comparing performance with all and reduced features on SVM classifier

Classifier	Sensitivity	F1 score
With all features	82 %	84 %
With reduced features	89 %	88 %

Table 3. Comparing performance with all and reduced features on MLP NN classifier

Classifier	Sensitivity	F1 score
With all features	84 %	85 %
With reduced features	100 %	92 %

IV. CONCLUSION AND FUTURE SCOPE

The results claim the power of GA for parameter optimization of ML models and opti-mal feature selection utilizing MLP NN and SVM classifiers. Performance is enhanced further using Feature Engineering and Exploratory data analysis in the form of remov-ing data imbalance, imputing missing values, removing correlated features and treating categorical data. Research findings claim that though Grid search is used for hyperpa-rameter tuning but

cannot be used for feature selection and thus cannot fulfil multi-objective optimization..

Future work may test power of GA for finding best set of classifiers in an ensemble, find hyperparameter values for ensemble learners and impute large missing data as well. Current work can be extended utilizing NearMiss undersampling technique for balancing dataset and Multiple imputation with chained equations (MICE) for imputing missing values where multiple columns have missing data as in the case of Hungarian and Switzerland heart disease datasets. Currently the work is dealt with same number of neuron per layer for MLPNN, hence efforts shall be put in this direction in future work.

Abstract— **traditionally the use of biometric devices has improved our ability to provide authenticated access to physical installations. With the rise in security breaches in recent years, many organizations believed that two- factor authentication would be the answer. [4]Voice Biometric can be one of the factors of authentication. In this paper, there will be three phases- Feature Extraction, Training and Matching. The features will be extracted by using MFCC (Mel Frequency Campestral Co-efficient) technique. In the training phase the extracted features will be trained using the Gaussian Mixture Model (GMM). In the last phase, the algorithm on a dataset and the model will be used to predict the appropriate classes by finding the log likelihood of voice sample.**

Keywords— MFCC- Mel-frequency Cepstral Coefficients GMM-Gaussian Mixture ModelEM- Expectation Maximization

I. INTRODUCTION

With recent advancement in technology voice recognition has become one of the efficient measure that is used to provide protection to human's computerized and electronic belongings. . It is one of the types of biometric that is used to identify and authenticate user on the basis of his/her voice. [2]Voice recognition is divided into two types: text dependent and text independent. Text dependent recognition identifies user against a phrase while text independent recognition identifies the user irrespective of what he is saying. The success in both cases depends upon the various speaker characteristics which differentiate the one speaker from other. All voice recognition systems comprises of two modules, feature extraction and feature matching. In feature extraction, data from the voice sample is extracted to represent the certain speaker and in feature matching the extracted features from the input voice sample is matched against a set known speaker. Speaker recognition methods can be divided into text-independent and text-dependent methods. In a text-independent system, speaker models capture characteristics of somebody's speech which show up irrespective of what one is saying. In a text-dependent system, on the other hand, the recognition of the speaker's identity is based on his or her speaking on one or more specific phrases, like passwords, card numbers, PIN codes, etc. Every technology of speaker recognition, identification and verification, whether text- independent and text dependent, each has its own advantages and disadvantages and may require different treatments and techniques. The choice of which technology to use is application-specific. At the highest level, all. Speaker recognition systems contain two main modules feature extraction and feature matching

II. EASE OF USE

A. Entertainment:

Voice recognition can be used to change TV or radio channels, open and close screens, and play movies. It can also help personalize customer experience. For instance, services such as Netflix and Hula can be personalized by determining the age of the user through voice analysis, enabling them to access age-appropriate content.

B . Healthcare:

The global healthcare biometric market is expected to reach USD 14.5 billion by 2025, according to a recent report by Grand View Research, Inc. In an industry where data security is paramount, physicians can use voice biometrics to dictate and record patient's health conditions directly into the system and securely retrieve patient's personal history. This can significantly benefit patients who need to share medical records between various doctors. The system can also help dramatically reduce fraud for providers and payers by automating payment collection, and improve patient satisfaction by offering an additional payment option.

C. Banking:

Customers can use voice authentication to operate bank lockers. Banks, on the other hand, can leverage the system to enable highly secure and advanced voice-based payments. With fraud on the rise, credit card companies and banks such as Citibank and ANZ use voice biometrics to proactively identify fraudsters and authenticate callers at their call

centers.*D. Education:* Educational institutions can use voice recognition to provide flexibility to students with visual disability, helping them take online exams using voice authentication.

E. Independent Software Vendors:

For ISVs, voice authentication can enable enterprise sign on mechanisms such as those based on Active Directory, enabling authentication uniformity across enterprise applications and strengthening compliance with accessibility standards.

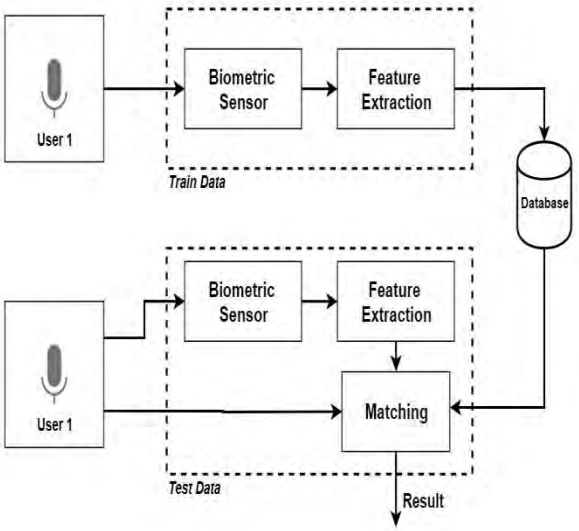

Fig. 1: Architecture

III. HOW IT WORKS

The first step in any voice recognition system is for the user to give an input by speaking a word or a phrase into a microphone as shown in Fig. 1. Then an analog to digital converter converts the electrical signal into digitized form and stored it in the memory. The computer then attempts to determine the meaning of a voice sample by matching it with a template that has a known meaning. This is an analogy to the traditional inputs from a keyboard. The greatest hurdles in Speaker- independent speech recognition systems are articulations and variety of accents used by the people having different nationalities. Other factors that present a challenge to voice recognition technology are acoustical noise and variations in recording environment which are beyond speaker variability. The developed system is consisting of three processes:

- Features extracting
- Training
- Matching

In first process, the developed system will result as computed features of human voice. These features are voice features which are taken from the persons. These features are extracted by using MFCC (Mel Frequency Campestral Coefficient) technique. [1] MFCC is used as the acoustic features of human voice. It considers the human voice pitch in the form of frequencies and scale them on the Mel scale, these extracted features are unique to others. In training process, the extracted features are trained using the Gaussian Mixture Modeling. Expectation Maximization (EM) algorithm is used to train the extracted features of human voice in system and then finally used to store in database. In the last phase, the model so constructed will be used in predicting the appropriate class using the validation dataset. We implement MFCC with GMM techniques in order to identify the speaker.

A. Abbreviations and Acronyms

MFCC: Mel Frequency Cepstral Coefficients
GMM: Gaussian Mixture Model
Expectation Maximization Units

B. Algorithms

1) MFCC Algorithm:

Mel Frequency Cepstral Coefficients (MFCCs) are a feature widely used in automatic speech and speaker recognition. They were introduced by Davis and Mermelstein in the 1980's, and have been state-of-the-art ever since. Prior to the introduction of MFCCs, Linear Prediction Coefficients (LPCs) and Linear Prediction Cepstral Coefficients (LPCCs) (click here for a tutorial on cepstrum and LPCCs) and were the main feature type for automatic speech recognition (ASR), especially with HMM classifiers. [6] The Mel scale relates perceived frequency, or pitch, of a pure tone to its actual measured frequency. Humans are much better at discerning small changes in pitch at low frequencies than they are at high frequencies. Incorporating this scale makes our features match closely to what humans hear.

2) GMM Algorithm:

In training process, [3] the extracted features are trained using the Gaussian Mixture Modeling. It recognizes the speaker on the basis of log probability of voice vector and compares it to previously stored value. The log probability, equal to the stored value provides access to the entire speaker. Suppose there are K clusters (For the sake of simplicity here it is assumed that the number of clusters is known and it is K). So mu and sum is also

estimated for each k. Had it been only one distribution, they would have been estimated by maximum-likelihood method. But since there are K such clusters and the probability density is defined as a linear function of densities of all these K distributions.

3) Expectation-Maximization

It is used to estimate the maximum likelihood and it returns the mean Variance Weight W and log Probability. The essence of Expectation-Maximization algorithm is to use the available observed data of the dataset to estimate the missing data and then using that data to update the values of the parameters.

C. Applications

Entertainment
Healthcare
Banking
Education
Independent software vendors (ISV)

D. Advantages

Increased Security
Decreased Fraud
Improved Customer Experience
Reduced Costs
High Reliability Rate
Easy to use
Minimally Invasive

E. Methodology

The proposed system was designed using methodology of incremental model. Incremental Model is used for designing, integrating and testing the system. Incremental Model is chosen for this system because system can be developed and delivered in increments, accommodate changes that evolve with time, are easy to test and debug and easier to manage risks involved.

F. Objectives

- To makes a system that identifies a person by processing his/her voice.
- To make system more secure by preventing unauthorized access.
- Performance Evaluation of proposed framework by comparing the performance of existing Voice Recognition System.
- Design of a Security Template to secure Voice recognition system
- To develop or improve existing algorithms to make the Voice recognition accurate on Voice with background noise. And also increase the security of a system to a certain extent when combined with another security step.

IVR (Interactive Voice Response) systems as shown if Fig.2, can be built to interact with customers and the voice print can be used to authenticate the customer and progress in the task which he/she wants to do. These systems can be used in multiple domains for example, telecommunication domain for verification of the user, banking domain for a customer to check balance, change pin or password, withdraw money, social media websites to login, etc.. This system can be used in any domain where security is a concern.

All of us are aware of the word 'jackpotting' which is nothing but illegally withdrawing money from an ATM. An ATM can be built with a feature of voice recognition so that only authorized customers can do the transactions safely and securely.

IV. FUTURE SCOPE

This paper is on how voice authentication can be used in day to day life to make systems more secured because security is a very important thing in today's world with everything going digital. A system is highly vulnerable to impersonation attacks i.e. authentication and authorization attacks. Impersonation means gaining access to resources without the correct credentials. System cannot figure out who the user is until and unless correct username match to correct password. Bringing biometrics in picture reduces a burden of task like remembering credentials and entering whenever it is needed. Voice authentication will reduce time

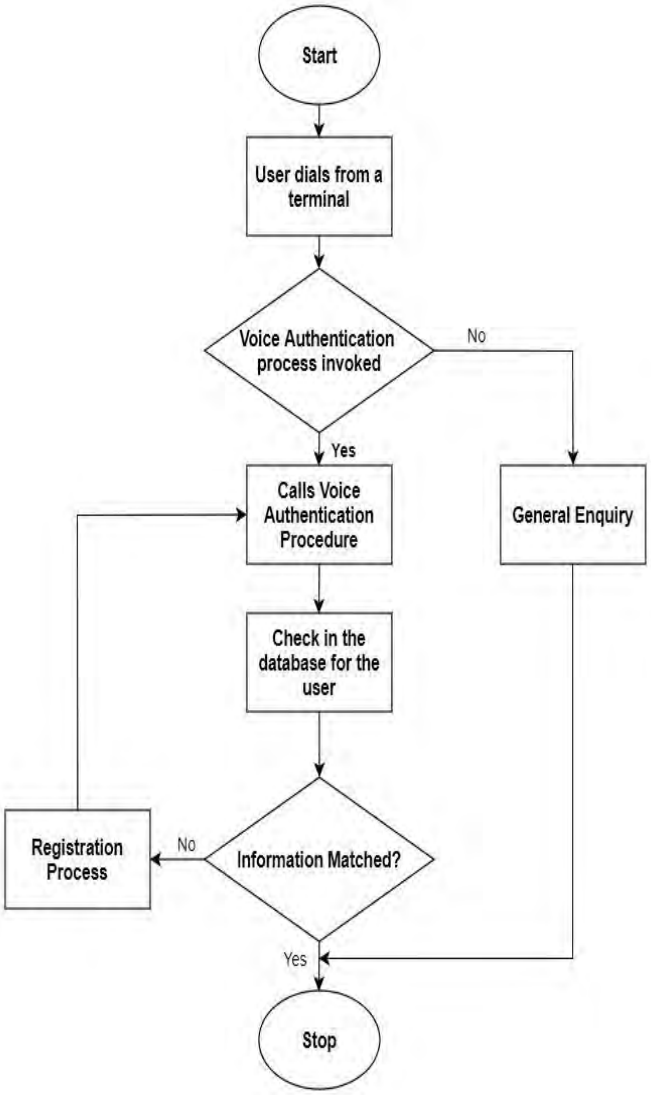

Fig. 2: IVR Flowchart. IMPACT ANALYSIS

Current solutions for passwords and authentication are insecure and have been hacked very regularly. Biometric based authentication provides a promising solution because voice biometrics, fingerprints, creates unique identifiers for individuals [9]. With the rise in security breaches in recent years, many organizations believed that two-factor authentication would be the answer. Voice Biometric can be one of the factors of authentication. A more commonly overlooked advantage of voice biometric solutions is that they actually hold the potential to significantly improve customer experiences. With voice biometrics products, callers no longer need to provide passcodes or PINs or provide answers to challenge questions in order to verify their identity. This makes voice biometrics ideal for various Omni channel and multichannel deployments, because once a customer is enrolled; his or her voiceprint can be leveraged across all of your company's support channels. This seamless experience not only makes the process easier and more efficient for your customer, but it also leads to improved CSAT, NPS, and Customer Effort Scores, as highlighted by recent Forrester research. In fact, it has been found that voice biometrics can reduce the time it takes to verify a caller's identity from. This advantage offers the ability to dramatically improve not only call personalization, but also customer experiences. There is many different ways that voice and speech recognition is helping commercial organizations. Many business concerns that want to excel at customer service use this 'cutting-edge' technology to enhance their customer interaction experience and reduce organizational expenses. Since voice authentication technology can take the place of living agents, it can also eliminate all problems, such as unauthorized access, theft of confidential documents, fraud etc. Through Voice Recognition technology, all calls can be handled by the system rather than a receptionist. This ensures a seamlessly uniform experience. Furthermore, the customers will be fully satisfied with the quality of the service. Voice authentication is a tremendous boon for organizations which will help them secure their confidential data from unauthorized access. Moreover, instead of remembering the pin code of bank account, customers can easily access their account and carry out their activities effortlessly and all of this will

increase customer satisfaction as they will get rid from the burden of remembering pin codes of their bank accounts.

V. CONCLUSIONS

In this paper, efforts have been made to overcome existing security threats by implementing two factor voice authentications. Limitation of uncontrolled environment conditions related to authentication using voice recognition has been taken care of in this paper. MFCC features were used which solved the problem of unfavourable human conditions such as sore throat as it models the vocal tract, tongue and teeth which affects the voice of an individual.

VI. ACKNOWLEDGMENT

We sincerely thank our guide Ms. Veena Kulkarni for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. Sheetal Rathi, Dean Academic, Dr. R.R Sedamkar, the Principal, Dr. B. K. Mishra and the college management for their support.

Customer Relationship Management using Data Mining techniques

Shukla anurag,Jha Nilesh,Mohd Salim,Prof. Rashmi Thakur
Computer Engineering, TCET
University of Mumbai
shuklaanurag998@gmail.com,nilesh.jha412@gmail.com,shaikhsalim3105@gmail.com,rashmi.thakur@thakureducation.org

ABSTRACT-

Customer relationship management (CRM) is an approach to manage a company's interaction with current and potential customers. It utilizes information examination about clients' history with an organization to improve business associations with clients, explicitly concentrating on client maintenance and at last driving deals development.

Customer relationship management has many components such as Sales Force automation, Human Resources management, Customer Service, Business reporting, Analytics etc. In this paper, we will be discussing our approach for building various tools used for Customer relationship management.

INTRODUCTION

In a Business to Business atmosphere, suppliers and service providers typically ought to perceive the characteristics of their customers. Customer attraction and satisfaction are the main objectives of any leading company. This paper discusses the methods used for building the tools which help in CRM tasks like Customer Loyalty prediction, Market Basket Analysis, Feedback Chabot etc.

RFM analysis

RFM analysis1 has been utilized in direct marketing for many decades (Baier, Ruff, & Chakra borty, 2002).

This system identifies client behavior and represents client behavior characteristics by 3 variables as follows:

(1) Regency of the last purchase which refers to the interval between the time that the latest consuming behavior happens and present.

(2) Frequency of the purchases which refers to the number of transactions in a particular period.

(3) Monetary value of the purchase which refers to consumption money amount in a particular period.

RFM analysis is utilized in many ways by practitioners; therefore, RFM analysis can mean different things to different people. Classic RFM implementation ranks each customer on valuable parameters against all the other customers, and creates an RFM score for each customer/product. The first step is to sort the customer file according to how recently customers have purchased from the firm. Then database divided into equal quintiles and these quintiles are assigned the numbers 5 to 1. Therefore, the 20% of the customers who most recently purchased from the company are assigned the number
5; the next 20% are assigned the number 4, and so on. The next step involves sorting the frequently, monetary. Therefore, the database is divided into 125 roughly equal groups (cells) according to regency, frequency, and monetary value. Customers/products with high scores are usually the most profitable

LITERATURE REVIEW

E-business customer service by Anton, J., Hock, M.: e-Business Customer Service. The Anton Press, Santa Monica, CA. They defined CRM as a comprehensive business and marketing strategy that integrates technology, process, and all business activities around the customer. The widespread use of the web technology presents an opportunity for businesses to use the Internet as a tool for electronic customer relationship management (e-CRM). Gaps identified in this paper is that testing by means of the statistical analysis method of Structure Equation Model (SEM) yields results which are not applicable in real life scenarios as per our findings.[1]

E-CRM web service attributes as determinants of customer satisfaction with retail web sites by Richard Feinberg and Rajesh Kadam of International Journal of Service Industry Management. Despite widespread agreement that CRM/e-CRM has direct and/or indirect impact on customer satisfaction, sales, profit, and loyalty, the significance of e-CRM and the various e-CRM features in influencing customer satisfaction has not been well researched. According to Feinberg and Kadam, profits increase by 25–80% when customer retention rates increase by five points. Gaps identified in this paper are unable to determine both empirical and conceptual relationship between e-CRM features and customer satisfaction, and e- CRM features and customer loyalty.[2]

Managing Customers Relationships in the e-Business Economy by Jayanta Chatterjee of Journal of Scientific & Industrial research.

CRM as a discipline which focuses on automating and improving the business processes associated with managing customer relationships in the area of sales, management, customer service, and support. Gaps identified in this paper are unable to define beyond the need to create a more entrepreneurial atmosphere to cope with uncertainty and rapid market/consumer change.[3]

Customer relationship management

Since the early 1980s, the concept of customer relationship management in marketing, and consists of four dimensions: customer identification, customer attraction, customer retention and customer development has gained its importance. It is difficult to find out a totally approved definition of CRM. We can describe it as a comprehensive strategy and process of acquiring, retaining and partnering with selective customers to create superior value for the Company and the customer (Parvatiyar & Sheth, 2004). CRM is a comprehensive business and marketing strategy that integrates technology, process, and all business activities around the customer (Anton, 1996; Anton & Hoeck, 2002). Brown points out that CRM as ‘‘the key competitive strategy you need to stay focused on the needs of your customers and to integrate a customer facing approach throughout your organization’’ (Brown, 2000). Chatterjee also defines CRM as a discipline which focuses on automating and improving the business processes associated with managing customer relationships in the area of sales, management, customer service, and support (Chatterjee, 2000). According to Feinberg and Kadam, profits increase by 25–80% when customer Retention rates increase by five points (Feinberg & Kadam, 2002). CRM projects often fail and only about 40% of CRM implementations are successful (Feinberg & Trotter, 2001).

Customer loyalty

Creating a loyal B2B customer base is not only about maintaining numbers of customer overtime, but it is creating the relationship with business customers to encourage their future purchase and level of advocacy. Equipped with the knowledge of their business customers’ loyalty levels, a supplier will be able to figure how their endeavors to maintain good relationships can contribute to its profit levels. Some authors believe that loyal customers offer a steady stream of revenue for a company by remaining with the brand/supplier and rejecting the overtures of competitors (Lam, Shankar, Erramilli, & Murthy, 2004; Reich held & Teal, 1996). Considering this with the nature of large purchase and transactions in a B2B setting; there are gigantic rewards for those suppliers who succeed in creating and maintaining loyal customers. Some Authors have proposed several theories to link variables that one usually finds in relationship marketing and business marketing to the loyalty construct. In the B2B context, evidence shows that relationship elements affect customer loyalty. For example, Ricard and Perrien found that relationship practices have a direct impact on customer loyalty (Ricard & Perrien, 1999). Other Authors provide empirical evidence linking several constructs such as relationship quality, trust, involvement, satisfaction, purchase development, organizational change, and switching costs to influence B2B customer loyalty and retention (Chow & Holden, 1997; Eriksson & Vaghult, 2000). In some researches, customer lifetime value (CLV) or loyalty is evaluated in terms of recency, frequency, monetary

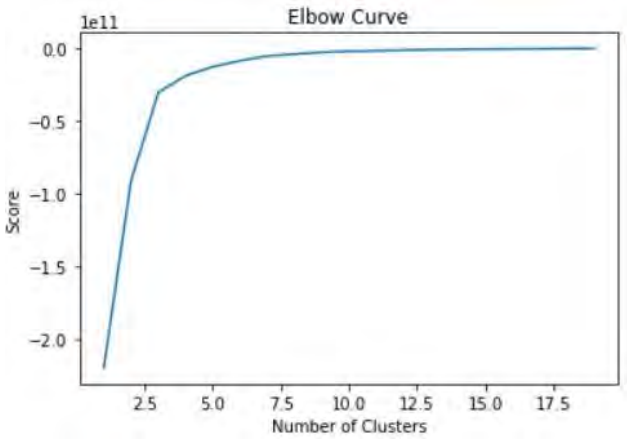
variables namely the integrating rate of each cluster, that is

Cj1 = wRCjR + wFCjF + wMCjM

where wR, wF, wM are the relative importance of the RFM variables (Liu & Shih, 2005). Other researches for classifying customer value have proposed a model based on computing the distance between the center of cluster and zero point as high value refers to most customer loyalty(Cheng & Chen, 2008).

METHODOLOGY

Steps for Customer Segmentation based on Loyalty:
1. Pre-processing of data by removing null values from the dataset and removing negative values from appropriate columns.
2. Transformation of data into the format required for RFM analysis. The dataset should be in the form of (Customer_ID, Recency, Frequency, Monetary)
3. Finding the optimal value of k using the elbow method.
The elbow method is a heuristic method of interpretation and validation of consistency within cluster analysis designed to help find the appropriate number of clusters in a dataset. It is often ambiguous and not very reliable, and hence other approaches for determining the number of clusters such as the silhouette method are preferable.



4. Applying k-means algorithm to cluster the data into segments based on customer loyalty.
Clustering is the process of grouping a set of physical objects into similar groups. A cluster is a collection of data objects that are similar to one another within the same cluster and are dissimilar to the objects in other clusters (Han & Kamber, 2001). K
one of the well-known algorithms for clustering which is very sensitive to the choice of a starting point for partitioning the items into K initial clusters. We can compare the performance of different clustering methods using intraclass method when the grating mer n K-Means is number of fixed cluster of K value is defined as

$$F(K) = 1 \Big/ K\sum_{n=1}^{k}$$

Steps for Market Basket Analysis:
1. Pre-processing of data by removing null values from the dataset and removing negative values from appropriate columns.
2. Transform the data into format required for Apriori Algorithm.
3. Applying Apriori algorithm to mine frequent datasets
Apriori is an algorithm for frequent item set mining and association rule learning over relational databases. It proceeds by identifying the frequent individual items in the database and extending them to larger and larger item sets as long as those item sets appear sufficiently often in the database. The frequent item sets determined by Apriori can be used to determine association rules which highlight general trends in the database: this has applications in domains such as market basket analysis.
Apriori uses a "bottom up" approach, where frequent subsets are extended one item at a time (a step known as candidate generation), and groups of candidates are tested against the data. The algorithm terminates when no further successful extensions are found.
Apriori uses breadth-first search and a Hash tree structure to count candidate item sets efficiently. It generates candidate item sets of length
sets of length k − 1. Then it prunes the candidates which have an infrequent sub pattern. According to the downward closure lemma, the candidate set contains all frequent k - length item sets. After that, it scans the transaction database to determine frequent item sets among the candidates.
The pseudo code for the algorithm is given below for a transaction database T, and a support threshold of
Usual set theoretic notation is em
that T is a multi set. C k is the candidate set for level k. At each step, the algorithm is assumed to generate the candidate sets from the large item sets of the preceding level, heeding the downward closure

lemma. c o u n t [c] accesses a field of the data structure that represents candidate set
initially assumed to be zero. Many details are omitted below, usually the most important part of the implementation is the data structure used for storing the candidate sets, and counting their frequencies.

```
Apriori(T, ε)
    L_1 ← {large 1 − itemsets}
    k ← 2
    while L_{k−1} ≠ ∅
        C_k ← {c = a ∪ {b} | a ∈ L_{k−1} ∧ b ∉ a, {s ⊆ c | |s| = k − 1} ⊆ L_{k−1}}
        for transactions t ∈ T
            D_t ← {c ∈ C_k | c ⊆ t}
            for candidates c ∈ D_t
                count[c] ← count[c] + 1
        L_k ← {c ∈ C_k | count[c] ≥ ε}
        k ← k + 1
    return ⋃_k L_k
```

Conclusion

The proposed procedure has shown that for the purpose of clustering, when we combine the expanded WRFM model into K-means algorithm, we can see a tremendous improvement in classifying accuracy in order to reach to an excellent CRM. As the distance and the integrated rate of each cluster commonly used by many researchers as a separate and independent parameters, in this study the combination of these two parameters has been considered in clustering and classification analysis. The result of statistical test for model validation has shown that the developed methodology for CRM has an acceptable result with a high level of confidence in comparing with other commonly used models by researchers. The proposed CRM methodology can be used by industries as well as service sectors in evaluating their customers loyalty in a most efficient and effective manners. The statistical interpretation of how support, confidence and lift can correlate with marketing strategies take some time and know how on the field where it's being applied.

Abstract— **The human voice is very versatile and carries a multitude of emotions. Emotion in speech provides additional insights about human actions. Through analysis of those practical features of speech, we can better understand people's intentions, whether they are unhappy customers or fans. Man is able to easily determine a speaker's emotion, but the field of emotion recognition through machine learning is an open research area. We begin to study emotion in speech by finding an emotion. In particular, we examine the classification of anger in speech samples. In our analysis of emotions, we begin by delineating the data used, and through this analysis, we investigated whether CNN is the best algorithm for selecting features that are relevant for predicting emotions. [8]. We also consider several machine learning models with which emotions are classified. A variety of machine learning techniques for the analysis of vocal patterns to determine emotions have been proposed with varying levels of success and accuracy. However, the accuracy of each technique is based on the number of machines under consideration and the machine learning tools / techniques used [1] [5]. The accuracy of emotion is high when using a large number of attributes and examples.**

Keywords—Delineating, CNN (Convolutional Neural Network)

I. INTRODUCTION

The human voice consists of sounds that are used by a person to use acoustic folds, such as to perform acoustic activities such as talking, singing, laughing, shouting, etc. Frequency of the human voice is particularly a part of the human sound generation system with vocal cords or folds being the primary source of the sounds produced. Other sound production mechanisms originating from the same general area of the body include the production of inconsistent consonants, clicks, whistles, and whispers.

Generally, the mechanism for generating human voice can be divided into three parts; Lungs, larynx folds and articulators The human voice and associated speech patterns can be characterized by several features, the primary ones being pitch, loudness or sound pressure, timbre and tone [2]. Pitch is an auditory sensation in which a listener assigns musical tones to relative positions on a musical scale based primarily on their perception about the frequency of vibration [5] [7]. Pitch can be quantified as a frequency, but is based on the subjective perception of a sound wave. Sound oscillations can be measured to obtain a frequency in hertz or cycles per second. Pitch is independent of the intensity or amplitude of the sound wave. A high-pitched sound indicates fast oscillations, whereas, a low-pitched sound corresponds to slow oscillations. The pitch of complex sounds such as speech and music notes corresponds to the repetition rate of periodic or nearly-periodic sounds, or the reciprocal of time intervals between similar repetitive events in the sound wave. Loudness is a subjective perception of sound pressure and can be defined as a characteristic of auditory sensation, in the context of which, sounds can be ordered on a scale ranging from quiet to loud [8]. Sound pressure is the local pressure deviation from ambient, average or equilibrium atmospheric pressure, which is caused by the sound wave [9]. Sound pressure level (SPL) is a logarithmic measure of the effective pressure of a sound relative to a reference value and is often measured in units of decibels (dB). The lower limit of hearing is defined as SPL of 0 dB, but the upper limit is not clearly defined. Timbre is the perceived sound quality of a musical note, sound, or tone [5]. Timbre distinguishes different types of sound production and enables listeners to distinguish different instruments in the same category. Physical characteristics of sound that determine the perception of time include spectrum and envelope. Figure 1 shows a sound wave. In simple words, timbre is that one particular sound is considered different from another sound, even if they are the same pitch and louder.

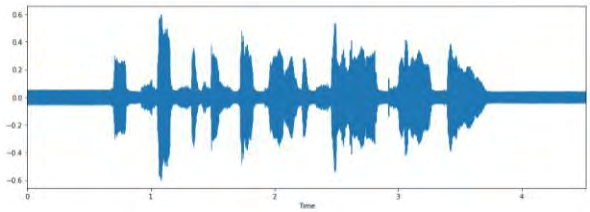

Figure 1: Waveform of sample audio file

II. PROPOSED WORK

This section describes an algorithmic approach to devoting human emotions through voice and speech-pattern analysis. To achieve this objective, three test cases were investigated, corresponding to three emotional states: normal emotional state, angry emotional state, and nervous emotional state. To carry out the analysis, four vocal parameters will be taken into consideration: pitch, SPL, timbre, and time interval between consecutive words of speech. To represent a time table quantitatively, its temporal envelope for advance and decay times will be considered. The primary function of the proposed algorithmic approach is to explore the different emotional states by analyzing deviations from the general emotional state to the above four parameters. Pitch of sound is the characteristic of sound by which an acute note can be distinguished from a grave or flat note. If a pitch is high, the sound is called sharp and if the pitch is low, the sound is flat. The pitch of sound is determined by the rate of vibration or frequency of the sound wave. Pitch is simply the rate at which vibrations are produced. It is usually expressed as the number of hertz. Sound pressure level (SPL) is a logarithmic measure of the effective pressure of a sound relative to a reference value and is often measured in units of decibels (dB). Timbre is the perceived sound quality of a musical note, sound, or tone. Timbre distinguishes different types of sound production and enables listeners to distinguish different instruments in the same category. Physical characteristics of sound that determine the perception of time include spectrum and envelope. The time interval between words is the average difference of time between two consecutive words in speech.

• Case 1: General Emotional Status This test case consists of pitch, SPL, timbre, and word-time interval data obtained from speech samples that were at the speaker's comfort and general emotional state. This test case serves as the basis for the remaining two test cases. All parameter statistics represent the average values obtained from the indicated samples. As shown in Table I, for the purpose of demonstration, data from two speech samples have been analyzed.

	Pitch (Hz)	SPL (dB)	Timbre ascend time (s)	Timbre descend time (s)	Time gaps between words (s)
Speech Sample 1	1248 Hz	Gain -50 dB	0.12 s	0.11 s	0.12 s
Speech Sample 2	1355 Hz	Gain -48 dB	0.06 s	0.05 s	0.12 s

T able 1: Average values of vocal statistics obtained from recorded speech samples for a normal emotional state

Case 2: Angry Emotional State This test case contains pitch, SPL, timbre, and word-timing gap statistics derived from speech samples, which are characterized by increased pitch, usually in an emotional state stimulated by the speaker. . All parameter statistics represent mean values obtained from speech samples, as shown in Table II. The same speech samples that were previously used in Case 1 have been used in Case 2, but with a distinctly distinct form of an agitated or angry emotional state.

	Pitch (Hz)	SPL (dB)	Timbre ascend time (s)	Timbre descend time (s)	Time gaps between words (s)
Speech Sample 1	1541 Hz	Gain – 30 dB	0.13 s	0.10 s	0.09 s
Speech Sample 2	1652 Hz	Gain – 29 dB	0.06 s	0.04 s	0.10 s

Table 2: Average values of vocal statistics obtained from recorded speech samples for an angry emotional state

Case 3: stereotypical emotional state This test case consists of pitch, SPL, timbre, and word-time interval data obtained from speech samples that were in the speaker's nervous or overwhelmed emotional state. Speech samples that were previously used in Case 1 have been used in Case 3, but with a different intonation typical of a panicked emotional state, as shown in Table III.

	Pitch (Hz)	SPL (dB)	Timbre ascend time (s)	Timbre descend time (s)	Time gaps between words (s)
Speech Sample 1	1443 Hz	Gain – 46 dB	0.13 s	0.09 s	0.13 s
Speech Sample 2	1560 Hz	Gain – 44 dB	0.07 s	0.04 s	0.14 s

Table 3: Average values of vocal statistics obtained from recorded speech samples for a panicked emotional state

From the three table it can be seen that the average pitch for a speech sample of normal emotional state is 1300Hz as compared to 1500Hz for panicked emotional state and 1600Hz for angry emotional state. Hence pitch increases in going from normal to panicked to angry emotional state.

Similarly, for sound pressure level (SPL), angry emotional state has relatively lower SPL followed by panicked emotional state, with the normal emotional state having highest SPL. The time gap between words is the least in angry emotional state as a person in angry state speaks faster. Normal emotional state and panicked emotional state, on the other hand, have comparable time gaps between words

REQUIREMENTS
Software Requirements-

- Front End-Pyqt5
- Back End-ML Model using Python on Jupyter
- Operating System

Hardware Requirements-

- Min Memory: 4GB
- Storage size: 10GB
- Dedicated Graphics Memory
- Processor: Intel i3 or higher Training audio

III. ARCHITECTURE

Dataset:

This dataset consists of 1500 audio file inputs from 24 different actors. 12 men and 12 women where these artists record short audio in 5 different emotions, namely 1 = neutral, 2 = calm, 3 = happy, 4 = fearful, 5 = angry. Each audio file is named in such a way that the 7th character corresponds to the different emotions they represent.

Libraries to be used:

LibROSA:

Librosa is a python package for music and audio analysis. It provides the necessary building blocks to create music information retrieval systems. Librosa's load function will read in the path of an audio file and return a tuple with two items. The first item is an 'audio time series' (type: array) for the audio track. The second item in the tuple is the sample rate that was used to process the audio.

Keras:

Keras is a high-level neural network API, written in Python and capable of running on top of TensorFlow, CNTK, or Theano. This allows for easier and faster prototyping. It supports the combination of both a compatible network and a recreative network as well as both.

TensorFlow:

TensorFlow is a Python library for fast numerical computing created and released by Google. It is a foundation library that can be used directly to create a deep learning model, or by using a wrapper library that simplifies the process built on top of TensorFlow.

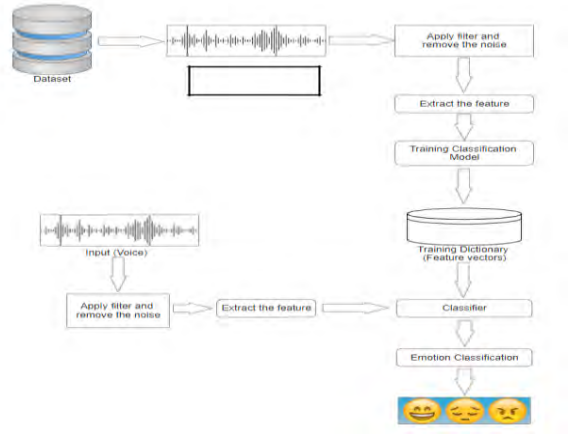

Figure 2: Architecture of model

IV. TECHNOLOGY USED

Front end: The following techniques will be used to design the structure of the project:

1) PyQt5:
PyQt5 is a comprehensive set of Python bindings for Qt v5. It is implemented as more than 35 extension modules and enables Python to be used as an alternative application development language for C ++ on all supported platforms including iOS and Android.

PyQt5 can also be embedded in C ++ based applications to allow users of those applications to configure or enhance the functionality of those applications.

Back End: The back end technique used in the project:
1) Python:

Python is an interpretive, high-level, general-purpose programming language. Created by Guido van Rosum and first released in 1991, Python's design philosophy emphasizes code readability with notable use of critical WhatsApp. Its language-building and object-oriented approach aims to help programmers write clear, logical code for small and large scale projects. Python is dynamically typed and garbage is collected. It supports several programming paradigms, including procedural, object-oriented and functional programming.
One of the aspects that makes Python in general such a popular option is its abundance of libraries and frameworks that facilitate coding and save development time. Machine learning and deep learning are exceptionally well crafted.

NumPy used for scientific computation, SciPy for advanced computation, and scikit-learn for data mining and data analysis are among the most popular libraries with heavy-hitting frameworks such as TensorFlow, CNTK, and Apache Spark Work. In terms of machine learning and deep learning, these libraries and frameworks are in essence Python-first, while some, such as PyTorch, are written specifically for Python.

2) Jupyter:

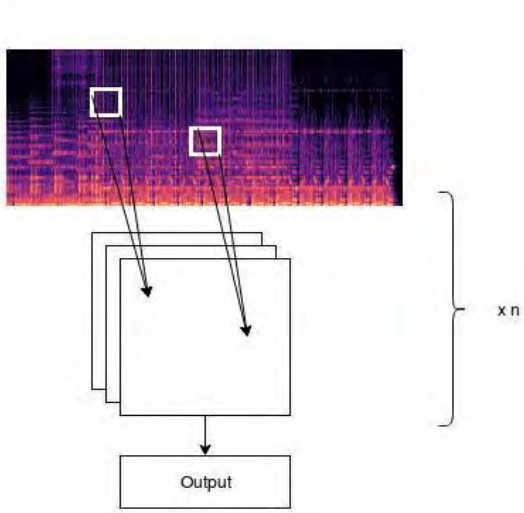
Jupiter Notebook (formerly iPython Notebook) is a web-based interactive computational environment for creating Jupiter Notebook documents. The term "notebook" can generally refer to several different entities, mainly Jupiter Web Application, Jupiter Python Web Server, or Jupiter Document Format depending on the context. A macro notebook document is a JSON document that has a version schema, and contains an ordered list of input / output cells that can contain code, text (using markdown), mathematics, plots, and rich media, typically ending with ".ipynb". Detailed.

Jupiter Notebook can connect to multiple kernels to allow programming in multiple languages. By default Jupiter notebook ships with the iPython kernel. As of the 2.3 release (October 2014), there are currently 49 Jupiter-compatible kernels for several programming languages, including Python, R, Julia, and Haskell.

The notebook interface was added to IPython in the 0.12 release (December 2011), renamed Jupyter Notebook in 2015 (IPython 4.0 - Jupyter 1.0).

V. METHODOLGY

The log-mail spectrogram is an advanced method for classifying audio using a mail-spectrogram instead of a raw audio wave. The mel spectrogram represents the short-term power spectrum of a sound, which is based on the linear cosine conversion of the log-in spectrometer spectrum. Frequency of a nonlinear mel scale. The mel spectrogram transforms the input raw sequence into a 2D feature map where one dimension represents time and the other represents frequency and the value represents amplitude. At a high level, each audio file from the repository is processed and



used to create a feature vector with a label corresponding to emotion.

Figure 3: Log-Mel Spectrogram

The next step involves removing features from audio files that will help our model learn between these audio files. For feature extraction we use the Librosa library in Python which is one of the libraries used for audio analysis. Here are some things to note. When removing features, all audio files are timed for 3 seconds to achieve the same features. The sampling rate of each file is doubled, keeping the sampling frequency constant to obtain more features, which will help classify the audio file when the size of the dataset is smaller. After extracting the features, we apply the feature selection algorithm to determine the most relevant results and apply different models to the features with the highest scores. The most straightforward technique involves determining the average energy of the signal. This metric indicates the "volume" of the speaker, along with the total energy

in the signal. Duration also provides insight into emotion, as do statistics such as maximum, minimum, range, mean, and standard deviation of both the signal and the spectrum. These may indicate fluctuations in volume or pitch that may be useful in determining emotions. We also process signals in the frequency domain via the (fast) Fourier transform. We use window samples to obtain an accurate representation of the frequency content of the signal at different points in time. Taking the square value of the signal in each window sample, we can obtain the power spectrum. We use the values of the power spectrum as features, but we also find frequencies that have the greatest power. We obtain the three largest frequency peaks for each window and combine them into a feature vector. In addition, we detect maximum and minimum frequencies with sufficient power for each time frame and use these values to determine the frequency range for each frame. The auditory spectrum can be obtained in a uniformly spaced interval by mapping the power spectrum to the auditory frequency axis by combining forest transformer bins.

VI. RESULT AND DISCUSSION

From what has been reviewed above, it can be said that the algorithm performs with an accuracy of 72%. The 5 emotions, 10 possibilities considering both male and female voices, can be classified successfully. The classification of male voices from female voices has been achieved with 100% accuracy. Above planned comparisons of sample feature table reveal that different features of an audio file have different ranges, responsible for varying emotions. For two speech samples of different emotions some attributes may be similar but they will never be identical. Results (Average Precision):

1 D: 0.754
2D: 0.849
Average predictions of both: 0.883

The 2D mail model outperforms the 1D raw wave model but the average of the two different models is quite different. This is probably because each model learns different representations and makes different types of mistakes and on average each model fixes the errors of the other in some way.

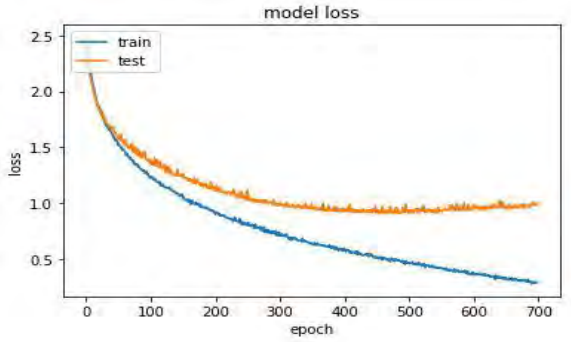


Figure 4: Graph depicting model loss

As seen in the figure above, the loss in testing set for every successive epoch decreases at a lesser rate than the training dataset resulting in an overall lesser loss in the testing phase.

VII. CONCLUSION

Model construction was a challenging task as it involved a lot of trial and error methods, tuning and so on. The model is very well trained to distinguish between male and female voices and is isolated with 100% accuracy. The model was designed to detect emotions with over 70% accuracy. Accuracy can be increased by including more audio files for training. Reducing human emotion through voice and speech analysis is a practical feasibility and may possibly be beneficial for improving human conversational and persuasion skills. This paper presents an algorithmic approach to the detection and analysis of human emotions based on voice and speech processing. Three test cases have been investigated, which relate to three emotional states: general emotional state, angry emotional state, and nervous emotional state. Each case displays vocal features associated with the trait that may help differentiate the associated emotional state. As the scope of future work, more complex emotional states can be analyzed such as cheerful, sad, brooding, surprise, etc. When conducting the proposed study, the speech data were sampled at a rate of ten sample points per second. To improve the accuracy of the mean attribute values, a greater number of sample points can be considered. Furthermore, in the proposed approach, only four characteristics were analyzed to detect different emotional conditions. To improve recognition accuracy, other secondary vocal features may also be evaluated.

Design and Development of Agricultural Drone for Plant Health Analysis

Mrs. Vaishali Nirgude, Yogesh Bharambe, Divesh Singh, Vedang Binsale
Computer Department
Thakur College of Engineering and Technology
Mumbai, India
vaishali.nirgude@thakureducation.org, yogesh01bharambe@gmail.com, diveshsingh2210@gmail.com, vedang.binsale@gmail.com

Abstract— **Agricultural drones let farmers see their fields from the sky. This overview of the field can reveal many issues such as irrigation problems, soil variation, and pest and fungal infections. The combination of these factors allows the farmer to distinguish between healthy and unhealthy plants, a difference not always clearly visible to the naked eye. Thus, these views can aid in assessing crop growth and production. The project is to develop an autonomous flying quadcopter, fitted with a GPS tracking system and programmed to be able to autonomously fly from one location to a different location using GPS coordinates. Its goal is to act as a proof-of-concept for a small scale autonomous geographical area mapping and find plant health using VARI algorithm.**

Keywords— VARI (Visible Atmospherically Resistant Index), NDVI (Normalized Difference Vegetation Index), UAV (Unmanned Ariel Vehicles), GIS (Geographical Information System), GPS Module and Telemetry

I. INTRODUCTION

Remote sensing supported drones (UAV- Unmanned Aerial Vehicle) is a rapidly developing field of technology, which allows new possibilities for monitoring of the environment. Due to technological innovations lightweight multi- and hyper spectral sensors have become available which may be carried by small drones. The applications for UAV can comprise precision agriculture, vegetation monitoring and forest monitoring [1]. Drone based mapping enables to map agricultural lands with a very high spatial resolution, which enables to observe even small anomalies in vegetation [2]. Such anomalies in vegetation/ plants could be caused by, for example, drought induced uneven germination and growth, seedling loss caused by flooding and anoxia, disease outbreak, pest invasion, unbalanced nutrient availability and uptake, and overwintering damages [2] [3] [4].

II. LITERATURE SURVEY

Nandyal Suvarna - "Agridrone: Automation of Agriculture using IoT". IJISRT Journal (2019). This paper discusses a system which consists of a flying drone fitted with a camera eye to record images of crops in a scheduled time. The work involves developing an intelligent system by building a knowledge-base to guide agriculturists. The knowledge-base includes various cases of various crops and decisions based on crop image analysis. From captured images, the parameters that are planned for analysis by image processing are The image of the plant will be acquired using the
external camera eye fitted on drone which is interfaced with Raspberry Pi along with other different sensors modules through IOT. This image is then diagnosed to measure moisture content in soil and amount of green in leaves.

Ahmad - "Aerial mapping using high resolution digital camera and unmanned aerial vehicle for Geographical Information System." 2010 6th International Colloquium on Signal Processing & its Applications, IEEE (2010). This study concentrates on the use of high-resolution digital camera and a very light platform known as unmanned aerial vehicle (UAV) as data acquisition system in capturing digital aerial photographs. The acquired digital aerial photographs were processed using image processing software to produce digital map and digital orthophoto. The results showed that an accuracy of sub-meter can be obtained using the employed method. In Geographical Information System (GIS), it is quite common that topographic map and orthophoto are used as a base map. Hence, the findings from this study could also be used as an input for GIS. Reinecke - "The influence of drone monitoring on crop health and harvest size." 2017 1st International Conference on Next Generation Computing Applications (NextComp), IEEE (2017). This paper looks at the benefits of drones in agriculture, and their limitations, illustrating from examples how drones operate on farms. Different features of drones are discussed, specifically how they assist farmers in maximizing their harvest by detecting problems early

and managing the crops by using specific cameras to detect pests and water shortages.

Santos - "Indoor waypoint UAV navigation using a RGB-D system." 2015 Workshop on Research, Education and Development of Unmanned Aerial Systems (RED-UAS), IEEE (2015). This paper presents a method for estimating the orientation and position of an unmanned aerial vehicle (UAV), through processing information provided by a RGB- D sensor and an inertial measurement unit (IMU) in order to inspect predefined points in an indoor environment.

Roberts - "GPS Guided Autonomous Drone.", University of Evansville (2016). The project is to design an autonomous flying drone, specifically a quadcopter. The drone is fittedwith a GPS tracking system and programmed to be able to autonomously fly from one location to another using GPS coordinates. The goal of the project is to act as a proof of concept for small scale autonomous aerial delivery similar to that nearing deployment by Amazon.

F.G. Costa and et.al - The use of unmanned aerial vehicles and wireless sensor network in agriculture applications. IEEE Int. Geoscience and Remote Sensing Symposium, 2012. Unmanned aerial vehicles (UAVs) represent technological developments used for precision agriculture. They provide high-resolution images taken from crops and when specific indices are applied, useful outputs for farm management decision-making are produced. The current paper provides a literature review on the use of UAVs in agriculture and specific applications are presented

III. EASE OF USE

A. Monitoring Crop Production

Drones have already proven to be effective at recording the canopy reflectance over vineyards. To measure the growth of crops over a season, aerial images can be taken at the start of the season, at predetermined intervals during the season and just prior to harvesting to illustrate the growth across the field, as well as highlighting any rows that show signs of stinted growth due to poor irrigation or low initial nitrogen content [3]. Birds may fear a scarecrow for a time, but they will soon realize it is not alive and return in numbers –meaning the only solution is a lethal one. Larger animals like baboons and deer can only be kept away with tall often electrified fences with empty cans to make a noise. In the midst of all these preventative measures, farmers may forget about a section of an orchard or field – the consequences of which will only be apparent when it is too late to remedy. Crop diseases can be devastating and classified as fungal, bacterial or viral. Drones equipped with Infrared cameras can see inside plants, giving a clear image of the condition thereof. If a farmer can detect an infection before it spreads, preventative measures can be taken

Like removing the plant -before the infection spreads to neighboring plants. Drones can be equipped with a multispectral camera that can detect the water content underground, which can allow a farmer to determine if a crop row is parched or over hydrated. Farmers can adjust their irrigation until even water table is created, eliminating water as a source of crop distress. If multispectral camera is not available, the drone can still take overhead pictures of the fields and highlight areas where plants seem discolored or smaller than the rest of the field. This technique can also be used to detect underground leaks in existing irrigation systems [2] [4].

B. CRIME AND DAMAGE REPORTS

The drone can aid the authorities in identifying the vehicle employed by the criminals, speeding up the investigation. Also, some farmers have employed drones as guards to patrol entrances and along fences.

C. Forestry

Open Forest can use drone-based forest and landscape mapping to provide a new perspective for valuation, monitoring and research. Hundreds of pictures taken by drones are mapped together to large and high resolution orthomaps. These orthomaps can then be used for analysis, planning and management via the GIS systems [2]. Nova drone uses drone technology to improve forest management and operational planning, including the monitoring of illegal activities.

IV. PROPOSED WORK

For this Project, we have built a Quadcopter Drone for agriculture surveillance and analysis. The additional functionality/component is "*ublox neo 7m gps with compass*"

– it is a gps component with inbuilt compass in it; it will be used to guide the drone without any manual guidance from any personnel from organization [4] [5].

With the help of Telemetry components, the directions to the drone can be given from any android phones through an application. Another component is "*Xmate 16 Mega pixel Waterproof Camera*" – Used for recording the whole agricultural land and take HD Images for further analysis.

After Flight and recording of data of crop, it will be passed through a set of code. We will use VARI (Vegetation Atmospheric Resistant Index) Algorithm for Analysis of Crop health.

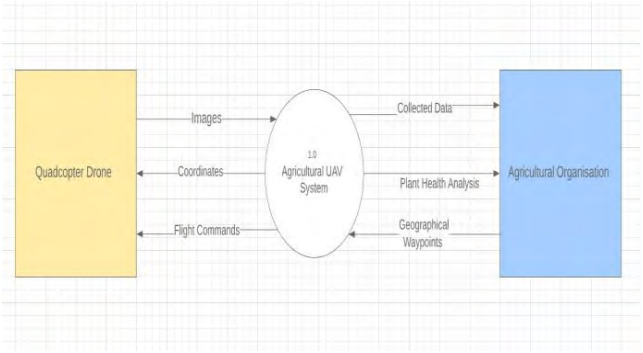

Figure 1: Structural model - DFD Level 0

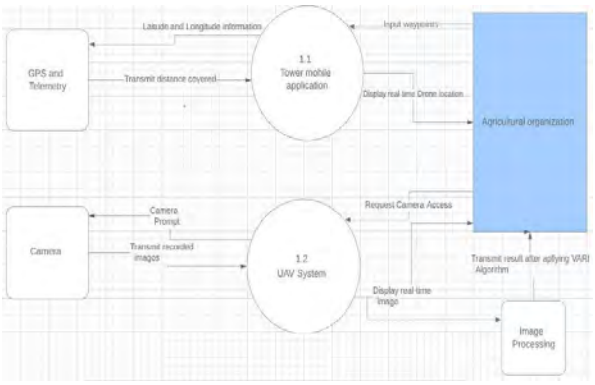

Figure 2: Structural model - DFD Level 1

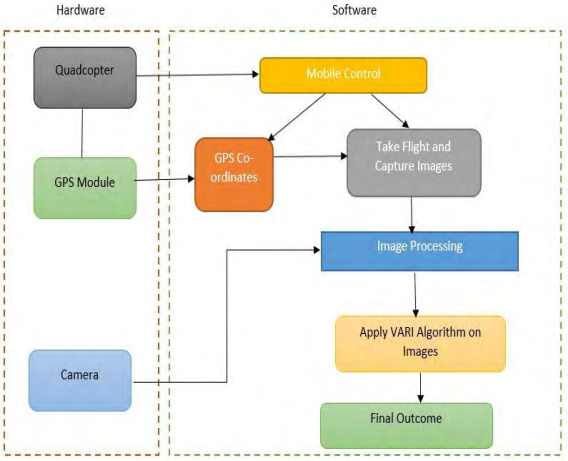

Figure 3: Flow Diagram

A. VARI Algorithm

VARI Index can be given as:

$$VARI = \frac{Green - Red}{Green + Red - Blue}$$

VARI algorithm is a vegetation index used to record plants health. For VARI algorithm, RGB (standard) cameras, which capture Red, Green, and Blue light, is used for imaging purposes. The Visible Atmospherically Resistant Index (VARI) was designed to work with RGB cameras. VARI is a measure of "how green" a picture is. VARI is meaningful when working with non-NDVI imagery, hence it is not intended as a substitute for NDVI algorithm. RGB images with the VARI algorithm applied make it possible to detect areas of crop stress in a vegetation field [5] [7].We can measure plant health using drone imagery because healthy plants

reflect light differently than unhealthy plants. Plants that are healthier tend to reflect more green light than red light, which is why they appear green. Plants also reflect near-infrared light that's invisible to the naked eye but are often detected with near-infrared sensors.

Plant health algorithms like VARI and NDVI use the data generated by the proportions of sunlight captured across different bands (red, green, blue and sometimes near-infrared) to compute numerical values (between 0 to 1) for every pixel of a given drone image/ map. Maps with plant health algorithms are then assigned color based on those numerical values, which makes it easy to spot unavoidable plant diseases [6].

B. GPS MODULE AND TELEMETRY

A GPS module can provide an estimation of your drone's altitude. However, GPS modules are rather inaccurate and can only offer you a position to within 5m. However, by combining measurements for other sensors, the flight controller can get a better picture of what the drone is doing. The main feature employed by the GPS module is that you simply can autonomously fly your drone to way-points, so your drone can potentially fly on its own from takeoff to landing.

The telemetry modules are the actual radio devices, which aids in waypoint navigation.

C. APPLICATIONS

- Land surveying
- Cadastral maps
- Topographical surveys

Precise measurements

- Land management and development
- Monitor plant health
- Perform plant count
- Optimize plant ROI

D. ADVANTAGES

Easy to use

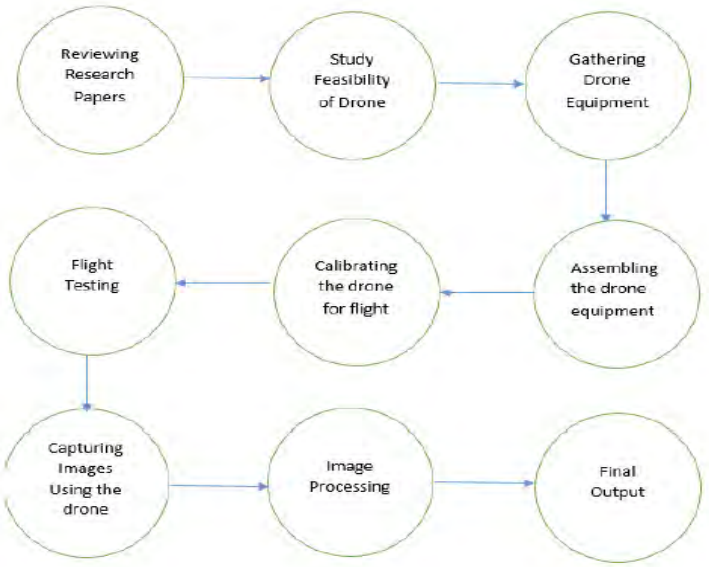
Cost effective

- Automated; requires less human interaction due to GPS and Telemetry
- Can be controlled through any Android mobile
- Recorded images pass through VARI algorithm, yielding plant's health

E. METHODOLOGY

For this project, Scrum methodology is used which is an agile software development methodology. By adopting this methodology, every team member can know the progress of the project. Following this model, our method can be described by the following flow graph:

Figure 4: Methodology



F. Drone Connections

Figure 5: Flight Controller Connections

The above Figure shows the connection of all components to APM 2.8 processor for automated operation.

V. RESULTS AND DISCUSSION

An autonomous drone such as the one constructed in this project (a Quadcopter) can have many uses in practical applications. Among other things, a GPS guided drone could be used for military and defence purposes.

Hence, there is no doubt that the combination of the UAV and the digital camera could be used and explored further for GIS application, mapping and other applications. However, user must be aware that the area covered by the digital camera is very small.

The major advantage of Drone is the auto landing capability which reduces the risk factors designed in a simple and cost-effective manner. It also helps in analysing plant quality and health by using VARI algorithm. Regarding the functioning of the drone, we have used Mission Planner application to program the drone to take flight. For formation of orthomosaic maps and calculating VARI indexes, we would be using WebODM application.

The top view of final constructed quadcopter is:

Figure 6: Top View of Quadcopter

To determine plant health, our quadcopter captures images of the fields/ area and processes them via VARI algorithm. The program outputs a value between 0 to 1; 0

Indicating bad plant health and 1 indicating good plant health.

The sample output (health) for good and bad crops, processed by VARI algorithm are:

Figure 7: VARI Index for bad crops

Figure 8: VARI Index for good crops/ plants

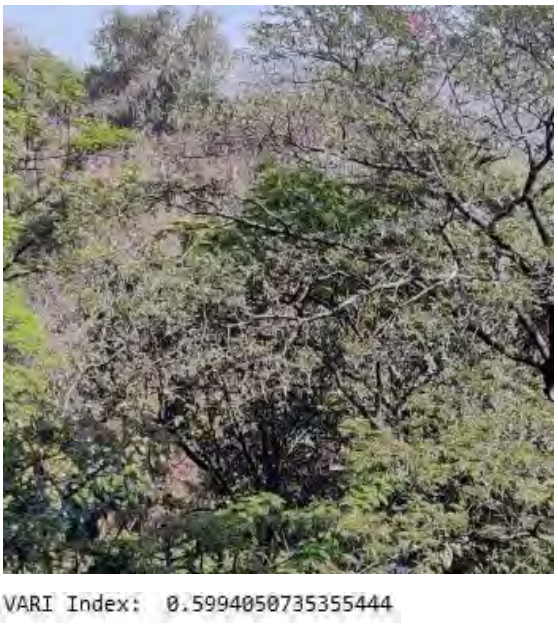


Figure 8: VARI Index for good crops/ plants

ACKNOWLEDGMENT

We wish to express sincere thanks to our guide Mrs. Vaishali Nirgude and our Computer department for providing research opportunity, so that we can research all this about Agricultural drone. We also extend our heartfelt thanks to our colleagues, family members and well- wishers.

Abstract— **Health care practices involve collecting all kinds of patient data which would help the doctor correctly diagnose the condition the subject is likely suffering from. This data could be everything from the simple symptoms observed by the subject, initial diagnosis by a physician or a detailed test result from a lab. Thus far this data is only utilized for subjective analysis by a doctor who then ascertains the disease in play using his/her personal medical expertise. We posit that there is definite potential for application of data mining routines on this rich reserve of patient data. Employing apposite data mining techniques, useful patterns and conclusions could be drawn from the raw data at our disposal. These findings could in turn be utilized in a number of productive ways like to carry out automated diagnosis, equip doctors with a better understanding of the causes and factors in play behind a particular disease. Automated diagnosis in particular could prove very useful for the determination of non-critical diseases or in cases where a doctor may not be available to carry out diagnosis such as in case of being in a remote location.. We also aim to incorporate it in an application which will provide diagnosis, storing of patient information and provide visualization of that data.**

I. INTRODUCTION

Health care practices involve collecting all kinds of patient data which would help the doctor correctly diagnose the condition the subject is likely suffering from. This data could be everything from the simple symptoms observed by the subject, initial diagnosis by a physician or a detailed test result from a lab. Thus far this data is only utilized for subjective analysis by a doctor who then ascertains the disease in play using his/her personal medical expertise. We posit that there is definite potential for application of data mining routines on this rich reserve of patient data. Type 1 diabetes can occur in childhood or adolescence age. Type 2 diabetes usually affects the adults who are obese. In this type, the body resists observing insulin or fails to produce insulin. Type 2 generally occurs in the middle or aged groups. Moreover, there are other causes for diabetes such as bacterial or viral infection, toxic or chemical contents in food, autoimmune reaction, obesity, bad diet, change of lifestyles, eating habit, environment pollution, etc. Diabetes leads to various diseases such as cardiovascular complications, renal issues, retinopathy, foot ulcers, etc.

A. Problem Definition

Going to a doctor isn't always possible, there are plenty of reasons for this, the area could be facing with an epidemic causing the doctors to be occupied with the immediate case, the person could fall ill in the middle of the night, the problem could be severe and might require some information about the problem itself and how to make it bearable until the patient is taken to a doctor. It becomes necessary to provide an automated diagnosis tool to the people in order to address these issues.

II. LITERATURE REVIEW

Following is some of the search which has been reviewed for the proposed system: Shadegg Behave proposed, this system that comes under the category of data mining. The system performs data mining on patterns and correlation to predict the economic events. This system utilizes K-Nearest Neighbor for estimating values that will maintain a strategic distance from financial distress and bankruptcy [8]. In the current review k- Nearest Neighbor characterization technique, have been examined for economic estimating. Lately, after the situation of worldwide financial emergency, the quantity of bankrupt organizations has risen. Since organizations' financial distress is the principal phase of bankruptcy,[3] utilizing financial proportions for anticipating financial distress have pulled in a lot of consideration of the scholastics and also economic and financial institutions.[6]

Mohamed EL Kourdi et al. have proposed this system in which Naive Bayes (NB) which is a factual machine learning algorithm is utilized to order Arabic web documents. This system utilizes K-Nearest Neighbor for estimating values that will maintain a strategic distance from financial distress and bankruptcy. In the current review k-Nearest Neighbor characterization technique, have been examined for economic estimating. Lately, after the situation of worldwide [7] financial emergency, the quantity of bankrupt organizations has risen. Since organizations' financial distress is the principal phase of bankruptcy, utilizing financial proportions for anticipating financial distress have pulled in a lot of consideration of the scholastics and economic and financial institutions.[3] Kevin Beyer et al. have proposed this system that tries to explain what happens.

III. PROPOSED ARCHITECE

Supervised Learning algorithms learns the pattern fromPre-existing data and try to predict new result

based on the previous learning. ML algorithms are used to identify existing data like probability-based, function-based, rule-based, tree based, instance-based, etc. According to our model patients are required to provide their medical data for successful diagnosis of their diabetes test. The admin of the system will
Then choose one of the two appropriate algorithms available. Thus, after using the system, the prediction will be done whether the patient is diagnosed with diabetes or not. If the patient is found diabetic expert recommendations would be provided to the patient so that he/she can recover from diabetes.

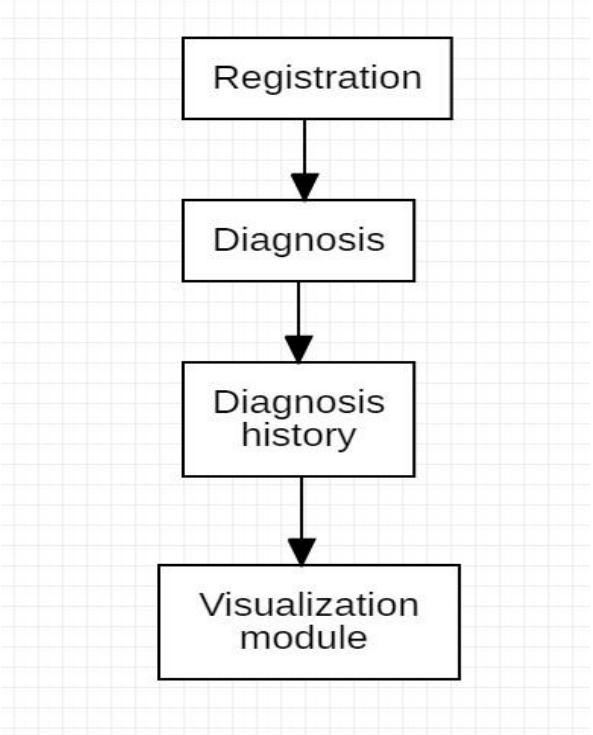

Fig. 1. Flowchart of Diabetes prediction Model

IV. METHODOLOGIES

A. K- Nearest Neighbors (KNN)

K-Nearest Neighbors is a supervised learning algorithm,
K- means a number of a vector. The working methodology of KNN is pretty simple, it's predict based on the value of Kparameter. Graphical representation of K Number Nearest Neighbors are depicted in following Fig. 3.

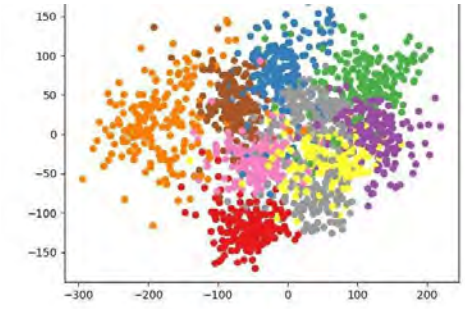

Fig. 3. Graphical representation of KNN working Procedure

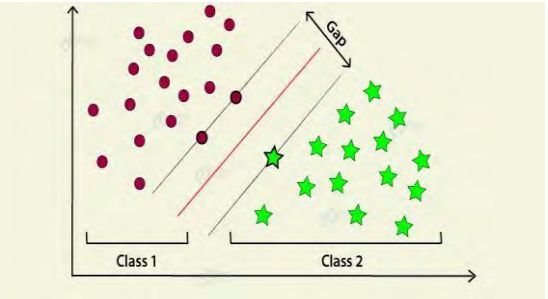
B. Support Vector Machine (SVM)

Support vector machine is a supervised learning algorithm mainly used for classification problem. Over fitting derives an ML model to misclassify the data from a given dataset. In that case SVM can prevent over fitting nature from samples data and produce better accuracy [8][9]. SVM possess a linear hyper plane with a margin which divides the dataset



into positive and negative samples [8][9].

Fig. 2. Graphical representation of SVM working procedure

C. Artificial Neural Network (ANN)

Artificial Neural Network (ANN) is considered as the method to represent human neuron in a Mathematical way by reflecting its learning and generalization abilities. ANN model can scale up a highly nonlinear system in which the
relationship between the variables is unknown or very complex [11].

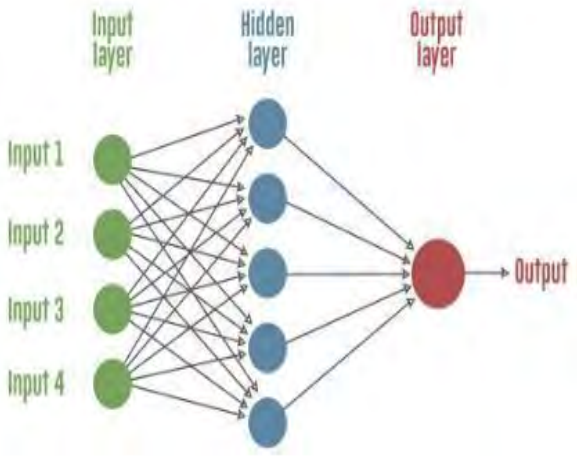


Fig. 4. General Structure of Artificial Neural Network with two hidden layer

A neural network is consist of various neurons followed by some layers. Nodes represent the structure of human neuron as like dendrite and axon where linked between nodes represents as axon with the weighted connection. The total structure of the neural network is shaped by input layer, one or more hidden layers, and the output layer where *ith* neuron represents a connection with *jth* neuron of total structure and
Wij represents as the strength of the link between neurons. The nodes of the structure of an ANN take

inputs (features) then send them to next hidden layer through some sort of weighted
link where *ith* nodes send data to *jth* nodes for processing and calculating the weighting sum and totaling a bias term (θ_j) V. RESULTS

In this section we will discuss regarding our results which we have achieved after experimental design. Following TABLE I. represents an insight description of our Pima Indian Dataset. This dataset is mainly based on the females those were living at Pima Indian heritage. Following 8 features ***(a-h)*** of Pima Indian dataset helps us to predict the diabetes of any Individuals with the help of our proposed methodologies.

a) Numbers of time Pregnant
b) Glucose Test
c) Blood Pressure
d) Triceps skinfold thickness
e) 2-Hour Serum Insulin
f) Body Mass Index
g) Diabetes Pedigree function
h) Age

Class	Attribute Number
Pregnancy Count	1
Glucose concentration in plasma	2
Blood pressure (diastolic, mm Hg)	3
Thickness of triceps skin fold (mm)	4
2-Hour serum insulin (μ U/ml)	5
Body mass index	6
Pedigree function of diabetes	7
Years of age	8

Following TABLE II depicts the average accuracy rate varies with training dataset size. We have experimented with different size of training data for SVM, KNN, GNB and
ANN. Without Min Max Scaling (MMS) it shows an average accuracy of 76.25% with Gaussian Naïve Bayes Algorithm.

Fig. 5. Implementation of different algorithms on the Pima Indian Diabetes dataset.

Here we have preprocessed diabetes dataset and applied different machine leaning algorithms .Then we found that KNN gives highest accuracy with 78.56% .This implementation is done in Anaconda.

Fig. 6. Confusion Matrix shows the result.

Web Page Implementation

Fig. 7. Analysis Form where user will get prediction

This is the Analysis form where patient will enter data and it will predict the disease according to it. Then after this prediction, diagnosis form will open in which recommendations for patient will be shown.

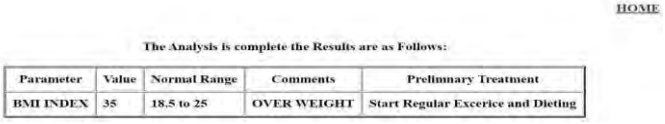

Fig. 8. Recommendation form where diagnosis will be obtained.

V. CONCLUSION

In this paper, we proposed a web based application for the successful prediction of Diabetes Diseases. From different machine learning algorithms Artificial Neural Network
(ANN) provide us highest accuracy with Min Max Scaling Method on Indian Pima Dataset. As we have proposed and developed an approach for diabetes disease prediction using machine learning algorithm, it has significant potential in the field of medical science for the detection of various medical
Data accurately. In near future our focus is to use a deep learning model and prepare a Location based Dataset from medical data for the successful prediction of diabetes disease.

Abstract—**Clusteringis oneof themostcommonexploratory dataanalysistechniqueusedtogetan intuitionaboutthe structureofthedata.Wetryto findhomogeneoussubgroups withinthedatasuchthatdatapointsineachcluster areas similaras possible.Clustering the databeforepredictionwould giveusaclearideaofhowto go aboutthedata.Predictionafter implementingthistechniquewouldgive reducederrors.Asa clustercontainsmorehomogenousdata,usingapredictoron thatclusterwillgiveappropriateresult. Predictionbasedon clusteringdependsontheaccuracyofclustering.Soto notgive intodrawbacksoftraditionalk-meansalgorithminclustering thedata,weusea2layeredk-meansalgorithmto improvethe formationofclusters. 2 layeredk-meansdealswiththeoutliers andnoisydataby subclusteringtheclusterandthusreducing errors intheclusters. In this paper, we areapplying the 2 layered k-meansalgorithminimprovingtheaccuracy ofthe clusters which inturn will helpinimproving theprediction accuracy.Thispapertakesyouthroughthestepsof2layeredk-meansalgorithmandclusteringthedata,and benefitsof clusteringbeforeprediction.Our experimentalresults demonstratethatour schemecan improvetheaccuracyofthe prediction.**

Keywords—clustering,sub-clustering,prediction, k-means, accuracy.

I. INTRODUCTION

Clustering isconsideredanunsupervised learning methodsincewedon'thave thegroundtruthtocomparethe output of the clustering algorithm to the true labels to evaluateitsperformance.*K*-meansalgorithmis asimpleand easy clustering methodwhichcanefficientlyclassifyalarge numberofcontinuousnumericaldataofhigh-dimensions. K-meansalgorithm isaniterativealgorithmthattriesto partition the dataset into*K* pre-defined distinct non-overlapping subgroupswhereeachdatapoint belongstoonly onegroup.Ittriestomake theinter-clusterdatapointsas similar as possible while also keepingtheclustersas differentaspossible.Itassignsdatapoints toaclustersuch thatthesumofthesquareddistancebetweenthe datapoints and thecluster'scentroidisattheminimum.The less variationwehavewithinclusters,themorehomogeneousthe datapoints arewithinthesamecluster.

However,itisvulnerabletooutliersandnoisydata,andit spends muchexecutivetimeinclassifyingdatatoo.Noisy data,outliers,andthedatawithquitedifferentvaluesinone clustermay reducetheaccuracyrateofdatamatching obtained by a pattern matching system since the cluster center cannot precisely describe the data in the cluster. Hence,thisstudyprovidesa2layer*K*-means algorithmto solveaboveproblems.In this algorithm,eachclusteris subdividedinto sub-clustersand thencombineswiththe traditionalk-meansalgorithmfordataclustering.Thegoal forundergoingaclusteranalysisisthat

1. Getameaningfulintuitionofthestructureofthe datawe'redealing with.
2. Cluster-then-predictwheredifferentmodelswillbe builtfordifferentsubgroups ifwebelievethere isa widevariationinthebehaviors ofdifferent subgroups.

The pre-processingtaskofusingclusteringtogainmore informationaboutthe dataimprovesthe predictionaccuracy. After clusteringour data, we train thepredictor on each clusterseparately ratherthantrainingthepredictoronthe entiredataset.

II. LITERATURESURVEY

After monitoring our dataset wefound that clustering before prediction would give us more optimized results. Herethe predictionisdependentonclusteringofourdata. Duetothedrawbacksofourtraditionalk-meansalgorithm inclusteringdata,wesoughtto modify howthedatapoints are clustered.Hencethe sub-clustering techniquewas proposed.Aftermodifyingourtraditionalk-meanswe are applyingthatmodifiedk-means algorithmto improvethe prediction of sales of diamonds. Modified k-means algorithmisusedinclusteringthe datainsimilarcategories. Clustering the data before predicting improves the predictionaccuracy.Hencewefocus,moreonthe clustering techniquesas itiscrucialinimprovingprediction.Oncethe clustersareformedwe applyapredictoralgorithmtopredict thesalesofdiamonds

III. SUB-CLUSTERING

K-meansalgorithminitializescentroidsby firstshufflingthe datasetandthenrandomlyselecting kdatapointsforthe centroids. However oneofitsdrawbacksis thatinitialcentroidpointsareselectedrandomlybecauseof whichalgorithmhas tore-iteratenumberof times,andalso accuracy ofthek-meansalgorithm dependsmuchonthechosencentralvalues.Hence,wechoose the initialcentroid points.A mostdiscrepantclustercentermethodisusedto selecttheinitialclustercenter.First,thedatais normalizedThe normalizationisusedtogetbetterresultsintheformof findingdistanceto haveexactcentroidand to removenoise datawhichisnot needed.

For taking two discrepant data points as initial cluster centers, we calculate the Euclidean distance of each data point from the origin. The data point with least distance from the origin is taken as C1 and the data point with largest distance from the origin is taken as C2. After that, it computes the data: C3 which is farthest from C1 and C2, C4 which is farthest from C1, C2 and C3, Ck which is farthest from C1, C2, …, and Ck-1, where C1, C2, …, and Ck are in S and are considered to be the initial cluster centers of the K clusters

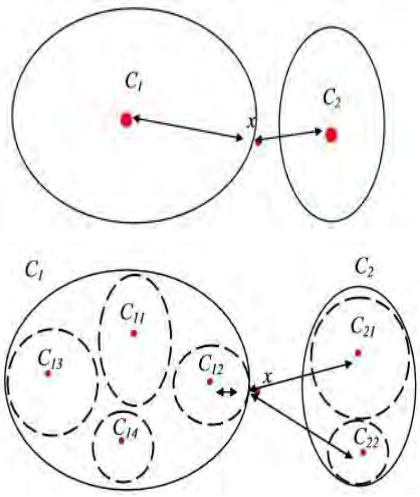

Figure1:Thereare2 clustersC1andC2

Thefigure aboveshowsthatbyusingtraditionalk-means algorithm,datapointxwillbelongtoclusterC2 asthe distancebetween xandcluster centerC2 islessthanthe distancebetweenxand theclustercenterC1.Butthedata pointxshouldbelongtoclusterC1asthe distancebetween theclusterC1 islessthanthedistancebetweenxandthe clusterC2.So toovercomethisdrawbackwesub-clusterthe clusterswhereeachclusterisdividedintosub-clusters.C1andC2 areclusteredintosub-clutered Sub-clustering algorithmusestraditionalk-meansalgorithm todivideeachclustersformedintog sub-clusterswith Cg1,Cg2,....,Cgk.As showninthe figure,aftersub-clustering theclusterswecansay thatxbelongstoclusterC1because thedistancebetweenxandsub-clustercenterC12 islesser than distance calculated between xandanyother cluster center.Thesub-clusteris notonly closesttothedatapoint, butalsobelongstotheclusterCG,andthenthedatapoint is classifiedintoC12.

IV. CLUSTERINGBEFOREPREDICTION

Clusteringisprobablythemost usedexploratorydata analysistechnique acrossdisciplinesandis frequently employedtogetanintuitionaboutthe structureofthedata, for findingmeaningfulgroups,alsoforfeatureextraction andsummarizing.Givenadataset,clustering itgivesa compressedrepresentation.This canbethoughtofasgiving thedatatoan operatorasinput (k-means)thatgives an outputofthesamedatabut taking muchfewerbitsto represent it. This transformation tells us something interestingaboutthedataanditsstructure whichcouldbe exploited toimprovethepredictive power.Onepotential wayofdoingsoisby trainingapredictoroneachcluster separately ratherthantrainapredictorontheentiredataset. This ideaofusingclusteringcoupledwithsimplepredictors beat more complex methods such as Support Vector Machines and Random Forests. To traina "prediction model",thefollowingsteps arefollowed:1.Clusterthe training dataintokpartitions2.Foreachpartitiontraina classifier/predictorusingthepoints insidethatclusterasits training set.3.Eachsuchpredictor representsa modelofthe cluster,andhenceis calledtheclustermodel

V. CONCLUSION

Ifweareusingsub-clusteringasourpreprocessingtask for prediction, then the accuracy of clusters isIf we are using sub-clustering as our pre processing task for prediction, then the accuracy of clusters iscrucial in predicting. The two-layer K-means algorithm isused to strengthen the accuracy of data clustering. In thispaper,sub-clustering algorithm is used to improve traditional k-means algorithm so that accuracy of prediction can be improved. It can give a better accuracy rate of resultsthan the methods used without clustering.

abhisingh03101997@gmail.com, shashimourya1@gmail.com, dhaneshakolu9@gmail.com

Abstract **:-Implementing system for emotion detection from from facial expression With combination of neural network for the recognition of different facial emotions (happy, sad, angry, fear, surprised, neutral etc..). Humans are capable of producing thousands of facial actions during communication that vary in complexity, intensity, and meaning. Purposed system depends upon human face as we know face also reflects the human brain activities or emotions. In this project neural network has been used for better results.**

I. INTRODUCTION

This algorithm automatically extracts features and their motion information, discriminate subtly different facial expressions, and estimate expression intensity is showing how Emotion recognition using brain activity performs its task. We know that emotions play a major role in a Human life. At different kind of moments or time Human face reflects that how he/she feels or in which mood he/she is. Humans are capable of producing thousands of facial actions during communication that vary in complexity, intensity, and meaning. Emotion or intention is often communicated by subtle changes in one or several discrete features. The addition or absence of one or more facial actions may alter its interpretation. In addition, some facial expressions may have a similar gross morphology but indicate varied meaning for different expression intensities. In order to capture the subtlety of facial expression in non-verbal communication, I will use an exist tings emulator which will be able to capture human emotions by reading or comparing facial expressions.

III. TECHNOLOGY USED

TensorFlow TensorFlow is an end-to-end open source platform for machine learning. It has a comprehensive, flexible ecosystem of tools, libraries and community resources that lets researchers push the state-of-the-art in ML and developers easily build and deploy ML powered applications. TFlearn is a modular and transparent deep learning library built on top of Tensorflow. It was designed to provide a higher-level API to TensorFlow in order to facilitate and speed-up experimentations, while remaining fully transparent and compatible with it. TFLearn features include: Easy-to-use and understand high-level API for implementing deep neural networks, with tutorial and examples. Fast prototyping through highly modular built-in neural network layers, regularizers, optimizers, metrics...

• Full transparency over Tensorflow. All functions are built over tensors and can be used independently of TFLearn.

• Powerful helper functions to train any TensorFlow graph, with support of multiple inputs, outputs and optimizers.

• Easy and beautiful graph visualization, with details about weights, gradients, activations and more...

• Effortless device placement for using multiple CPU/GPU.

The high-level API currently supports most of recent deep learning models, such as Convolutions, LSTM, BiRNN, BatchNorm, PReLU, Residual networks, Generative networks... In the future, TFLearn is also intended to stay up-to-date with latest deep learning techniques.

IV. IMPLEMENTATION DETAIL

Steps :

• First, we use haar cascade to detect faces in each frame of the webcam feed.

• The region of image containing the face is resized to 48x48 and is passed as input to the ConvNet.

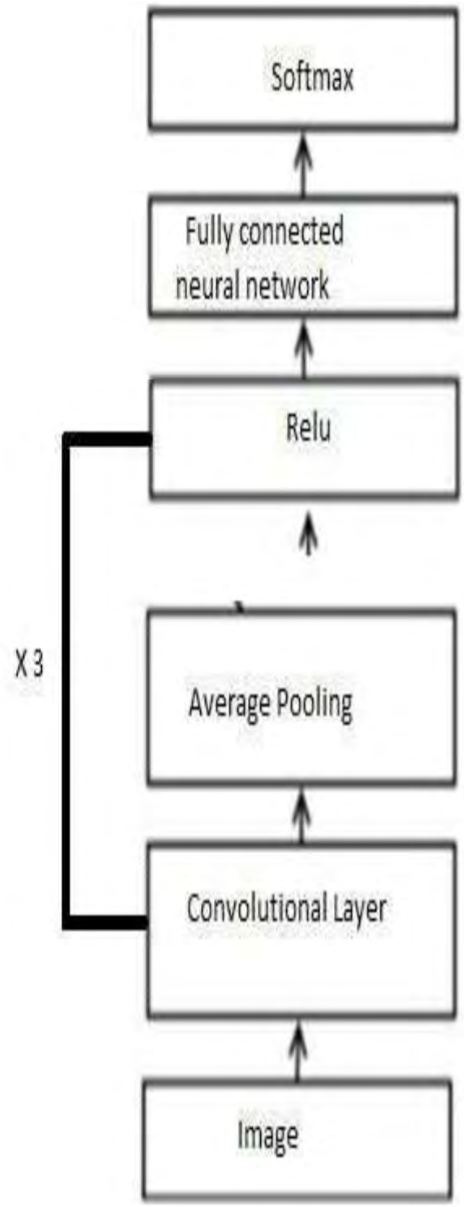
• The network outputs a list of softmax scores for the seven classes. The emotion with maximum score is displayed on the screen.

• A Haar Cascade is basically a classifier which is used to detect the object for which it has been trained for, from the source.

• The Haar Cascade is trained by superimposing the positive image over a set of negative images. The training is generally done on a server and on various stages. Better results are obtained by using high quality images and increasing the amount of stages for which the classifier is trained.

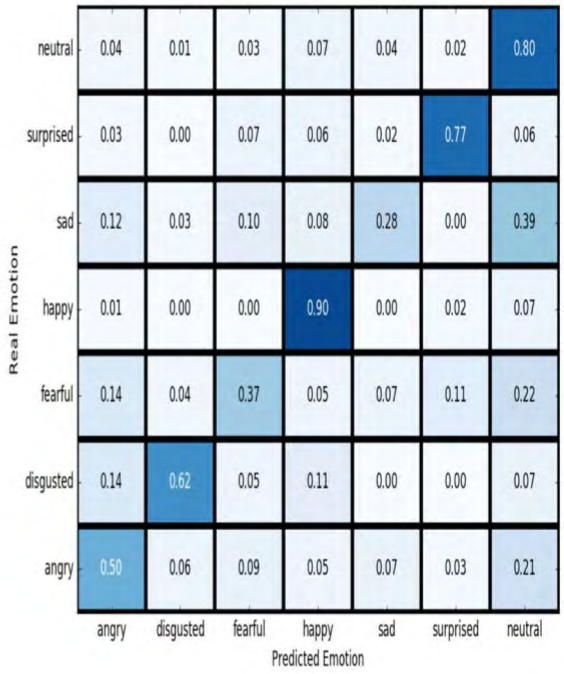
VI. BLOCK DIAGRAM/FLOWCHART

5.1Block Diagram

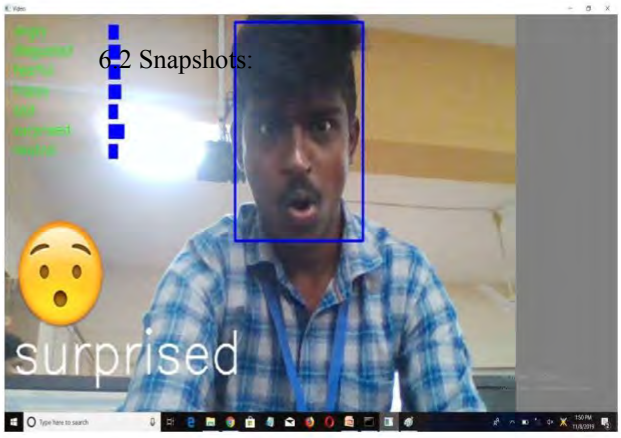


V. RESULT

6.1 Expected Outcome:



6.2 Snapshots:



VII. CONCLUSION:

Sign language gesture recognition as the study found out will be helpful to deaf people in assisting them to interact with computers. All the participants also appeared to be interested, involved and motivated by the system. However, it was not easy for most of the participants to place their hand on the rectangular box, which was considered to be the region of recognition. Hence it is appropriate to recommend that a bigger area is required so that the participants will not have to struggle to place the hand in the region before they start performing the gestures. For the system to be effectively applied in a controlled environment like a deaf classroom then a white background can be placed behind every seat of the computer user to reduce the challenge of complex background noise and improve the background subtraction.

Abstract.: **We propose a simple and successful method for visualizing and classifying malware using image processing techniques. Malware binaries are visualized as gray-scale images. Mal- ware coders change small parts of the original source code to produce a new variety. Images can capture small changes and the global structure. Hence, malware variants belonging to the same family appear very similar as images. These images are also different from images of other malware families. In the internet age malware poses a serious and evolving threat to the security making the detection of malware of utmost concern. Security vendors are doing their best to defend against malware attacks but unfortunately with millions of malware discovered monthly they cannot achieve that, thus novel approaches such as deep learning are needed.**

Keywords: deep learning, malware binaries, malware detection, image processing

I. INTRODUCTION

Malware is malicious software to infiltrate the secrecy, integrity, and functionality of a system, such as viruses, worms, trojans, backdoors, spyware. With computers and the Internet being essential in everyday life, malware is a serious threat to their security. It is estimated that one in four computers operating in the India are infected with malware. The threat posed by malware is not only emotional, but financial as well. According to a recent report from cyber crime department, up to one billion dollars was stolen in roughly two years from financial institutions worldwide, due to malware attacks. As a result, the detection of malware is of major concern to both the anti- malware industry and researchers

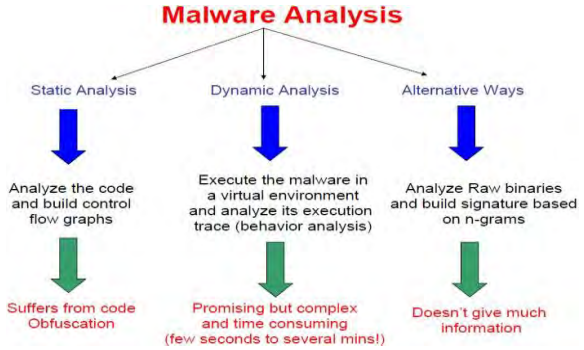

Fig1:Various Techniques of Malware Analysis

In order to pro- tect legitimate users from the attacks, the majority of anti-malware software products (e.g., Comodo, Symantec, Kaspersky) use the signature-based method of detection. Signature is a short string of bytes, which is different for each known malware so that its future examples can be correctly classified with a small error rate. However, this method can be easily evaded by malware attackers through the techniques such as en- cryption, polymorphism and obfuscation. Furthermore, malicious files are being spread at a rate of thousands per day, making it difficult for this signature-based method to be effective. In order to combat the malware attacks, intelligent malware detection techniques need to be investigated. As a result, many researches have been conducted on intelligent malware detection by applying data mining and machine learning techniques in recent years Based on different feature representations, differ- ent kinds of classification methods, such as Artificial Neural Network (ANNs), sup- port Vector Machine (SVM), Naive Bayes (NB), and Decision Tree (DT), are used for model construction to detect malware[1] . Most of these methods are based on shallow learning architectures. Though they had isolated success in malware detec- tion, shallow learning architectures are still somewhat lacking behind with respect to malware detection problems.

Deep learning (DL), a new frontier in data mining and machine learning, is starting to be leveraged in industrial and academic research for different applications (e.g., Com- puter Vision) . A multilayer deep learning architecture is of superior ability in feature learning[1]. More importantly, deep learning architectures overcome the learning dif- ficulty through layer wise pretraining, i.e. pretraining multiple layers of feature detec- tors from the lowest level to the highest level to construct the final classification model. This inspires us to devise a malware detection architecture based on deep learning

II. RELATED WORK & LITERATURE REVIEW

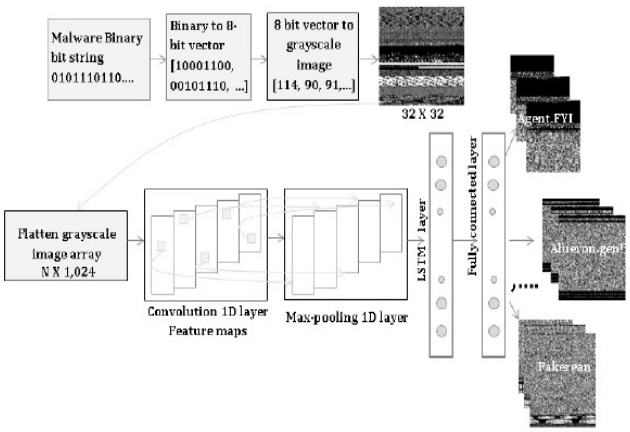
Signature-based method is widely used in anti-malware industry. However, malware authors can easily evade this signature-based method through techniques such as en- cryption, polymorphism and obfuscation. Driven by the economic benefits, the

quan tity, diversity and sophistication of malware has significantly increased in recent years. In order to effectively and automatically detect malware from the real and large daily sample collection, new, intelligent malware detection systems have been devel- oped by applying data mining and machine learning techniques. These intelligent malware detection systems are varied in their uses of feature representations and clas- sification methods. Naive Bayes on the extracted strings and byte sequences was ap- plied in which claimed that Naive Bayes classifier performed better than traditional signature-based method[1].Due to its superior ability in feature learning through multilayer deep learning archi - tecture, deep learning is feasible to learn higher level concepts based on the local fea - ture representations. As a result, researchers have paid much attention to deep learn- ing methods in the domains of natural language processing, computer vision, etc. In recent years, limited research efforts have been made to the malware detection using deep learning. we attempt to explore a deep learning architecture with the CNN model to learn generic features of malware and thus to detect newly unknown malware.

III. PROPOSED METHODOLOGY

Malware is a threat for every modern organization. Attackers and cybercriminals are always coming up with new malicious software to attack their targets. Security ven - dors are doing their best to defend against malware attacks but, unfortunately, with millions of malware discovered monthly, they cannot achieve the target. Thus, novel approaches such as deep learning are needed. Convolutional Neural Networks (CNNs) is a deep learning approach to tackle the image classification problem, or what we call computer vision problems, because classic computer programs face many challenges and difficulties to identify objects for many reasons, including light - ing, viewpoint, deformation, and segmentation.

Fig 2: System Architecture [1]



This technique is inspired by how the eye works, especially the visual cortex function algorithm in animals. CNN are arranged in three-dimensional structures with width, height, and depth as characteristics. In the case of images, the height is the image height, the width is the image width, and the depth is RGB channels. To build a CNN, we need three main types of layers: Convolutional layer: A convolutional operation refers to extracting features from the input image and multiplying the values in the fil- ter with the original pixel values Pooling layer: The pooling operation reduces the di- mensionality of each feature map. Fully-connected layer: The fully-connected layer is a classic multi-layer perceptrons with a softmax activation function in the output layer.

IV. TENSOR FLOW

Libraries**:** It is an open source artificial intelligence library, using data flow graphs to build models. It allows developers to create large-scale neural net- works with many layers. TensorFlow is mainly used for: Classification, Perception, Understanding, Discovering, Prediction and Creation.

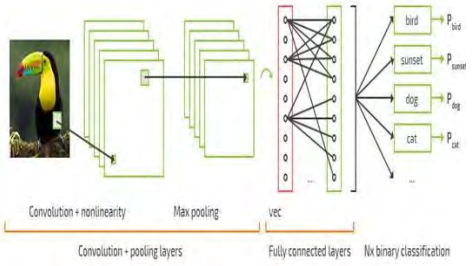


Fig 3: Working of CNN's

4.2 Keras Libraries: Keras is an open-source neural-network library written in Python. It is capable of running on top of TensorFlow, Microsoft Cognitive Tool- kit, Theano, or Plaid-ML. Designed to enable fast experimentation with deep neural networks, it focuses on being user-friendly, modular, and extensible.

4.3 Python Script: A plain text file containing Python code that is intended to be di- rectly executed by the user is usually called script, which is an informal term that means top-level program file.

4.4 Fast ai library: Jeremy Howard and Rachel Thomas, founders of fast.ai. fast.ai can be described as a research lab bundled with courses, an easy- to-use Python library with a huge community. Their library wraps popular deep learning and machine learning libraries for common workflows and provides a user-friendly interface

V. CONVOLUTIONAL NEURAL NETWORKS

In this work, CNN network composed of convolution 1D layer, pooling 1D layer and fully connected layer. A CNN network can have more than one convolution

1D layer, pooling 1D layer and fully connected layer. In convolutional 1D layer, the filters slide over the 1D sequence data and extracts optimal features. The fea- tures that are extracted from each filter are grouped into a new feature set called as feature map. The number of filters and the length are chosen by following a hyper parameter tuning method. This in turn uses non-linear activation function, Relu on each element. The dimensions of the optimal features are reduced using pooling 1D layer using either max pooling, min pooling or average pooling. Since the maximum output within a selected region is selected in max pooling, we adopt max pooling in this work. Finally, the CNN network contains fully con- nected layer for classification. In fully connected layer, each neuron contains a connection to every other neuron. Instead of passing the pooling 1D layer fea - tures into fully connected layer, it can also be given to recurrent layer, LSTM to capture the se- quence related information. Finally, the LSTM features are passed into fully con- nected layer. The architecture of a ConvNet is analogous to that of the connectivity pattern of Neurons in the Human Brain and was inspired by the organization of the Visual Cortex. Individual neurons respond to stimuli only in a restricted region of the visual field known as the Receptive Field. A collection of such fields overlap to cover the entire visual area. A ConvNet is able to successfully capture the Spatial and Tem- poral dependencies in an image through the application of relevant filters. The archi- tecture performs a better fitting to the image dataset due to the reduction in the number of parameters involved and reusability of weights. In other words, the network can be trained to understand the sophistication of the image better.

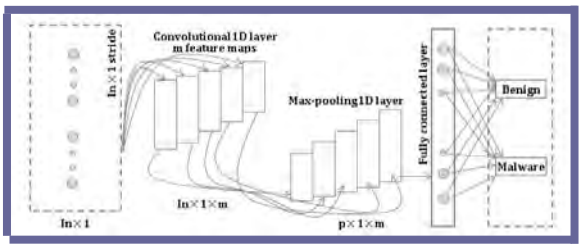

Fig 4:Workflow for malware Detection

1] To achieve the goal of malware detection, in this project we use Convolutional neural networks. (CNN). CNN's utilize the concept of deep learning to extract features from an image.

2] The project starts with the collection of malware and benign binaries and then converting these binaries to 8-bit vector representation (1000 0011…) and thereafter converting these values to image pixel values of 0 and 255. Here 0 represents black while 255 represents white.The values between 0 and 255 represent shades of grey.

3] Thus through this process the malware binaries are converted into a grayscale im- age. The feature extraction of grayscale image helps us to determine whether the given sample is malware or benign.

4] The Pre-processing required in a convolutional neural network is much lower as compared to other classification algorithms.

5] A Conv-Net is able to successfully capture the Spatial and Temporal dependen- cies in an image through the texture pattern, frequencies in image, intensity, or color features, using different techniques such as Euclidean distance, or mean and standard deviation, to generate later feature vectors. In our case, algorithms such as a color lay- out descriptor, homogeneous texture descriptor, or global image descriptors (GIST) can be used. GIST can be accurately calculated using a python library is known as the Pyleargist.

6] The malware is transformed into grey scale images by reading 8-bit unsigned in- tegers. The width of image is defined by file size and height is allowed to vary depend- ing on the width and file size. The malware images are resized to two-dimensional (2D) matrix of 32 × 32 and mapped into 1x1024 size array. Each feature array is nor- malized using L2 normalization.

7] This transformation becomes necessary as the grey scale image that is being used is 2-Dimensional and the convolutional neural network layer is one dimensional, so we need to reduce the dimensions of the image from 2-D to 1-D.Reducing the dimension of the image makes it compatible for passing it to the convolutional layer and thus suit- able to extract features.

VI. RESULTS AND DISCUSSION VII.

This project explores a novel technique of detecting malware through images. It imple- ments detection through images by implementing convolutional neural networks. con- volutional neural networks are a deep learning concept which effectively can capture the texture features of an image to understand whether the given sample is malware or not. convolutional neural networks have been proved to be the most effective tech- nique giving an accuracy of about 98%, which is much higher compared to other ma- chine learning algorithms such as SVM, KNN, Decision trees, which have been earlier experimented with it. This Deep learning approach proves to be a much better than sig- nature-based approaches which were initially used for malware detection. This tech- nique could also prove much useful in case of polymorphic viruses which change

their signatures at every stage of propagation evade detection by signature-based antiviruses.

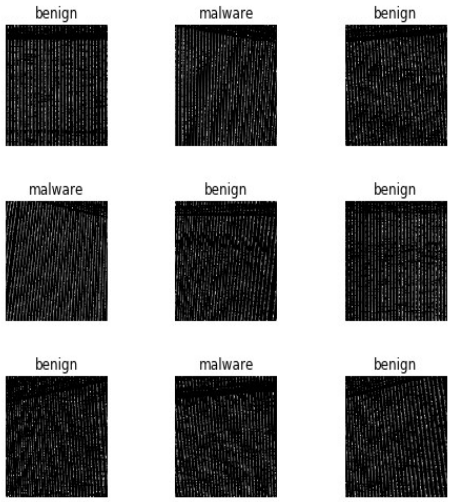

Fig 5: Input dataset consisting of grayscale, malware and benign images

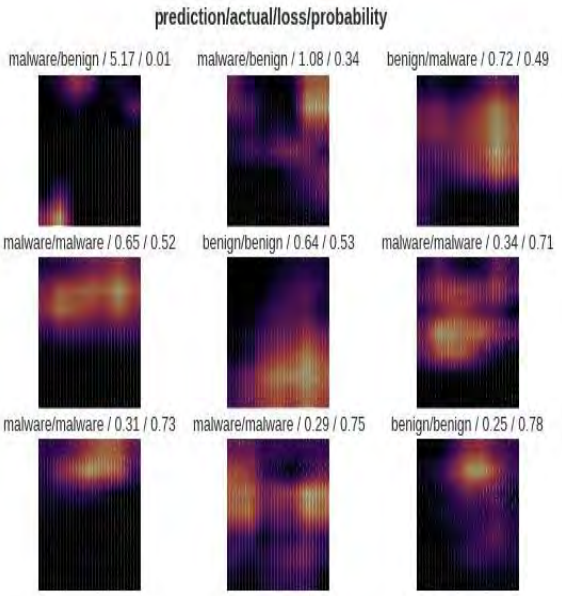

Fig 7: Multiclass classification

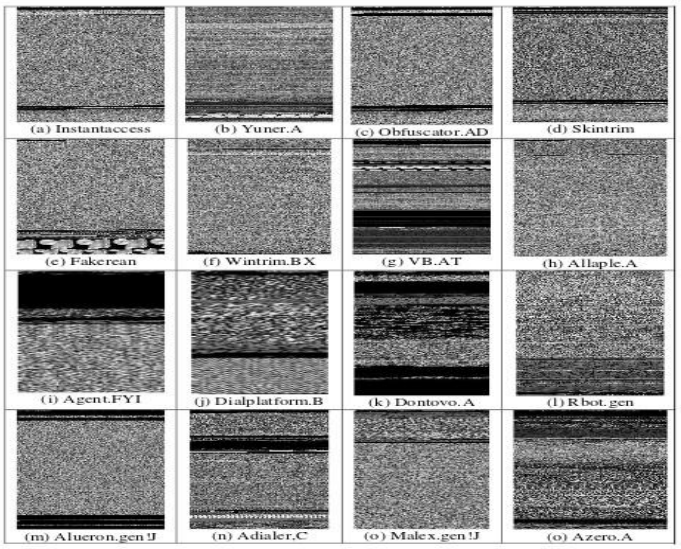

Fig 6: Output Predicted by CNN

6.1 Expected output is to implement multi-class classification of malware families. Image of a variants of a malware belonging to the same family will have similar prop- erties or texture. We aim to capture the texture of the images to classify a incoming im- age into a particular malware family. We use here about 25 malware families in which the incoming image is classified. We implement this system by implementing CNN's

VIII. CONCLUSION

The performances obtained by deep learning architectures outperformed classical MLAs in static, dynamic and image processing-based malware detection and categorization. However, in the dynamic analysis-based malware detection study, the deep learning architectures are applied on the domain knowledge extracted features. This can be avoided by collecting memory dumps for binary files at run time and then memory dump file can be mapped into grayscale image. The deep learning architectures are vulnerable in an adversarial environment. The method generative adversarial network can be used to generate samples during testing or deployment stage. In the proposed work, the robustness of the deep learning architectures is not discussed. This is one of the significant directions towards future work since the mal- ware detection is an important application in safety-critical environment. A single misclassification can cause several damages to the organization.

IX. ACKNOWLEDGEMENT

We sincerely thank our guide Dr. Megharani Patil for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.We thank the HOD, Dr. Sheetal Rathi, Dean Academic, Dr. R.R Sedamkar, the Principal, Dr. B. K. Mishra and the college management for their support.

Implementing System For Object Recognition Using Image Segmentation

Guided By. Ms. ASHWINI PATIL, Group Members Names: RAJ PURAIYA, BALWANT DEO

Abstract: **Object detection with help of image Processing are important and challenging tasks in many computer applications such as vehicle navigation, surveillance and autonomous robot Navigation. Video observation in a dynamic environment, especially for humans and vehicles, is one of the current challenging research topics in computer fields. Dynamic environment is a key technology to fight against crime, public safety, terrorism and for efficient management of traffic. Object Detection in image processing is the first relevant step of information and circumstantial subtraction is a very popular approach.**

Detecting and tracking of human body parts is important in considerate human activities. Intelligent and automatic safety observation systems have become an active research area in

Recent time due to an increasing demand for such Systems in public areas such as airports, underground stations and mass events. It is very difficult for a human machinist to effectively detect events as they happen. Recently computer vision research has to address ways to routinely some of this data, to assist human operators.

Keywords: Object Detection, Convolution Neural Network, Deep Learning, Image Recognition.

I .INTRODUCTION

The Object recognition is the area of artificial intelligence (AI) and other AI implementations to recognize various effects and articles. Object Recognition allows robots and AI programs to pick out and recognize objects from inputs like video and camera images. Google and Microsoft are among the companies working in the area -- Google's Driverless car and Microsoft's Kinect system both use object recognition. The object recognition technology is closely related to social life, object recognition technology is an important branch of computer vision, object recognition technology is along with the modern computer technology, image processing, artificial intelligence, and pattern recognition theory developed a new kind of object recognition technology. To realize the recognition of images, the first to get corresponding image by image acquisition device, so that the digital image.

Object recognition involves a lot of information operation, requiring high processing speed and recognition precision, real-time and fault-tolerance of the neural network in accordance with the requirements of object recognition. Object recognition method, aiming at the limitations of traditional methods, and the complex situations such as images show different state, in the process of image processing algorithm for the image segmentation study and its improvement. Progressions curtail or maybe break. Numerous investigators presently trust that these problems range unit partly related with diet consumption. The project aim is to develop associate degree application for estimating nutrition calories and improve people's consumption conducts for health-care. Provided that employers, patients with suitable and smart explanations that enable them live their food consumption and gather nutritional info area unit the primary valued visions near long run interfering and no-hit treatment programs and it are often conjointly employed in agricultural sector, grocery store.

II. RELATED WORK

The robotic fruit harvesting system is developed with the help of fruit detection algorithm using multiple structures identical intensity, color, alignment and edge of the fruit images. With the help of improved multiple feature-based algorithm, the detecting effectiveness is attained up to 90% for various fruit items [1]. For the exploration of the image FFB, the expansion of out-of-doors image inspection of oil palm fruit fresh bunches (FFB) are essential. The software examination generates the accurate prototypical and connection component amongst the light intensity in kin to value of FFB from RGB element of image occupied [2]. The on-line valuation of the superiority of fruits the calculation of the effectiveness of these methods concerning the next superiority facets hereby size, color, stem position and recognition of outer flaws is offered [3]. The main stages of the pipeline are segmentation of items from background, feature extraction mainly based on color, and classification with Gaussian Bayes classifier [4]. An automatic spherical fruits recognition system in the natural conditions facing difficult situations such as shadows, bright areas, occlusions and overlapping fruit [5] Convolutional neural Network achieved ample improved than did outdated approaches By means of handcrafted features. Complete comment of competent convolution kernels, we inveterate that color structures are vital to nutrition image identification [6]. Defined nutrition identification consuming a minor dataset, which was proposed to be second handed in a Smartphone based food classification scheme [7]. Which identifies unhealthy foods beginning cartridges of eating and guess meal calories created on identifying diets [8, 9] Involvement towards creating the prevailing point-of-purchase surroundings a lot of causative to the choice of healthy choices [11, 13]. The employment of processers to research pictures has

several possible claims for mechanism skillful farmed everyday jobs. So as to boost the practicality and suppleness of the popularity scheme form and size options may be shared in conjunction by color and texture structures [12]. Results with SVM area unit clearly superior to those found with the easy Naïve Bayes classifier [14]. The model on several alternative object classes variable over compactness and form. In their case this refinement is answerable for a tenth increase in performance relative to their initial recognition hypotheses [15]. The scheme automatically discoveries the amount of each element familiarized make the nourishment oppression information providing on its tag composed with the nourishment data for a smallest of a number of the elements [16]. The typical for this duty may be useful to pre-processing of food article identification or cull ender the exploration outcomes of inquiries associated with food, meals or dishes. They achieved high accuracy ninety-six, ninety-five and ninety-nine within the 3 datasets respectively [17].

They cantered on characteristic food things in a picture by victimization image process and segmentation, food classification victimization SVM, food portion volume activity, and calorie activity supported food portion mass and biological process tables [18]. MT-Diet improves the accuracy of machine-controlled food identification to eighty-eight.93%, a twenty fifth increase with relation to competitive techniques [19]. A diet proof of identity structure that mixes international and native options for a lot of correct visual portrayal of food things. By smearing late call fusion-based rules to every discrete feature network we are able to growth the proper classification percentage by over 7% [20]. The processes of food recognition and calorie estimation area unit performed in cloud server. A mean recall rate of ninety.98%, preciseness rate of ninety-three.05%, and accuracy of ninety-four.11% compared to fifty.8% to half of 1-mile accuracy of alternative existing food recognition systems [21].

Mushrooms, in spite of the nice variability determined among species, represent a remarkable food item that may contribute to the formulation of a well-balanced diet [22]. The results of the current study showed that this modification may be wont to predict organic food shopping for intentions and self-reported shopping for behavior [23]. VBM could be a quick rising technology because of the increasing affordability and capability of camera and computing hardware/software, may be employed in recognition system [24]. The recovery of biotic process info directly from the recipes by oppression NLU/IE techniques. They used NLG. Techniques to supply the answer [25]. Algorithmic theorem learns from food intake of human. Improves accuracy for classification algorithm [26]. 79.2% classification percentage with the highest 5 applicants once ground-truth leaping containers square measure given. It's higher eleven.0% than methodology conveys available on a smartphone that accept color histogram [27]. 79.2% classification accuracy given and developed android based application [28].

A. Deep Learning

Deep learning is a module of a broader conception of machine learning ways supported learning knowledge and its illustrations. Learning are often carried in 3 ways managed, semi-supervised or unattended. Deep learning consists of following architectures like deep neural ne process, audio recognition, social network filtering, computational linguistics, bio-informatics, medical image analysis, material scrutiny and parlor game programs, wherever they need made results love and, in some cases, superior to human specialists.

B. Object Detection

Manatee recognition may be a skill associated with idea and image process that contracts with spying instances of similar objects of a particular category (such as Food, Animal, buildings, or cars) in digital pictures and videos. It is domains of item recognition signify face detection and ordinary finding. The applications of Object detection area unit employed in varied field of pc vision, as well as image reclamation and video police work. The categorification of each object class is be contingent on its own features and attribute

– For example, all Oranges are round. Object class detection uses these features and feature of every objects. For example, when looking at orange, it states its feature like shape, color, texture etc.

III. SYSTEM METHODOLOGY

Designed for the goal of object recognition maltreatment convolutional neural network, we have a inclination to probable a scheme that rounds on decent phones, and which document the employer to need an image of the nutrition and aware the amount of calorie feasting automatically. AN app that takes image of fruits and categorize object in different category and provides nutrition value once you snap an image of your plate, the app uses the pictures to form the comparison. It then provides you with an inventory of things that area unit the foremost doubtless foods. you will not see one choice with everything on your plate. Instead, you will see every known item listed separately.

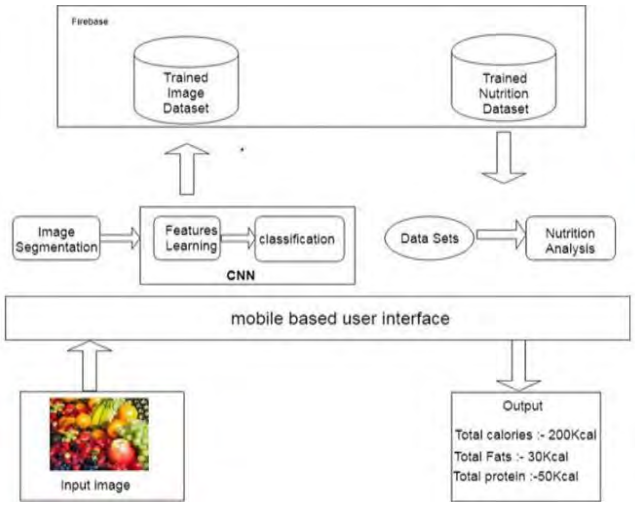

Fig.1. Proposed Architecture

This system is powered by Convolutional Neural Network. The method of object recognition is applied mistreatment Convolutional neural network mistreatment Tensor Flow. The system use base of operations cubic centimeter at the backend wherever the customaries trained model area unit host which can dynamically serve the user input. The output is generated by classifying the image and provides useful information to user such as Name, Calories & Diet. This technology is used to quickly and accurately identify food items.

This is an assistive calorie amount system to help patients and doctors embellishment in their match in contradiction of diet-related fitness situations. The discovery effectiveness can be achieved up to 90% for different foods captured from different position and surfaces. Every food item recognized by the system is paired with detailed nutrition information. Only if users/patients with suitable and smart resolutions that service them amount their nutrition consumption and gather dietary info in the direction of continuing anticipation and fruitful action plans. It's too benefit in the superstore and farming segment to stream well vegetal and fruits

A. *Basic CNN Components*

It is encouraged by biological procedures of neurons that resemble the connectivity outline amongst the neurons of the animal visual cortex. The specific cortical neurons reply to inducements only the rare area of the pictorial field. The pictorial arena of dissimilar neurons temperately overlays such that they cover the pictorial meadow. CNN is a scheme much like a multilayer perceptron that has been intended for shortened processing supplies. As connected to the other image organization algorithms, it has less pre-processing. CNN consists of a dissimilar layer which are an input layer, and output layer, and a hidden layer that includes multiple convolutional layers, pooling layers, fully connected layers and normalization layers.

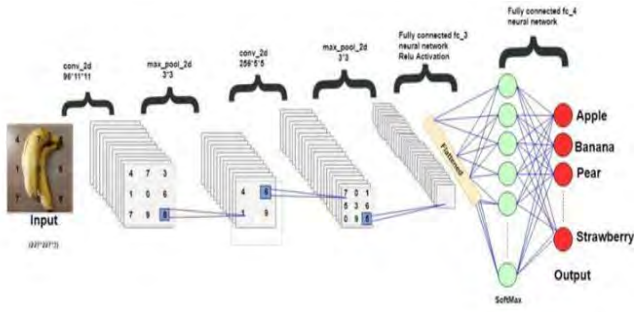

Fig. 2. CNN Architecture

The last hidden layer produces an output values forming a vector x =x. The output neural layer is can classify among n=1…n categories with a SoftMax activation function. Each of the n categories is assigned with conditional probabilities to classify. In each node in the output layer the pre-activated values will consist of the scalar products w(Tj)x where wj∈{w1,w2,…,wn}.However, the activation of this output layer will take through the softMax function which will map the vector of image to vector of n element in[0,1].

$$Zj = wTj * x$$

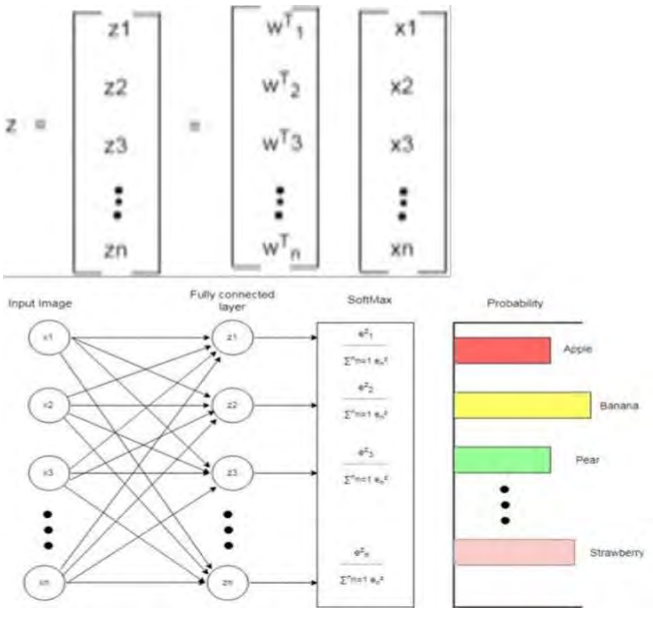

Fig.3. Soft Max Function

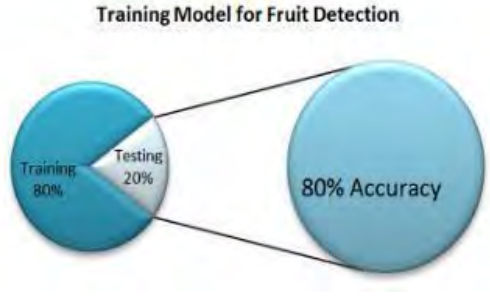

Fig.4. Training Model for Fruit Detection

In the Above figure, overall 1000 images of per object has been skilled in the exercise model for fruit detection amongst which 80% of data is skilled data and 20% of data is challenging data which delivers 80% of accuracy.

IV. EXPERIMENTAL CONDITIONS

Fig.5. CNN Result for object Detection for strawberry

In Fig.5 and Fig.6 following object are detected with their name and nutrition value of that object is shown after calculation which is done by Convolutional Neural Network (CNN).

Fig.6. CNN Result for object Detection of PEAR with Nutrition Values

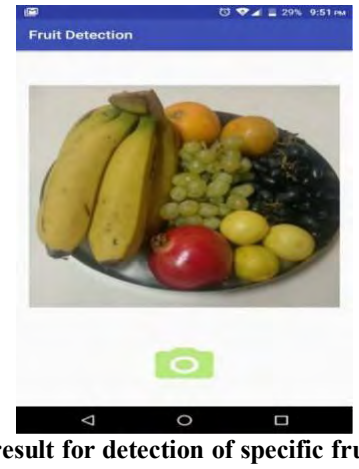

Fig.7. CNN result for detection of specific fruits from multiple food

In fig.7 object will be detected with their name after calculation which is done by Convolutional Neural Network (CNN).

V. CONCLUSION

In this paper, we have described the growth of an Object detection system using CNN, which run on mobile devices. We erected a object image dataset from capturing multiple images of a particular object, applied Convolutional Neural Network to the identification of 20 objects, and calculated its presentation. Convolutional Neural Network achieved much improved performance and efficiency than did old-style approaches using handcrafted structures. Complete comment of skilled convolution kernels, we inveterate that color geographies are important to food image recognition. We applied Convolutional Neural Network to object discovery, finding that Convolutional Neural Network expressively outperformed a baseline method. After recognition, algorithm fetches the object values of detected object and display it to the user.

Abstract - **Data is the collection of various statistics which is fundamental for running the algorithms. The missing in the data can make the algorithms work differently. Hence, missing data is exciting but common probleminmachinelearningandstatisticalanalysis.They can be caused by various sources such as death ofpatients during ongoing treatment, users not responding in a survey, errors in the database during deletion or updating ofinformation,andsoon.Thekindofcategoriestheycome depends on the degree of relationship between the nature of the observed values and missing data. Thus, understanding the appropriate analysis for using the data needs the understanding of the mechanism for handling missingdata.There are various techniques methods have been used for handling the missing data in textbooks, literatures and standard courses. The importance of these techniques in medical science and clinical trials has made some of them gaining resurgence in the recent decade. But, there are also some drawbacks associated with some of them when used for data mining algorithms. Also, there is a need to avoid bias or the over- or under-estimation of variability.**

We are using here case deletion and some imputation techniques from various fantastic python packages like fancy-impute missingpy, sklearn-imputer and pandas. The techniques will be used to impute the missing values on Framingham dataset, which further will be examined for implementing different machine learning algorithms. This examination will help to analyze the best imputation technique by comparing them using different performance measures and parameters, such as accuracy, specificity, precision, ROC curve area, etc. The underlying principles of machine learning methods and model-based imputation methods can also be explored.

Keywords-- Missing, Data frame, fancy impute

I. INTRODUCTION

Thetechnologiesareevolvingwitheachday. Many of the technologies give out the results on the basisofdata.Oneofthecommonproblemsinmostof the scientific research domains such as medicine, Biology or Climatic Science is missing data. Measurement error, non-response or deleted aberrant value, low signal-to-noise ratio, and mishandling of samples are some of the common sources for missing data. It introduces an element of ambiguity into analysis of data. The missing in data can cause the propertiesofstatisticalestimatorssuchaspercentages, variances or means, resulting in misleading conclusionsandlossofefficiency.Thisproblemisthe most common issue encountered by the algorithmand machine learning practitioners when they analyze the real-world data. In many applications ranging from survey response in social sciences to gene expression in computational biology, various degree of missing data is present. As many machine learning algorithms and statistical models rely on whole data sets, it is necessary to handle the missing data appropriately. There are number of techniques have been proposed for imputing with statistical predictions in place of missingoremptytuples,theprocessisgenerallycalled as 'missing dataimputation'.

Thus, it is very important to have complete datasets for accurate use of the data and decision making processes. The many reasons for missing of datacanincludethemanualdataentryprocedure;data recorded and transferred errors, and incorrect measurement. One of the significant examples of real world data is clinical data as it plays an importantrole in discovering and implementing machine learning and data mining algorithms, the effect of clinical data on lifestyle can be serious, hence there is a need of manipulating and analyzing this type of data. , There are three types of missing values; (a) Missing at Random (MAR), and (b) Missing Not at Random (MNAR) (c) Missing Completely at Random (MCAR). The categorization has been done on the relation between the incomplete attributes and other completedattributes.Whenthemissingvaluedoesnot depend on any of incomplete variables or other completed variables, the missing value comes under MCAR. It means the attribute A being missing is independentoneithercompletedataBorA.Whenthe variable being missing is independent from the values

of that variable, but it somehow depends on other dataset variables, i.e. where the distribution ismissing itselfbutdependonothervariable'sdata,suchmissing data is MAR. The last category, MNAR is non-ignorablecasewhichisneitherMCARnorMAR.The probability of data being missing from an attribute depends on the value of that attributeitself.

II. LITERATURE SURVEY

In the papers we have studied, the different imputation methods were chosen to cover techniques broadly applied in the literature and representative of various statistical strategies

Briefly, three out of these methods were based on mean, K-Nearest Neighbour (KNN), Fuzzy K-Means (FKM) while other were Singular Value Decomposition(SVD),BayesianPrincipalcomponent Analysis (bPCA) and Multiple Imputations by Chained Equations (MICE). The imputation using mean consists of substituting the missing value for a givenvariablebytheaverageoftherowvaluesofthat variable; KNN is the K-Nearest Neighbour where it substitutes the each missing value by average of the individual sample or set of K-nearest neighbours. FKMisFuzzyK-meanswhichisanextensionofKNN based on clustering. SVD is Singular Value Decomposition which imputes value based on the Eigen values while bPCA is a Bayesian Principal component Analysis which again uses Eigenvaluesfor imputing the missing value. Finally, MICE are an iterative algorithm based on chained equations which usesimputationmodelspecifiedseparatelyforeachof the variable while involving other variables as predictors.[5] There are some numerous modelsbased imputation techniques that can be categorizedinto explicit model based and implicit model based. Expected Maximization (EM) is one of the examples of explicit model while implicit model includes methods like K-nearest neighbor (KNN), weight KNN, RBFN and Multi-Layer Perceptron (MLP). Another way of categorization of imputation is single imputationandmultipleimputation.Singleimputation is simple method like mean imputation or Expected Maximization (EM). Multiple imputation include imputationmultipletimesonsamemissingvaluesuch asMICE[3].Theobjectiveoftheresearchreportedin previous papers is to manipulate and compare a set of imputation methods on different size of datasets like small datasets, large datasets and analyze them over different parameters like RMSE, UCE, SCE, and Execution Time. This analysis over these parameters will result the most useful imputation method to impute the missing value datasets[1].

Googlesearchofanymethodassociatedwith term 'missing data' gives an idea of their respective popularity. As expected, Mean has produced the most number of hits approximately 210000 results, followedbyMICE,SVDandKNN(17700,14500and 12700respectively.bPCAandFKMhasgiventheless popular around 2560 and 5220 hits respectively. However,thebestmethoddoesnotneedtobepopular. So, there was need of some performance measuresfor comparing these methods. These performance measures are: RMSE, UCE, SCE and the execution time[2].Theresultsweremeasureddifferentforsmall datasets and larger datasets. The overall summary is given in the table below. For the small datasets, FKM has given better RMSE, UCE and SCE than other methods but Execution time was not good. While for large datasets, bPCA has been best for all the performance measures. Thus, overall bPCA andFKM has outperformed the other methods. KNN, SVD and MICE has also given good results. Mean method has not been so good for imputation purpose[4].

III. METHODOLOGY FOR IMPUTATION

Computers has provided with the advance ability to learn without being explicitly programmed. This advanced ability is a Machine Learning which is a type of Artificial Intelligence. Machine learning

helps to develop the computer programs that can change when exposed to new data. The Python community has developed many modules to help the programmers implement machine learning. The many machine learning packages like fancy impute, missingpy, datacompy are installed. The many machine learning libraries like pandas, numpy, scikit-learnhasbeenusedtoimplementthemachinelearning models.

DROPPING ROWS WITH MISSING VALUES:

One of the simplest strategies for handling missing is to eliminate records that contain a missing value.Thatmeanstherowsinthedatasetthatcontains

Steps for Dropping Columns:

Step 1: Analyze Data Frame with NaN Values

Step 2: Drop the Columns with NaN Values in Pandas Data Frame

Step 3 (Optional): Reset the Index

IMPUTATION BY REPLACING WITH MEAN

VALUE:

The imputation is the technique to using a model to replace missing values. There are differenteven of the missing value tupple, that row will be dropped from the dataset. Pandas provides the dropna() function which can be use to remove all the rows from the dataset that contains the missing data. The easiest way to dropping rows is to remove rows containing NA; either when any column contains NA or all columns contain NA. Dropping the rows containing NA values in any of the column will result in reduction in number of rows. This effect can cause the datasets with less number of rows where dropping the rows with any missing value can cost us losing of necessary information.

Steps for Dropping Rows:

Step 1: Analyze Data Frame with NaN Values

Step 2: Drop the Rows with NaN Values in Pandas Data Frame

Step 3 (Optional): Reset the Index

DROPPING COLUMNS WITH MISSING VALUES:

Apart from dropping the rows, another strategyforhandlingmissingdataistodropthewhole column that contains the missing value tupple. This can be done by removing all the columns that contain any of the missing value. Pandas provides the data.drop () function where data() can be used to remove the columns. But the problem becomes significantly more complicated, when working with the data frame because the degree of information loss issohigh.Itmayalsohappenthatthecolumnoftarget variable contains the missing value and gets dropped by applying this method. If the column is sparsely populated, it might drop the columninstead.
ways which can be considered when replacing amissing value. When the data is in continuous form, replacingwiththemeanvaluecangivethebestresults. The imputing performed on training data will have to beperformedinnewdatawhenpredictionsareusedto finalize the model. There is need of consideration when selecting the way of imputation of missing values. Imputing the missing values with mean is just substitutingthemissingvaluesbyaveragevalueofthe complete column. All the missing values in that particular column will be the same evaluated average value. Pandas provide fillna() function for imputing the mean value in place of missingvalues.

IMPUTATION BY REPLACING WITH MODE VALUE:

One of the other imputation methods is by substituting the most frequent value of that column in place of missing values. This imputation method is called as Mode imputation method. Mode is the most repeated value of the particular column. This method does not involve the evaluation of any value but only toselectthevaluewhichgetsrepeatedmostnumberof timesinthecolumn.Thiscanbedonebytheusingthe pandas library which provide fillna() function for imputing the mean value in place of missing values. For using the mode method by fillna() function, the type used will be 'mode'.

Steps for Replacing with Mode Technique:

Step 1: Analyze Data Frame with NaN Values

Step 2: Compute the Mode of the column containing the NaN value

Step 3: Fill the missing tupple with the computed Mode Value using fillna () function

Step 4: Repeat the process for another column containing NaN value

IMPUTATION USING KNN ALGORITHM:

K- Nearest Neighbour is an algorithm which is useful for matching a point with its K closest neighbours in a multi-dimensional space. It can be used for many kind of data like discrete, continuous, categorical and ordinal which makes it particularly useful for dealing with all kind of missing values.
The strategy behind using KNN imputation method is that a point value can be approximated by thevaluesofitsclosestpoints,basedonothervariables. Thereneedtoconsiderationofmanyparameterswhen using KNN; one is to look for number of neighbours (value of K). If the value of K is low, it will increase theinfluenceofnoiseandtheresultsgeneratedwillbe less generalizable. While high value of K will tend to blur local effects which we are actually looking for. Thus it is recommended to take an odd value of K for binary classes to avoidties.

Steps for Replacing with Mean Technique:

Step 1: Analyze Data Frame with NaN Values

Step 2: Compute the Mean of the column containing the NaN value

Step 3: Fill the missing tupple with the computed Mean Value

Step 4: Repeat the process for another column containing NaN value

KNN Algorithm:

Step 1: Analyze Data Frame with NaN Values

Step 2: Select the number of neighbours i.e. value of K

Step 3: Compute the Euclidean Distance of empty tupple with its neighbour

Step 3: Fill the missing tupple with the computed Value using KNN imputer

IMPUTATION USING MULTIPLE IMPUTATIONSBYCHAINEQUATION(MICE) ALGORITHM:

same record with some the multiple iterations, the process is called multiple imputations. A imputation technique based on the multiple imputations is called asMultipleImputationbyChainedEquations(MICE). This technique has lot of advantages over the single imputation. MICE technique work with the assumption that the kind of missing data is missing at Random (MAR) data. The strategy behind workingof this technique is to run the multiple regressionmodels and each missing value is modelled conditionally depending on the observed (non-missing) values. MICE technique uses all the other variables in the dataset to predict any other missing value. Fancy imputer library provides special function mice that willdetectwhichvariablearethedatasethavemissing information. There is a matrix called as predictor matrix which gives information about the variables in the dataset were used to produce predicted values for matching. Consider an example where variables x1,x5,y2-y5 were used to create predicted values for y1.As we did not mentioned any seed value, the algorithm by default chose one random value; so if thereisanyneedforreproducingtheimputation,there could set a seed value for random numbergenerator.

MICE Algorithm:

Step 1: Analyze Data Frame with NaN Values

Step 2: Predict the value using the nearby variables in the Data frame for the tupple containing value NaN

Step 3: Converge the value to the nearest value of prediction

Step 4: If the stopping condition is met

IMPUTATION USING MISS FOREST ALGORITHM:

Random forest algorithm is one of the efficient machine learning algorithms for implementing the machine learning models. There is an extended version of Random Forest algorithm which can be used for imputing the missing value in the dataset. This extended imputation technique is knownasMissForestalgorithm.Bydefault,themodel

On the basis on number of times of imputation can be done, it can be distributed into two categories; single imputation and multiple imputations. When the value is getting imputed to beginstheimputationofmissingvaluesofthecolumn (which is expected to be a variable) with the least number of missing values (let his column be called as candidatecolumn).Theinitialstepistofillinganymissing values of the non-candidate, remaining, columns with an initial guess, which is the column mode for all the columns representing categorical variables while column mean representing for numericalvariables.Thecategoricalvariablesmustbe explicitly identified during the imputer's fit () method call. After the initial step, the imputer fits a random forest model with the candidate column as output variable and the remaining columns as the predictors overallrowswherethecandidatecolumnvariablesdo nothaveanymissingvalues.Afterthefittingofmodel, the rows with missing values of candidate column are imputed using the prediction form fitted Random Forest. The non-candidate column rows act as input dataforfittedmodel.Further,theimputermovesonto next candidate column with the second smallest number of missing data among the non-candidate columns in the first round. The whole process repeats itself for each of the column having missing values, possibly over epoch or multiple iterations for each column, until the stopping condition ismet.

Miss Forest Algorithm:

Step 1: Analyze Data Frame with NaN Values

Step 2: Compute Normalized Root Mean Squared Error for the tupple containing value NaN

Step 3: Iterate the steps until stopping Condition is met

Step 4: If the stopping condition is met for iteration

Do: Impute the computed value in empty tupple

Step 5: Repeat the process for another tupple in Data frame containing NaN value

METHODOLOGY FORPREDICTION

LOGISTIC REGRESSION

A statistical method for analyzing thedataset having one or more independent variable that determines an outcome which is measure is with a dichotomous variable. This method is known as Logistic Regression. In this regression model, the target variable is dichotomous variable i.e. target variable only contain data codes as 0 (false/failure) or 1 (true/success).

DECISION TREE

A learning method for approximation of discrete-valued target functions and the function is represented by set of if-then rules in the form of tree shape structure is known as Decision Tree Learning method. These learned trees act as model to fit the independent variables data as conditions and outcome variable as decisions based on the respective conditions.

RANDOM FOREST

Decision Tree model used for classification can give efficient results. Another model can also be used for classification to enhance the efficiency of results. Instead of using a single decision tree model, we can collective use group of decision tree models whichcanproducetheresultslikeforest(collectionof trees). This algorithm is called as Random Forest algorithm and the classifier used by Random forest is called as Random forest classifier. In the random forest, each individual decision tree spits out a class prediction and the class which consists of most number of votes turn out to be the model'sprediction.

METHODOLOGY FOR EVALUATING PERFORMANCE

- ACCURACY
- SENSITIVITY
- SPECIFICITY
- PRECISION
- F1-SCORE
- ROC-AREA UNDERCURVE

SYSTEM ARCHITECTURE

The architecture of system consists of some finite steps. The process begins with large dataset without any missing value in the dataset. After that, thedatasetisintroducedwithsomeamountofmissing value by deleting the random values of records of randomly selected rows or columns. The degree of missing value introduced can be ranged from 5% to 45%. If the dataset which is already incomplete and percentageofmissingvaluesmorethan45%,thenuse ofsuchdatasetsshouldbeavoided.Thenextstepisto apply the imputation techniques on the dataset. The datasets which are made complete by imputing the missing values by imputations techniques are applied by some machine learning algorithms. The results generatedarethencomparedonthebasisofsomeperforman ce measures parameters. The results are analyzed for multiple times of simulation and the conclusions are made about the best imputation technique.

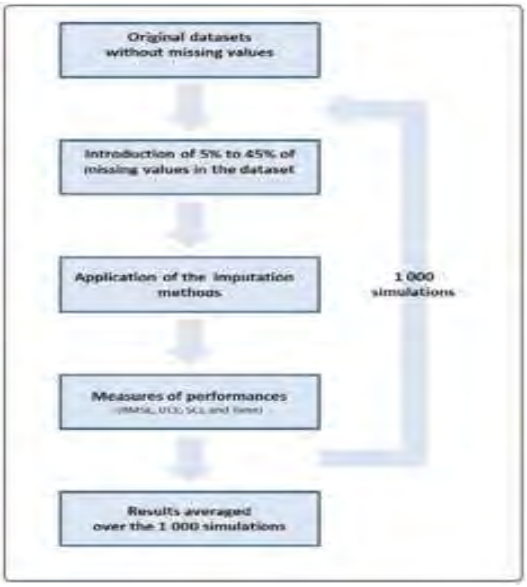

Fig 1. Basic flowchart for Imputation process using Algorithms

IV. RESULTS AND DISCUSSIONS ACCURACY

Table I. Accuracy of the model fitted to datasets by

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.8561	0.7486	0.8251
DROPPING COLUMN	0.8498	0.7517	0.8317
MEAN IMPUTATION	0.8537	0.7507	0.8356
MODE IMPUTATION	0.8538	0.7421	0.8427
KNN IMPUTAION	0.8537	0.7515	0.8388
MICE IMPUTATION	0.8530	0.7445	0.8317
MISS FOREST IMPUTATION	0.8537	0.7531	0.8396

The above table is depicting the accuracy values of the model obtained from the results of each of the algorithm fitted to the Framingham dataset whose missing values are imputed by the aboveseven different imputation techniques. The highest accuracy

is 0.8561 for the model Logistics Regression when fitted to dataset imputed by dropping row imputation technique. For the Decision Tree model, the maximumaccuracyobtainedis0.7531forMissForest Technique while the same gives accuracy of 0.8396 which is highest for Random forestmodel.

SENSITIVITY

Table II. Sensitivity of the model fitted to datasets by different imputation techniques

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.8574	0.8532	0.8415
DROPPING COLUMN	0.8419	0.8564	0.8544
MEAN IMPUTATION	0.8542	0.8597	0.8504
MODE IMPUTATION	0.8543	0.8596	0.8560
KNN IMPUTAION	0.8542	0.8591	0.8509
MICE IMPUTATION	0.8536	0.8545	0.8492
MISS FOREST IMPUTATION	0.8537	0.8560	0.8538

The above table is for Sensitivity values of the model obtained from the results of each of the algorithm fitted to the Framingham dataset whose missing values are imputed by the above seven different imputation techniques. The highest sensitivityvalueis0.8597forthemodelDecisionTree when fitted to dataset imputed by Mean imputation technique. For the Logistics Regression model, the maximum sensitivity obtained is 0.8574 for Dropping Row method while the Random forest model gives maximum sensitivity of 0.8360 when fitted to dataset imputed by Mode Imputationtechnique.

SPECIFICITY

Table III. Specificity of the model fitted to datasets by different imputation techniques

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.7272	0.2552	0.3684
DROPPING COLUMN	0.5555	0.2087	0.3392
MEAN IMPUTATION	0.8125	0.2211	0.3142
MODE IMPUTATION	0.8126	0.2155	0.4523
KNN IMPUTAION	0.8125	0.2196	0.3548
MICE IMPUTATION	0.8000	0.1971	0.2631
MISS FOREST IMPUTATION	0.8571	0.2079	0.4000

The above table is for Specificity values of the model obtained from the results of each of the algorithm fitted to the Framingham dataset whose missing values are imputed by the above seven different imputation techniques. The highest Specificity value is 0.8571 for the model Logistics Regression when fitted to dataset imputed by Miss Forest imputation technique. For the Decision Tree model, the maximum Specificity obtained is 0.2211 for Dropping Column method while the Random forest model gives maximum Specificity of 0.4523when fitted to dataset imputed by Mode Imputation technique.

PRECISION

Table IV. Precision of the model fitted to datasets by different imputation techniques

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.9967	0.8449	0.9803
DROPPING COLUMN	0.9962	0.8522	0.9702
MEAN IMPUTATION	0.9972	0.8520	0.9879
MODE IMPUTATION	0.9973	0.8327	0.9739
KNN IMPUTAION	0.9973	0.8447	0.9786
MICE IMPUTATION	0.9972	0.8457	0.9842
MISS FOREST IMPUTATION	0.9981	0.8382	0.9804

The above table is for precision values of the model obtained from the results of each of the algorithm fitted to the Framingham dataset whose missing values are imputed by the above seven different imputation techniques. The highestprecision value is 0.9981 for the model Logistics Regression when fitted to dataset imputed by Miss Forest imputation technique. For the Decision Tree model, the maximum precision obtained is 0.8522 for Dropping Column method while the Random forest modelgivesmaximumprecisionof0.9879whenfitted to dataset imputed by Mean Imputationtechnique.

F1-SCORE

Table V. F1-Score of the model fitted to datasets by different imputation techniques

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.9218	0.8482	0.9034
DROPPING COLUMN	0.9184	0.8526	0.9102
MEAN IMPUTATION	0.9202	0.8491	0.9155
MODE IMPUTATION	0.9203	0.8460	0.9109
KNN IMPUTAION	0.9202	0.8555	0.9105
MICE IMPUTATION	0.9198	0.8492	0.9149
MISS FOREST IMPUTATION	0.9203	0.8481	0.9146

The above table is for F1-Score of the model obtained from the results of each of the algorithm fittedtotheFraminghamdatasetwhosemissingvalues are imputed by the above seven different imputation techniques. The highest F1-Score is 0.9218 for the model Logistics Regression when fitted to dataset imputed by Dropping Row imputation technique. For the Decision Tree model, the maximumF1-Scoreobtained is 0.8555 for KNN imputation method while theRandomforestmodelgivesmaximumF1-Scoreof 0.9155 when fitted to dataset imputed by Mean Imputationtechnique.

ROC-AREA UNDER CURVE

Table VI. ROC-Area under Curve of the model fitted to datasets by different imputation techniques

ALGORITHMS / IMPUTATION TECHNIQUES	LOGISTICS REGRESSION	DECISION TREE	RANDOM FOREST
DROPPING ROW	0.5229	0.5516	0.5121
DROPPING COLUMN	0.5111	0.5230	0.5411
MEAN IMPUTATION	0.5314	0.5332	0.5271
MODE IMPUTATION	0.5316	0.5439	0.5354
KNN IMPUTAION	0.5317	0.5652	0.5199
MICE IMPUTATION	0.5292	0.5223	0.5329
MISS FOREST IMPUTATION	0.5296	0.5390	0.5412

The above table is for ROC-Area under Curve (AUC) of the model obtained from the results of each of the algorithm fitted to the Framingham dataset whose missing values are imputed by the above seven different imputation techniques. The largest AUC is 0.5652 for the model Decision Tree when fitted to dataset imputed by KNN imputation technique. For the Logistics Regression model, the maximum AUC obtained is 0.5317 for KNN imputation method simultaneously while the Random forest model gives maximum AUC of 0.5412 when fitted to dataset imputed by Miss Forest Imputation technique.

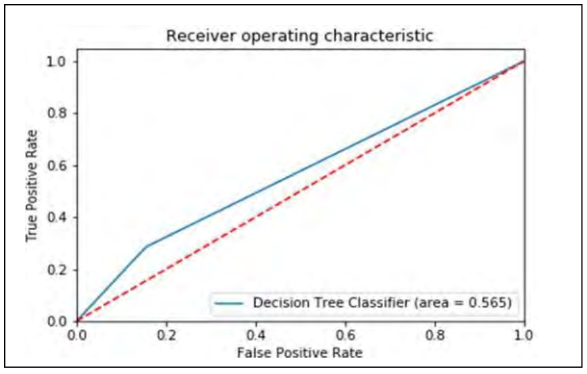

Fig 2. ROC curve for Decision Tree Classifier fitted on dataset imputed by KNN Imputation Technique

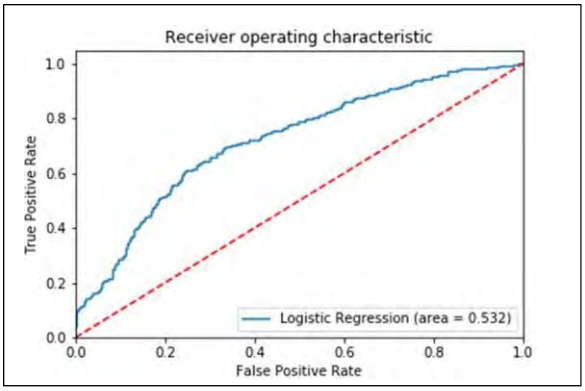

Fig 3. ROC curve for Logistic Regression fitted on dataset imputed by KNN Imputation Technique

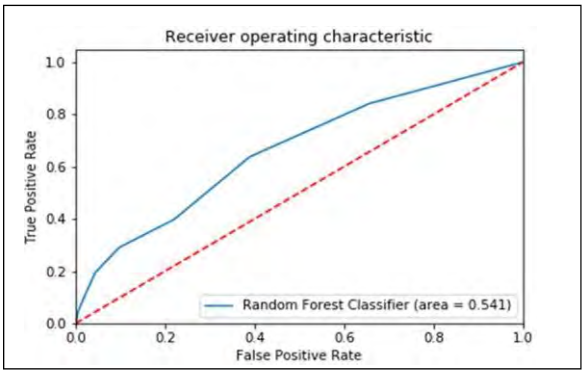

Fig 4. ROC curve for Random Forest fitted on dataset imputed by Miss Forest Imputation Technique

V. CONCLUSION AND FUTURE SCOPE

The complete datasets generated used for fitting on the three different machine learning models viz. Logistic Regression model, Decision Tree Classifier and Random Forest classifier. Several resultsobtainedarethenmadecomparisononthebasis of six different performance measures i.e. Accuracy, Sensitivity,Specificity,Precision,F1-ScoreandROC-Area under curve. The simple imputations like Dropping Row and Dropping Column led the loss of information while Mean and Mode imputations filled the same value for a column. The MICE and Miss Forest imputation methods involved lot of evaluation of values to impute. Thus, the ROC-Area under curve ofDecisionTreeislargestwhenappliedonthedataset imputed by KNN imputation technique. That means Decision Tree algorithm works well among the three algorithms. The ROC curve area obtained on dataset imputed by KNN gives largest area for two different machine learning models. Therefore the Framingham dataset imputed by KNN imputation imputes best

values among the other imputation techniques. Also KNN imputation method over other is that itimputeswithout loss of information. Further, the complex cases like imputing for nominal or longitudinal data can also be considered for analyzing in future with some careful attention. There is also some area of improvement where the advance performance measures like Cohen-Kappa score could be used for better understanding and comparison of the models fitted to imputed datasets.

Design and Development of System for Music Instruments Identification Using SVM

Pooja Trivedi,Suraj Maurya,Pratik Baheti,Vaishali Nirgude
Thakur College of Engineering and Technology
Mumbai, India
surajmaurya029@gmail.com,pratikbaheti13@gmail.com,vaishali.nirgude@thakur education.org

Abstract— **Music instruments are hard to classify as many of them have a very minor difference in their sound signature. It is hard even for humans a while to differentiate between similar sounding instruments. Main focus of this system is to classify instrument recording. This identification system has been implemented by various algorithms like K-Nearest Neighbors (KNN), Convolutional Neural Network (CNN), Naïve Bayes, Support Vector Machine (SVM), etc. By comparing the algorithms, SVM gave better accuracy than K-means, Naïve Bayes and it is also less complex than CNN. Therefore, the proposed system will be implemented by using SVM. All the previous work is done on static dataset only but this system is also focusing on dynamic data as well. The input to this model consist of individual audio recording for each instrument in Wav format. To perform feature abstraction firstly audio file is processed by the district Fourier transform to normalized signal and label each example with a unique integer corresponding to instrument class. Then by MFCC technique features are extracted and use this data to classify, analyses and train multi- class SVMs to make predictions on the test set. The system is expected to give approximately more than 90% of accuracy as outcome.**

Keywords— **Music Instrument Identification, SVM, Prediction of Musical Instrument, Classification of Instruments, MFCC.**

I. INTRODUCTION

Music is formed by using various instruments and vocals from a person's in most cases. Music instruments are hard to distinguish as they have a very small difference in their sound architect. Even humans cannot properly differentiate between similar sounding instruments. Instrument sounds played by Different artists are also different as each one of them have their own style and character and also the quality of the instrument brings some differences. Recognizing which instrument is playing in a music will help in recommending songs to a user more accurately as by knowing persons listening habit we can know if they prefer a particular instrument and make better recommendations to them. These suggestions could be tailored according to a person's liking. Searching for music will also be benefited as from the longest time only way songs or music has been searched is by typing its name or an instrument, this can be optimized as we can add more filters to the search and fine tune the parameters instruments. Anyone who is searching for an artist can easily sort songs based on instruments which are being played in the background. It can also help to see which instruments are more popular and where this may help to cater more precisely to a selected portion of the populous [1]. Using SVM to classify images has been extensively researched and has produced highly accurate results. Using these detailed results and applying them to segregate instruments is our goal. Ample research has also been carried out to classify instruments. SVM have been used for classifications in many applications since many years with great results and to apply these to instrument recognition in music is the key idea which may help to achieve satisfactory results.

III. PROPOSED WORK

In this model, the dataset is applied on different algorithms like KNN, K-means, SVM, etc. and because of the accuracy measure of SVM, it will be being used for implementation of this system.

Support Vector Machines (SVMs) are one among foremost popular strong machine learning algorithms for classification, for their simple use and wide success. SVM is one among the efficient algorithm in machine learning. It is systematic in computation and vigorous in high dimension. SVM can also be used for classification as well as regression problems. The architecture is very much simple. The number of features required for recognition is less.

All the previous work is implemented on the static dataset. So in this model we are trying to focus on Dynamic dataset as well. The basic block diagram of the system is, as shown in the Fig. 1.

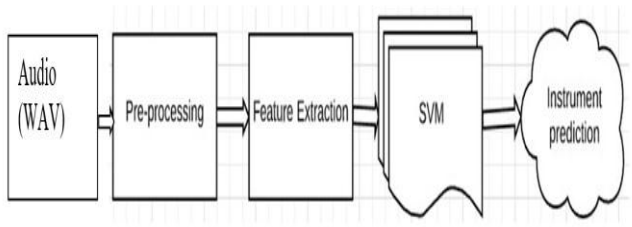

Fig. 1: Block Diagram

A. Dataset

The database is maintained which consists of all the different sound samples of musical instruments. The Database of music are the sets which have been classified into two sets i.e. training and testing.

B. Pre-Processing

Then in preprocessing step, it focuses on two stages of reading sounds and noise removal. To increase the accuracy of instrument recognition and to improve the strength of the signal Noise Reduction is used. Pre-processing is also used because the efficiency of subsequent feature extraction and classification stages can be increased so that it can enhance the overall retrieval performance.

C. Feature Extraction

After completion of pre-processing, main part of the project is executed- feature extraction. For different musical instruments different features will be extracted. Feature extraction is used to minimize the amount of data and to extract the meaningful and useful information from the given audio signal for a particular retrieval task.

D. Applying Algorithm

Further in the next step SVM algorithm is applied on the dataset to classify the instruments. Support Vector Machine works on principle based on training through inputs, using supervised learning techniques to classify data. This algorithm have somewhat complex hierarchy and design but it provides good results. The biggest plus point of SVM is that it easy to train. After the dataset passes through the algorithm, the result is then generated which consist of predicted instruments.

IV. METHODOLOGY

In ML, support vector machines (Support Vector Networks) are supervised learning models with associated learning algorithms that analyze the processed information and recognize patterns which are used for classification and multivariate analysis [5]. Given a group of training examples, each clear as belonging to at least one of two categories, an SVM training algorithm builds a model that allots new examples into one category or the opposite, making it a non-Probabilistic binary linear classifier. An SVM model may be a Representation of the examples as points in space, mapped in order that the samples of the separate categories are divided by a transparent space that is as large as possible [3].

SVM is a useful technique for data classification. Even though it's considered that Neural Networks are easier to use than this, however, every so often unsatisfactory results are obtained. A classification task usually involves with training and testing data which contains some data instances. Each example in the training set contains one target values and several attributes. The objective of SVM is to generate a model which predicts target value of knowledge instances within the testing set which are given only the attributes.

The Fig. 2 shows the process of Feature Extraction.

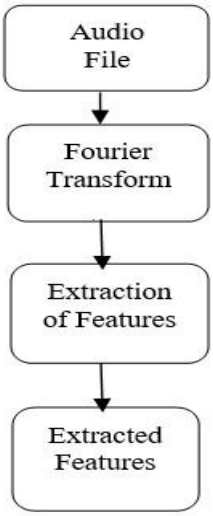

Fig. 2: Feature Extraction

Firstly, the audio file that is taken for consideration.

Then the audio fie is processed by using the Fourier Transform. It consist of transforming the sample of audio from time domain to frequency domain. This process results int frequency spectrum.

Feature extraction helps in representing the examples to be classified in terms of feature vectors or pairwise similarities. In this system, MFCC is used for extraction of features.

Finally, the extracted features are used further for classification of music instruments.

MEL-FREQUENCY CEPSTRAL COEFFICIENTS (MFCC)

MFCC is one of the standard feature among all feature set. MFCCs are consider as a way of representing the spectral information in a sound. Each and every coefficient has a value for each frame of the sound. MFCC is now being utilized in speech research and voice identification systems. In the sound identification system, the Mel-scale frequency is analogous to the perceived frequency, and is the most ordinary used simple frequency scale transformation equation, as described below. Let Mel be the Mel frequency and f be the actual frequency [4].

$$mel(f) = 2595 \cdot \log_{10}(1 + \frac{f}{700})$$

Fig. 3: MFCC Formula

The following Fig. 4 shows the basic working of SVM [6].

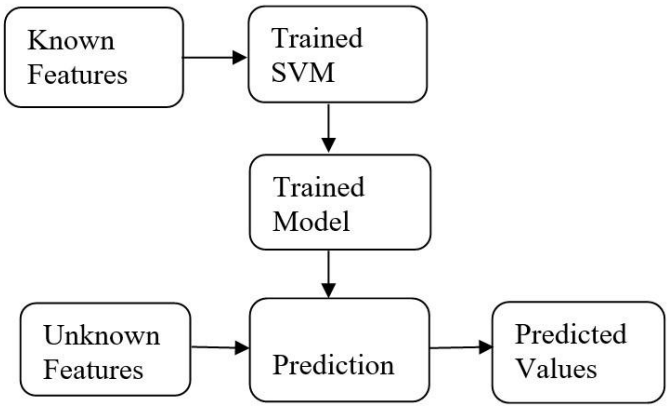

Fig. 4: Prediction of values using SVM

The Algorithms works on two datasets- training and testing.

The features of known are the training set and are passed for training the model. If the algorithm is trained properly by using sufficient training dataset, then it will predict more accurately for the unknown sets.

After the model has been trained by using the training set, it can be used for predicting the values of unknown features which are nothing but the testing set.

The testing set is passed for SVM prediction and the result of this set is the predicted values.

In this case it is the classified list of music instruments which are being played in the music track.

V. RESULTS AND DISCUSSION

The problem of classifying musical instruments is solved by this system. By using the SVM algorithm and performing operations on it will be able to generate classified musical instrument list. So, after the implementation of the project the output should come as successful classification of the instruments that are played in the audio file. The outcome should be with maximum accuracy in showing the instruments. Implementation on static dataset gave us the accuracy of 99% as shown in the Fig. 5. For the dynamic dataset 90% of accuracy is expected in the result.

```
In [19]: # Recall - the ability of the classifier to find all the positive samples
         print("Recall: ", recall_score(test_classes, predicted_labels,average=None))

         # Precision - The precision is intuitively the ability of the classifier not to
         #label as positive a sample that is negative
         print("Precision: ", precision_score(test_classes, predicted_labels,average=None))

         # F1-Score - The F1 score can be interpreted as a weighted average of the precision
         #and recall

Accuracy: 0.99  , 149
Number of samples: 150
```

Fig. 5: Accuracy Result

The instruments which were used for the classification were cello, flute, oboe, sake, trumpet, viola. Confusion matrix is the raw result from automatic classification, presented in percentage. The values in diagonal cells are the accuracy of classification. For reading the value, system predicted 24 samples right out of 25 for Cello and it predicted 25 samples out of 25 right for Flute. Fig. 6 shows the Confusion Matrix for the results.

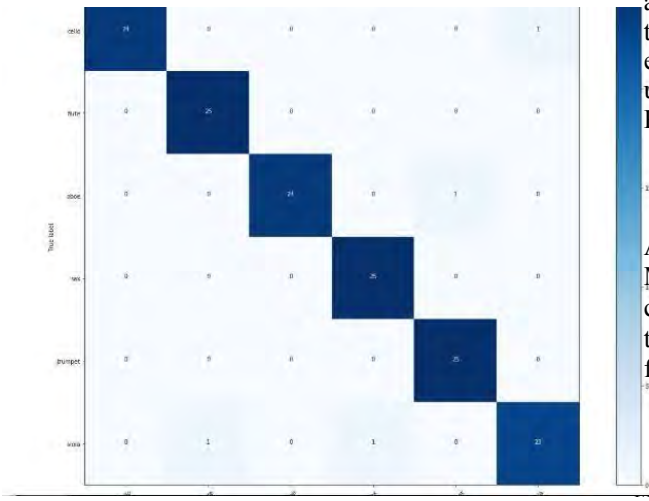

Fig. 6: Confusion Matrix

VI. Conclusion

When identifying musical instruments, selecting an indicative subset of features to predict on is extremely important. Selection of the most excellent contributing features to be extracted and the selection of the top suited method of classification are the most important decisions to be made for the content based audio classification. SVMs can be trained efficiently for audio classification. First, a group of training data is out there and can may be used to train a classifier. Second, once trained, the calculation in a SVM depends on a usually small number of supporting vectors and is speedy. Third, the distribution of audio data in the feature space is complex and different classes may have overlapping or interwoven areas. A kernel based SVM is well right to handle such a situation. SVM, implements mapping of inputs onto a high dimensional space with a group of non- linear basis functions. SVM can be used to study a variety of representations, such as neural nets, splines, polynomial estimators, etc, but there is a exclusive optimal solution for each selection of the SVM parameters. The results of the proposed scheme suggest the successful classification of musical instruments. Choosing the right feature for classifier can not only improve the accuracy, but also reduce attributes. Less attributes and higher accuracy are the basis of real-time automatic classification systems.

VII. Future Scope

The scope for exploring this system is endless. The future work can be done by combining MFCC with other features or using some feature selection algorithms to reduce attributes and eliminate similarity to get maximum marginal SVM. Less attributes and higher accuracy are the basis of real-time automatic classification systems.

Also Deep learning algorithms, Neural Networks algorithms when combined with feature extraction techniques gives the maximum accuracy. This can be explored for the real time systems and can also be used for different applications of Music Instrument Retrieval.

Design and Development of System for Removal of Background in Images using Semantic Segmentation

Saurabh. B . Jha,Saurabh. P. Jha,Meetu Bhardwaj ,Dr. Sheetal Rathi
Computer Engineering
TCET Mumbai, India
saurabh.jha009@gmail.com, saurabhjha57@gmail.com meetubhardwaj15@gmail.com ,

Abstract— **Image segmentation is that the task of partitioning a picture into multiple segments. This makes it a whole lot easier to analyze the given image. And essentially, that is what we are always striving for in computer vision. This is quite almost like grouping pixels together on the idea of specific characteristic(s). Now these characteristics can often lead to different types of image segmentation. Image segmentation may be a longstanding computer Vision problem. Quite a few algorithms have been designed to solve this task, such as the Watershed algorithm, Image thresholding, K-means clustering, Graph partitioning methods, etc. removal of background images also require image segmentation where we divide the fore image with background image and gets it available for analysis. Removing the background from the image makes the fore image easy to study and becomes much useful for the e-commerce sites for sale where the images are required to have white back**

Keywords—Artificial Intelligence, Segmentation, Image.

I. INTRODUCTION

Image segmentation is that the division of an image into regions or categories, which correspond to different objects or parts of objects. Every pixel during a picture is allocated to a minimum of one among sort of those categories. an honest segmentation is typically one during which, pixels within an equivalent category have similar greyscale of multivariate values and form a connected region and neighbouring pixels which are in several categories have dissimilar values. The results of image segmentation could also be a group of segments that collectively cover the entire image, or a gaggle of contours extracted from the image (see edge detection). Each of the pixels during a neighbourhood are similar with regard to some characteristic or computed property, like colour, intensity, or texture. Adjacent regions are significantly different with regard to the same characteristic(s). When applied to a stack of images, typical in medical imaging, the resulting contours after image segmentation are often used to create 3D reconstructions with the help of interpolation algorithms like marching cubes. Having no background within the image helps to know the foe image properly and helps the customer visiting the e-commerce sites view the merchandise more appropriately and evaluate it properly before making any purchase. E-commerce sites make sure the product available at their websites are authentic and of excellent quality. Customers don't have privilege to see the merchandise physically like old fashioned shopping in order that they need to make sure the product is clearly visible to them through pictures altogether different angles possible. During this any kind of background may create complexity in understanding the merchandise so it's best to get rid of the background from the image.

II. ALGORITHM AND DESIGN PHASE

Block Diagram

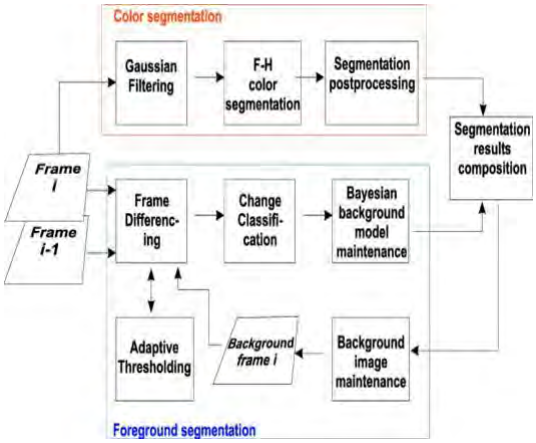

Fig: General System Block Diagram

Description:

In the overall system the image get divided into multiple frames which later goes under differencing and classification for experience learning and takes a background maintenance to differentiate fore and background image. Further it goes under segmentation and is restored using thresholding

III. PROPOSED WORK

Cleaning: -To remove noise, we use a simple median filter to remove the outliers, but one can use a different noise removal approach or artefact removal approach. The artefact vary across acquisition systems (microscopy techniques) and may require complicated algorithms to restore the missing data. Artefacts commonly fall into two categories:

- blurry or out-of-focus areas
- imbalanced foreground and background (correct with histogram modification)

Segmentation: -For this article, we limit segmentation to Otsu's approach, after smoothing an image using a median filter, followed by validation of results. You can use an equivalent validation approach for any segmentation algorithm, as long because the segmentation result's binary. These algorithms include, but aren't limited to, various Circular Thresholding approaches that consider different color space.

Some examples are:

- Li Thresholding
- An adaptive thresholding method that is dep indent on local intensity
- Deep learning algorithms like UNet used commonly in biomedical image segmentation
- Deep learning approaches that semantically segment an image

Validation: -We begin with a ground truth data set, which has already been manually segmented. To quantify the performance of a segmentation algorithm, we compare ground truth with the anticipated binary segmentation, showing accuracy alongside simpler metrics. Accuracy are often abnormally high despite a coffee number of true positives (TP) or false negatives (FN). In such cases, F1 Score and MCC are better quantification metrics for the binary classification. We'll go into detail on the pros and cons of these metrics later. For qualitative validation, we overlay the confusion matrix results i. e where exactly the true positives, true negatives, false positives, false negatives pixels are onto the grayscale image. This validation also can be applied to a color image on a binary image segmentation result, although the info we utilized in this text may be a grayscale image. In the end, we'll present the entire process in order that you'll see the results for yourself. Now, let's look at the data –and the tools used to process that data.

Loading and visualizing data

We will use the below modules to load, visualize, and transform the data. These are useful for image processing and computer vision algorithms, with simple and complex array mathematics. The module names in parentheses will help if installing individually.

FIG (importing modules)

Individual tiles can be mapped to run on
Multiprocessing/multithreaded (i.e. distributed
Infrastructure), then stitched back together to get the
Complete segmented image.
Fig loading and visualizing

Pre-processing
Before segmenting the info, you ought to undergo the dataset thoroughly to work out if there are any artifacts thanks to the imaging system. In this example, we only have one image in question. By watching the image, we will see that there aren't any noticeable artifacts that might interfere with the segmentation. However, you'll remove outlier noise and smooth a picture employing a median filter. A median filter replaces the outliers with the median (within a kernel of a givensize).

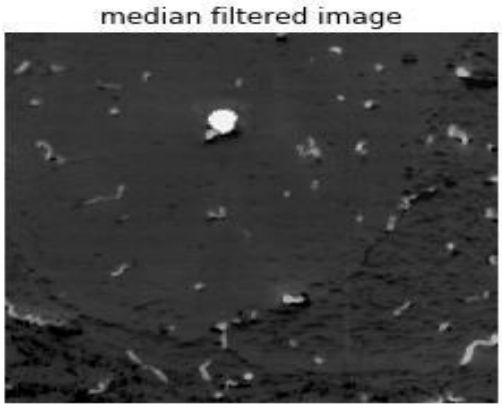

Fig: Median Filter Image

To determine which thresholding technique is best for segmentation, you could start by thresholding to determine if there is a distinct pixel intensity that separates the two classes. In such cases, you can use that intensity obtained by the visual inspection to binarize the image. In our case, there seem to be a lot of pixels with intensities of less than 50 which correspond to the background class in the inverted grayscale image.

Although the distribution of the classes isn't bimodal (having two distinct peaks), it still features a distinction between foreground and background, which is where the lower intensity pixels peak and then hit a valley. This exact value areoften obtained by various thresholding techniques. The segmentation section examines one such method intimately. *Visualize histogram of the pixel intensities*

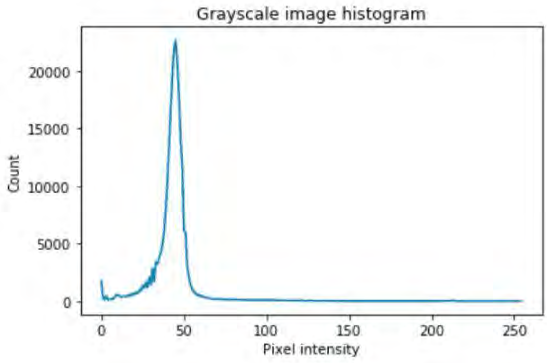

Fig: Grayscale Image Histogram

IV. REQUIREMENTS

Software Requirements-
- Front End-HTML, CSS, JavaScript o Back Python, Jupyter, Spyder
- Operating System

Hardware Requirements-
- Min Memory: 4GB o Disk size: 1TB
- Processor: 64bit CPU with 8 cores and speed of 2.4 GHz

User Requirement –

- Interface for inputting image o Output alteration space
- Output collection space

V. METHODOLOGY

The purpose of developing this project is to upgrade the automatic removal technique and make the process much faster. In this AI helps the user to make the output as per their choice and alter the specification as per their choice. User enabled camera or platform to run the system is to be compatible to receive desired output. Since the system is getting developed by artificial intelligence system keeps learning from the previous images and learning given.

It enables all the libraries required for the processing. Every iteration it visualizes the data to ensure the smooth procedure flow.

Segmentation: -
After removing noise, you'll apply the sk-image filters module to undertake all thresholds to explore which thresholding methods fare well. Sometimes, in a picture, a histogram of its pixel intensities isn't bimodal. So, there could be another thresholding method which will fare better like an adaptive thresholding method that does thresholding supported local pixel intensities within a kernel shape. It's good to ascertain what the various thresholding methods

results are, and sk-image filters thresholding try all threshold () is handy for that.

The simplest thresholding approach uses a manually set threshold for a picture. On the opposite hand, using an automatic threshold method on a picture calculates its numerical value better than the human eye and should be easily replicated. For our image during this example, it looks like Otsu, Yen, and therefore the Triangle method are performing well. the opposite results for this case are noticeably worse.

We'll use the Otsu thresholding to segment our image into a binary image for this text. Otsu calculates thresholds by calculating a worth that maximizes inter-class variance (variance between foreground and background) and minimizes intra-class variance (variance within foreground or variance within background). It does well if there's either a bimodal histogram (with two distinct peaks) or a threshold value that separates classes better.

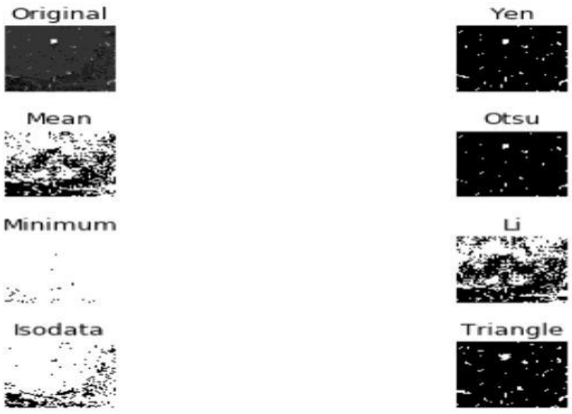

Fig: Otsu Visualization

Otsu thresholding and visualization

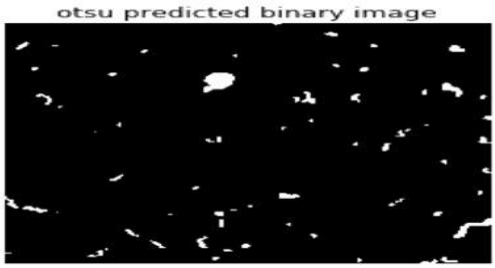

Fig: Otsu Binary Image

If the above simple techniques don't serve the aim for binary segmentation of the image, then one can use UNet, ResNet with FCN or various other supervised deep learning techniques to segment the images. To remove small objects thanks to the segmented foreground noise, you'll also consider trying skimage.morphology.remove_objects(). Validation

In any of the cases, we'd like the bottom truth to be manually generated by a person's expertly within the image type to validate the accuracy and other metrics to see how well the image is segmented.

The confusion matrix

We use sklearn.metrics.confusion_matrix() to urge the confusion matrix elements as shown below. Scikit-learn confusion matrix function returns 4 elements of the confusion matrix, as long as the input may be a list of elements with binary elements. For edge cases where everything is one binary value(0) or other(1), sklearn returns just one element. We wrap the sklearn confusion matrix function and write our own with these edge cases covered as below:

Groundtruth

Predicted	Foreground (255, vessels)	Background (0, tissue)
Foreground (255,vessels)	True Positive (TP)	FP (False Positive)
Background (0, tissue)	False Negative (FN)	TN (True Negative)

Fig: Image Confusion Matrix

Accuracy: - -Accuracy is a common validation metric in case of binary classification. It is calculated as

$$\frac{TP + TN}{TP + TN + FP + FN}$$

Fig:Accuracy Formula

where TP = True Positive, TN = True Negative, FP = False Positive, FN = False Negative

It varies between 0 to 1, with 0 being the worst and 1 being the best. If an algorithm detects everything as either entirely background or foreground, there would still be a high accuracy. Hence, we'd like a metric that considers the imbalance in school count. Especially since the present image has more foreground pixels (class 1) than background 0.

F1 score

The F1 score varies from 0 to 1 and is calculated as:

$$\frac{2*TP}{2*TP + FP + FN}$$

Fig: *F1 Score value*

with 0 being the worst and 1 being the simplest prediction. Now let's handle F1 score calculation considering edge cases. An F1 score of above 0.8 is considered a good F1 score indicating prediction is doing well.

MCC**:** -*MCC* stands for Matthews Correlation Coefficient, and is calculated as:

$$\frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

Fig: Mathhews Correlation Coefficient

It lies between -1 and +1. -1 is absolutely an opposite correlation between ground truth and predicted, 0 is a random result where some predictions match and +1 is where absolutely everything matches between ground and prediction resulting in positive correlation. Hence, we need better validation metrics like MCC.

In MCC calculation, the numerator consists of just the four inner cells (cross product of the elements) while the denominator consists of the four outer cells (dot product of the) of the confusion matrix. In the case where the denominator is 0, MCC would then be ready to notice that your classifier goes within the wrong direction, and it might notify you by setting it to the undefined value (i.e. numpy, nan). But, for the aim of getting valid values, and having the ability to average the MCC over different images if necessary, we set the MCC to -1, the worst possible value within the range. Other edge cases include all elements correctly detected as foreground and background with MCC and F1 score set to 1. Otherwise, MCC is about to -1 and F1 score is 0.

To learn more about MCC and therefore the edge cases, this is often an honest article. To understand why MCC is better than accuracy or F1 score more in detail, Wikipedia does good work here.

Finally, we will compare the validation metrics by result, side-by-side.

Accuracy is close to 1, as we have a lot of background pixels in our example image that are correctly detected as background (i.e. true negatives are are naturally higher). This shows why accuracy isn't an honest measure for binary classification.

F1 score is 0.84. So, during this case, we probably don't need a more sophisticated thresholding algorithm for binary segmentation. If all the pictures within the stack had similar histogram distribution and noise, then we could use Otsu and have satisfactory prediction results.

The MCC of 0.85 is high, also indicating the ground truth and predicted image have a high correlation, clearly seen from the predicted image picture from the previous section. Now, let's visualize and see where the confusion matrix elements TP, FP, FN, TN are distributed along the image. It shows us where the threshold is picking up foreground (vessels) when they are not present (FP) and where true vessels are not detected (FN), and vice-versa.

Validation visualization

To visualize confusion matrix elements, we find out exactly where within the image the confusion matrix elements fall. For example, we find the TP array (i.e. pixels correctly detected as foreground) is by finding the logical "and" of the bottom truth and therefore the predicted array. Similarly, we use logical boolean operations commonly called as Bit blit to find the FP, FN, TN arrays.

Then, we can map pixels in each of these arrays to different colors. For the figure below we mapped TP, FP, FN, TN to

The CMYK (Cyan, Magenta, Yellow, Black) space. One could similarly also map them to (Green, Red, Red, Green) colors. We would then get a picture where everything in red signifies the wrong predictions. The CMYK space allows us to differentiate between TP, TN.

We use opencv here to overlay this color mask onto the first (non-inverted) grayscale image as a transparent layer. This is Called Alpha compositing:

Fig: Overlay Mask

VI. TECHNOLOGY USED

1) Python

Python is an interpreter, object-oriented, high-level programing language with dynamic semantics. Its high-level inbuilt data structures, combined with dynamic typing and dynamic binding, make it very attractive for Rapid Application Development, also as to be used as a scripting or glue language to connect existing components together. Python's simple, easy to find out syntax emphasizes readability and thus reduces the value of program maintenance. Python supports modules and packages, which inspires program modularity and code reuse. The Python interpreter and therefore the extensive standard library are available in source or binary form for free of charge for all major platforms, and may be freely distributed.

2) *Jupyter Notebook*

The Jupyter Notebook is a a living online notebook, letting faculty and students weave together computational information (code, data, statistics) with narrative, multimedia, and graphs. Faculty can use it to line up interactive textbooks, filled with explanations and examples which students can test out right from their browsers. Students can use it to elucidate their reasoning, show their work, and draw connections between their classwork and therefore the world outside. Scientists, journalists, and researchers can use it to open up their data, share the stories behind their computations, and enable future collaboration and innovation

3) *Spyder:*

A spider is a software program that travels the online (hence the name "spider"), locating and indexing websites for search engines. All the main search engines, like Google and Yahoo!, use spiders to create and update their indexes. These

Programs constantly browse the online, traveling from one hyperlink to a different.

VII. CONCLUSION

The current system being used is developed using advanced photoshop due to which accuracy is not obtained whereas the new system is developed using Artificial Intelligence helping to attain optimization. Segmentation will make the task much faster than the manual technology. Process of bulk images processing can be thought due to this. It will help the seller and buyer both on the e-commerce webpages as the seller can easily and quickly obtain the desired image. Buyer can evaluate the product more accurately due the precise image uploaded. Artificial Intelligence makes the process faster and quicker just as required in today's world

Abstract—**Voice is the basic and most used way of communication used for interaction. Numerous technologies enable machines to respond correctly and reliably to human voices and provide convenient and valuable services. Speech recognition is an useful application of Digital Signal Processing and has many real-world applications. Automatic Speech Recognition of gender, age group, emotion and disease from speech segments can be done using digital speech processing and pattern recognition techniques. Speaker recognition is the process of automatically recognizing who is speaking on the basis of individual information included in speech waves. The main aim of this study is to create an accurate system for voice analysis. Acoustic coefficients were used to form test and reference templates.**

Keywords—voice analysis, voice feature extraction, speech processing, emotion recognition

I. INTRODUCTION

Interactive communication is an interface which involves the exchange of reciprocal ideas and emotions. Gestures and sound are a way of conveying information in a human-to- human interaction. Speech, a special form of sound, is one of the vital ways of conveying information between people. Words are not sole component of speech. Acoustic properties of speech also carry important affecting features. Emotions exist in every part of the speech. Emotions in speech are transmitted from one communicator to another during an interaction. As a result of exchange of emotions during an ongoing conversation, emotional state of a speaker may straightforwardly trigger an panelist emotional state resulting in a change in the speech style or tone.

Timbre, speech rate, and length are certain characteristics that discriminate human voices, mainly male and female voices. Distinction in gender can not be predicted by vocal speech. Some voice pitch may vary between male and female so it is difficult to predict male and female accurately. We can identify the gender of the respective speaker with the help of techniques used for speech processing in real time environment. Voiced fold thickness is the main reason behind the difference that can be calculated between the genders. Another reason that contributes to is the style in which the person speaks and the present physical situations.

II. FEATURES SELECTION

Many different speech feature extraction methods have been proposed over the years. Methods are distinguished by the ability to use information about human auditory processing and perception, by the robustness to distortions, and by the length of the observation window. Due to the physiology of the human vocal tract, human speech is highly redundant and has several speaker-dependent features, such as pitch, speaking rate and accent. An important issue in the design of a speech emotion recognition system is the extraction of suit-able features that efficiently characterize different emotions. Although there are many interesting works about automatic speech emotion detection there is not a silver bullet feature for this aim. Since speech signal is not stationary, it is very common to divide the signal in short segments called frames, within which speech signal can be considered as stationary. Human voice can be considered as a stationary process for intervals of 20 ms to 40 ms. If a feature is computed at each frame is called local, otherwise, if it is calculated on the entire speech is named global. There is not agreement in the scientific community on which between local and global features are more suitable for speech emotion recognition.*A.*

A.GENDER RECOGNITION FEATURES

Together with the Mel Frequency Cepstral Coefficients (MFCC) pitch is the most frequently used feature since it is a physiologically distinctive trait of a speaker's gender. Other employed features are formant frequencies and bandwidths, open quotient and source spectral tilt correlates energy between adjacent formants, fractal dimension and fractal dimension complexity jitter and shimmer (pitch and amplitude micro-variations, respectively) harmonics-to- noise-ratio, distance between signal spectrum and formants.

B. EMOTION RECOGNITION FEATURES

Coherently with the wide literature in the field, a set of 182 features have been analysed for each the recorded speech signal, including: Mean, adjustment, median, minimum, maximum and range of the amplitude of the speech Mean, variance, minimum, maximum and range of the formants; Energy of the Bark sub-bands Mean, variance, minimum, maximum and range of the Mel-Frequency Cepstrum Coefficients Spectrum shape features Centre of Gravity, Standard Deviation, Skewness and Kurtosis; Mean and standard deviation of the glottal pulse period, jitter local absolute, relative usual perturbation, difference of difference period and (–ve) point period perturbation quotient. various classification techniques like vector quantisation, dynamic time wrapping, support vector machine, Gaussian mixture model and artificial neural network. This paper described all these techniques in detail.

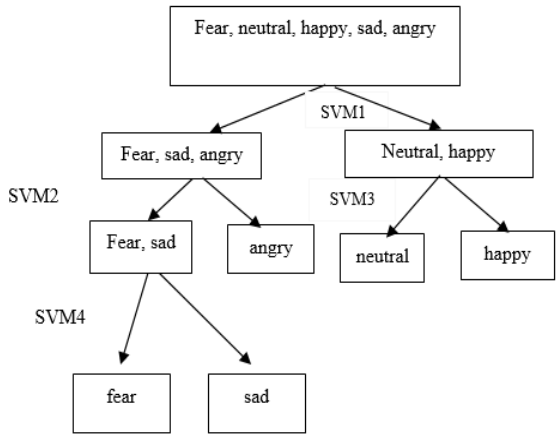

Figure 1: Overview of emotion analysis

C. DISEASE RECOGNITION

Voice features are extracted using some DSP techniques. These features contain information on health of voice tract and of the organs cooperating in speech production. These features represent the particular voice and may be used to discriminate voice of healthy and unhealthy persons. The time field analysis, spectrum analysis, cepstrum analysis, glottal waveform analysis are used to extract the voice

D.AGE GROUP RECOGNITION

Voice is a feature which changes with gender, age and state of mind. Features drastically change as we age. Higher pitch voice in men , lower pitch voice in women, reduced volume and projection of the voice(or thin voice) ,reduced vocal resolution , struggle being heard in noisy situations, tremor or shakiness in the voice, etc .These symptoms are amplified by the reduced hearing ability that commonly occurs in our peers as we age.

III. SYSTEM ARCHITECTURE

We have two phases: testing and training phases. We sampled and tested hundreds of voice samples in the testing phase. All the results of these voice samples are stored in the database. The human voice goes through the following steps: Features of voice are extracted these features are passed through different algorithms to find out the different results we want. First we pass the features through gender identification model, then through age classification algorithm and then emotion. From the testing phase, a feature model is created. This feature model is used for prediction of voices in the training phase.features. These features are then classified into groups using

IV.TECHNOLOGY USED

[1]MFCC

In sound processing, the mel-frequency cepstrum is a representation of the short-term power spectrum of a sound, based on a linear cosine transform of a log

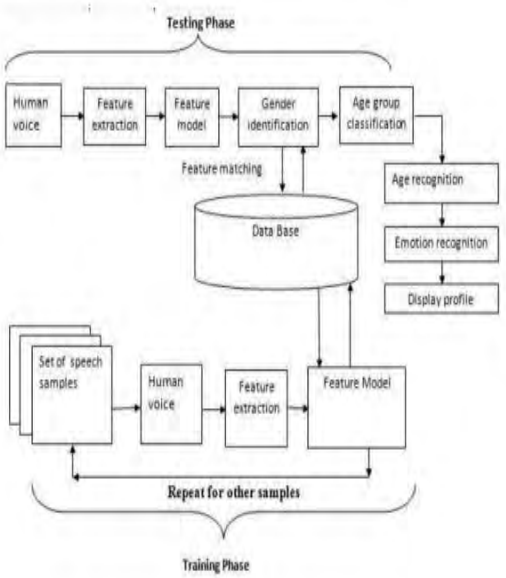

Figure 2: System architecture

power spectrum on a nonlinear mel scale of frequency. Mel- frequency cepstral coefficients are coefficients that collectively make up an MFC. It is used to extract different features of voice like pitch, frequency ,loudness,etc.

[2] HMM

Modern general-purpose speech recognition systems are based on Hidden Markov Models.HMMs are used in speech recognition because a speech signal can be viewed as a short-time stationary signal. In a short time- scale, speech can be approximated as a stationary process.Another reason why HMMs are popular is because they can be trained repeatedly and are simple and computationally feasible to use.We have used HMM in gender identification. [3] GMM Gaussian Mixture Modelling are basically used to model the speech feature distribution.We have used it along with HMM.

[4] Tkinter

Python provides many methods of creating a Graphical User Interface GUI. Tkinter is one of the easiest and most popular methods of creating a GUI in python.It is an in- built Tk GUI toolkit provided in python.Due to easy programming we have used tkinter to develop the GUI.

[5] Pygame

Pygame is a cross-platform set of Python modules mainly designed for writing video games.It also has sound libraries designed to be used with the Python programming language.

[6] SciPy

SciPy is an open-source Python library used for scientific computing and technical computing. SciPy contains modules for FFT, signal and image processing,We have used it along with MFCC to extract voice features.

[7] Librosa

Librosa is a python package for music and audio analysis. It provides the building blocks necessary to create music information retrieval systems

VII. CONCLUSION

This review paper is to create a smart system which can be used in client interaction ,law implementation,speaker identification and psychological analysis. This can be achieved by a easy microphone transducer with some programming

involved. Thousands of inputs can be given and the voice acknowledgement can be achieved to find the age range of a person who has spoken. This can also provide cyber security. Further modifications can be made for the same. The proposed system, able to recognize the emotional state of a person starting from acoustic signals registrations,is composed of 4 functional blocks: Gender Recognition (GR) ,age group recognition(AGR),Disease recognition(DR), Emotion Recognition (ER). They have been implemented by a Pitch Frequency Estimation method, Support Vector Machine ,MFCC,ANN etc.(SVM) classifiers (fed by properly selected audio features), which exploit the GR subsystem output. The performance analysis shows the accuracy obtained with the adopted emotion recognition system in terms of recognition rate and the percentage of correctly recognized emotional contents. The experimental results highpoint that the Gender Recognition (GR) subsystem allows increasing the overall emotion recognition .This happens due to the prior knowledge of the speaker gender.The results show that with the employment of a features selection algorithm, a satisfying recognition rate level can still be obtained also reducing the employed features and, as a con-sequence, the number of operations required to identify the emotional contents. This makes feasible future development of the proposed solution over mobile devices.

VIII. ACKNOWLEDGMENT

We would like to thank all our professors who helped us in making this review paper successful. We thank Mr. Shailesh Sangle for guiding us in progressing in our paper. We thank TCET for providing an opportunity for us to present our paper. We at last thank the almighty and our parents who helped us in achieving it.

Abstract— **in today's fast paced world, information on the internet is increasing at a very rapid rate. Because of this increasing information in the internet, text summarization is gaining more and more attention among the researchers. A system for text summarization is presented in this chapter. The specific problem under consideration is text summarization for key data extraction from research papers. This system aims to alleviate the burden of going through multiple lengthy research papers from the shoulders of the researchers by creating a summary of the desired research papers. The proposed system will make use of futuristic technologies like Natural Language Processing (NLP), Deep Learning and Attention Encoder Decoder Recurrent Neural Networks (RNN). NLP is used for parsing, reduction of words and to generate text summary in abstractive summarization. However at present NLP is a low cost technique and lacks precision. We propose a new dataset consisting of a select bunch of research papers to ensure the correctness of the system.**

Keywords— Neural Networks, Text, Summarization, NLP, Deep Learning, Encoder Decoder

I. INTRODUCTIN

Information and digital data in particular has expanded exponentially in the last few years. The world saw a dotcom boom at the turn of this century and it is estimated that 90% of the data has been created in the last 2 years alone. This increase in information has also led to a need to obtain a summarized version of data that can convey the basic crux of a situation in fewer words. With time becoming a rare commodity, individuals are constantly looking to acquire more in less time. This ideology formed the basis of our topic selection – to convey more by using less. Data Summarization as a concept has been cherished right from the inception of data not just digitally but also in ancient times for written content. Summaries were often substituted for the original document whenever time was a restricting parameter. However, the amount of information produced digitally has eclipsed all the other forms of information combined. This has led to summarization becoming more essential than ever before.

II. HISTORY

A. Automatic Summarization

Automatic summarization is the process of shortening a text document with software, in order to create a summary with the major points of the original document. Technologies that can make a coherent summary take into account variables such as length, writing style and syntax.

Automatic data summarization is part of machine Learning and data mining. The main idea of summarization is to find a subset of data which contains the "information" of the entire set. Such techniques are widely used in industry today. Search engines are an example; others include summarization of documents, image collections and videos. Document summarization tries to create a representative summary or abstract of the entire document, by finding the most informative sentences, while in image summarization the system finds the most representative and important (i.e. salient) images.[Citation needed] For surveillance videos, one might want to extract the important events from the uneventful context.

Most early work on single-document summarization focused on technical documents. Perhaps the most cited paper on summarization is that of (Luhn, 1958), that describes
Research done at IBM in the 1950s. In his work, Luhn proposed that the frequency of a particular word in an article provides an useful measure of its significance. There are several key ideas put forward in this paper that have assumed importance in later work on summarization. As a first step, words were stemmed to their root forms, and stop words
Were deleted. Luhn then compiled a list of content words sorted by decreasing frequency, the index providing a significance measure of the word. On a sentence level, a significance factor was derived that reflects the number of occurrences of significant words within a sentence, and the linear distance between them due to the intervention of non- significant words. All sentences are ranked in order of their significance factor, and the top ranking sentences are finally selected to form the auto-abstract.

Edmondson (1969) describes a system that produces document extracts. His primary contribution was the development of a typical structure for an extractive summarization experiment. At first, the author developed a protocol for creating manual extracts that was applied in a set of 400 technical documents. The two features of word frequency and positional importance were incorporated from the previous two works. Two other features were used: the presence of cue words (presence of words like significant, or hardly), and the skeleton of the document (whether the sentence is a title or heading). Weights were attached to each of these features manually to score each sentence. During evaluation, it was found that about 44% of the auto-extracts matched the manual extracts

B. Machine Learning Models

In the 1990s, with the advent of machine learning techniques in NLP, a series of seminal publications appeared that employed statistical techniques to produce document extracts. While initially most systems assumed feature independence and relied on naive-Bayes methods, others have focused on the choice of appropriate features and 3 on learning algorithms that make no independence assumptions. Other significant approaches involved hidden Markov models and log-linear models to improve extractive summarization. A very recent paper, in Contrast, used neural networks and third party features (like common words in search engine queries) to improve purely extractive single document summarization.

The methods and models used were –

1) *Naive-Bayes Methods*
2) *Rich Features and Decision Tree*
3) *Hidden Markov Models*
4) *Neural Networks*

C. Mult- Document Summarization

Extraction of a single summary from multiple documents has gained interest since mid-1990s, most applications being in the domain of news articles. Several Web-based news clustering systems were inspired by research on multi-document summarization, for example Google News, Columbia News Blaster, News In Essence. This departs from single-document summarization since the problem involves multiple sources of information that overlap and supplement each other, being contradictory at occasions. So the key tasks are not only identifying and coping with redundancy across documents, but also recognizing novelty and ensuring that the final summary is both coherent and complete.

D. Problem Definition

The primary problem definition in our project is about extracting key information from research papers by using a text summarization tool. It involves the objective of reading the input data in the form of articles or documents which are analyzed and preprocessed in order to split it into several segments that are each attributed values. These are then converted into concrete semantic statements using several algorithms which will be mentioned. Our problem definition covers the concept of converting convoluted, mammoth data into a useful segment which is concise, yet does not lose the essence of the original document.

The project was conceptualized keeping in mind the fundamental goal of creating a tool which is able to convert towering amounts of data into concise summaries which have the potential to not just save time but also help reduce the amount of space required to save the data. File sizes can decrease by a huge percentage if the essence of the article is maintained and the paper has a lossless summary derived. While there are several milestones that we have determined, some of them are – obtaining keywords from articles and papers, creating a summary without diving into specifics, creating a summary that contains the specifics as well, obtaining semantically correct outputs which are human readable in nature.

The scope of this project is obtaining a tool which can efficiently translate data into a summarized form suitable for human readers. It involves detecting and extracting key words which can be used in generating the summary. Word groups based on glove values using RNN, LSTM and training our data set forms the basis of our implementation. These are useful to generate both extractive summaries and abstraction based summaries which will help to simplify major documents; in our case, that refers to the research papers and articles that we will use as a data set. Our end product deliverable will be a summary that will be lossless in terms of quality of information and be efficient enough to contain all the specifics of the original document. With no hardware requirements, the primary tool will be created and trained using existing libraries and frameworks by working on available workspaces like Google Colab

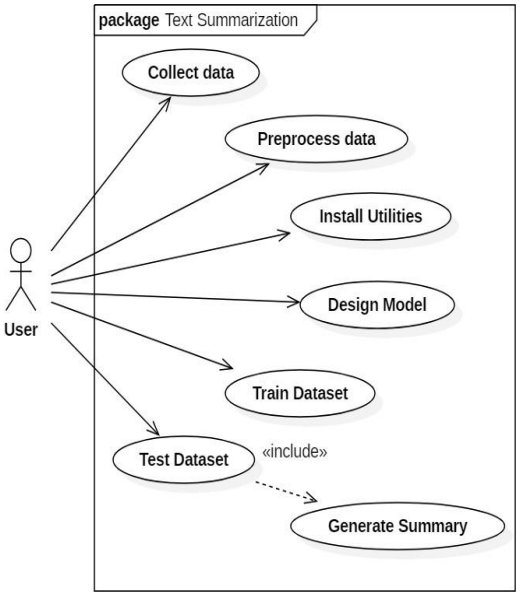
The project has a lot of scope of becoming something revolutionary, purely because of the sheer application that it incorporates due to the constantly booming data sources. While we intend to create a tool that will primarily focus on research papers and articles within a particular domain or realm, it is highly possible to expand the scope of the project to a wide array of applications. News articles have been converted into smaller bytes by In Shorts which shows the significance of summarization. Market trends, sentiment analysis, political inclinations and personal data points on individuals can all be summarized to provide a detailed yet concise output which can be stored in a much more controlled manner, using much lesser space. As someone looking to venture in the realm of Data Science, this concept holds widespread applications because it can assist in improving the process of preprocessing. Relevant keywords and data summaries can help eliminate the garbage values which will in turn speed up the process of extracting useful insights from available information..

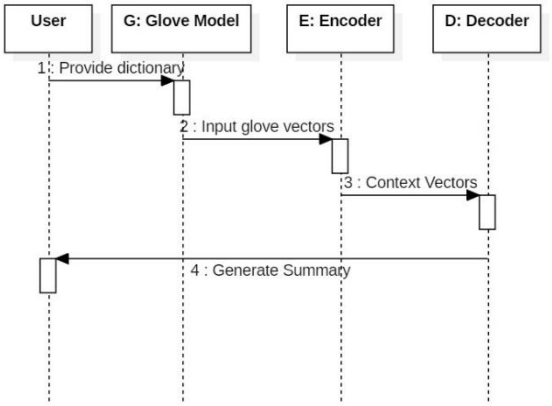
E. Proposed Aspects of the Project

This report is built to generate implementation approaches to address text summarization. It is built to simply run on Google Colab, in one notebook so one would only need an internet connection to run these examples without the need to have a powerful machine. The model generated is being trained using multiple data sets which have the potential to create a refined tool that can implicitly generate lossless summaries while keeping the crux and specifics of the information intact.

A seq2seq network with various rich features is used to begin
with the implementation. It's a machine translation model that was introduced by Google. Using deep learning, the model not just takes the current word into account but also its neighborhood. It takes as input a sequence of words and generates an output sequence of words. It does so by use of the recurrent neural network (RNN). Although the vanilla version of RNN is rarely used, its more advanced version i.e. LSTM or GRU are used. The concept of a pointer generator

is introduced to solve some flaws prevailing within the seq2seq network

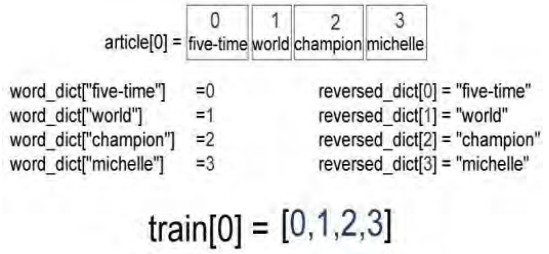




III. .SYSTEM ANALYSIS

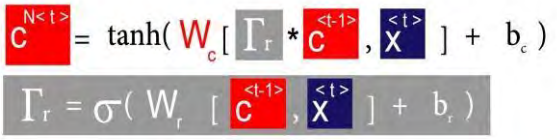
A. Techniques Used

*1) **Word Embedding** – For the text summarization to work, you must represent your words in a dictionary format. Each word in the corpus should have a representation in the dictionary. We would need the reverse operation also. After building the dictionary for our data, we would begin to build the actual dataset that would be used in our algorithm. The dataset would be represented by simply getting the collection of word dictionary for the words in the given sentence.*



*2) **Seq2seq** - RNN has a many-to-many architecture with same lengths for both input and output. However for text summarization, we need to have the ability to have different lengths for input and output. We need a special network that takes input of length (Tx), and generates another output of another different length (Ty), this architecture is called Encoder Decoder. Both the Encoder- Decoder here are RNN network, but encoder uses input, and generates an output state that is then used as input to decoder stage. However, there are 2 main problems with the RNN unit namely exploding gradients and vanishing gradients. Both GRU & LSTM solves the problem of vanishing gradients that normal RNN unit suffers from, they do it by implementing a memory cell within their network , this enables them to store data from early within the sequence to be used later within the sequence.*

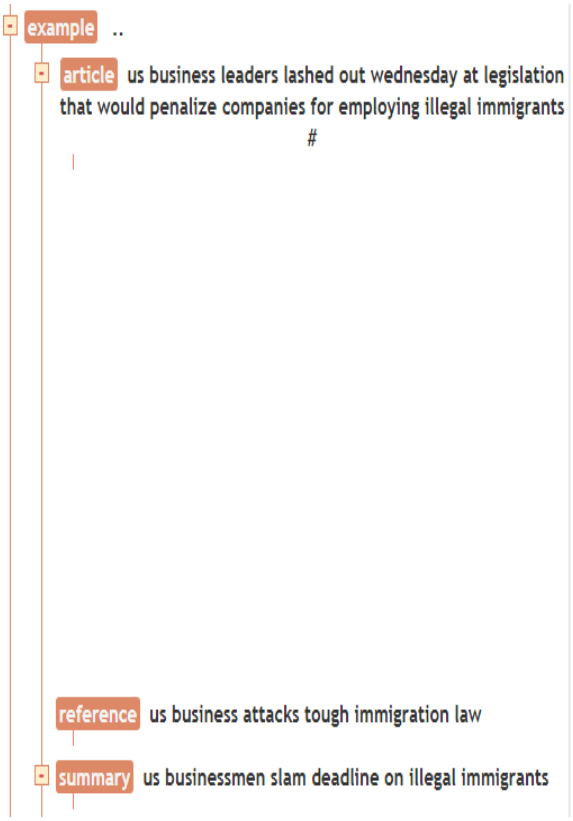
*3) **Gated Recurrent Unit (GRU)** - We have 4 main equations that govern the GRU:*



C here denotes for the memory cell , here it would be the output of the GRU cell. The N sub letter denotes that it is the newly proposed C value (we would use it latter to generate the real c output of the GRU. So here the new proposed output C (candidate), would depend on the old output C (old candidate) , and the current input at that time. To remember the value of C (candidate), we use another parameter called F (gate update) , this would control whether or not we would update the value of C via a sigmoid function. We also have a learnable (Fr) parameter to learn the relevance between C new and C old.

B. Algorithm

C. User Interface Design(Snapshot of Result)



IV. CONCLUSION

We have successfully been able to work on several aspects of creating a tool for text summarization. The state of the art has been found to be efficient, but this is the case of abstractive summarization methods, with the same data that we utilized. Of the literature reviewed, we found that the
best-performing methods extractive methods close to 11%.

Understandably, it is difficult to reach high values with extractive methods. We created and used algorithms to find and break the sentences to words that would generate the best summaries. Glove values have been used above while we utilized the concept of encoder-decoder to obtain words that can be related. We believe that such a metric should be "mandatory" on any paper proposing an extractive summarization method, as it sets a good reference - the direct opposite of the random baseline. The seq2seq method is implemented in its entirety but is improved on by using modern methods to increase efficiency.

The interesting thing is the variation, showing that summaries vary in their use of original words. By changing the methods by which we are generating summaries and training the models, we will be generating varied summaries for the same data set.

V. ACKNOWLEDGMENT

The preferred spelling of the word "acknowledgment" in America is without an "e" after the "g". Avoid the stilted expression "one of us (R. B. G.) thanks ...". Instead, try "R.B. G. thanks...". Put sponsor acknowledgments in the unnumbered footnote on the first page.

Abstract **The following section provides an overview of the derived web application for the descriptive online examination system. The current way of checking subjective paper is adverse. Evaluating the Subjective Answers is a critical task to perform. When human being evaluates anything, the quality of evaluation may vary along with the emotions of Person. In Machine Learning, all result is only based on the input data provided by the user.To begin with the purpose of the system is to conduct online descriptive exam in an efficient manner in terms of cost, time and safety, the system also tend to provide the area of improvements required by both teacher and student. The system would use the Natural Language Processing (NLP) for verification of answers and would use web development technology for the design of the web application. We are trying to extract meaning from the answer so that online assessment can be more accurate.**

Keywords: Tokenization, lemmatization,Stop words, bags-of-words, part of speech(POS), WordNet.

I. INTRODUCTION

Online Descriptive answer Assessment, an online tool that tackles your test requirements with friendly interfaces. It is mainly focused on managing university/school type exams containing descriptive questions or a mix of descriptive and objective type questions.

The current way of checking subjective paper is adverse. Evaluating the Subjective Answers is a critical task to perform. When human being evaluates anything, the quality of evaluation may vary along with the emotions of Person. In Machine Learning, all result is only based on the input data provided by the user.

The following section provides an overview of the derived web-application for the subject online examination system. To begin with the purpose of the document is presented and is intended to the audience. Subsequently, the scope of the project specified by the document is given particular focus on examination system and its relevant benefits. To conclude, a document overview is provided to felicitate better examination process**.**

.

II. LITERATURE SURVEY: -

Thomas N. T. Ashwini Kumar and Kamal Bijlani implemented e-learning system like Learning Management System (LMS) to assess candidate's descriptive answers and provide immediate feedback to teachers.[5] This is implemented by comparing candidate's answers with teacher's ideal set of answers using latent semantic analysis. Then evaluating order of previous and upcoming words in the answer using positional indexing based on the keyword list added by the teacher. Then final score is generated.

C rater [4] is a technique used for the content scoring. This content scoring is based on model building which makes various answer model for candidate's short answer. ETS (Education Testing Service) is used for examining small answer of candidate having near about 100 words. It uses systematic method & rubrics element which specify accurate & significant terms which should be exist in candidate's answer. The problem of dissimilar answer contents of candidate is resolved using c-rater. C rates includes the steps like Model building, C Rater automatically processes, maintaining algorithm gold map, Apply candidate answer**.**

III. TECHNOLOGY USED

NLP: - Natural Language processing is a wide domain covering concepts of Computer Science, Artificial Intelligence and Machine Learning. It is used to analyze text or how humans speak. One of the applications of NLP is Semantic Analysis(Understanding the meaning of text).

Django: - Django is a high-level Python Web framework that encourages rapid development and clean, pragmatic design. Built by experienced developers, it takes care of much of the hassle of Web development, so you can focus on writing your app without needing to reinvent the wheel. It's free and open source.

React JS: -Reactis a JavaScript library for building user interfaces. React can be used as a base in the development of single-page or mobile applications, as it is optimal for fetching rapidly changing data that needs to be recorded. However, fetching data is only the beginning of what happens on a web page, which is why complex React applications usually require the use of additional libraries for state management, routing, and interaction

with an API: Redux' React Router and axiosare examples of such libraries.

IV. IMPLEMENTATION DETAIL

Several methods have been suggested for descriptive answer assessment. The approaches are mainly based on text mining technique which involves keyword matching, sequence matching and quantitative analysis and semantic analysis.

- The system will use herically organized oracle system for assessment.
- System will use NLP to generate meaning for assessment.
- The system will be useful for subjective questions.
- The accuracy is high due to meaning extraction.

There are many ways text analytics can be implemented depending on the business needs, data types, and data sources. All share four key steps.

Step 1: Data Acquisition:

Text analytics begins with collecting the text to be analyzed -- defining, selecting, acquiring, and storing raw data. This data can include text documents, web pages (blogs, news, etc.), and online reviews, among other sources. Data sources can be internal or external to an organization.

Step 2: Data Preparation:

i. Once data is acquired, the enterprise must prepare it for analysis. The data must be in the proper form to work with machine learning models that will be used for data analysis. There are four stages in data preparation:

ii. Text cleansing removes any unnecessary or unwanted information, such as ads from web pages. Text data is restructured to ensure data can be read the same way across the system and to improve data integrity (also known as "text normalization").

iii. Tokenization breaks up a sequence of strings into pieces (such as words, keywords, phrases, symbols, and other elements) called tokens. Semantically meaningful pieces (such as words) will be used for analysis.

iv. Part-of-speech tagging (also referred as "PoS") assigns a grammatical category to the identified tokens. Familiar grammatical categories include noun, verb, adjective, and adverb.

v. Parsing creates syntactic structures from the text based on the tokens and PoS models. Parsing algorithms consider the text's grammar for syntactic structuring. Sentences with the same meaning but different grammatical structures will result in different syntactic structures.

Step 3: Data Analysis:

Data analysis is the process of analyzing the prepared text data. Machine learning models can be used to analyze huge volumes of data, and the outcome is typically produced as an API in JSON format or in a CSV/Excel file. There are many ways data can be analyzed, two popular approaches are text extraction and text tagging.

Text Extraction is the process of identifying structured information from unstructured text. Text Tagging is the process of assigning tags to text data based on its content and relevance.
Two common models for text tagging are "bag of words" and "Word2vec."

The bag-of-words method is the easiest method to understand, but it's outdated and has been deprecated. This method simply counts the number of words within the text content regardless of location and context. The disadvantage of this technique is that it does not offer a way to understand context from words content with a higher word count is given a higher (and, falsely, more relevant) score.

Word2Vec has become the preferred method of text tagging. Text collected for Word2Vec is turned into a vector, which provides relevant information about words (including synonyms). For example, the terms "man" and "boy" can be closely related. Word2Vec also understands that the words "humor" and "humour" should be treated the same way. Word2Vec produces a mesh of related words. The closer the words are to each other in the neural network, the stronger their relationship to each other. This neural net allows algorithms to better understand the context of words, so data scientists can generate better analysis of content relevancy.

We are checking the similarity between two answers using some NLP methods such as synsets(), wup_similarity(),etc. Synsets are organized in a Hypernym tree. This tree can be used for reasoning about the similarity between the Synsets it contains. The
closer the two Synsets are in the tree, the more similar they are. The wup_similarity() method is short for Wu-Palmer Similarity, which is a scoring method based on how similar the word senses are and where the Synsets occur relative to each other in the hypernym tree.

Step 4: Data Visualization:

Visualization is the process of transforming

$$\text{Wu} - \text{Palmer} = 2 * \frac{\text{depth}\,(\text{lcs}(s1, s2))}{(\text{depth}\,(s1) + \text{depth}\,(s2))}$$

analysis into actionable insights, representing the data in graphs, tables, and other easy-to-understand representations. Organizations can use a wide variety of commercial and open source visualization tools.

The Role of Natural Language Processing:

NLP is a component of text analytics. Most advanced text analytics platforms and products use NLP algorithms for linguistic (language-driven) analysis that helps machines read text. NLP analyzes words for relevancy, including related words that should be considered equivalent, even if they are expressed differently (e.g., humor vs. humour). It's the workhorse behind steps 2 and 3 described above.

One popular application of NLP is identifying relevant, quality content for search engines. For example, Google uses NLP in several ways, the most prominent of which is in search engine organization and categorization. Long ago, a webmaster could achieve a higher rank in Google search results just by stuffing keywords into web content, so Google revised how its search engine processed content using numerous algorithms and NLP. NLP helps Google identify "spammy" content and categorize it. Google may de-index this content, penalize it, or simply rank it much lower than other content.

NLP is also used in email spam filters. Spammers try their best to evade such filters by changing words around, purposely misspelling words, or using synonyms. Email spam filters use a variety of factors to identify and block spam, phishing, and malicious content. Gmail's filter, for example, incorporates machine learning and NLP to perform "sentiment analysis." If content is determined to likely be spam, the content is sent to the user's junk folder. For some content, Gmail deletes the message.

A decade ago, application of NLP was comparatively complicated. AI-based technologies (including NLP and text analytics) have evolved considerably, and there are many cloud services, commercial products, and open source platforms businesses can leverage. Here are few open source NLP applications:

- Stanford CoreNLP
- Natural Language Toolkit
- Apache Lucene and Solr
- Apache OpenNLP
- GATE and Apache UIMA
- A Final Word

Text analytics isn't new, but it is still unfamiliar to many organizations. With APIs,cloud-based AI services, and open source platforms available today, your business can leverage the power of text analytics to get a competitive edge by better understanding your customers and improving your brand's value.

V. RESULT AND DISCUSSION

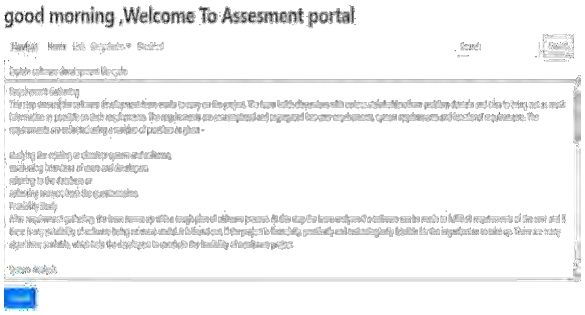

Fig 6.1 Teacher's Dashboard

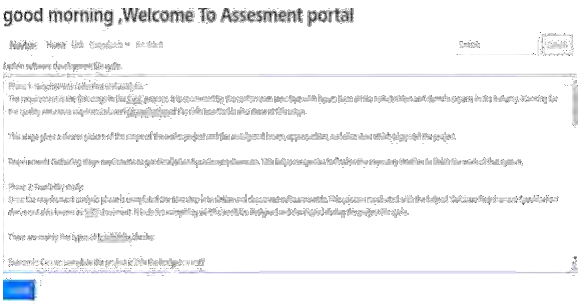

Fig 6.2 Student's Dashboard

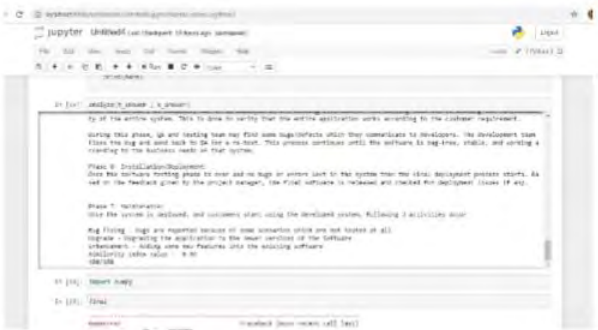

Fig 6.3 Result

VI. CONCLUSION

In this project we are using Natural Language Processing (NLP) technique for automatically evaluating the answer sheet in the form of text document for both objective and subjective type questions. The answer sheet is evaluated within the time limit. The mistakes that can occur during manual correction are reduced. Topics to be taught once again are also suggested. The work can be extended by parallelizing the evaluation process and reducing the time of evaluation.

Enhanced Interactive Intelligent Tutoring System

Dr. Anand Khandare, Rahul Yadav, Shubham Yadav, Mittal Jethva
Dept. of Computer Engineering
Thakur College of Engineering and Technology
Mumbai,India
parryrpy@gmail.com, ssubham.98@gmail.comm, mittaljethva.mj@gmail.com

Abstract— **Intelligent Tutoring System(ITS), is a computer-based self-learning system where students learn a specific topic. An Intelligent Tutoring System provides personalized learning content to students based on their requirements and preferences. And based upon their performance the analysis part will be done.**

ITS will contain a student's module and an adaptive engine. The student will be categorized based on bloom's taxonomy. The adaptive engine will use different pedagogy for each student to make the platform more interactive and challenging for the students. An adaptive system here, the next step of instruction which dependent upon student's performance. The objective of the system is to identify the capability of a student and the performance improvement needed by the student. And motivating the student for his/her learning process to give the appropriate encouragement, praise or reproach message. It is important to understand and represent the student's internal psychological states.

Keywords— ITS, Interactive, Motivation.

I. INTRODUCTION

Intelligent Tutoring System(ITS); is an important research area in which computer science and technology are used in education. It plays a very important role in Artificial Intelligence technology, in the absence of guidance from the human tutors to help learners acquire knowledge and different skills. Since from the '90s, many other countries have attached the great importance to intelligent tutoring systems research, and its application, and had made great achievements. However, with in-depth research, many problems came to light. For example, in the traditional ITS, the student is the passive recipient of teaching content. It lacks an interaction between systems and the students. Also, the traditional ITS model of the learners is not very successful, either too complicated to be handled, or toosimple that it lacks practical value. Thus, in the late 1990s, ITS researchers began to reconsider the application of artificial intelligence in ITS. Many new technologies have been applied to ITS, including multimedia, Internet-based distributed education, hypermedia technology. However, the introduction of new technology does not reduce the importance of artificial intelligence in teaching, on the contrary, these new technologies are of practical significance only when combined with artificial intelligence. This paper focuses on the application of artificial intelligence technology in ITS by describing the structure and function of the intelligent tutoring system and discusses several development trends of ITS.

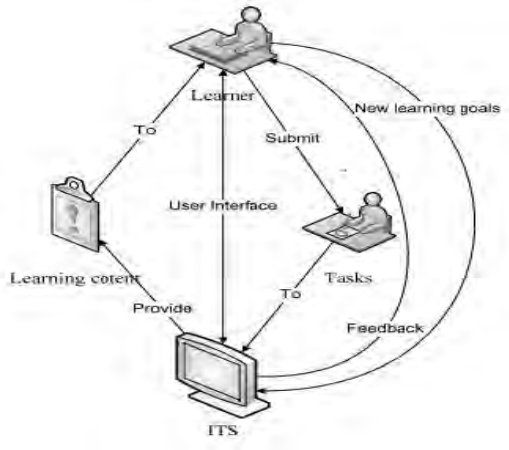

FIGURE 1. OVERVIEW OF SYSTEM FLOW

Technology-enhanced learning is a type of learning where self-motivation, communication, and efficiency are used. ITS is a system and technologies where adaptive learning technologies are used, which helps to individualize and personalize the learning process according to the individual's needs, analyze the knowledge of the students

Even a student's mood and emotions, as well as the learning style also get analyzed. Intelligent tutoring system work as a multi-agent system. Adaptive learning is the process of generating a unique learning experience for each student based on their personality, interests, and performance to achieve their goals such as academic improvement, learner satisfaction, effective learning process and many more. As the figure above shows, some important aspects of the implementation of the intelligent tutoring system to communicate with the student one's system need a strong user interface. This makes a student more comfortable while using the system .we can make the system more feasible and attractive to increase a student's comfort level.

II. LITERATURE REVIEW

Intelligent tutoring system(ITS) implementation can enhance the growth of students by the self-study method. There were much research has been done to implement these projects, And identify the limitations. Although it's difficult to implement the system by identifying each student's IQ level and also based upon that motivating student to perform more better, still

researcher is working on the problems. But this implementation will help a student to self-analyze and problem and work on the weak aspect by themselves. And by which student gets benefits to their academic as well as knowledge gaining skills.

Year	Author	Main Objective	Limitations
2019	Juhar Ahmed Abdella , Nazar Zakir[2]	An approach to identify the students' frustration in an ITS, inspired by the better accuracy of data-mining approaches, and the use of theory in modelling affective states.	Develop a based ITS and multiple basic questions make the scheme ITS.
2018	Craig, Scotty. [1]	ITSs typically operate by assessing a wide variety of learner characteristics and needs, sometimes at a very fine-grained level, and then adapting instruction according to principles of learning.	Difficult to and identify inner complexity.
.2013	Rajendran, Ramkumar & lyer, Sridhar & Murthy, Sahana & Wilson, Campbel & Sheard, Judy.[4]	An approach to identify the students frustration in an A limitation in the ITS, Inspired by the better accuracy of data-mining scalability of approach approaches, and the use of theory in modelling affective states.	A limitation scalability
2011	Praveen Kumar[4]	Develop web-based ITS and used multiple choice Instant feedback is absent questions to make the evaluation scheme independent of subject and studied different teaching-learning strategies.	In the document is quite small and in that project.
2009	Soldato, Teresa & Du Boulay, Benedict.	Discussion on motivation-based tactics and Not flexible contrast them with instruction .	Not flexible and the solution was not enough to rectify the problems.

TABLE 1 TABULAR REPRESENTATION OF THE VARIOUS LITERATURE SURVEY

III. COMPONENTS OF SYSTEM

Like any other instructional system, the component represents the content to be taught, the device to understand and analyze the amount of knowledge that the student has, with the suitable teaching strategy, and a system for other communication issues. In computer-assisted instruction, all these components are in one structure whereas in ITSs they are separated and this gives more flexibility to the student and the machine in a way that they can have a one-to-one interaction just as when student and teacher sit down and attempt to teach and learn together (Park, Perez, and Seidel, 1986). Another advantage of these modules being separated shows itself when one attempts to make changes in the program; the change could be done only in one component of the program and the alteration of the whole programming content is not required. The three components mentioned below are referred to as

problem-solving or expertise module, student model and tutoring module, with the user interface.

A.EXPERTISE MODULE

An expertise module also called a problem-solving module consists of the domain knowledge that the system intends to teach to the student. The nature of knowledge is important while answering questions about intelligence. The Artificial intelligence community classifies knowledge into three categories i.e. conceptual, procedural, and imagine; and they worked with all three kinds of knowledge in the design of tutoring system programs. chaotic and nonlinear, problems have evolved out to be a better technique in capturing the structural relationship between the performance and its cognitive factors more accurately than many other statistical techniques. Basically in literature, different sets of input variables are used to predict value returns. Different input variables are used to predict the same set of returned data. Some researchers use i/p data from a single time series while others considered the inclusion of exclusive market information and macro-economic variables. Some researchers even pre-processed these input data sets before feeding it to any machine learning or AI algorithms.

B. STUDENT MODULE

The student model is used to assess the amount of knowledge that the student has in the material that is intended to be taught, to predict the learning behavior of the individual user and to identify the causes of errors. To evaluate the student model there are four major information sources which are:

- implicit (problem-solving behavior of the student),
- explicit (direct questions asked to the student),
- historical (assumptions based on the student's experience),
- structural (assumptions based on the difficulty of the subject-material).

This sophisticated procedure of creating a student model can be resolved to some extent by considering the student as a subset, simplification, or deviation of the expert's (computer's) knowledge. Simple pattern recognition is applied to a student's response history for making inferences about his understanding of the skill and his reasoning process used to derive the response.

C**. TUTORING MODULE**:

Once the student model has been selected and the expertise in the subject domain is given, the expert tutor selects an initial efficient teaching strategy based on the student's previous performance. This teaching strategy is modified as the student model evolves and the pedagogical strategies used may include presenting increasingly complex concepts or problems. The fundamental issues for a tutor as listed by Dede are:

Whether to intervene in the information flow,
What to discuss,
Which presentation strategy to use,
How much to say.

IV. DATA COLLECTION

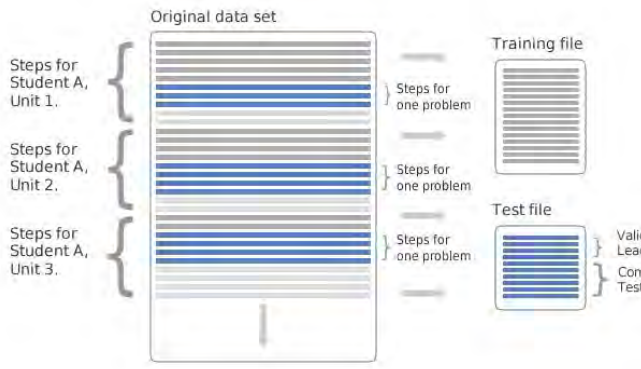

FIGURE 2 ORGANIZATION OF DATASET

Attribute	***Description of Attributes***
Subject ID	Id number of a subject.
Student ID	Id number of student.
Subject Name	Name of a subject chosen.
Student Name	Name of a student.
Last Attempted	Last question which student has attempted.
Number Of Attempts	Total number of questions which being answered.
Course Completion time	Time taken by the student to complete a particular course.
Average Time	Average time required by all students .
Hint For reference	Hint provided for the student for reference.
Level of student	In which level student has been performing.
Solution Of Questions	Solutions provided for each questions in the topic.
Confidence Test Score	Total scored obtained in confidence test which is basically full length test.
Attempts in Confidence Test	Total number of attempted question in confidence test.

Average Score of Confidence Test	Total average score of confidence test of all students.
Motivational Data	Slogan's or quotes which help the students to boost their confidence.

TABLE 2
DESCRIPTION OF ATTRIBUTES INVOLVED IN THE DATASET

V. ALGORITHM USED IN SYSTEM

A. Case-Based Reasoning

Case-based reasoning, or training examples, where the cases, are stored and accessed to solve new problems. To get a prediction for nearly new example, those cases that are similar, or very close to the new example are used to predict the targeted value of the new example. This is one of the extremes of learning problems where, unlike the decision trees algorithm and neural networks, relatively little work must be done offline, and virtually all of the work is performed at execution time. Case-based reasoning is used for classification and regression techniques for data. It is also applicable when the case is complicated, such as in legal cases, where the cases are complex legal rulings, where the cases are difficult to give solutions to complex problems.
For this method to work, a distance metric is required to measures the distance between two close examples. First define a metric for the domain of each feature, in which the values of the features are converted to a numerical scale that is used to compare values.

$$d(e_1, e_2) = \sqrt{\sum_i w_i * (X_i(e_1) - X_i(e_2))^2}.$$

The weights could be provided as an input. It is also possible to learn the weights. The learning agent would try to find weights that minimize the error in predicting the value of each component of the training set, based on every other instance in the given training set.

B. Support Vactor Machine

The Support Vector Machine (SVM) is a supervised machine learning algorithm that is used for both classification or regression problems. However, it is mostly used in classification problems. In this algorithm, we plot the data item in on an n-dimensional space with the value of each feature being the value of a particular co-ordinate. Then, we perform a classification operation by finding the hyper-plane that differentiates the two classes. Support Vector Machine is primarily a classifying method that performs classification tasks by creating multidimensional spaces that separate the different cases of different class values.
This system supports both regression and classification tasks and it can handle multiple continuous and categorical values. For categorical variables, a dummy variable is well created with case values as either 0 or 1. For this type of SVM, training are involves the minimization of the error function:

$$\frac{1}{2} w^T w + C \sum_{i=1}^{N} \xi_i$$

Subject to the constraints

$$y_i \left(w^T \phi(x_i) + b \right) \geq 1 - \xi_i \text{ and } \xi_i \geq 0, i = 1, \ldots, N$$

Here C is the capacity constant, w is the vector of a coefficient, b is a constant, and represents parameters for handling no separable or input data. The index i labels the different N training cases. Here data represents the class labels and xi represents the independent variables. The kernel is generally used to transform data from the input to the feature spaces. It has been noticed that the as much larger the C, that much more the error is detecting. Thus, C should be select with care to avoid overfitting data. In contrast to Classification support vector machine Type 1, the Classification Type minimizes the error function:

$$\frac{1}{2} w^T w - v\rho + \frac{1}{N} \sum_{i=1}^{N} \xi_i$$

subject to constraints forms:

$$y_i \left(w^T \phi(x_i) + b \right) \geq \rho - \xi_i, \xi_i \geq 0, i = 1, \ldots, N \text{ and } \rho \geq 0$$

In a regression support vector machine, you have to estimate the functional dependence of variable y on a set of the independent variables x. It assumes that, like other regression problem, that the relation between independent and dependent variables is given by a function f plus the addition of some additive noise values.

VI. CONCLUSION

We analyzed the requirements and objectives of our project. We created a basic block diagram representing the functionality of our project also, we analyzed software to be used for efficient execution. We came across various algorithms and datasets which will be beneficial for our project. We are currently working on identifying more algorithms suitable for our project. We are also working on dividing our project into modules and working collectively on each module. These modules will be the basic building blocks of our project which will be coded and integrated later.
This project is only the first step towards achieving that goal. This modular architecture ensures that every module can be extended and developed separately. It opens up a lot of different approaches for future research and development purposes.

VII. ACKNOWLEDGMENT

We sincerely thank our guide Dr. Anand Khandare for his guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

The most broadly used current designs are video-based
Eye-trackers. A camera focuses around one or both eyes and records eye movement as the individual gazes at some kind of stimulus. Most modern eye-trackers use the focal point of the pupil and near-infrared non-collimated light to make corneal reflections (CR). The vector between the pupil centre and the corneal reflections can be utilized to calculate the point of gaze on the surface or the gaze direction. A basic calibration process of the individual is usually required before using the eye tracker.

Two general types of infrared / near-infrared eye-tracking methods are used: bright-pupil and dark-pupil. Their distinction depends on the location of the illumination source with respect to the optics. In the event that the illumination is coaxial with the optical path, then the eye acts as a retro reflector as the light reflects off the retina making a bright pupil impact similar to red-eye. If the illumination source is counter balanced from the optical path, then the pupil appears dark because the retro reflection from the retina is coordinated away from the camera. The Eye gaze System must be used in an environment where there is less infrared light. The System works best away from windows, and in a room lit with fluorescent or mercury-vapour lights, which are low in infrared.

In this research survey, various algorithms, models and methods have been studied. Based on review, certain significant parameters and components that affect the precision and efficiency of eye gaze techniques have been recognized. Different eye gaze-based HCI models and algorithms have been read for additional examination and investigation. Early work on intuitive eye-tracking applications depends primarily on users with inabilities but can also be used for general users managing with portable computers.

III. PROPOSED WORK

Eye gaze or eye tracking is a technique of accessing your computer or communication aid using a mouse, controlled with your eyes. The systems follow your eyes with astonishing precision to see where you are looking on the screen. You would then be able to choose the item you are looking at by dwelling, blinking or clicking with a switch.

The project works by having lights and cameras that are continually sending and receiving data. The camera gets light reflections from your pupils and interprets the movement of your eyes into mouse cursor movements. It takes just seconds to finish a one-time calibration.

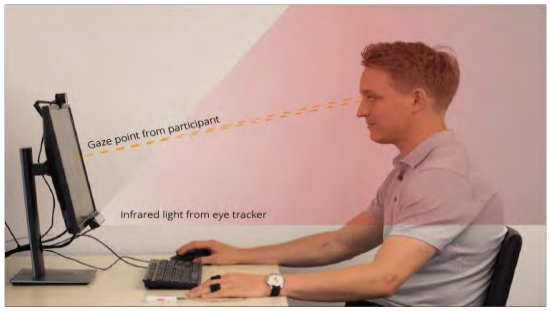

Figure 1: Proposed working Mechanism

As a user sits in before the screen, a specialized video camera mounted above/below the screen observes one of the

User's eyes. Advanced image-processing algorithm in the system consistently examines the video image of the eye and figure out where the user is looking on the screen. Nothing is appended to the user's head or body. In detail the process can be described as follows:

The Project uses the corneal reflection/pupil-centre method to figure out where the user is looking on the screen. As infrared-sensitive video camera, mounted underneath the System's screen, takes 60 pictures for each second of the user's eye. A low power, infrared light-emitting diode (LED), mounted in the centre of the camera's focal point illuminates the eye. The LED reflects a little bit of light off the surface of the eye's cornea. The light also radiates through the pupil and reflects off of the retina, the back surface of the eye, and causes the pupil to appear white. The bright-pupil impact improves the camera's image of the pupil and makes it simpler for the image processing functions to find the centre of the pupil. The computer calculates the person's gaze point, i.e., the direction of where he is looking on the screen, on the basis of the relative positions of the corneal reflection and pupil centre within the video image of the eye.

Theproposedsystemfulfilsallofthefunctionsof regularinputsources(Mouse,VirtualKeyboard etc.), and the user will be able to interact with the system efficiently.

 the proposed system provides more natural and more convenient communication mechanism for user-computer dialogue and could also avoid annoying user with unwanted responses to their actions.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

Although not in a full working condition, the proposed methodology of our project provides a good accuracy, with a stable precision of the gaze point. Experimented in various light conditions, the system works more efficiently in scenarios where there is less illumination from behind the user. Our goal to create a light weight and low cost system, with only the basic requirement of personal computer or laptop with a web cam, to an extent has been successful, with an additional requirement of Near Infrared (NIR) camera, the accuracy and precision of the system increases vastly.
The comparison is shown in the table below:

From the above table it is clearly evident that using an infrared based camera provides better accuracy than just a basic webcam. Also the difference in precision of the gaze point between the two methods is vast. Hence, we have decided on using a NIR camera, to get an almost accurate result
Snapshot of sample working is shown below:

Abstract—**Cricket, particularly the Twenty20 configuration, has greatest vulnerability, where a solitary over can totally change the force of the game. With a great many individuals following the Indian Premier League (IPL), building up a model for anticipating the result of its matches is a genuine issue. A cricket coordinate relies on different components, and right now, factors which fundamentally impact the result of a Twenty20 cricket coordinate are distinguished. Every player execution in the field is considered to discover the general weight (relative quality) of the group. A multivariate relapse based arrangement is proposed to ascertain purposes of every player in the class and the general load of a group is figured dependent on the past exhibition of the players who have showed up most for the group.**

Right now, recent years information of IPL containing the players subtleties, coordinate scene subtleties, groups, ball to ball subtleties, is taken and broke down to make different inferences which help in the improvement of a players execution. Different highlights like how the scene or hurl choice has impacted the triumphant of the match in most recent ten years are additionally anticipated. AI and Data extraction models are considered for forecast is Random Forest Regressor. AI models were prepared and utilized for anticipating the result of each 2018 IPL coordinate. We will perform three types of prediction toss-winner prediction, 2nd inning score prediction and the actual winner prediction. The forecast outcomes are great.

Keywords— Regression, Random Forest Regressor, Prediction, Data Extraction

I. INTRODUCTION

Machine learning is a branch of artificial intelligence that targets at resolving real life engineering issues. It gives the chance to learn without being unequivocally customized and it depends on the idea of gaining from information. It is so much predominantly used dozen a times a day that we may not even know. The upside of machine learning (ML) techniques is that it uses mathematical models, heuristic learning, knowledge acquisitions and decision trees for decision making. In this manner it provides controllability, observability and stability.

The sport of cricket is played in different configurations, i.e., One Day International, T20 and Test Matches. The Indian Premier League (IPL) is a Twenty-20 cricket tournament league built up with the goal of advancing cricket in India and in this way supporting youthful and skilled players. The league is an annual event where teams representing various Indian cities go up against one another. The teams for IPL are selected by means of an auction. Players' auctions are not a new phenomenon in the sports world. However, in India, selection of a team from a pool of available players by means of auctioning of players was done in Indian Premier League (IPL) for the first time. Due to the involvement of money, team spirit, city loyalty and a massive fan following, the outcome of matches is very important for all stake holders. This, in turn, is dependent on the complex rules governing the game, luck of the team (Toss), the ability of players and their performances on a given day. Various other natural parameters, such as the historical data related to players, play an integral role in predicting the outcome of a cricket match. A way of predicting the outcome of matches between various teams can aid in the team selection process . However, the varied parameters involved present significant challenges in predicting accurate results of a game. Besides, the accuracy of a prediction depends on the size of data utilized for the same.

Further, several predictive models are also built for predicting the result of a match, in light of every player's past performance just as some match related data. The developed models can help decision makers during the IPL matches to access the strength of a team against another. The contributions of the presented work are as per following:

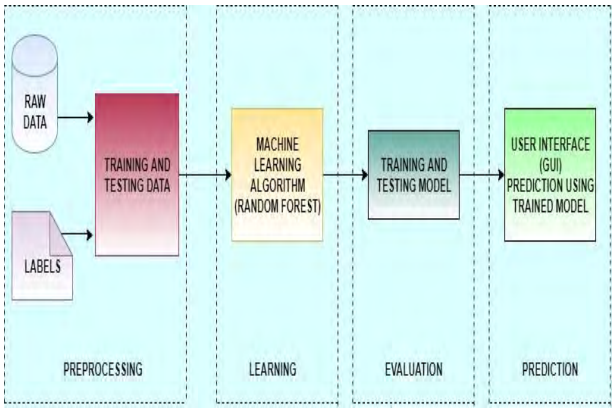
To predict the toss winning team of the match based on the city in which the match is played.

To predict the performance of a team in the 2 inning depending on the run made, wickets fallen and numbers of overs left.

To successfully predict the outcome of IPL matches.

II. METHODOLOGY

The overall working of our project can be explained through the following abstract diagram.



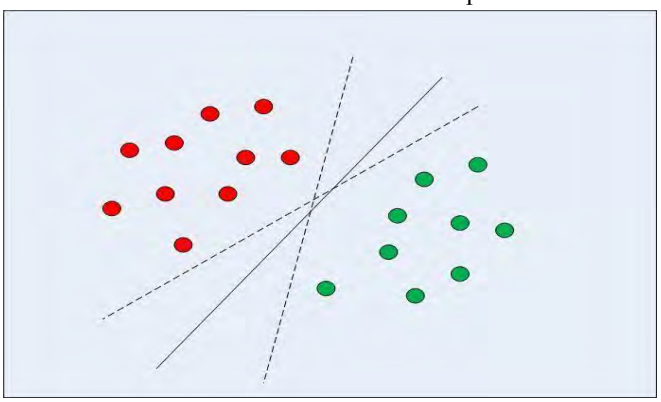
The methodology consists of 3 main stages- Data Pre-processing, Data Preparation, Encoding the data. Initially, the IPL dataset of 10 years is taken. In data pre-processing phase, the data is incomplete, noisy and inconsistent. The data preparation is significant for achieving optimal results. This involves choosing an outcome measure to evaluate different predictor variables. In data Encoding phase, label each term with short names and encode them as numerical values for predictive modelling as implemented below. matches.replace (['MumbaiIndians','KolkataKnightRiders','RoyalChallengersBangalore','DeccanChargers','ChennaiSuperKings','RajasthanRoyals','DelhiDaredevils','GujaratLions','KingsXIPunjab','SunrisersHyderabad','RisingPuneSupergiant','KochiTuskersKerala','PuneWarriors'],['MI','KKR','RCB','DC','CSK','RR','DD','GL','KXIP','SRH','RPS','KTK',PW'],inplace=True)encode={'team1':{'MI':1,'KKR':2,'RCB':3,'DC':4,'CSK':5,'RR':6,'DD':7,'GL':8,'KXIP':9,'SRH':10,'RPS':11,'KTK':12,'PW':13},'team2':{'MI':1,'KKR':2,'RCB':3,'DC':4,'CSK':5,'RR':6,'DD':7,'GL':8,'KXIP':9,'SRH':10,'RPS':11,'KTK':12,'PW':13},'toss_winner':{'MI':1,'KKR':2,'RCB':3,'DC':4,'CSK':5,'RR':6,'DD':7,'GL':8,'KXIP':9,'SRH':10,'RPS':11,'KTK':12,'PW':13},'winner':{'MI':1,'KKR':2,'RCB':3,'DC':4,'CSK':5,'RR':6,'DD':7,'GL':8,'KXIP':9,'SRH':10,'RPS':11,'KTK':12,'PW':13,'Draw': 14}}
The test dataset is taken as input to the learning algorithm, evaluates different scenarios like toss winner, toss decision and team winner. Thus, new data is obtained with final prediction.

A. Support Vector Machine

A support vector machine is a type of supervised machine learning classification algorithm. SVMs were first seen in
1960s and were later refined in 1990s. However, they are becoming somewhat popular because of their ability to achieve brilliant results. SVMs are implemented in a different way when we compare them to other machine learning algorithms.

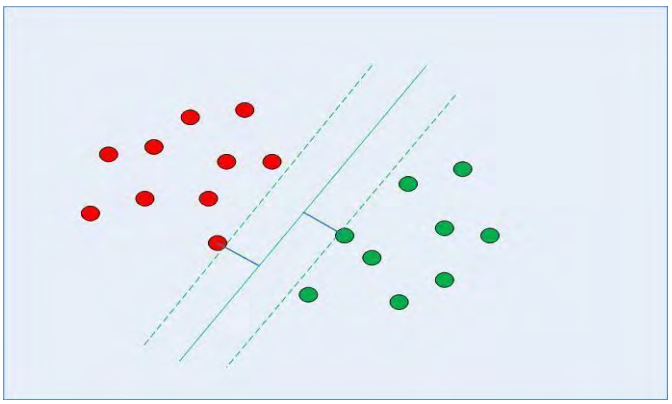
In case of linearly separable data in two dimensions, as shown, a typical machine learning algorithm tries to find a boundary that divides the data in such a way that the misclassification error can be minimized. There can be several boundaries that correctly divide the data points. The presence of dashed lines and solid line is used to classify the data.

SVM differs from the other classification algorithms in the way that it chooses the decision boundary that maximizes the distance from the nearest data points of



all the classes. An SVM finds the most optimal decision boundary that can be made.

The most optimal decision boundary is the one which has maximum margin from the nearest points of all the classes. The nearest points from the decision boundary that maximize the distance between the decision boundary and the points are called support vectors as seen in the figure. The decision boundary in case of support vector machines is called the maximum margin classifier, or the maximum margin hyper plane.



We identified certain problems with SVM which is why we could not use it in the project. Some of them have been mentioned below.

1. SVMs do not perform well on highly skewed/imbalanced data sets. These are training data sets in which the number of samples that fall in one of the classes far outnumber those that are a member of the other class. Customer churn data sets are typically in this group because when you collect the training set, among a million customers during a particular time period, there would be very few who have actually churned.

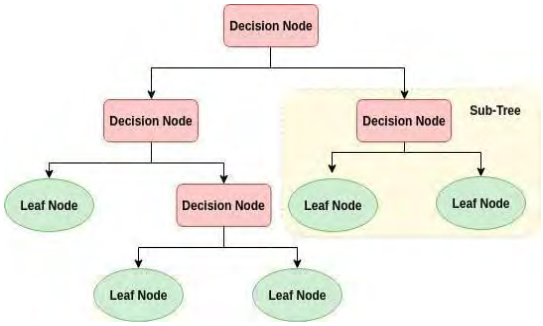
2. SVMs will not work well in multiple classes. They should not be used when there are a number of classes. Then you have to get back to a binary classifier itself and a voting mechanism to classify the classes among all the classes that are at hand.

3. The number of training samples should be much greater than the number of features. SVMs will not

work otherwise. Therefore, we need a lot of training samples if we want to use SVM

B. Decision Tree Classifier

A decision tree is a tree structure which is like a flowchart, where an internal node represents an attribute or a feature, the branch represents a decision rule, and outcome is represented by each leaf node. Root node is the topmost node of the tree. Partition can be made on the basis of attribution value. It partitions the tree in recursively manner call recursive partitioning. Decision making is the use of this flowchart like structure. It's visualization like a flowchart diagram which easily mimics the human level thinking. Decision trees are easy to understand and interpret, that is why they can be used too.



White-box models are the type of models which one can clearly explain how they behave, how they produce predictions and what the influencing variables are. White box has two properties or features that they have to be understandable and transparent as well. Decision tree is white box example. Unlike Neural Network and black box, it shares internal decision making logic. Neural Network algo is slower training time as compared to this. The time complexity of decision trees is a function of the number of records and number of attributes in the given data. Distribution-free or non-parametric method is used in decision tree, which does not depend upon probability distribution assumptions. High dimensional data with good accuracy is an important feature of decision tree.

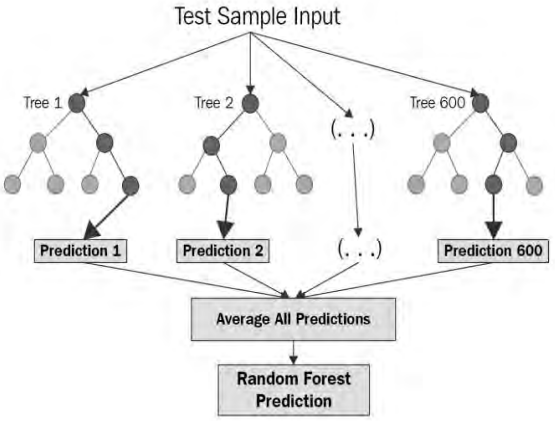
We identified certain problems with SVM which is why we could not use it in the project. Some of them have been mentioned below.

1. Small changes in data brings large change in structure causing instability.
2. For a Decision tree sometimes calculation can go far more complex compared to other algorithms.
3. Decision tree often involves higher time to train the model.
4. Decision tree training is relatively expensive as complexity and time taken is more.

C. Random Forest

Random forests is a supervised learning algorithm. Classification and regression can be done using random forest. Most flexible and easy to use algorithm is random forest. Forest is made of many trees. Forest becomes more robust with an increase in number of trees. Decision trees are made on randomly selected data samples, then it get a prediction form from each tree, and the best solution bymeans of voting. Feature importance factor is also provided by the random forests.

Having a variety of applications, such as recommendation engines, image classification and feature selection, it can be used to classify loyal loan applicants, identify fraudulent activity and predict diseases. Accuracy and robustness in provided by the random forests because of the number of decision trees participating in the process. Overfitting problem is avoided in the random forests too. Biases are cancelled out very nicely due to the average and hence it increases the accuracy of the prediction. The algorithm can be used in both classification and regression problems. Random forests can also handle missing values. There are two ways to handle these: using median values to replace continuous variables, and computing the proximity-weighted average of missing values. You can get the relative feature importance, which helps in selecting the most contributing features for the classifier.



Random forest is a bagging technique but not a boosting technique. The trees in random forest run in parallel sequence. There is no interaction among the trees while building them. It operates by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees.

A random forest is a meta-estimator (i.e. it combines the result of multiple predictions) which aggregates numerous decision trees, with some supportive adjustments:

1. The number of features that can be split on at each node is limited to some percentage of the total (which is known as the hyperparameter). This guarantees that the ensemble model does not depend too intensely on any individual

feature, and makes fair use of all potentially predictive features.

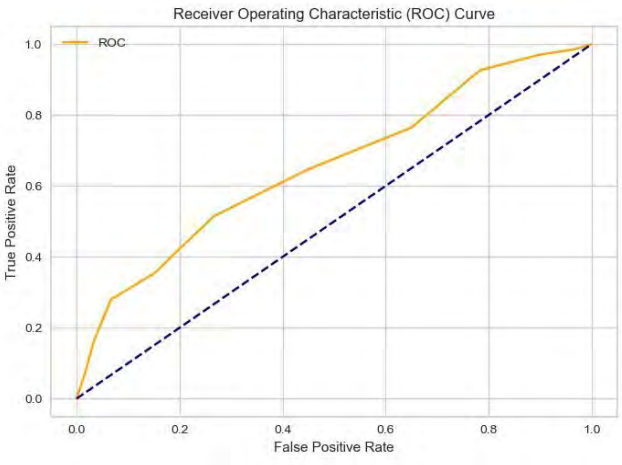
2. Each tree draws a random sample from the original data set when generating its splits, adding a further component of randomness that prevents overfitting.

In Machine Learning, performance measurement is an fundamental task. Therefore, when it comes to a classification problem, we can rely on an AUC - ROC Curve. At the point when we have to check or visualize the performance of the multi - class classification problem, we use AUC (Area Under The Curve) ROC (Receiver Operating Characteristics) curve. It is one of the most significant evaluation metrics for checking any classification model's performance.

In the figure below, one can see the true positive rate vs the false positive rate for the random forest. We tested the algorithm for a particular dataset and it gave an accuracy of
78.67% which was the highest among the algorithms. Moreover, random forests can handle missing values very well. Although it takes slightly more time than the other algorithms, we decided to go for it because our primary focus is to make the prediction with maximum accuracy.

Apart from this, random forest also give the following advantages:-

- The predictive performance can compete with the best supervised learning algorithms
- They provide a reliable feature importance estimate
- They offer efficient estimates of the test error without incurring the cost of repeated



model training associated with cross-validation

III. PROPOSED WORK

When we started working on the project, we wanted to carry out live web scrapping to take the player data from the internet and use it for analysis so that we could make a prediction. At that time, our primary focus was speed as we wanted to make the prediction after every over of the second innings. Such a system would help us consider the records of matches directly. However, storing the dataset offline would mean that we would have to keep updating that data manually. A scrapping code would automate this. Web scraping, web harvesting, or web data extraction is data scraping used for extracting data from websites. Web scraping software may access the World Wide Web directly using the Hypertext Transfer Protocol, or through a web browser. We used beautiful soup library to make sure that we could scrap the data. Although we tried to make the scrapping thing work, it was not possible. The problem with scrapping is that the websites do not allow scrapping of data very easily. Moreover, a slight change in the HTML code of the website could hamper the results of the data in a very significant way. Websites keep changing this code on a regular basis to prevent scrapping for taking place. Therefore, it becomes really difficult to carry out scrapping. A scrapping code which works right now may or may not work after two months. This could be a huge problem as we would need to change the code every now and then and that the code could stop giving the correct results at any point of time. Primarily, we were scrapping player data and team data from websites like ESPN Cricinfo and Cricmetric. Also, we were finding out the record of one batsman against all the bowlers of the opposition lineup. This data was going to be used to carry out the prediction of the winner of the match.

As you can see above, the user is asked to enter the teams that are playing in the match. Moreover, the date is to be entered as well. This is the date till which all the matches will be considered for making the prediction. The ground ID is the one on cricinfo website. This was making use of scrapping. However, we are now going to use the same model for making the prediction of IPL data. We have data of about 9 seasons which will be used to make the prediction. The UI will change accordingly. We will make a system which will predict the winner of the toss and their decision as well. Moreover, we will be able to predict the score that will be made by the team chasing and hence the winner of the game. After pre- processing and feature generating, we will use the machine learning to generate models which can be used to predict the results.

IV. CONCLUSION

With growing interest in the sport of cricket over the past few years, a need for tool which can predict the results of the match in advance has to be developed. Though there are lots of tools available in the market,

there accuracy lacks in the way they take factors into consideration. To give an edge to those existing classifiers, our project aims to also take into consideration some important factors like team composition, performance of players in past few matches, batting and bowling averages of the players in each team and winning probability of team batting first at a specific venue against a specific opponent. All these important factors along with toss and venue has taken into account and a classifier will be generated to give better results. Along with these a user interface has also been generated so that even a layman can interact with our system with ease.

The project currently takes into account the important factors from previous matches and then predicts the result before the match starts. But we can also take the ongoing match details to predict the result. So, the future work will be to combine both the previous data with ongoing match data to have much more better results. Also, the prediction can be extended to not only predict the winner of the match but also the expected runs to be scored by both teams.

Selection of the best team for a cricket match plays a significant role for the team's victory. The main goal of this paper is to analyze the IPL cricket data and predict the players' performance. Here, three classification algorithms are used and compared to find the best accurate algorithm. Random Forest is observed to be the best accurate classifier to predict the best player performance. This knowledge will be used in future to predict the best team.

Abstract— ***Article arranging is utilized in many bundling industry at the hour of definite dispatch .In these day manual item arranging is a conventional methodology favored by ventures. Consequently decided endeavor have been done to create and structure programmed procedure which can naturally sort and check object dependent on shading sensor and picture preparing instrument. Through shading, we can approve, track separate various articles in progressively better way. Color sensor is utilized to recognize shade of item. This strategy can be used to recognize moving items on transport line and can be recognize by shading sensor. Shading is the most well-known component to recognize between objects, arranging, perceiving and following. For the most part robot is mounted with a camera or the camera is mounted in the workspace to distinguish the article. This innovation can be utilized in material dealing with in coordination's and bundling industry where the articles traveling through a transport line can be isolated utilizing a shading identifying robot. Right now 'Object' calculation is written in MATLAB for playing out the activity. The 'Object' calculation is executed to distinguish the question and send the proper directions to the microcontroller utilizing sequential correspondence for the robot to play out the arranging activity***

Keywords: Mat lab, Color Object Counting, Image Processing, Object Sorting and Adriano Uno

INTRODUCTION

Arranging of items is a troublesome mechanical Procedure. Nonstop manual arranging makes consistency Issues. This undertaking depicts a working model intended for programmed arranging of articles dependent on the Shading. TCS230 sensor is utilized to identify the shade of the item and the Adriano Uno MATLAB are utilized to control the general procedure. The recognizable proof of the shading depends on the recurrence examination of the yield of TCS230 sensor. Two transport lines are utilized, each constrained by independent DC engines.

The principal belt is for setting the item to be broke down by the shading sensor, and the subsequent belt is for moving the holder, having isolated compartments, so as to isolate the items. The trial results guarantee that the model will satisfy the requirements for higher creation and exact quality in the field of mechanization. Machines can perform profoundly dull undertakings superior to people. Laborer exhaustion on sequential construction systems can bring about decreased execution, and cause difficulties in keeping up item quality. A representative who has been playing out an examination task again and again may in the long run neglect to perceive the shade of item. Mechanizing a significant number of the undertakings in the enterprises may assist with improving the proficiency of assembling framework. The motivation

III. EXISTING SYSTEM

In the current framework the items are arranged physically for the most part by individuals. This makes a propensity for human mistakes to come into record and consequently bring about the work turning out badly. On the off chance that articles or parts in ventures are not arranged accurately, at that point there is item being blemished. a high possibility of tremendous turmoil and the last

IV.PROPOSED SYSTEMS

The disadvantages of existing systems can be overcome using the proposal systems. In the proposed system a color sensor will be mounted on top of the conveyor belt along with a proper support. The color sensor will detect the color of the object based on the frequency and will send this information to Mat lab. This will help to keep track of the objects of a particular color and also record when they were detected.

V. TECHNICAL OVERVIEW

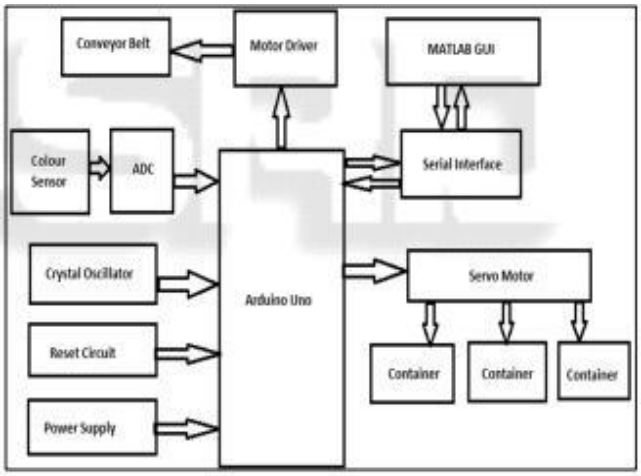

Fig. 1: Diagrammatic representation

The main objective of the system being developed is to detect the object which is coming from the conveyor belt with the help of a TCS230 color sensor and sort the object based on their color. The conveyor belt is being driven by a motor which is connected to the Adriano Uno via a driver as the voltage required by the motor is more than what the Adriano Uno can provide. The frequency of color which is detected by the color sensor is sent to the Adriano Uno which in turn tells if the object has to be separated or not based on the programming done in the Adriano Uno software installed on the computer. The GUI is developed with the help of Mat lab in order to display the object detected and sorted. Thus Mat lab plays a key role over here. Some LED's are mounted upon the Adriano Uno which will blink according to their respective colors when the object of that color is detected. Object Sorting System based on Color Sensing using Mat Lab (IJSRD/Vol. 4/Issue 11/2017/068) All rights reserved by www.ijsrd.com 243

VI. DESIGN OF THE SYSTEM

Design of the system will include: 1) Adriano Uno: The Adriano Uno is a microcontroller board based on the ATmega328 (datasheet). It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz crystal oscillator, a USB connection, a power jack, an ICSP header, and a reset button. 2) Color Sensor: The Color Sensor is a complete color detector. It consists of a TAOS TCS3200 RGB sensor chip and 4 white LEDs. It can detect and measure a nearly limitless range of visible colors to a certain degree. 3) Dc Motor: A DC motor is any of a class of rotary electrical machines that converts direct current electrical power into mechanical power. The most common types rely on the forces produced by magnetic fields. Nearly all types of DC motors have some internal mechanism, either electromechanical or electronic, to periodically change the direction of current flow in part of the motor. 4) Motor Driver: A motor driver is a little current amplifier; the function of motor drivers is to take a low-current control signal and then turn it into a higher-current signal that can drive a motor. 5) Mat lab: MATLAB (matrix laboratory) is a multiparadigm numerical computing environment and fourth-generation programming language. A proprietary programming language developed by Math Works, MATLAB allows matrix manipulations, plotting of functions and data, implementation of algorithms, creation of user interfaces, and interfacing with programs written in other languages, including C, C++, C#, Java, Fortran and Python.

VII. TECHNOLOGY USED

Why Mat lab Instead of VB? Code written right now effectively comprehensible. Mat lab has more highlights when contrasted with Visual Basic. This language exceeds expectations at simultaneousness when contrasted with Visual Basic. Mat lab has a decent Library Distribution instrument when contrasted with Visual Basic. Mat lab is entirely appropriate for Real Time Applications. Mat lab has a wide scope of implicit Pre-Written codes which make the undertaking of coding less troublesome and efficient. Fig. 2: Mat lab Software

VIII. ADVANTAGES OF MATLAB

Mat lab is an easy to use and effectively reasonable language. Codes written right now to be entirely solid. Mat lab is helpful for numeric and logical processing. Its essential information component is the framework. A straightforward whole number is viewed as a grid of one line and one section. Vector zed tasks. The graphical yield is upgraded for collaboration. Mat lab's usefulness can be enormously extended by the expansion of tool stash. An enormous (and developing) database of implicit calculations for picture preparing and PC vision applications MATLAB permits you to test calculations promptly without recompilation. You can type something at the direction line or execute a segment in the supervisor and quickly observe the outcomes, extraordinarily encouraging calculation improvement. The MATLAB Desktop condition, which permits you to work intuitively with your information, encourages you to monitor records and the factors and improves regular programming troubleshooting undertakings the capacity to peruse in a wide assortment of both normal and area explicit picture designs. The capacity to call outer libraries, for example, OpenCV.

IX. HISTORY OF MATLAB

Cleve Moller, the chairman of the computer science department at the University of New Mexico, started developing MATLAB in the late 1970s. He designed it to give his student's access to LINPACK and EISPACK without them having to learn FORTRAN. It soon spread to other universities and found a strong audience within the applied mathematics community. Jack little, an engineer, was exposed to it during a visit Moller made to Stanford University in 1983. Recognizing its commercial potential, he joined with Moller and Steve Bangers. They rewrote MATLAB in C and founded Math Works in 1984 to continue its development. These rewritten libraries were known as JACKPAC. In 2000, MATLAB was rewritten to use a newer set of libraries for matrix manipulation, LAPACK. MATLAB was first adopted by researchers and practitioners in control engineering, Little's specialty, but quickly spread to many other domains. It is now also used in education, in particular the teaching of linear algebra, numerical analysis, and is popular amongst scientists involved in image processing.

X. MATLAB FEATURES

Significant level language for logical and designing registering. Work area condition tuned for iterative investigation, structure, and critical thinking. Designs for imagining information and devices for making custom plots. Article Sorting System dependent on Color Sensing utilizing Mat Lab (IJSRD/Vol. 4/Issue 11/2017/068) All rights held by www.ijsrd.com 244 Apps for bend fitting, information grouping, signal examination, and numerous other space explicit errands. Extra tool compartments for a wide scope of building and logical applications. Instruments for building applications with custom UIs. Interfaces to C/C++, Java®, .NET, Python®, SQL, Hardtop®, and Microsoft® Excel® without royalty arrangement choices for sharing MATLAB programs with end clients.

XI. REQUIREMENT ANALYSIS

A.Possibility Study

The possibility study assumes a significant job in the investigation of the framework. The very choice of the framework expert, to structure a specific framework depends whether the framework is attainable or not. Henceforth, the attainability study shapes the essential of the framework. The plausibility study can be ordered into: 1) Technical Feasibility It has been resolved that the innovation required for the arranged framework is open which this innovation might be coordinated into the apparatus. Specialized examination has conjointly assessed the present framework to search out that it can't be redesigned keep with the client's needs. Consequently, we'd prefer to make a total new framework that obliges the specific needs of the client. The tip client might be outfitted with the pre-referenced equipment and code necessities. 2) Operational Feasibility There are two parts of operational plausibility for the framework. One angle is that of specialized execution and other is of Acknowledgment. It has been resolved that the framework can give right and convenient information required for the end client needs. Additionally it has been resolved that the framework will be acknowledged by the two clients with and without specialized information. 3) Economic Feasibility The financial practicableness of the framework is primarily engaged with its cash angles. It decides if the undertaking is financially conceivable. As the equipment and PC code are as of now out there basically inside the market, no greater speculation is to be made toward that path, the sole cost concerned is that of executing the framework. The side framework utilizes mat lab that is uninhibitedly out there. The backend is worked in c coding that the is put forth out there with clear attempts and lower cost.

XII. MATLAB INTEGRATES WORKFLOWS

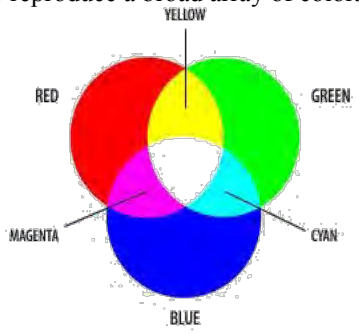
Major engineering and scientific challenges require broad coordination to take ideas to implementation. Every handoff along the way adds errors and delays. MATLAB automates the entire path from research through Production. You can: Build and package custom MATLAB apps and toolboxes to share with other MATLAB users. Create standalone executable to share with others who do not have MATLAB. Integrate with C/C++, Java, .NET, and Python. Call those languages directly from MATLAB, or package MATLAB algorithms and applications for deployment within web, enterprise, and production systems. Convert MATLAB algorithms to C, HDL, and PLC code to run on embedded devices. Deploy MATLAB code to run on production Hardtop systems. MATLAB is also a key part of Model-Based Design, which is used for multi domain simulation, physical and discrete-event simulation, and verification and code generation. Explore Simulink, Sims cape™, and State flow® to learn more about Model-Based Design.

XII. HARDWARE AND SOFTWARE REQUIREMENT

A. Hardware Requirement
Adriano Uno
Conveyer belt
Power supply
TCS230 color sensor
Dc motor
Servo motor
B. Software Requirement
-Mat lab

XIII. RGB COLOUR MODEL

The RGB color model is a color model in which consists of red, green and blue light are added together in various ways to reproduce a broad array of colors.



2. HSV Color MODEL The HSV shading space has the accompanying three parts: H – Hue (Dominant Wavelength). S – Saturation (Purity/shades of the shading). V – Value (Intensity). Shade (H) characterizes the shading itself. Immersion (S) is the measure of dim from zero percent to 100 percent in the shading. The worth (V) Component catches the measure of light falling on it in this way it changes because of brightening changes. HSV utilizes just one channel to depict shading, making it extremely instinctive to determine shading as appeared in figure.

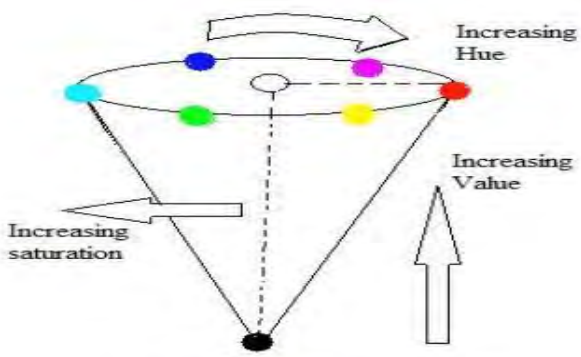


Figure-2 HSV Colour model

XIV. SERVOMOTOR

Servomotors are used in applications such as robotics, CNC machinery or automated manufacturing. The servo motor has some control circuits and a potentiometer (a variable resistor)

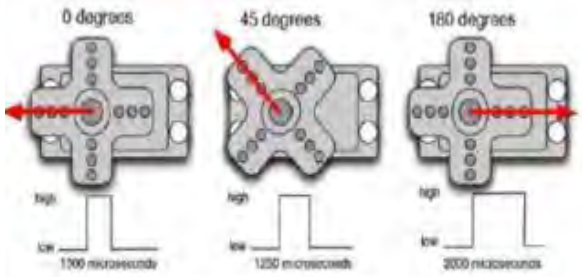

Figure 4. Servomotor Rotation

XIV. CONCLUSION

The conclusions drawn from results given by algorithms used for automatic cooler object counting and sorting in prototype system design to implement automation in automatic technique to determine cooler of object ,object count and sort object based on color using image processing approach are as follows, An approach for object cooler detection, count calculation and object sorting has been implemented. Implemented system gives accurate result for purely Red, Green and blue colored objects. With some software changes this system can be used for different shades of basic specified cooler. Due to use of automation in cooler determination and count calculation process, manual Pot allows the control circuitry to monitor the current angle of the servo motor. If the shaft is at the correct angle, then the motor shuts off. If the circuit finds that the angle is not correct, it will turn the motor the correct direction until the angle is correct. The output shaft of the servo is capable of traveling somewhere around 180 degrees. Usually, it's somewhere in the 210 degree range, but it varies by manufacturer. A normal servo is used to control an angular motion of between 0 and 180 degrees. If the output position differs from that required, an error signal is generated which then causes the motor to rotate in either direction, as needed to bring the output shaft to the appropriate position. As the positions approach, the error signal reduces to zero and the motor stops. Servomotors measure both the position and also the speed of the output shaft. They may also control the speed of their motor, rather than always running at full speed. Both of these enhancements, usually in combination with a PID control algorithm, allow the servomotor to be brought to its commanded position more quickly and more precisely, with less overshooting. The servo turn rate, or transit time, is used for determining servo rotational velocity. This is the amount of time it takes for the servo to move a set amount, usually 60 degrees. The servomotor rotation is shown in figure 4.For example, suppose you have a servo with a transit time of 0.17sec/60 degrees at no load, this means it would take nearly half a second to rotate an entire 180 degrees.

efforts are reduced which leads to improving accuracy as well as saves money and time.

Abstract— **The scheduling of movie screenings in the multiplexes these days is heavily based on the managers' gut feeling. Movie theatres can maximize their profits using a model that analyzes a lot of factors like the genre of the film, it's budget, the popularity of the lead actors, the estimated revenue, etc. to predict a near to optimal outcome. The main aim proposed is to screen a movie based on the availability of the targeted audience and to maximize the predicted revenue. The prediction of the revenue of the movie also depends on a variety of factors like its budget, popularity, associated production companies and most importantly release date. To release a movie in the perfect time is to maximize the revenue estimate. This makes it necessary to reform the existing system of manual movie scheduling and replacing it with a movie forecasting model that learns from previous data. However, the limitations are as follows: Firstly, considering the complexity of movie forecasting, it becomes excessively difficult to carry out micro-scheduling which deals with the internal distribution of movie screenings both with respect to space and time of these and hence, we may settle for macro-scheduling which describes a model which specifies the optimal dates for screening the movie. Secondly, a few more factors may add to the perfect time for the release of the movie, like the weather and the location of a multiplex. These cannot be fixed and would vary. To understand the significance of the movie release dates on the revenue generated, we have to gauge their dependence using the optimized and powerful decision tree-based ensemble Machine Learning model of XGBoost that uses a gradient boosting framework.**

Keywords—Movie Forecasting, Micro-scheduling, Macro- scheduling, Decision Tree , Ensemble Based, XGBoost, Gradient Boosting Framework

I. INTRODUCTION

1.1 Introduction

Living in a completely tech-era, where almost every stuff we see daily is mostly automated, the scheduling of movie releases remains to be one of those tasks which require manual effort. The manual effort required proves to be frustrating, cumbersome and most importantly does not guarantee to yield optimal results. Optimality is a large scope here in terms of the targeted audience, revenue generated, etc. All of these though does not singlehandedly depend on the release date of the movie, but the release date is one of those variable factors which on an appropriate modification, can push up the revenue generated. Hence by varying the release date based on the availability of the targeted audience, would surely help in strategizing an appropriate date for the release of the movie. As proved ahead, the only feasibly varying component on which the revenue generated depends largely on is the release date of the movie. Taking an example to support this claim, an animation movie meant to entertain the kids would do no good to the revenue if it is screened at a time when the kids are not free(for example during exams, or during weekdays when they have schools). Going in-depth, it is understood that each movie has a targeted audience, even though it tries to capture all age- groups equally. The targeted audience depends on factors like the genre of the movie, its lead actors, its directors, production house, etc. These are pretty repetitive which would help to train the model based on this data helps to learn out of the experience

1.2 Motivation

Forecast model used to assist film studios as even a single movie can be the difference between crore of rupees of profit or loss in a given year. Forecast model also used to assist cinema hall/multiplex owners in planning out movie schedules for forthcoming box-office weekends. Forecast model will let the people effectively schedule the movies in less time without doing any manual calculations. This model will find out the target audience for a particular movie so that the profit will be more.The current existing system for scheduling movies is done manually with pen & paper by specialists. Despite the combination of a programmer's analytical mind & a broad knowledge about movies & audience of individual theatres, an analytical model can help do better

1.3 Literature Survey

Is about a marketing decision support system in the movie industry. The decision support system of interest is a model that generates weekly movie schedules in a multiplex movie theater. A movie schedule specifies, for each day of the week, on which screen(s) different movies will be played, and at which time(s). The model integrates elements from marketing with approaches from operations research .Therefore, it consists of two parts: (i) conditional forecasts of the number of visitors per show for any possible starting time, and (ii) a scheduling procedure that quickly finds a near optimal schedule .[2] proposes the use of a review system for predicting the success rate of a movie. Moviegoers' opinions of a movie before and after the release of the movie will be determined using sentiment analysis. [3] introduces the concepts of

neural networks and presentsan overview of the applications of neural networks in decision support systems (DSS).[4] suggests that movie theatres could improve profits by using a more data- driven approach such as movie attendance forecasting model. Eilashberg used linear regression model, standard logit model and nested logit model. [5] proposes a DSS for movie investment sector using machine learning techniques. It proposes the use of Support Vector Machine(SVM), Neural Network(NN) and Natural Language Processing(NLP).

1.4 Problem Definition

There is a heavy interdependence between the movie release date and the revenue it generates. This is possibly the only feasible and variable factor(that can be easily changed without creating much complications) which influences the revenue. The major task is to maximize the revenue generated by optimally fixing the movie's release date. This though sounds simple, depends a lot of other factors.

1.5 Problem Solution

The aim is to forecast the Box-office revenue for a film using Machine Learning algorithm Decision Tree,by adding the computed influence of each parameter of a movie that is believed to affect its revenue.In this project we also aim to find the target audience for the movie and also aiming to effectively schedule the movie so that the revenue generated will be maximum.

1.6 Proposed System

We propose a system that would help to efficiently schedule the movies to be released in the theatres such that the entertainment revenue generated is optimized. Different genres of movies are meant to entertain a different audience altogether. To increase the revenue generated, it would be best to release the movie when the targeted audience is free. For example, an animation movie is meant to entertain the kids of age group ranging from 3 to 8, or action-packed film is more likely to entertain boys of age group say 3 to 12, etc. So releasing these movies at the time of school exams would in no way help in optimizing the revenue. Apart from these, it is also necessary to consider certain other factors like the location of the multiplex, the actors' popularity, etc. These together in a combined way determine the popularity of the movie among the targeted crowd. The more the popularity, the more is the audience which automatically increases the revenue collected.

1.7 Objectives

System to efficiently schedule the movies to be released in the theatre

System to learn the target audience based on various features like the actors genres of the movie Schedule the movies as per the availability of the targeted audience Optimize the entertainment revenue generated Elimination of the current manual (pen & paper) approach.

1.8 Scope

The scheduling of movie screenings in the multiplexes these days is heavily based on the managers' gut feeling. Movie theatres can maximize their profits using a model that analyzes a lot of factors like the genre of the film, it's budget, the popularity of the lead actors, the estimated revenue, etc. to predict a near to optimal outcome. The main aim proposed is to screen a movie based on the availability of the targeted audience and to maximize the predicted revenue. The prediction of the revenue of the movie also depends on a variety of factors like its budget, popularity, associated production companies and most importantly release date. To release a movie in the perfect time is to maximize the revenue estimate. This makes it necessary to reform the existing system of manual movie scheduling and replacing it with a movie forecasting model that learns from previous data.

1.9 Application

Living in a completely tech-era, where almost every stuff we see daily is mostly automated, the scheduling of movie releases remains to be one of those tasks which require manual effort. The manual effort required proves to be frustrating, cumbersome and most importantly does not guarantee to yield optimal results. Optimality is a large scope here in terms of the targeted audience, revenue generated, etc. All of these though does not singlehandedly depend on the release date of the movie, but the release date is one of those variable factors which on an appropriate modification, can push up the revenue generated. Hence by varying the release date based on the availability of the targeted audience, would surely help in strategizing an appropriate date for the release of the movie. As proved ahead, the only feasibly varying component on which the revenue generated depends largely on is the release date of the movie. Taking an example to support this claim, an animation movie meant to entertain the kids would do no good to the revenue if it is screened at a time when the kids are not free(for example during exams, or during weekdays when they have schools).

1.10 Impact

Going in-depth, it is understood that each movie has a targeted audience, even though it tries to capture all age- groups equally. The targeted audience depends on factors like the genre of the movie, its lead actors, its directors, production house, etc. These are pretty repetitive which would help to train the model based on this data helps to learn out of the experience. So, obtaining the past data to determine the future most probable targeted audience would help in mapping a movie to the most optimal release dates. The project

would help in better scheduling of release dates which contributes to the revenue generated, helping in maximizing it.

1.11 Organization

Basically, the first step of the project involves understanding and assessing the interdependence between the scheduling and revenue generation. Once this, is completed the scheduling of movie releases as per the availability of the targeted audience is to be done. The past data of movies which has a lot of components like lead actors, production house, director, genres etc. is to be used to get appropriate and optimal results.

1.12 Expected Outcome

The expected outcome of our project is to find out the effective cost for the movie so that the revenue generation will be maximum and also expecting to find out the exact target audience for a particular movie based on the genre of the movie and to effectively schedule the movie in the film industry so that we can get more profit from movie based on weekly basis.

1.13 Limitations

Limitations in this domain are as follows: Firstly, considering the complexity of movie forecasting, it becomes excessively difficult to carry out micro-scheduling which deals with the internal distribution of movie screenings both with respect to space and time of these and hence, we may settle for macro-scheduling which describes a model which specifies the optimal dates for screening the movie. Secondly, a few more factors may add to the perfect time for the release of the movie, like the weather and the location of a multiplex. These cannot be fixed and would vary.

II. METHODOLOGY

A. Workflow

Firstly, to prove that there is a vast interdependence between the release date of the movie to the revenue, we design a model which predicts the revenue of the movie, doing so, using the optimized and powerful decision tree- based ensemble Machine Learning model of XGBoost that uses a gradient boosting framework. This model would help us gauge the important of various features in deciding or rather, maximizing the entertainment revenue.
Further, once it is proved that the release date of a movie stands out as one of the most important features to predict a movie's revenue generated, we would move on to the part of movie forecasting that is, its release date scheduling using the below demonstrated workflow

Figure 1 is a self-explanatory figure that demonstrates the general approach to solve the problem.

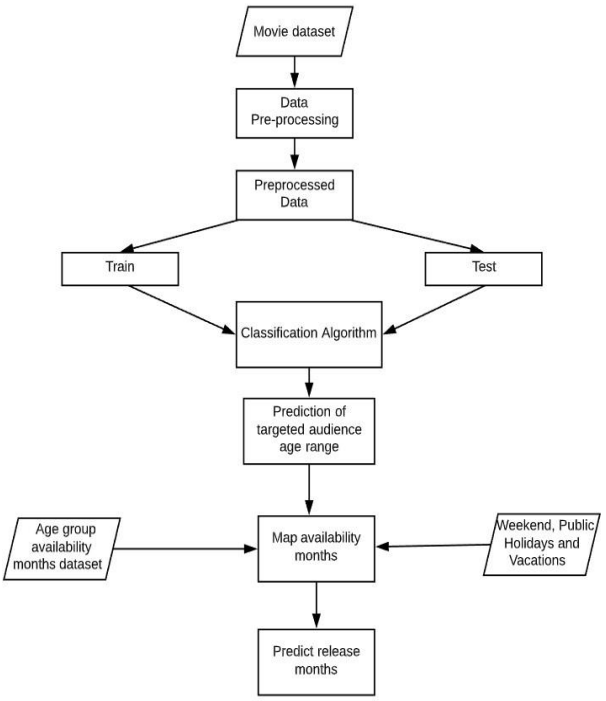

Fig 1: Workflow/ Work Methodology

III. RESULTS AND DISCUSSION

To prove that there is a vast interdependence between the release date of the movie to the revenue, we design a model which predicts the revenue of the movie, doing so, using the optimized and powerful decision tree-based ensemble Machine Learning model of XGBoost that uses a gradient boosting framework. This model would help us gauge the important of various features in deciding or rather, maximizing the entertainment revenue.
Dataset source: Kaggle Environment used: Google Colaboratory

Following are the snapshots of working as well as outputs obtained:

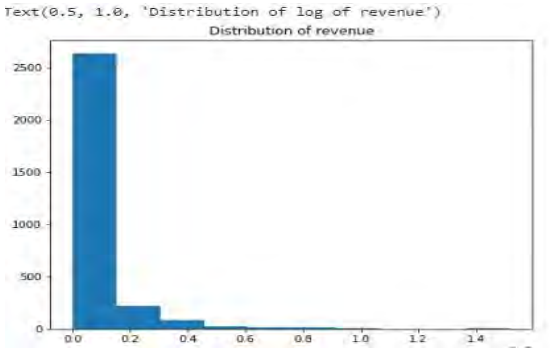

Fig 2: Distribution of Revenue

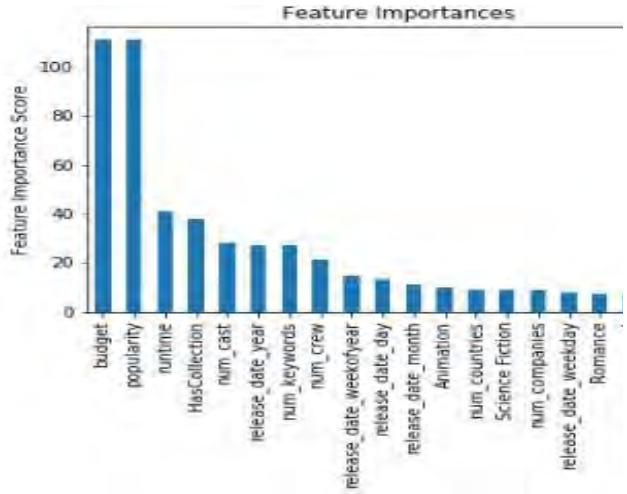
Figure 2 demonstrates the distribution of revenue .



The shaded region in the form of histogram graph exhibits the abundance of movies lying in that particular revenue scale.

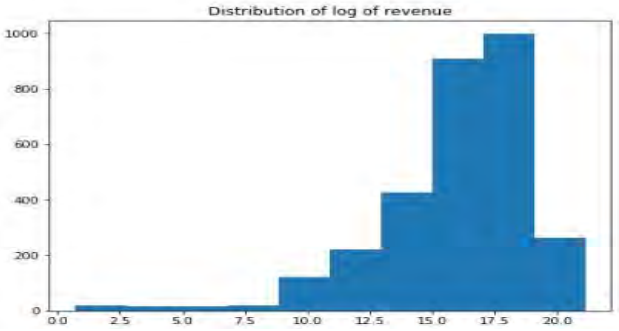


Fig 3: Distribution of log of revenue

Figure 3 demonstrates the distribution of logarithmic revenue.

The histogram graph includes the shaded region that specifies the abundance of movies in the dataset lying in the paritcular logarithmic of revenue scale.

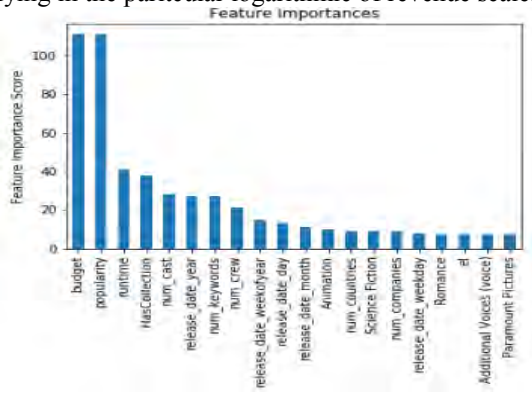

Fig 4: Feature Importance Score Graph

Figure 4 is one of the most important conclusions we draw from the dataset which governs the core of this research paper.

Feature Score graph points out how heavily or lightly would the entertainment revenue generated from the movie released depend on the corresponding factor or feature present along the x-axis of the given graph.

Relative % = Relative probability of dependence * 100%

The histogram graph has along y axis the relative percentage of dependence. As probability lies in range [0,1], relative percentage lies in the range of [0,100].

As per the Figure 4, budget and popularity of the movie heavily determine its revenue generated. That is, if a movie is more popular and its budget is towards the higher end , its more probable to yield a higher revenue.

The runtime of the movie as well as its cast affect the movie's revenue. But out of all of these, one of the easily variable factors that decide the revenue of a movie heavily is its release date. Hence, it is very evident that manipulation of the release date of the movie has a heavy impact on the revenue generated from the released movie.

IV. CONCLUSION

From the above implementation it is clearly seen that the revenue depends not only the release date but also the year, day and month. In fact it depends on the mere fact whetheher its released on weekend or a weekday. Such a small thing can make a vast difference. But the best part is, this can be planned and released optimally to give the best desired results.

V.ACKNOWLEDGEMENTS

- We sincerely thank our guide Dr. R. R. Sedamkar for his guidance and constant support and also for the stick to our backs.
- We also thank the project coordinators for arranging necessary facilities and resources and supporting and promoting among us the culture of research necessary to carry out the required research.
- We thank the Head of the Department, Dr. Sheetal Rathi, the Principal, Dr. B.K. Mishra and the college management for their support.

Abstract - **Text summarization is an approach to summarize the massive amount of information into an abridged form by the process of selection of substantial information and discarding immaterial and redundant information. There are many applications where summary of large documents such as news headlines, market review, short messages on mobile, research work, medical need such as patients history for further treatment, business analysis etc. are needed. Text summarization can be classified into Extractive Summarization and Abstractive Summarization. An extractive summary involves selection of significant sentences from the original documents based on different attributes or features of sentences. Abstractive Summarizationprovidescrisp, efficient and more human-like summary but due to its complexity, much research hasn't been conducted in its domain. The paper aims to depict the usage of RNN and ConceptNetNumberbatch tool for Word Embedding to create powerful summaries of the product reviews obtained from any E-commerce websites .**

Keywords:NeuralNetworks,TextSummarization,Abstractive Summary, Deep Learning, Natural Language Processing

I. INTRODUCTION

A. NEED

In the current scenario where enormous information is available on the internet, it is most important to devise an intuitive approach in order to extract the apt information in a quick and efficient manner. As it is a tedious task for human race to manually extract the summary of large documents of text, so the need of Automatic Text Summarizer arises. Text summarization is the process of recognizing the premier significant information in a document or set of related documents and transforming it into a compact version such that the overall meaning of the original text isretained.

B. RELATEDTHEORY

Synopsis of a huge text is generated using text summarization techniques which is a sub domain of Natural Language Processing(NLP). Text can be summarized using two simple methods, they are NLP based method and deep learning based method.

The popularity of Automatic Text Summarization rose in the early 1950's. Hans Peter Luhn published a paper in 1958 titled "The automatic creation of literature abstracts". To obtain meaningful sentences from the literature he utilized methods like word and phase frequencies for summarization. In 1969 Harold P Edmundson carried out a few significant researches in the domain of automatic text summarization. To extract influential sentences for text summarization he used features such as the presence of words used in the title appearing in the text, location of the sentences, and cue words. Post this,the topic garnered a lot of attention in the field of Research & Development.

Later developments were greatly influenced by the rise of Machine Learning techniques in 1990's that used different techniques to create literature abstracts. Neural Network and common words in search engine queries are emerging methods to further improvise document summarization.Some of the technologies commonly used to create efficient summaries are:

i. *Deep learning*:

Neural Networks (NN) are also utilized for Natural Language Processing (NLP), including Summarizers. Neural networks are viable in practically solving almost any machine learning classification problem. Deep learning uses deep neural networks to learn good representations of the input data, which would then be utilized to perform specific tasks.

ii. Long Short Term Memory (LSTM)Units

The LSTM is a RNN architecture that can remember past contextual values. These stored values do not modify over time while training the model. There are four components in LSTM which are LSTM Units, LSTM Blocks, LSTM Gates and LSTM Recurrent Components. LSTM Unit store values for long time or for short time. LSTM has no activation functions for their recurrent components. Since there are no activation function the values ofunits does not change for some period until the context is changed. A LSTM Block contains such many units. LSTM's are considered as deep neural networks. These LSTM's are implemented in parallelsystems

iii. Encoders andDecoders

Encoder-Decoder LSTM approach has proven very

effective for seq2seq prediction problems. The architecture comprises of two models-one which is responsible for reading the input sequence and getting it encoded into a fixed-length vector and second one for decoding the fixed-length vector and to output the predicted sequence.

iv. Word Embedding

A word embedding is a learned portrayal for text where words that have the same meaning have a similar representation .Each word is mapped to one vector and the vector values are learned in such a way that represents a neural network, and thus thetechnique is frequently lumped into the field of deeplearning.

C. APPLICATIONS

The project is of use when there is a massive amount of data to be analyzed in order to draw a intuitive conclusion. Data nowadays is increasing at an exponential rate. Thereby giving rise to a problem of analyzing it and drawing various profitable results from it. This is where summarization comes into picture. Basically summarization is a technique in which large dataset is summarized into small countable lines of data, so that a user could get something meaningful out of it in a short span oftime. Thismodel also can help in reviewing websites, blogs, news articles, webpage and books. Data nowadays is generated from a lot of source as mentioned above. There are a lot of categories in which data may be segregated but segregating such a massive volume of data is not imaginable. So the model aims to generate summaries of the reviews provided on an e-commerce site in order to aid the firm in the decision making process to make insightful decision regarding thebusiness.

II. LITERATUREREVIEW

After surveying a number of resources and papers, a number of principles were understood and a gap analysis has been represented using a tabular representation in Table 1

III. PROBLEMDEFINITION

The problem definition in our project involves extracting key information from information source by employing a text summarization tool. This project aims to read the input file which may be in sort of documents to be analyzed and preprocessed so as to separate it into several segments that would each be attributed with values. These are then transformed into concrete semantic statements using several algorithms which can be mentioned. Our problem definition covers the concept of converting convoluted, mammoth data into a useful segment which is concise, yet doesn't lose the essence of original document.

IV. PROPOSED METHODOLOGY

Neural sequence-to-sequence models deliver a viable innovatory approach for abstractive text summarization (they are not limited to merely selection and rearrangement of passages fromtheoriginal text). However, these models have two shortcomings firstly they are prone to reproduction of inaccurate factual detail and moreover they hold a high tendency to repeat themselves [1]. In this work standard Long Short-Term Memory(LSTM) sequence-to- sequence attentional model has been used. This method uses a local attention model for generating each word of the summary reliant on the input sentence. While the model is structurally simple, it can easily be trained end- to-end and scalable to a huge amount of training data. The reconstructed paragraph was evaluated using standard metrics such as ROUGE, depicting that neural models are capable of encoding texts in sucha way that syntactic, semantic, and discourse coherence is preserved.The first step is to acquire data.The downloaded dataset,which is in a CSV file is read by a program and in second stepis cleaned.The preview is obtained. The cleaning phase consists of removing stopwords, removing null entries, replacing contractions with their longer forms, and removing unwanted characters like symbols and emojis. Stopwords are only removed from Text part of the reviews, they are not removed from Summaries to sound like more natural phrases. After processing the data, it will have only two columns i.e. text and summary, Once the data is cleaned, it is tokenized and converted into vectors so that it can be processed by the model.Then loading of the pre-trained ConceptNetNumberbatch word embedding takes place. The number of missing words in the embedding is found by comparing all the tokens from our reviews data to loaded embedding.Tokens such as <unk> are added for those words which are unknown and <pad> is a used in the end of line to indicate that it's the end of line. Finally, the sorting of the summary and text by the length of text, i.e. from shortest to longest is carried out. A Model will be designed which will be used while training. Since we are using TensorFlow,our major effort goes into building graphs. We will create few placeholders to hold our data and other parameters. Then we will create our bi-directional encoder, which will generate its own representation of inputdata.

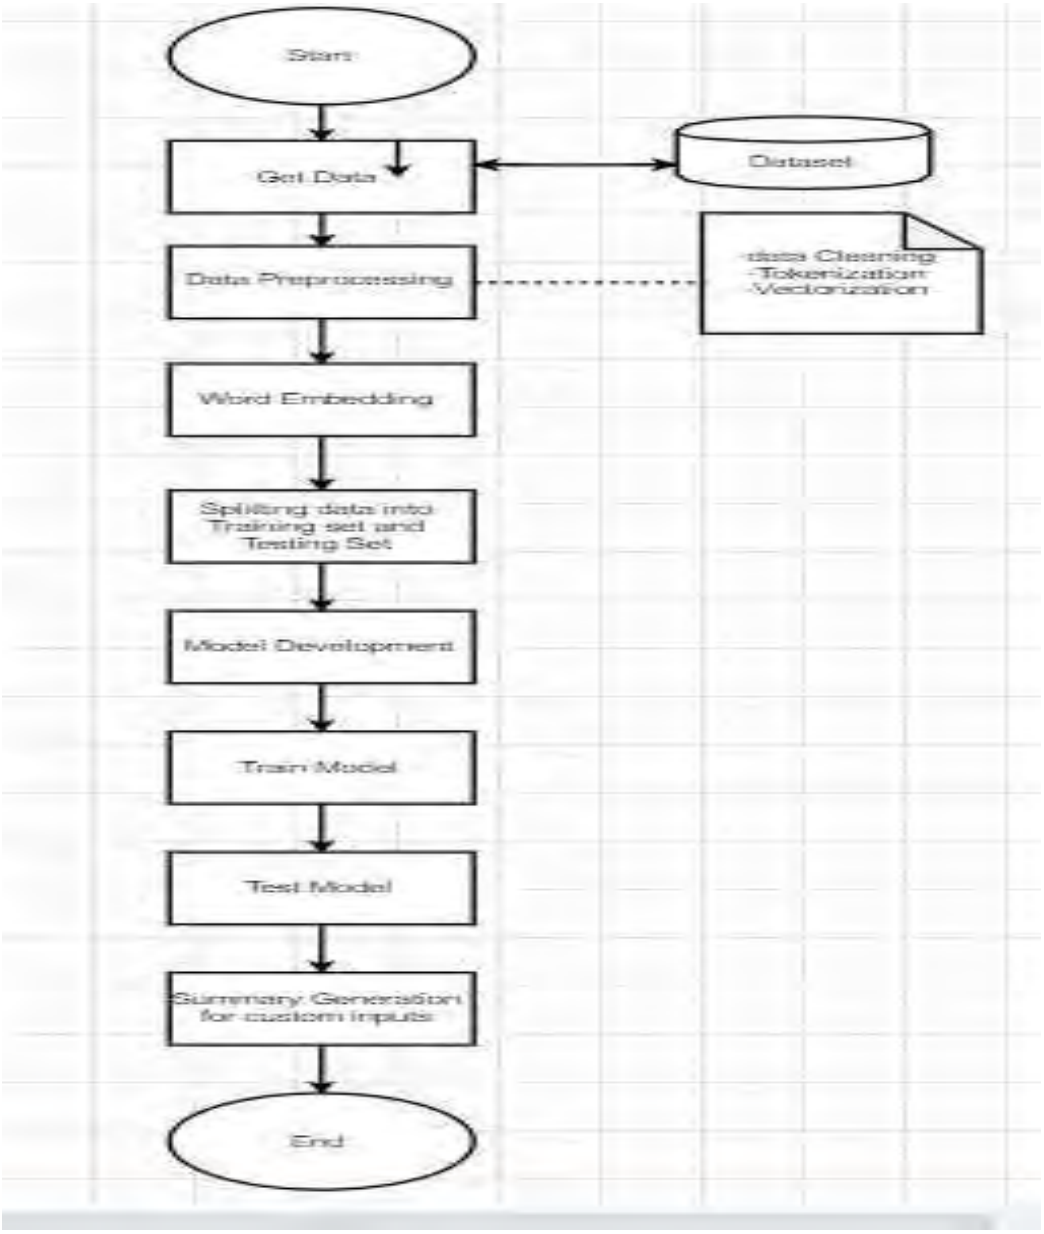

FIG 1:FLOWCHART DEPICTING SUMMARIZATION

V. RESULTS &DISCUSSIONS

The snapshots numbered Fig 2 and Fig 3 depict the initial preview of dataset and the results obtained post its cleaning. Thecleaningphase involves of removal of stopwords, null, null entries ,unwanted characters replacement of contractions with their longer forms, and removal of. After processing the data, it will have only two columns i.e. text and summary.

FIG 2: PREVIEW OF THE DATASET

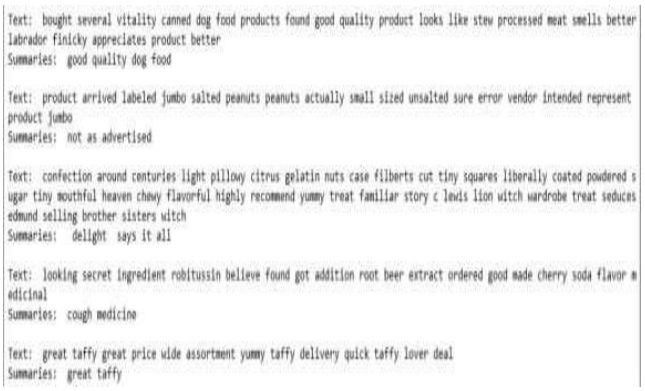

FIG 3: AFTER CLEANING THE DATA

Text Summarization is one of the inspiring field of research because it has many applications where we need summary of the large documents such as news headlines, market review, short messages on mobile, medical, business analysis etc.Abstractive summary methods produces highly relevant, crisp, information rich and less redundant summary, but because of its complexity less research has been carried out in the field of abstractive summarization. Although the interest in summarization has been developing and new approaches are being devised constantly, the task of automatic summarization has still unansweredquestions,
e.g. how to accomplish a deeper understanding of the document topic (natural language understanding, NLU), how to handle long documents, and how to enhance the evaluation strategies. Finding solutions to these questions will pave the way for further research in this area.

VI. ACKNOWLEDGEMENT

We sincerely thank the project co-ordinators for arranging the necessary facilities to carry out theproject work. We also extend our heartfelt thanks to our colleagues, family members and well- wishers.

Abstract— **Problems at the intersection of language and vision are of notable importance both for the diverse set of applications they offer and as challenging research questions. Introducing the task of open ended and free-form Visual Question Answering (VQA). A VQA system produces a natural language answer as the output while taking an image and a free-form, open-ended, natural language question about the image as inputs. Visual questions selectively target various areas of an image, including background details and underlying context. A system that succeeds at VQA typically needs a more comprehensive understanding of the image and complex reasoning than a system producing generic image captions. VQA is also amenable to automatic evaluation, since many open-ended answers contain only a few words or a closed set of answers that can be provided in a multiple-choice format. Visual questions target different areas of an image, including background details and underlying context.**

Keywords— Neural Networks, Text, Summarization, NLP, Deep Learning, Encoder Decoder

I. INTRODUCTION

Vision and language problems like visual question answering and image captioning have become more popular in recent years because the computer vision research community is progressing beyond recognition and towards solving multi-modal problems. The complex structure of language makes problems at the intersection of vision and language very challenging. We shall introduce the task of free-form and open ended Visual Question Answering (VQA). A VQA system takes as input a picture and a free-form, open-ended, tongue question about the image and produces a tongue answer because the output. This task which is goal-driven is applicable to scenarios like when visually-impaired users or intelligence analysts actively elicit visual information.
For our methods, we develop a 2-channel image (vision) question (language) model that ends with a softmax over K possible outputs. We choose the highest K = 1000 most frequent answers as possible outputs. The set of answers covers 83% of the train+val answers. This combined image + question embedding is then passed to an MLP– a fully connected neural network classifier with 2 hidden layers and 1000 hidden units (dropout 0.5) in each layer with tanh nonlinearity, followed by a softmax layer to obtain a distribution over K answers. The complete model is learned end-to-end with a cross-entropy loss. VGGNet parameters are frozen to those learned for ImageNet classification and not fine-tuned within the image channel. Although VGG is old, it was used because of its portability and ease of use, as well as due to the fact that it is very well understood.

II. HISTORY

A. VQA

Several recent papers have begun to review visual question answering. However, unlike our work, these are fairly restricted (sometimes synthetic) settings with small datasets. As an example, [1] only consider questions whose answers come from a predefined closed world of 16 basic colors or 894 object categories. [1] Also considers questions generated from templates from a hard and fast vocabulary of objects, attributes, relationships between objects, etc. In contrast, our proposed task involves open-ended, free-form questions and answers provided by humans. Our goal is to extend the range of data and sorts of reasoning needed to supply correct answers. Critical to achieving success on this harder and unconstrained task, our VQA dataset is 2 orders of magnitude larger than [1], [2] (>250,000 vs. 2,591 and 1,449 images respectively). The proposed VQA task has connections to other related work: Some has studied joint parsing of videos and corresponding text to answer queries on two datasets containing 15 video clips each. [3] Uses crowdsourced workers to answer questions on visual content asked by visually-impaired users. In concurrent work, [2] proposed combining an LSTM for the question with a CNN for the image to get a solution. In their model, the LSTM question representation is conditioned on the CNN image features at whenever step, and therefore the final LSTM hidden state is employed to sequentially decode the solution phrase. In contrast, the model developed during this paper explores “late fusion” – i.e., the LSTM question representation and therefore the CNN image features are computed independently, fused via an element-wise multiplication, then skilled fully connected layers to get a softmax distribution over output answer classes. It generates abstract scenes to capture visual sense relevant to answering (purely textual) fill-inthe-blank and visual paraphrasing questions. Some use visual information to assess the plausibility of sense assertions. One introduced a dataset of 10k images and prompted captions that describe specific aspects of a scene (e.g., individual objects, what is going to happen next). Concurrent with our work, some collected questions & answers in Chinese for COCO images. One automatically generated four sorts of questions using COCO captions.

B. Various Works

Text-based Q&A may be a well-studied problem within the NLP and text processing communities. Other related textual tasks include sentence completion. These approaches provide inspiration for VQA techniques. One key concern in text is that the grounding of questions. As an example, one synthesized textual descriptions and QA-pairs grounded during a simulation of actors and objects during a fixed set of locations.

VQA is of course grounded in images – requiring the understanding of both text (questions) and vision (images). Our questions are generated by humans, making the necessity for common- sense knowledge and sophisticated reasoning more essential.

Describing Visual Content- associated with VQA are the tasks of image tagging, image captioning, and video captioning, where words or sentences are generated to explain visual content. While the tasks require both visual and semantic knowledge, captions can often be non-specific. The questions in VQA require detailed specific information about the image that generic image captions are of little use [3].

Several papers have explored tasks at the intersection of vision and language that are easier to gauge than image captioning, like co reference resolution or generating referring expressions for a specific object in a picture that might allow a person's to spot which object is being mentioned. While concrete and task-driven, a limited set of visual concepts (e.g., color, location) tend to be captured by referring expressions. We shall demonstrate, a richer sort of visual concepts emerge from visual questions and their answers.

C. Problem Definition

The primary problem of our project is generating answers to visual questions which can be done using concepts of Image Recognition and Deep Learning. There are many potential applications for VQA. The foremost immediate is as an aid to blind and visually impaired individuals, enabling them to urge information about images both on the online and within the world. For instance, as a blind user scrolls through their social media feed, a captioning system can describe the image then the user could use VQA to question the image to urge more insight about the scene. More generally, VQA might be wont to improve human-computer interaction as a natural thanks to query visual content. A VQA system also can be used for image retrieval, without using image meta-data or tags. For instance, to seek out all images taken during a rainy setting, we will simply ask 'Is it raining?' to all or any images within the dataset. Beyond applications, VQA is a crucial basic research problem. Because an honest VQA system must be ready to solve many computer vision problems, it are often considered a component of a Turing Test for image understanding.

The overarching goal of VQA is to extract question-relevant semantic information from the pictures , which ranges from the detection of minute details to the inference of abstract scene 2 Figure 1: Object detection, semantic segmentation, and image captioning compared to VQA. The center figure shows the perfect output of a typical object detection system, and therefore the right figure shows the semantic segmentation map from the COCO dataset [10]. Both tasks lack the power to supply contextual information about the objects. The captions for this COCO image range from very generic descriptions of the scene, e.g., a busy town sidewalk next to street parking and intersections, too much focused discussion of one activity without qualifying the general scene.

D. Proposed Aspects of Project

This report is built to generate implementation approaches to address text summarization. This project will be helpful to the social networking or ecommerce companies, as well as to the blind people who want to get acquainted with technology. It will be helpful to these companies as these questions could then collect feedback and connections, and replies to various customer questions could then directly be generated. It shall benefit the blind man as solutions shall be given to their various questions, thus reducing human help and making them more capable.

This uses a classic CNN-LSTM model, where Image features and language features are computed separately and combined together and a multi- layer perceptron is trained on the combined features. While VGG Net is not the best CNN model for image features, GoogLeNet and ResNet have superior classification scores, but VGG Net is very versatile, simple, relatively small and more importantly portable to use. It takes as input a sequence of words and generates an output sequence of words. Extracting image features involves, taking a raw image, and running it through the model, until we reach the last layer. In this case our model is not 100% same as VGG Net, because we are not going to use the last two layer of the VGG. It is because the last layer of VGG Net is a 1000 way softmax and the second last layer is the Dropout. The question has to be converted into some form of word embeddings. Most popular software right now is Word2Vec. VQA is a simple model which combines features from Image and Word Embeddings and runs a multiple layer perceptron. By implementing this project not only are we enabling companies to save precious time and money, but also empowering various people by making it easier for them to join the technology ecosystem and live with it. Since the project works on images, combining them with the questions asked allows us to produce very accurate answers, with further proof that once enough data is provided to this model, it will produce even better results.

III. SYSTEM ANALYSIS

A. Methods

For our methods, we develop a two-channel image question model that culminates with a softmax over K possible outputs. We choose the top K = 1000 most frequent answers as possible outputs. This set of answers covers 82.67% of the train+val answers. We describe the different components of our model below.

Image Channel: This channel provides an embedding for the image. We experiment with two embeddings –

1. The activations from the last hidden layer of VGGNet are used as 4096-dim image embedding.
2. These are 2 normalized activations from the last hidden layer of VGGNet.

Question Channel**:** This channel provides an embedding for the question. We experiment with these embeddings:

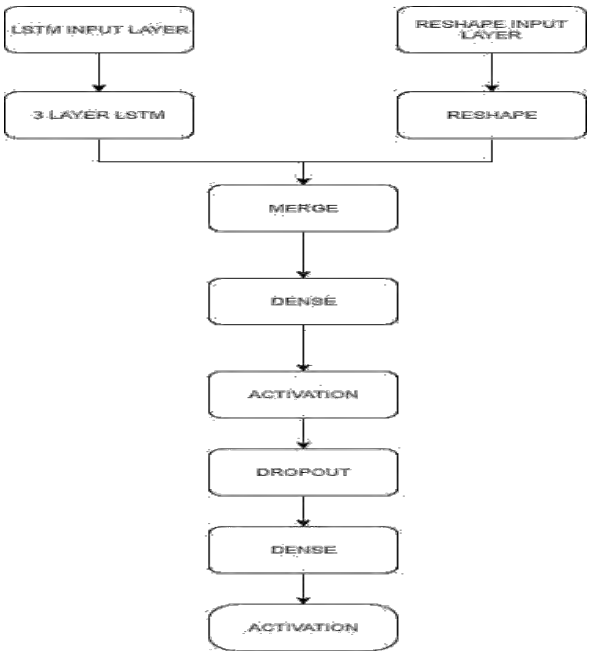

Figure 1

1)Bag of Words Question: the highest 1,000 words within the questions are used to create a bag-of-words representation. Since there's a robust correlation between the words that start a question and therefore the answer (see Fig. 5), we discover the highest 10 first, second, and third words of the questions and make a 30 dimensional bag-of- words representation. These features are concatenated to urge a 1,030-dim embedding for the question.

2) LSTM Q: An LSTM with one hidden layer is employed to get 1024-dim embedding for the question. The embedding obtained from the LSTM may be a concatenation of last cell state and last hidden state representations (each being 512-dim) from the hidden layer of the LSTM. Each question word is encoded with 300-dim embedding by a fully-connected layer + tanh non-linearity which is then fed to the LSTM. The input vocabulary to the embedding layer consists of all the question words seen within the training dataset.

3) Deeper LSTM Q: An LSTM with two hidden layers is employed to get 2048-dim embedding for the question. The embedding obtained from the LSTM may be a concatenation of last cell state and last hidden state representations (each being 512-dim) from each of the 2 hidden layers of the LSTM. Hence 2 (hidden layers) x 2 (cell state and hidden state) x 512 (dimensionality of every of the cell states, also as hidden states). this is often followed by a fully-connected layer + tanh non-linearity to rework 2048-dim embedding to 1024-dim. The question words are encoded within the same way as in LSTM Q.

Multi-Layer Perceptron (MLP): The image and question embeddings are combined to get one embedding. 1) For BoW Q + I method, we simply concatenate the BoW Q and that i embeddings. 2) For LSTM Q + I, and deeper LSTM Q
+ norm I methods, the image embedding is first transformed to 1024-dim by a fully-connected layer + tanh non-linearity to match the LSTM embedding of the question. The transformed image and LSTM embeddings are then fused via element-wise multiplication. This combined image + question embedding is then passed to an MLP – a totally connected neural network classifier with 2 hidden layers and 1000 hidden units (dropout 0.5) in each layer with tanh non-linearity, followed by a softmax layer to get a distribution over K answers. The whole model is learned end-to-end with a cross-entropy loss. VGGNet parameters are frozen to those learned for ImageNet classification and not fine-tuned within the image channel. We also experimented with providing captions as input to our model. We assume that a human-generated caption is given as input. We use a bag-of-words representation containing the 1,000 hottest words within the captions because the caption embedding (Caption). For BoW Question + Caption (BoW Q + C) method, we simply concatenate the BoW Q and C embeddings.

B. Technology Involved

There are primarily these approaches for achieving better troubleshooting results using the proposed technique: The question has got to be converted into some sort of word embeddings. Preferred is Word2Vec whereas lately state of the art uses skip-thought vectors or positional encodings. Extracting image features consists of taking a raw image, and running it through the model, until we reach the last layer. VQA may be a simple model which mixes features from Image and Word Embeddings and runs a multiple layer perceptron. Several technologies are used which include Keras+tensorflow framework, alongside training on VGGnet and Spacy. Keras is an open source,NN library written in Python. it's capable of running on top of TensorFlow, Theano, Microsoft Cognitive Toolkit or PlaidML.It was designed to enable fast experimentation with deep neural networks, it focuses on being extensible, modular and user-friendly. spaCy is an open-source software library for advanced NLP, written within the programming language Python. TensorFlow is an open-source software library for dataflow programming across a variety of tasks. it's a symbolic math library. VGG16 is a convolutional neural network model proposed by A. Zisserman and K. Simonyan from the University of Oxford within the paper "Very Deep Convolutional Networks for Large- Scale Image Recognition". Scikit-learn may be a free software machine learning library for the Python programing language. Scikit features various regression, classification and clustering algorithms including support vector machines, random forests, gradient boosting, k-means and DBSCAN, and is meant to interoperate with the Python's numerical and scientific libraries NumPy and SciPy.

C. User Interface Design

The UI has been kept simple and easily understandable due to the assumption that the target audience is not technology friendly. There is an upload button clicking on which will allow the user to upload the image. The box on the left of it shall show the file name and the text input box below it is for the user to explain the problem further. The troubleshoot button then submits this data further.

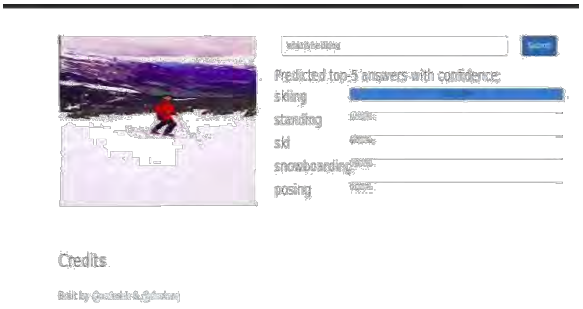

Figure 2

IV. CONCLUSION

As was expected, the vision-alone model that completely ignores the question performs rather poorly (open-ended: 28.13% / multiple-choice: 30.53%). In fact, on open-ended task, the vision-alone model (I) performs worse than the prior ("yes") baseline, which ignores both the image and question (responding to each question with a "yes"). To one's surprise, the language-alone methods which ignore the image perform surprisingly well, with BoW Q achieving 48.09% on open- ended (53.68% on multiple-choice) and LSTM Q achieving 48.76% on open-ended (54.75% on multiple-choice); both outperforming the closest neighbor baseline (open-ended: 42.70%, multiple- 10 choice: 48.49%). Our quantitative results and analyses suggest that this could be thanks to the language-model exploiting subtle statistical priors about the question types (e.g. "What color is that the banana?" are often answered with "yellow" without watching the image). For an in depth discussion of the subtle biases within the questions, please see. The accuracy of our greatest model (deeper LSTM Q + norm I selected using VQA test-dev accuracies) on VQA test standard is 58.16% (open-ended) / 63.09% (multiple-choice). We will see that our model is in a position to significantly outperform both the vision-alone and language-alone baselines. As a common trend, results on multiple-choice are better than open-ended. All methods are significantly worse than human performance. For some application domains, it might be useful to gather task-specific questions. As an example, questions could also be gathered from subjects who are visually impaired, or the questions could specialize in one specific domain (say sports). Bigham et al created an application that permits the visually impaired to capture images and ask open-ended questions that are answered by human subjects. These questions can rarely be answered using generic captions. Training on task-specific datasets may help enable practical VQA applications. We believe VQA has the distinctive advantage of pushing the frontiers on "AI-complete" problems, while being amenable to automatic evaluation. Given the recent progress within the community, we believe the time is ripe to require on such an attempt.

V. ACKNOWLEDGMENT

We sincerely thank our guide Ms. Ashwini Patil for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

We thank the HOD, Dr. Sheetal Rathi, Dean Academic, Dr. R.R Sedamkar, the Principal, Dr. B. K. Mishra and the college management for their support.

Abstract— **Visual analysis of clothing is a topic that is receivingincreasedattentioninthefieldsofcomputervisionand machine learning. In our project, we determine what kind (genre) of clothing is worn in a set of pictures and using the involvement (likes) on these pictures to identify which genre is liked the most by the audience. After identifying the clothing in thepicture,thesystemhasafeaturetosearchforsimilartypeof apparelontheinternetandprovidetheuserwithlinks.System, also, provide a facility to user to find a person using the cloth and background descriptions. This model will be able to detect thegarmentitemsandclassifytheclothingattributesforfashion illustrations. This field has applications in e-commerce, social media and criminallaw.**

Keywords— Deep Learning, Computer Vision, Clothes Detection, Clothes scouting

I. INTRODUCTION (*HEADING1*)

ThisVisualanalysisofclothingisatopicthatisreceiving increased attention in the fields of computer vision and machine learning. Our project is based on the same idea. We aredevelopingasystemthataimstoidentifytheapparel worn by the user and the likes obtained on that post. Using the datasetprovidedtoit,itwillidentifywhatkindofapparel the user has worn. It will let the user know about the other users who have worn similar apparel and have obtained morelikes than them. Also, the system will also assist the user by providing some online shopping website links so as to assist the users to shop the same kind of apparel. This system will help the users especially the fashion bloggers who influence the fashion sense of theusers.

Besides this, the system will do comparative analysis using the likes obtained on the user's post and obtain other inputs from the posts posted by the other users. The working ofthesystemcanbeextendedfurthertoprovideacomparative basedmodelthatdoesacomparativestudyonvariousaspects with web scoutingassistance.

Inthelastfewyears,rapidprogresswasobservedindeep learning, especially in convolutional neural networks, GPU hardwareprocessingacceleration,andimageprocessing.With the help of multiple GPU cores, we can, now, train our deep learningmodelonmorethanamillionhigh-resolutionimages tolearnfeaturerepresentationandclassifyclothingimages.Afeature of our paper is to detect the proper landmark of the clothes from an image and to recognize its attributes and characteristics of that item. The same feature can be used to automatically tag the images with proper attributes of the clothes present in that image.

Since the purpose (or aim) of our system is to provide a holisticsolutiontotheinfluencersabouttheirclothing, wedo notjustleavetheinfluencerwithastatementabout"Whatare theylikedmorein"or"whatcreatesmoreengagementontheir socialmedia".Webelieveingoingastepaheadandproviding another feature wherein, after figuring out your most liked appareltype,theprojectwillscanforsimilarappareltypeson the web, which is up for sale, and provide the link (URL) of the same. This gives the clients direct access to clothes that theiraudiencelikestoseethemin,withanoptiontogoon and buythem.Oncetheattributesoftheclothesarecapturedfrom theinputimage,thoseattributescanbeusedtoscrapetheweb tofindsimilartypesofapparelavailableone-shopswiththeir prize.

Adding to the ground functionality of the project, our projecthasfeaturesonthesidewhichcanbeofadditional use in this same domain of image processing and clothing detection. The additional feature being referred to is to recognizeandtrackthemovementofthesuspect.Thesuspect can be identified by the clothes he or she is wearing and the fashion accessories (like a bag, eyewear, hat, etc.) he or she was having, even if the suspect's face is notvisible.

II. LITERATURESURVEY

A. A Deep-Learning-Based Fashion Attribute Detection Model

They propose a data-driven approach for recognizing fashion attributes. They engineered a modified version ofthe FasterR-CNNmodelwhichistrainedonalarge-scaledataset with 594 fine-grained attributes. They opted forDeepfashion as their Dataset for the category and attribute predictiontask. They removed 45 unclear attributes such as "Girl" "Please" andmergedsemanticallysimilarattributessuchas"geo","geo prints"and"abstractgeoprints".However,theywereno tableto deal with wrongly labeled images and cross-domain attributes.

Their architecture consists of a Faster R-CNN object detectionframeworkwithResNet101andROI-alignwithtwo modifications: a pruning mechanism and additional clothing attribute branches parallel to the category branch. They approach learning, both, attributes and category as a multi- task learningproblem.

B. Clothes Detection and classification UsingConvolution NueralNetworks

ThispapergaveaninsightintotheapplicationofCNNfor clothdetection.

They used:

a. CNNwith1ConvolutionalLayer

b. CNNwith3ConvolutionalLayer

c. CNNwith4ConvolutionalLayer

They had the following approach for evaluation:

I. Split the original training data into 80% training and 20% validation to optimize theclassifier.

II. Train the model for 10 epochs. They used categorical_crossentropylossfunctionandAdamoptimizer.

III. Theythentrainedthemodelandevaluatedthelossand accuracy. The following table depicts the loss and accuracy obtained using the above threemodels.

Table 1: Loss and Accuracy table

Number of CNN Layers	Test Scores	Test Accuracy
1	0.2484	0.9104
3	0.2496	0.9079
4	0.2656	0.952

C. Clothing Landmark Detection Using DeepNetworks With Prior of KeyPointAssociations

Thispaperconsiderstheproblemoflandmarkpointdetection inclothesfortheupperbody,whichisimportantandvaluable for the clothing industry. Their paper also discusses how to use these landmarks to recognize the category of clothing worn by the person in the image. The first step in their paper is to use YOLO object detection [7]. YOLO will form a boundingboxaroundthedetectedclothes.Thenextstep isto resizetheboundingboxto256x256,whichisusedasaninput tothefollowingstepofdetectinglandmark.Theyengineered adeepend-to-endarchitecturewhichhasfourbuildingparts:

1) A subnetwork of the stacked convolutional layer that captures the features of an inputlayer.
2) Adeconvolutionstackthatoutputsresolutionpreserving, each in the size of the inputimage.
3) Anotherlayerofconvolutionwhichisaninputtotheloss function.
4) Calculatingtheprobabilityofapointusing(2)and(3)to find the most possible candidates for thelandmark.

For identification of the attributes of the clothes,their algorithm focuses on a particular region. For example, the collar part will have four landmark points; theminimumrectangle that covers these landmark points is extended from width and height by 40%, respectively, with the original rectangle at the center position. Next, this rectangle is extractedfromtheimageandthefourlandmarksareconverted intoafeaturevectorasaninputtotheconvolutionsubnetwork basedVGG-13[4].Then,thefourfeaturevectorsareaveraged toonevectorasthefeaturerepresentationofthewholeimage. On top of this feature representation, we construct two fully connected layers, followed by three sibling vectors corresponding to the discriminative representation of the collar type, the sleeve type, and the clothing category, respectively. Finally, softmax loss functions are defined in these siblingvectors.
This paper, however, does not talk about the lower-body or other garment types apart from clothes for the upper-body.

D. Convolutional Neural Networks for Fashion Classification and Object Detection

They were able to achieve an accuracy of 50.2% for clothing style classification and clothing and 74.5% for attribute classification. They used Apparel Classification with Style (ACS) Dataset, which contains 89,484 images that were cropped based on bounding boxes around the individual's upper body. Each image is labeled with one of the 15 clothing categories.

For clothing type classification they used Histogram of Oriented Gradients (HOG), Speeded Up Robust Feature (SURF), LBP, and color information. Achieving35.03%, 38.29%, and 41.63% accuracy respectively. They then finely tuned R-CNN model to detect clothingobject

Multi-Label Fashion Image Classification with

Minimal Human Supervision

This paper properly deals with noisy data by building a baseCNNwhichisusedtoextractfeatures.ThebaseCNN is combined with a label cleaning network and an image classifier. The input images to their architecture were resized to 256x256. The base CNN observed about +7% increase.

III. SYSTEM MODEL

A. Dataset

1. DeepFashion

DeepFashion is a large scale clothes database, with over 800,000 diverse fashion images containing several appealing properties. The dataset is a label with fifty categories and is annotated with one thousand descriptive attributes. Out of total images, only 0.5% of images were found with inconsistent labels and required correctlabeling.

Theimagesinthedatasetaresegregatedintofivesub-datasetswhichareCategoryandAttributePrediction, Consumer-to-shopClothesRetrieval,In-shopClothes Retrieval, and LandmarkDetection.

1.1 Fashion LandmarkDetection:

The landmarks correspond to a set of key points defined in the structure of clothes, such as sleeves, cuffs, hemline, and neckline [2]. Landmarks are important because they will help in identifying the categories and attributes of the clothes. Landmark detection dataset contains 123,016 JPG images and“Anno” folder which contains pixel co-ordinates for bounding box and landmark coordinates. The main purpose of this dataset is used to train the Deep Learning model to detect. The Upper-body clothes possess six fashion landmarks, lower-body clothes possessfourfashionlandmarks,andfull-bodyclothes possess eight fashionlandmarks.

Table 2Fashion Landmark Dataset Label Classes used in Landmark Detection Task

Dataset Attributes	Classes
Clothes Type	Upper-body clothes, Lower-body clothes, Full-body clothes
Variation type	Normal pose, Medium pose, Large pose, Medium zoom-in, Large zoom-in
Landmark Visibility	Visible, Invisible/ Occluded, truncated/cut-off

1.2 Category and Attribute Prediction this dataset contains 289,222 JPG images and an “Anno” folder which containscoordinates

2. Street2Shop

Thegoalofthisdatasetistomatchtheapparelrecognized fromtherealworldimagetoasimilariteminanonlineshop. Thesedatasetaimstoshowcasehowonewouldstyleanoutfit andhelpothersdecidewhethertheywanttopurchaseanitem. Thedatasetcontainsthe“Photos”txtfileandJSONfiles. The “Photos” file contains URL to 424,840 images and supports 11 clothing articles. Supporting 11 clothing articles is one morereasontousethisdataset.Sothatourmodelwillals obe able to recognize more wearables other than upper body clothesandlowerbodyclothes.TherearethreetypeofJSON files, which are test_pairs_{category}.json, train_pairs_{category}.json and retrieval_{category}.json. Since Street2Shop Dataset supports 11 clothing categories. Therefore,thisdatasethas33JSONfiles.TheretrievalJSON filehasthelistoftheidofphotosthatcomeunderitscategory. The test and train JSON file have a list of photo IDs and the co-ordinatesoftheboundingbox.EachJSONfilecontains an image ID of an image, which belongs to that particular category, and product ID. The dataset contains two types of images:

1) Street Photos: There are large variations in theimages. Variations in terms of lighting, indoor vs outdoor environments, body shapes and sizes of the people wearing theclothing,poseofthepeople,cameraviewingangle,anda huge amount of occlusion due to the layering of items in outfits.Inaddition,aphotomaydepicteitherahead-to-toeThe dataset is available online at http://www.tamaraberg.com/street2shop. It contains two files a “photos.txt” file and a “meta.zip” file. “Photos.txt” file contains the id of the image and its URL separated by commas. We wrote a python program to download those images and save them using their ID as the name.

B. SystemSpecification

Like other deep learning problems, it is crucial to have a computational system with powerful GPUs to train a deep learning model on a hefty amount of data..

Table 3 System Specifications

Component	Specification
RAM	16 GB
CPU	Intel I7
GPU	
Cuda Toolkit	10.2
Operating system	Ubuntu 18.04

Table III gives the detail configuration of the laptop on which we have carried out the experiments. We installed CUDA, a parallel computing platform and programming model developed by NVIDIA [11], to utilize the power of GPU cores.

Every method of this paper is implemented in Pytorch as it enables easy, fast, flexible experimentation and efficient production[10].Pytorchiseasytoperformexperiments ,asits syntaxisverysimilartothatofpython,yetprovidespowerful APIs and ecosystem. One of the main reasons for opting for pytorch is its support for data parallelism. Because of Data parallelism,thepytorchcandistributethecomputationalwork among multiple GPU cores which results in reduced training and testingtime.

C. Proposed Method

1. Clothing item and AccessoriesDetection

Itisveryimportanttodetectnotonlyoneclothingitem from the given frame but all clothing and fashion accessories like bags, belts, hats and so on. In this paper, our goal is to detect upper-body, lower-body and/or both full-body apparels and accessories that includehats,eyewear,footwear,bags,andbelts,ifany ofthemarepresent.Forthispurpose,wefine-tunethe pre-trained Faster-RCNN model to detect the present objects [13]. We created two models, the first model was trained on the DeepFashion dataset (Landmark detection benchmark) and second onStreet2Fashionshotorseveralpartial-bodyshots.Thesevividvarietiesreflect the extreme challenges and variations that we expect to find for clothing retrieval in real-worldapplications.

2) ShopPhotos:Theseareimagesoffashionmodelsorjust clothes from an e-commerce site. This dataset has 404,683 imagesfrom25differentonlineclothingretailersandwith11 clothing articles starting from small items as belts and eyewear, to medium size wearables like hats or footwear, to larger items as jackets, tops, orpants.

Collection of Street2Shop dataset:Dataset. The need to train the model on the Street2Fashion dataset was for the model to identify thefashionaccessories.Beforetraining,allimagesare resized to 512 x 512 size and are passed through the fastNIMeansDenoisingColored method of OpenCV packagetodenoisetheimages[12].Themodeloutputs the image with multiple bounding boxes around the clothes and other fashion accessories. In addition to this, the details are stored in a JSON file, an example is shown in figure I so that it can be used for further experiments.

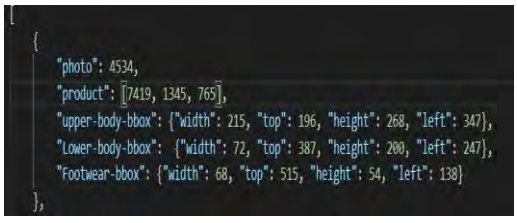

Figure IOutput JSON file of Clothes Detection Model

ThisoutputJSONfilecontainsthephotoid,productid and bounding box location for present clothing and accessories items. Table IV shows which color is assigned to which FashionItems.

Table 4 Color assigned to the bounding box

Items	Color assigned to the bounding box
Upper-Body Clothes	Green
Lower-Body Clothes	Yellow
Full-Body Clothes	Blue
Other Fashion accessories	Red

2. LandmarkDetection

Beforebeginningwiththelandmarkdetection,weuseour fine-tuned faster RCNN model to detect clothes and accessoriesandformboundingboxesaroundthesame. From the output JSON file, which is obtained from the detection process, we will focus only on bounding boxes for clothing (upper-body, lower-body, and full-body clothes). Then these selected regions of the image by bounding boxes arecropped from the image shown in figureII.

Figure II Cropping of the required region for landmark detection

Once the required regions are cropped out of the given imagestheyareresizedto512x512.Now,eachnewimageis passed through our custom made deep architecture, which is inspired by[3].

2.1. Deep Architecture

Figure III shows the deep architecture of our model and is drawn with the help of the online toolNN_SVGprovidedbyAlexNail[14].Inthis figure, the first two layers are the convolutional layersofsize512x512x64.Followedbyamax-poollayerof216x216x128andagainfollowed bytwoconvolutionallayers.Thisisrepeateduntil the size layer becomes 64 x 64. Since there are three max-pool layers, the size of the feature is too small to capture sufficient information to pinpointthelocationofthelandmark.Hence,we use three deconvolutional neural layers to map theoutputfeaturesonthesameimagesizethatof the input, which is 512 x 512. At the end of the architecture, the softmax function is used to

compute the probability for each landmark detected. For upper-body clothes, our network provide12 landmark points. For lower-body clothes,thenetworkprovides8landmarksand14 landmarks for full-bodyclothes.

3. Clothing attributeclassification

   To predict the category and attributes of the clothes presentinanimage,wewillusethelandmarkfeatures of the clothes extracted by the erstwhile network. We propose another network of neurons to recognize the attributesofapparelasindicatedinfigureIV.Indetail, the network uses a layer of dimension 2048 x N x N, where N is the number of landmarks provided by the previous layers as per the clothes location, three convolutionallayersfollowedbyalayerofninenodes, for each attribute except for the color, with softmax activationfunction.Forcoloridentification,thispaper usesfocusesontheregionwithintheboundingbox.If the same color is present in the maximum region then that color is declared as the color of the clothing, for which we trying to predict theattribute.

4. Clothes ScoutingAssistant:

   This feature can be implemented simply thanks to the vivid python web scraping packages and google's shopping search feature. The attributes predicted can beusedaskeywordstosearchtheshoppingsectionof google to find clothes that are similar to detected clothes.

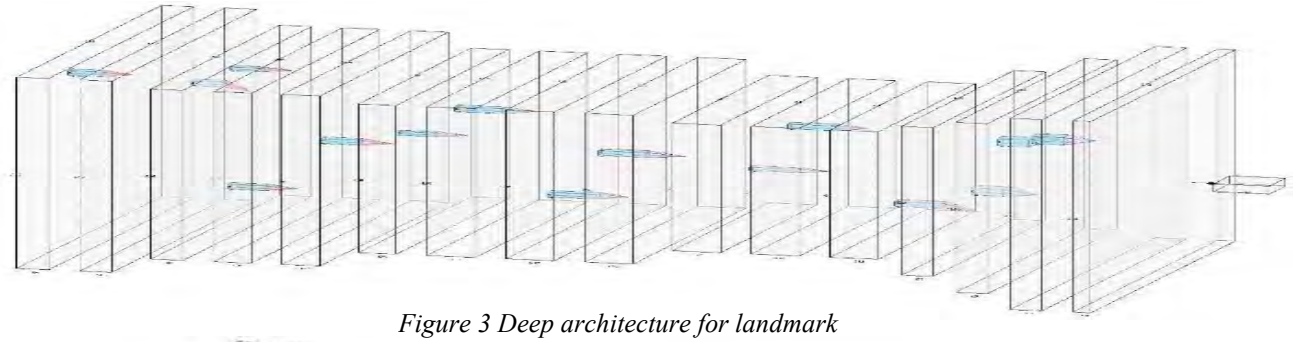

Figure 3 Deep architecture for landmark

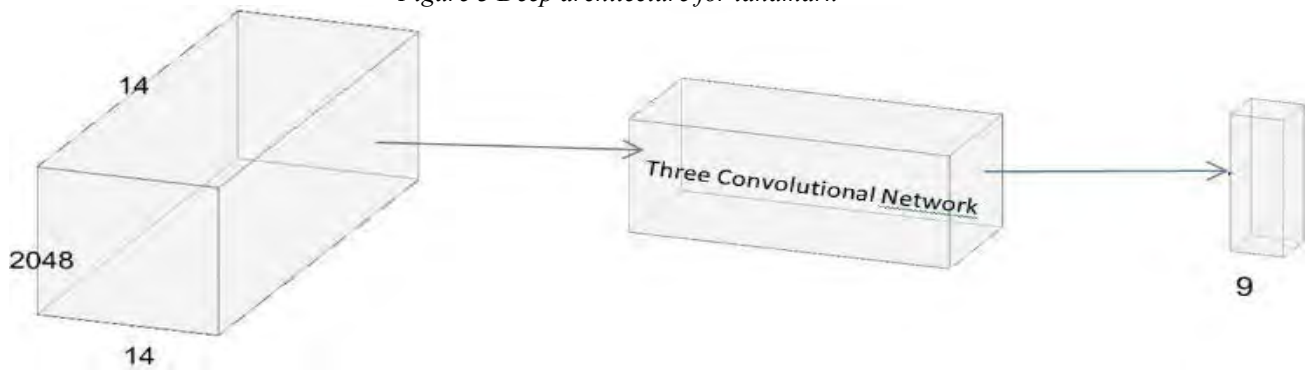

Figure 4 Clothes scouting output

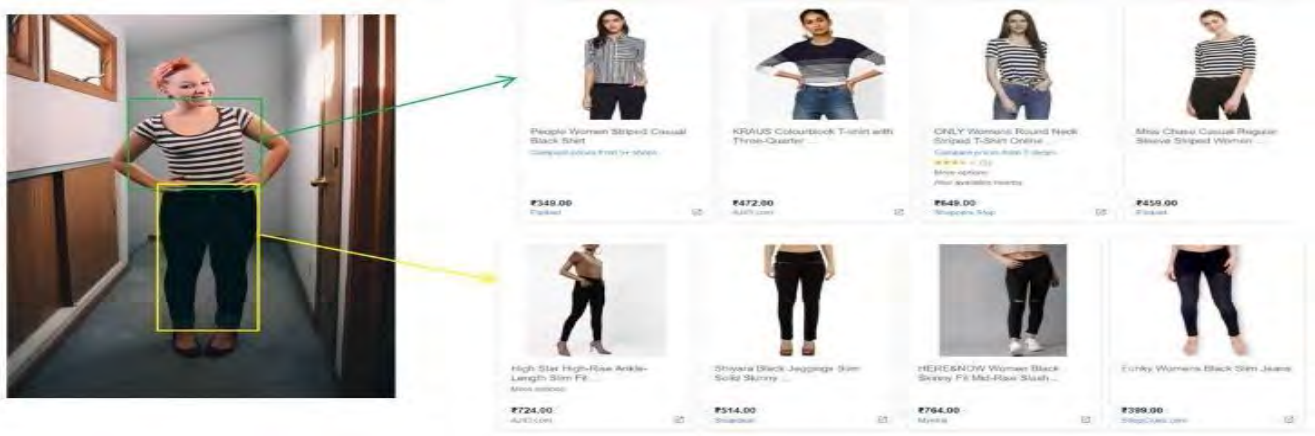

Figure 5 Clothes scouting output

IV. EXPERIMENTALRESULTS

A. *Clothing item and accessoriesdetection*

This model was trained on both datasets for 1000 epochs, that is, learning used no less than 90% of GPU's processing power. Still, there were small items like footwear or eyewear, in some images that the model was failed to detect. Figure VI (i& iii) depicts such examples where the footwear was not detected in (i) and the bag was not detected in (iii).

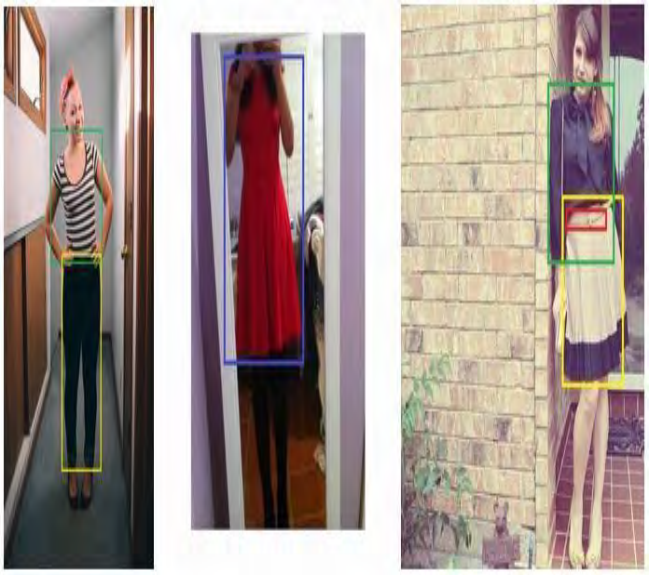

Figure 6 Clothes detection results

B. *LandmarkDetection*

To evaluate the Landmark detection model, we used normalized mean error as the evaluation metrics. The Thismodelwastrainedonbothdatasetsfor1000epochs ,thatnormalized mean error is defined as,

$$Normalized\ mean\ error\ = \frac{1}{n}\sum_{j=1}^{n}\sum_{i=1}^{n}\frac{\left|L_{(j)}^{(i)} - L_{(j)}^{(i)}\right|}{k\ x\ D_i}$$

Where $L_{(j)}^{(i)}$ represents the coordinate of the ith landmark point in the jth image, $L^{(i)}$represents the ithlandmark

coordinates of the jth image, k is the total number of landmarks, N is the number of test images, and Di is a normalized factor which is defined as Euclidean distance between the landmark points of left-shoulder to right shoulder in the ith image.

In the experiment, we used the training, testing, and validation images provided by the DeepFashion (Landmark prediction benchmark) dataset. Our model scores a normalized mean error of 0.1743. Figure VII shows some outputs of the model.

Figure 7 Clothes detection results

C. *Clothing Attribute Classification*

Since we created two models and the first model was trained and validated on the DeepFashion dataset and the second on the street2Shop. Once, the validation result reached an accuracy of more than 80%, we started the testing phase. The first model was tested on the street2Fashiondatasetandthesecondmodelwastested on the DeepFashion one. The images with the wrong prediction were evaluated in person and if any error was found in labeling, it was corrected manually. In this way, we cleaned the annotations of both datasets to increase their accuracy. Again the models were trained but now withtheviceversadatasets.Weevaluatedourmodelusi ng three evaluation metrics: recall, precision, and F1-Score and the overall score was 91%. Figure VIII gives the distributed scores for each attributeclass.

Figure VII Clothing attribute classification.

V. CONCLUSION

In this paper, we engineered an intelligent system based on deep learning to find the landmarks of the detected clothes and to find the attributes of the apparel using the landmarks.This could be done because of the datasets DeepFashion and Street2Shop, which are openly available. The system also focuses on social media and provides

	precision	recall	f1-score	support
Class 0	0.82	0.91	0.86	1000
Class 1	0.99	0.99	0.99	1000
Class 2	0.82	0.90	0.86	1000

Implementing Predictive Analysis System Of Medicines And Doctors Availability In Government Hosptials

Vikas Singh, Adit Rathi, Kevin Shah, Siddharth Tiwari, Mukul Suvarna
Department of Computer Engineering
Thakur College of Engineering and Technology
Mumbai, India
vikassngh@gmail.com, aditrathi98@gmail.com, kevinshah05@gmail.com, siddharthtiwari1212@gmail.com, mukulsuvarna15@gmail.com

Abstract— **The social issue of government hospitals i.e. availability of medicines and doctors is a troublesome one. Using the knowledge of software development, web development, analysis of the data and management of information systems, we can come up with an effective solution. This portal will enable the common people to identify best medicine for their symptoms and best doctor to treat that disease. It will provide the best suited medicine for the entered symptom. The interface will ask the user for various symptoms and duration of occurrence and then, the system will provide with necessary medicines and the seriousness of the symptoms, availability of doctors in the local hospitals.**

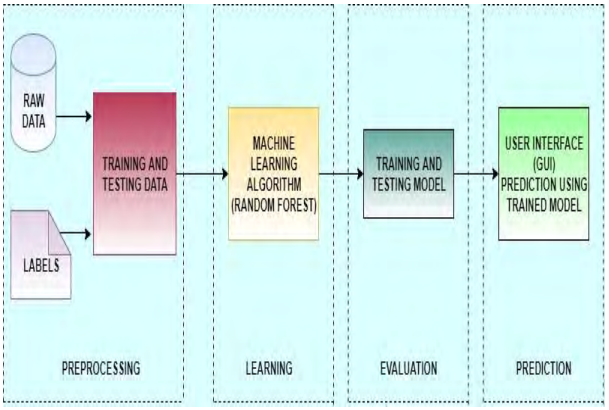
Keywords— Decision Tree, Naïve Bayes, Random Forest Regressor, Prediction, Data Extraction.

I. INTRODUCTION

In recent years, with the development of computer technologies, the puzzles with respect to Bayesian statistics and posterior distribution have been better solved. Meanwhile, Bayesian statistics successfully apply to economic, sociology and some other fields. In medical fields, the foreign scholars have solved some medical problems that are hard to be settled in classic statistics by using Bayesian classification. Naive Bayes is one of the most popular classification technique introduced by Reverend Thomas Bayes.
It is the application of computing and communication technologies to optimize health information processing by collection, storage, effective retrieval (in due time and place).The proposed system is mainly used by the all the people where confidentiality and integrity of the data has utmost importance. Computer assisted information retrieval may help support quality decision making and to avoid human error. Imagine a doctor who has to examine 5 patient records; he or she will go through them with ease. If the number of records grows with a time constraint, it is almost certain that the accuracy with which the doctor delivers the results will not be as high as the ones obtained when he had only five records to be analyzed.
At present in order to remain healthy, regular body diagnosis is necessary. Today, there are multiple sources available as individual prediction or recommendation system but the need of the hour is to have an integrated model comprising both. Also, it would be more appropriate and convenient if people could get basic diagnosis online 24x7 rather than visiting hospitals & clinics frequently. Thus, reducing cost and saving time. If certain anomalies found in the diagnosis then recommendation of nearby specialist and hospitals according to user's preference would facilitate in quick and appropriate treatment.

II. METHODOLOGY

The overall working of our project can be explained through the following abstract diagram. The high-level methodology used in this project is as follows:
Disease Prediction has been already implemented using different techniques like Neural Network, decision tree and Naïve Byes algorithm. Particularly heart related disease is mostly analyzed. From the analysis it was found that Naïve Bayes is more accurate than other techniques. So, Disease Predictor also uses Naïve Bayes for the prediction of different diseases.



The methodology consists of 3 main stages- Data Pre- processing, Data Preparation, Encoding the data.

A. Naïve Bayes

Naive Bayes classifiers are a collection of classification algorithms based on Bayes' Theorem. It is not a single algorithm but a family of algorithms where all of them share a common principle, i.e. every pair of features being classified is independent of each other. The dataset is divided into two parts, namely, feature matrix and the response vector.

- Feature matrix contains all the vectors(rows) of dataset in which each vector consists of the value of dependent features. In above dataset.
- Response vector contains the value of class variable (prediction or output) for each row of feature matrix.

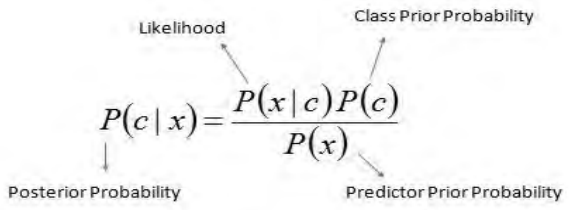
The fundamental Naive Bayes assumption is that each feature makes an:

- Independent
- Equal

Bayes' Theorem finds the probability of an event occurring given the probability of another event that has already occurred. Bayes' theorem is stated mathematically as the following equation:

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

where A and B are events and P(B) = 0.



$$P(c \mid X) = P(x_1 \mid c) \times P(x_2 \mid c) \times \cdots \times P(x_n \mid c) \times P(c)$$

Basically, we are trying to find probability of event A, given the event B is true. Event B is also termed as evidence.

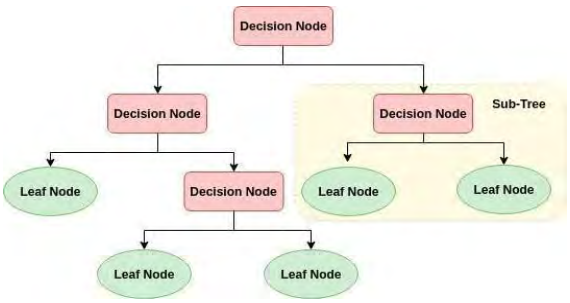
P(A) is the priori of A (the prior probability, i.e. Probability of event before evidence is seen). The evidence is an attribute value of an unknown instance (here, it is event B).

P(A|B) is a posteriori probability of B, i.e. probability of event after evidence is seen.

Naive Bayes algorithms are mostly used in sentiment analysis, spam filtering, recommendation systems etc. They are fast and easy to implement but their biggest disadvantage is that the requirement of predictors to be independent. In most of the real-life cases, the predictors are dependent, this hinders the performance of the classifier.

B. Decision Tree Classifier

A decision tree is a flowchart-like tree structure where an internal node represents feature(or attribute), the branch represents a decision rule, and each leaf node represents the outcome. The topmost node in a decision tree is known as the root node. It learns to partition on the basis of the attribute value. It partitions the tree in recursively manner call recursive partitioning. This flowchart-like structure helps you in decision making. It's visualization like a flowchart diagram which easily mimics the human level thinking. That is why decision trees are easy to understand and interpret.



White-box models are the type of models which one can clearly explain how they behave, how they produce predictions and what the influencing variables are. There are two key elements that make a model white-box: features have to be understandable, and the ML process has to be transparent. Decision Tree is a white box type of ML algorithm. It shares internal decision-making logic, which is not available in the black box type of algorithms such as Neural Network. Its training time is faster compared to the neural network algorithm. The time complexity of decision trees is a function of the number of records and number of attributes in the given data. The decision tree is a distribution- free or non-parametric method, which does not depend upon probability distribution assumptions. Decision trees can handle high dimensional data with good accuracy.

We identified certain problems with SVM which is why we could not use it in the project. Some of them have been mentioned below.

1. A small change in the data can cause a large change in the structure of the decision tree causing instability.
2. For a Decision tree sometimes calculation can go far more complex compared to other algorithms.
3. Decision tree often involves higher time to train the model.
4. Decision tree training is relatively expensive as complexity and time taken is more.

C. Random Forest

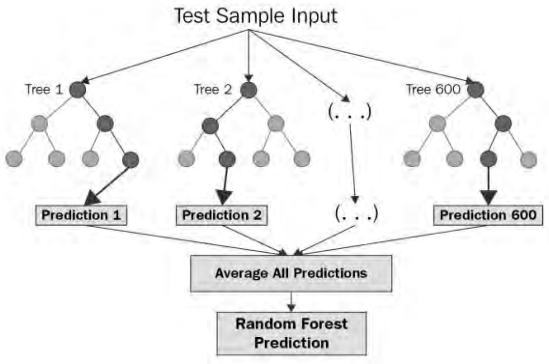
Random forests is a supervised learning algorithm. It can be used both for classification and regression. It is also the most flexible and easy to use algorithm. A forest is comprised of trees. It is said that the more trees it has, the more robust a forest is. Random forests creates decision trees on randomly selected data samples, gets prediction from each tree and selects the best solution by means of voting. It also provides a pretty good indicator of the feature importance.

Random forests has a variety of applications, such as recommendation engines, image classification and feature selection. It can be used to classify loyal loan applicants, identify fraudulent activity and predict diseases. Random forests is considered as a highly

accurate and robust method because of the number of decision trees participating in the process. It does not suffer from the overfitting problem. The main reason is that it takes the average of all the predictions, which cancels out the biases. The algorithm can be used in both classification and regression problems. Random forests can also handle missing values. There are two ways to handle these: using median values to replace continuous variables, and computing the proximity-weighted average of missing values. You can get the relative feature importance, which helps in selecting the most contributing features for the classifier.Random forest is a bagging technique and not a boosting technique. The trees in random forests are run in parallel. There is no interaction between these trees while building the trees. It operates by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees.

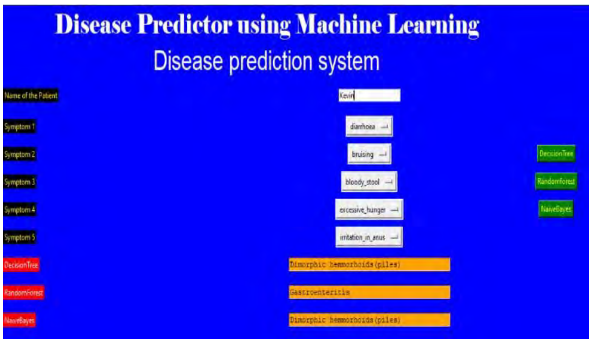
A random forest is a meta-estimator (i.e. it combines the result of multiple predictions) which aggregates many decision trees, with some helpful modifications:

1. The number of features that can be split on at each node is limited to some percentage of the total (which is known as the hyperparameter). This ensures that the ensemble model does not rely too heavily on any individual feature, and makes fair use of all potentially predictive features.
2. Each tree draws a random sample from the original data set when generating its splits, adding a further element of randomness that prevents overfitting.



III. PROPOSED WORK

An intelligent system for accurate disease prediction and medical facilities recommendation plays a major role in effective treatment. This system takes the symptoms from users and predicts the most accurate disease accordingly. Additionally, sensor module helps in continuous evaluation of vitals like heart rate, blood pressure and sugar level for patient which is fed in the system at runtime for analysis along with other external symptoms. Based on the prediction, system recommends the doctors according to user's preference out of nearest location with doctors having expertise for that particular disease to avail the required medications. Also, the users can provide their feedback for the recommended doctors.



IV. CONCLUSION

There are challenges to overcome, such as the high degree of variability and the degree of difficulty in complete capture and access; however, even with these challenges, the potential for improving patient care and hospital efficiencies is immense.

The number of medications a patient takes is predictive of medical complexity with simple models based on counts of the number of medications as effective as more complex models.

V. ACKNOWLEDGEMENT

We sincerely thank our guide Mr. Vikas Singh for his guidance and constant support. We also thank the project coordinators for arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. Sheetal Rathi, Dean Academic Dr. R.R Sedamkar, the Principal Dr. B. K. Mishra and the college management for their support.

Design Of System To Efficiently Choose Machine Learning Algorithms

Atharva Tendulkar,Athashree Vartak, Kasturi Dhotre, Mrs. Shiwani Gupta
Computer Engineering Departnment Thakur College of Engieerning and Technology, Mumbai.
tendulkaratharva@gmail.com,athashreeav5556@gmail.com,kasturid890@gmail.com,shiwani.gupta@thakureducation.org

Abstract— **In Machine Learning, the primary problem faced isn't implementation of algorithm but choosing the algorithm to be implemented for the chosen dataset. Thus, the common approach followed is implementing all the feasible algorithms and then choosing the one that performs best. The main drawback of this approach is that a hefty amount of time is wasted for training and testing data on myriad of algorithms. On the other hand, this time could be saved by understanding the mathematical approach used by the algorithms for fitting and evaluating the data to understand it's working. The approach followed here is based on the understanding of the algorithms and their background mathematical functioning to deduce the type of data it can perform well. The type of data here means the types of features (categorical or discrete), correlation among the independent variables (high or low) and the correlation of independent variables with dependent variables, etc.**

Thus, this approach will help in saving significant amount of time as a single or few numbers of algorithms are chosen instead of trying out many algorithms and then determining which works the best. But, here, the data will be needed to pre-processed and visualized to understand its nature in order to determine which algorithm is to be chosen. The visualization plays a crucial role as it helps in understanding the underlying information that cannot be realised in just a glance at the data and in turn requires series of processing and analysis.

Keywords: Machine Learning, Classification, Efficient, features, visualization

I. INTRODUCTION

Business practices and habits are very difficult to change especially in large and mature companies. Introducing new ways of working is extremely difficult, but making people work differently is almost impossible. There is huge cultural inertia in these companies and business industry in general. Use of Machine Learning is one of those changes that will make people work differently and will make business environments different in future.Machine Learning is a field of computer science which gives the computer the ability to deduce patterns and learn without being programmed explicitly. Machine Learning's primary aim is to provide training to an algorithm to perform required tasks. Machine Learning is one of the most important technologies with applications like Speech recognition, recommendations, fraud detection, and financial trading, etc. It contains various types like Supervised Learning, Unsupervised Learning, Semi- supervised Learning, and Reinforcement Learning which each has their own use cases and algorithms. Supervised Learning maps an input to an output based on example input-output tuples which is also known as labeled data. Machine Learning has 2 subclasses ie. classification and regression. A job is a classification task if the output is categorical and a regression task if the output is a continuous value.

II. PROPOSED WORK

The standard approach to standard machine learning models includes the following steps: Firstly, data needs to be acquired and pre-processed. Then, appropriate algorithm is applied to get the result. Then the result is evaluated on the basis of a variety of performance measures dependent upon the algorithm used.

The proposed method primarily includes detailed study of classification algorithms and understanding the mathematical basis of its functioning. This study will make the process of understanding and interpreting the results easy. The processing of determining the algorithm to be chosen for the required dataset requires pre-processing of data and visualization. Visualization plays a crucial role in understanding the data and its features.After detailed study of classification algorithms like Logistic Regression, Naïve Bayes, k-Nearest Neighbors (KNN), Support Vector Machine (SVM), Decision Tree, etc appropriate datasets are to be acquired. The process of obtaining the datasets is tedious as all the classification algorithms listed above have a different set of requirements and limitations like a particular algorithm might only need categorical values or maybe some other algorithm might not function well for correlated data, etc. Thus, such kinds of assumptions require a dataset that should follow all the expected conditions or if possible, the dataset needs to be transformed into the one that can be used as per the requirement.

The transformation mentioned here can include dealing with missing values by replacing the values by mean, median or applying another prediction algorithm to determine the missing value. It may also include scaling the the attributes, dealing with imbalanced datasets, and so on. Thus, after finalizing datasets, the algorithms must be applied upon the dataset decided. After training and testing the model, evaluation needs to be carried out on the basis of performance measures. For example,. In case of

Logistic regression, F1 score and ROC are better performance measures than accuracy. Therefore, each and every algorithm is to be evaluated on the basis of the appropriate performance measures. After evaluating the models, they need to be optimized. The process of optimization will differ from algorithm to algorithm. Hyper-parameter tuning is one of the methods of optimization. For example, in KNN the optimum value of k can be found using elbow method to optimize the result. On the other hand, in case of decision trees, the tree can be pruned to obtain the optimum results.

A. Advantages

- Less Time
- Understanding how algorithms actually works would help to give optimized results and will aid in interpreting results more efficiently
- Knowledge of algorithms and its mathematical working will help in understanding parameter tuning.

B. Methodology

For this project, Scrum methodology is used which is an agile software development methodology. On scrum projects, every member of the project team has the opportunity to know how the project is going at any given time. A Scrum process is distinguished from other agile processes by specific concepts and practices, divided into the three categories of Roles, Artifacts, and Time Boxes. Scrum is most often used to manage complex software and product development, using iterative and incremental practices. Scrum significantly increases productivity and reduces time to benefits relative to classic "waterfall" processes. Scrum processes enable organizations to adjust smoothly to rapidly-changing requirements and produce a product that meets evolving business goals.

C. Algorithms

Algorithm: Naïve Bayes

Naïve Bayes is classification algorithm which is based on 'naïve' assumptions that all the features are independent of each other. Naïve Bayes algorithm is faster and easy to implement but it makes assumptions makes it less powerful as compared to other algorithms. It uses probabilistic machine learning model for doing classification.

i. Advantages
- Easy, fast and Scalable.
- Works well with less training data.
- Works well with highdimensions.

ii. Disadvantages
- Carefully handle Laplace Correction.
- Assumption of independent features.

iii. Applications
- Works well with textual data.

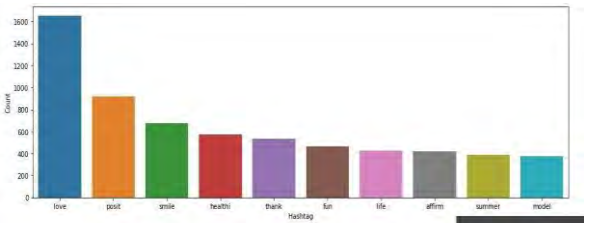

Figure 1: Count of non-racist hashtags

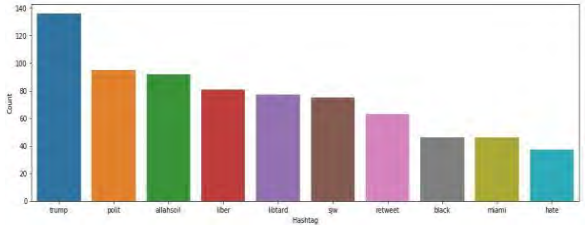

Figure 2: Count of racist hashtags

Algorithm: k-nearest Neighbours

The k-nearest neighbours (KNN) algorithm is one of the simple and easy-to-implement supervised machine learning algorithm that can be used to solve both classification and regression problems. KNN works by considering k nearest elements only and takes decision by vote majority. KNN is useful if we do not have and information about distribution of data. KNN is also called as lazy learner as training phase is fast as model is not built, but it computes distance every time when we run the algorithm.

i. Advantages
- Simple and easy to implement.
- No need to build model.
- No parameter tuning required.
- It makes no assumptions.
- Adaptive

ii. Disadvantages
- Slower as data increases.
- Lazy Learner.
- As number of dimensions increases, speed decreases.
- Problem when data is skewed.

iii. Applications
- Previously used in Recommendation Systems.
- Used when no information about distribution of data.
- When we want results faster.

```
#import GridSearchCV
from sklearn.model_selection import GridSearchCV
#In case of classifier like knn the parameter to be tuned is n_neighbors
param_grid = {'n_neighbors':np.arange(1,50)}
knn = KNeighborsClassifier()
knn_cv= GridSearchCV(knn,param_grid,cv=5)
knn_cv.fit(X,y)

print("Best Score:" + str(knn_cv.best_score_))
print("Best Parameters: " + str(knn_cv.best_params_))
```

```
Best Score:0.7721354166666666
Best Parameters: {'n_neighbors': 25}
```

Figure 3: Grid Search

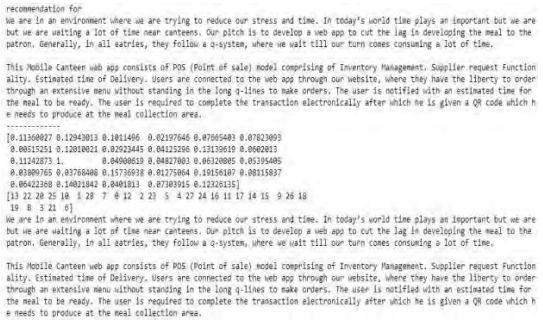

Figure 4: Use of KNN algorithm in Recommendation system

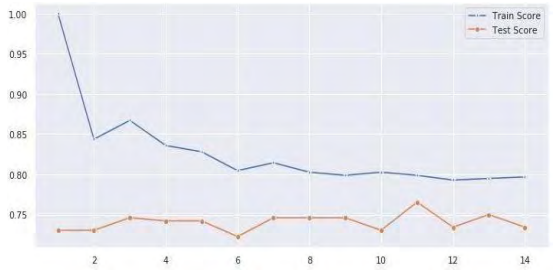

Figure 5: Training vs Testing graph for values of 'k'

Algorithm: Decision Tree Classifier

Decision tree is one of the most widely used classification algorithm. The goal of this algorithm is to create a model that predicts the value of a dependent variable by learning simple decision rules inferred from the data features. It uses a tree like model which represents decision rules.

i. Advantages:

- Easy to visualize decision rule.
- Can work well with noisy data
- Can deal with both numeric and categorial data.
- Almost no hyper-parameter tuning required

ii. Disadvantage:

- Can overfit data easily if not pruned properly.
- Works not so well with skewed data.
- Unstable.
- Biased trees are constructed if some classes dominate.

Algorithm: Logistic regression

Logistic Regression is one of the most popular classification techniques used in Machine Learning. It is primarily used to predict the categorical outcomes may it be binomial or multinomial values. Logistic Regression is termed as a special case of Linear Regression which uses the concept of log odds to determine the relationship of the independent variables with the dependent variables using log it function. Thus, the outcome obtained is actually a probability.

i. Advantages:

- It is computationally efficient.
- Performs better when unrelated and highly correlated features are removed.
- Can be easily combined with other algorithms to form a complex model.

ii. Disadvantages:

- Doesn't perform well with independent variables that aren't correlated with target variable and are much correlated to each other.
- It can't solve nonlinear problems as its decision surface is linear.

iii. Applications:

- It requires the independent variables to be very less dependent on each other ie. the independent variables should not be highly correlated.
- The independent variables are linearly related to the log odds (ie. by logit/sigmoid function).
- The sample size of the observations must be large.

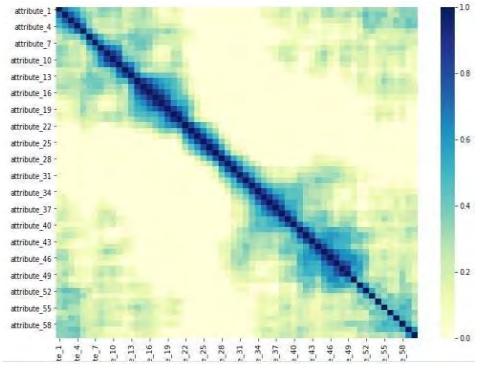

Figure 6: Heatmap of correlation of features

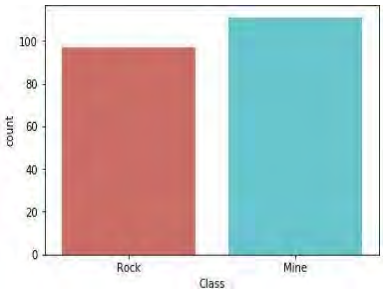

Figure 7: Count of class variables to check if dataset is balanced

Algorithm: Support Vector Machine

SVM is one of the most powerful classification techniques used in Machine Learning. SVM works by finding optimal hyperplane from given dataset which can classify data-points very well. It is primarily used for solving classification problems, but it even works well with regression problems. SVM can deal with non-linearity, small dataset and high dimensions very well.

i. Advantages:

- Can deal with outliers very well if we choose proper regularization parameters (C and Gamma).
- Effective when dimensions are higher.
- Works well even when training examples are less than number of features.
- Can classify linear as well as non linear data

by kernel trick.

- Efficient as we only need support vectors for making prediction.
- Almost works well with all use cases.

ii. Disadvantages

- Chances of overfitting if regularization parameters not chosen properly.
- Training time is more.

iii. Applications

Works almost well with all the use cases, but prominent of the use cases are:

- Image Classification
- Text Classification

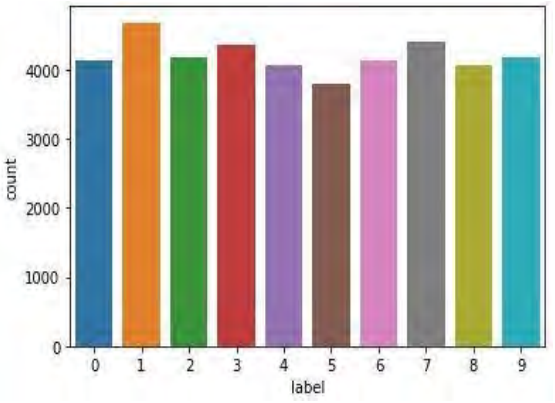

Figure 8: Count of digits to check if data is balanced

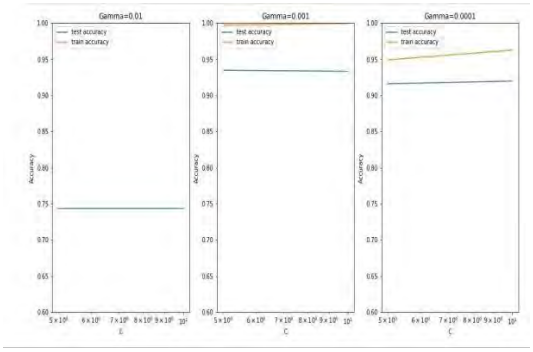

Figure 9: Training vs Testing accuracy at different values of ϒ

D. Observation

Table 1: Observation Table depicting performance measures

Classifier	Dataset	Performance Measures	
Naïve Bayes	Twitter dataset	Precision	82.5%
SVM	Handwriting Recognition dataset	Accuracy	94.4%
Decision Tree	Nursery dataset	Accuracy	86%
KNN	Diabetes dataset	Accuracy	76.5%
		F1 score	83%
		Precision	80%
		Recall	85%
		AUC	0.772
Logistic Regression	Sonar dataset	Accuracy	78%
		F1 score	76.2%
		AUC	0.777

Content Aggregator Using Web Scraper

Dr. Megharani Patil, Rahul Choudhari, Nitin Dwivedi, Abhishek Gupta
Department of Computer Engineering,
Thakur College Of Engineering and Technology
University of Mumbai
megharani.patil@thakureducation.org,rahulac1599@gmail.com, nitindwivedi88@gmail.com, abhig280031@gmail.com

Abstract - **Content Aggregator is an information hub where a user can access information as per his interests. Content Aggregator targets renowned websites and extract the latest information. Users can access the latest information easily from Content Aggregator.**
There is the huge and rapid growth in the unstructured data every moment. The production and generation of data is predicted to be 44 times in 2020 as compared to the data in 2009. All these figures and statistical data are amazing and growing in exponential pattern. Such data is unstructured in nature which Means the data of different and heterogeneous formats. Web scraping is a term used to describe the use of a program or algorithm to extract and process large amounts of data from the web. The ability to scrape data from the web is a useful skill to have. Let's say you find data from the web, and there is no direct way to download it, web scraping using Python is a skill you can use to extract the data into a useful form that can be imported. The Beautiful Soup package is used to extract data from html files. Recommendation system compares the data collected from users and create a list of items recommended to the user. They are an alternative search algorithm because it helps users to find items and information that they would not find themselves. At present the problem of recommendation systems keeps to himself a lot of interest.

Keywords: Web Scraping, Hybrid Recommendation, Beautiful Soup

I. INTRODUCTION:

A content aggregator is an individual or organization that gathers Web content from different online sources for reuse or resale. There are two kinds of content aggregators: (1) those who simply gather material from various sources for their Web sites, and (2) those who gather and distribute content to suit their customer's needs.

.

A Dive into Web Scraper World (IEEE) HMR Institute of Technology Delhi by Deepak Kumar Mahto HMR Institute of Technology and Management, Delhi. We studied about Data Extraction Using Web Crawler, some legal issues and Designing Principles. This involves various methods and techniques in Web Scraping. Gaps Identified in our project by this paper are unable to resolve absolute URL and handling of redirect loops. [1] Information Extraction Using Web Usage Mining and Web Scraping (IEEE) University of Information Technology New Delhi by Sanjay Kumar Malik SAM Rizvi Extraction of useful data from discovery patterns using web mining. Conversion of unstructured data into a designated format. Gaps identified are Web scraping is limiting as you must know the html formatting, and we need to find a way around that.

[2]. A Hybrid Approach using Collaborative filtering and Content based Filtering for Recommender System by JonAtle Gulla and R. Cenk Erdur. News recommendation have specific challenges when compared to the other domains. From a technical point of view there are many different methods to build a recommender system. Thus, while general methods are used in news recommendation, researchers also need some new methods to make proper news recommendations. In this paper we present the different approaches to news recommender systems and the challenges of news recommendation. Gaps identified are Key challenge is predicting the future interests of users for better recommendations News items should be structured and machine readable.

[3] We all use Web Browser to extract the needed information from the Web Site, if you think this is the only way to access information from the internet then you are missing out on a huge range of available possibilities. Web Scraper is one of those possibilities, in which we are accessing the information on the internet using some programs and pre written libraries. Most websites do not offer the functionality to save a copy of the data which they display to your computer. The only option then is to manually copy and paste the data displayed by the website in your browser to a local file in your computer - a very tedious job which can take many hours or sometimes days to complete.

Over the last few years consumption of news articles has shifted more and more from the written versions towards the web. Internet devices like Desktop, Laptop or even a Mobile Phone became more powerful, with larger screens and connected to the Internet, have had a great influence on this paradigm change. A critical problem associated with online news is related to the fact that the large number of daily articles can be overwhelming to the users. Recommendation services can largely improve the efficiency and accuracy of acquired information. These systems are designed to filter critical news, key events and

meaningful items that might be of interest to a reader. Recommendation system model keeps the count of user interests and accordingly shows relevant information

~~II.~~III. TECHNOLOGY USED: -

Flask: - Flask (source code) is a Python web framework built with a small core and easy-to-extend philosophy. Flask is considered more Python than the Jingo web framework because in common situations the equivalent Flask web application is more explicit. Flask is also easy to get started with as a beginner because there is little boilerplate code for getting a simple app up and running.

Web Scraping: - Web scraping (web harvesting or web data extraction) is a computer software technique of extracting information from websites.HTML parsing is easy in Python, especially with the help of the Beautiful Soup library.

Beautiful Soup: Beautiful Soup is a Python package for parsing HTML and XML documents. It creates parse trees that is helpful to extract the data easily. There are mainly two ways to extract data from a website:

1. Use the API of the website (if it exists). For example, Facebook has the Facebook Graph API which allows retrieval of data posted on Facebook.
2. Access the HTML of the webpage and extract useful information/data from it. This technique is called web scraping or web harvesting or web data extraction.

~~III.~~IV. IMPLEMENTATION DETAIL

Step 1 Scraping raw data:

Our target websites include data across various fields such as sports, news, etc. To scrape such sites, we take the help of Beautiful Soup Library and Requests Package present in Python Library. A target site is requested and a beautiful soup object is created with the help of data request. Various beautiful soup methods are applied to filter data and acquire desired result. Output can be stored in various formats such as .csv, json format, directly into

A database. The stored data is displayed on aggregator site as per user's recommendations and content viewing. Step 2 Model selection:

Our proposed system for recommendation system will work on hybrid model which is the combination of collaborative filtering and content-based filtering. These model will be Machine learning based and use linear regression as learning algorithm. Consider an example where 5 users has given rating to some of the articles, each article has a particular set of attributes which shows what kind of article it is. Let's assume that attribute 1 represent sports news and attribute 2 represents Entertainment news taking example of article 1 which has attribute 1 value of

0.99 And attribute 2 value of 0.02 which mean article 1 is mostly a sports based article.

	User A	User B	User C	User D	User E	Attribute 1	Attribute 2
Article 1	5	5	5	0	0	0.99	0.02
Article 2	5	?	5	0	?	1.50	0.01
Article 3	?	5	4	?	1	1.00	0.1
Article 4	0	0	?	5	5	0.09	1.3
Article 5	1	0	0	5	4	0.2	1.05

Note: Here the '?' indicates that the user did not encounter the article yet.

Fig 3.1 Example of data model

Content based approach

Content based recommendation identifies the similar items to those that the target user has liked in the past.

In the proposed model the content-based approach will try to predict the rating of the article which is not encounter yet with the help of attributes of the article.

Collaborative filtering approach

Collaborative filtering identifies the similarity between two or group of users which have similar interests. In collaborative filtering the model will predict the attributes value of articles with the help of ratting of different usersAnd recommend those articles which are very similar to user interest

Hybrid model

The hybrid model is derived from the above mentioned two methods. Each methods have its own advantages and disadvantages, to make recommendation system more reliable we use hybrid model. Hybrid model will try to work like both approaches at the same time i.e. it will try to compute both the new ratting of article for the different users and the attribute of new article. The Hybrid model will be trained using linear regression, like other linear regression model our hybrid model will basically compute the error cost and try to minimize the cost, the cost function is also derived for both models to make hybrid model more reliable

Step 3 Algorithm:

r(i,j) = 1 if user j has rated article i (0 otherwise)

y(i,j) = rating by user j on article I ɵ(j) = parameter vector for user j x(i) = feature vector for article i Cost function:

Minimize x(1), . . . , x(n) and ɵ(1), . . . , ɵ(m) Simultaneously:

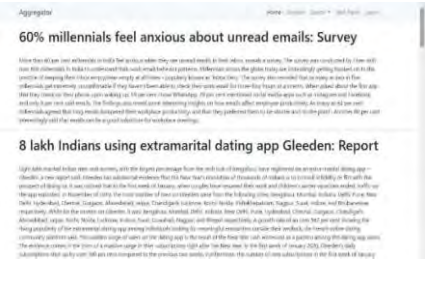

Fig 3.2 Cost function

Our goal is to minimize cost function these can be achieved by gradient descent by updating and x at every iteration.

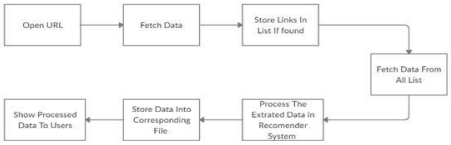

Fig 3.3 Weight update using gradient descent

Sample Code:-
Scraping Function on Target Site eg: FIFA World Rankings

From bs4 import Beautiful Soup import csv
Import requests def scrape ():
url="https://www.fifa.com/fifa-world- ranking/rankin-table/men/EON/wepAnan/ranking/men"f = csv.writer(opencsv/fifa rankings-men.csv', 'W'))
Html = BeautifulSoup(data.text, 'html.parser') x =html.find all(class='fi-t_ntext') f.writerow(['Rank', 'Name']) extracted_records = []

For i in x:
title =
i.text
record
= {
'title': title,
'rank': c
f.writerow([c,
title]])| c += 1
extracted_records.append (record)
Return (extracted records)

~~IV.~~ V. BLOCK DIAGRAM/FLOWCHART:

5.1 Block Diagram

The below fig 5.1 shows the principal component and function in news content aggregator and shows the flow of the process

$$x_k^{(i)} = x_k^{(i)} - \alpha\left(\sum_{j:r(i,j)=1}((\theta^{(j)})^T x^{(i)} - y^{(i,j)})\theta_k^{(j)} + \lambda x_k^{(i)}\right)$$

$$\theta_k^{(j)} = \theta_k^{(j)} - \alpha\left(\sum_{i:r(i,j)=1}((\theta^{(j)})^T x^{(i)} - y^{(i,j)})\theta_k^{(j)} + \lambda\theta_k^{(j)}\right)$$

Fig 5.1 Block Diagram

5.2 Web scraping Activity Diagram

The Activity diagrams fig 3.6.6 shows the graphical representations of workflows of
Stepwise activities and actions with support for choice, iteration and concurrency of content aggregator.

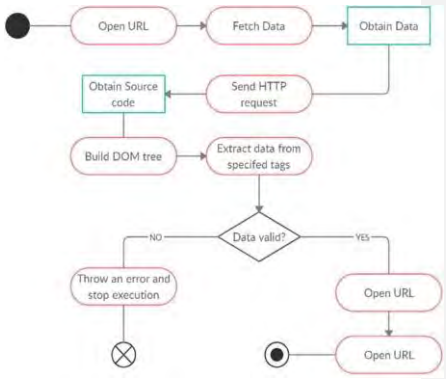

Fig 5.2 Web Scraping Activity Diagram6.
Result:

~~V.~~ VI. EXPECTED OUTCOME:

The expected Outcome of the project are:
1. Content Aggregator website which is an Information hub where a user can access Information as per his interests.
2. Users can access the latest information Easily from Content Aggregator.
3. The latest and trending news is Recommended to the user as per his Subscriptions and feed history.
Fig.

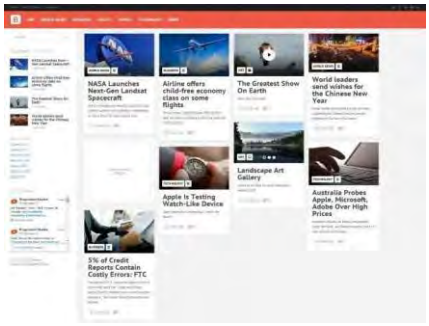

Fig. 6.1 Expected User Interface

- Snapshots:

From the data extracted from the target URL
The contents are stored in a CSV file and the
Data from the CSV file is displayed on the
Website

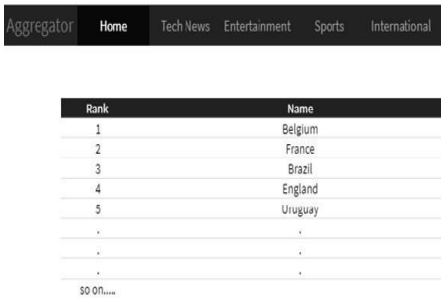

Fig. 6.2.FIFA Rankings

~~VI.~~ VII. CONCLUSION

Content Aggregator Using Web Scraper thus
Provides insight of extracting the information from
Websites in cases where it is difficult to fetch the
Information due to structure or format of the web page
And provide crisp look of those data on a single web
Page in more elaborative and effective way. Thus user
Accessing the web page will get only relevant
Information of every renowned web pages thus save
User time of searching all of the pages. The interest on
Online newspapers has been growing significantly over
The past years. In order to present the most relevant
News articles to users, different recommendation
Systems have been made available using various
Techniques in order to make access to large amounts of
Information more efficient.
Mobility, social networking and the large
Number of news providers, bring new challenges but
Also new opportunities to enhance access to information
And improve the user experience when browsing
Newspapers. Our hybrid recommendation system for
News in a mobile environment that takes into
Consideration aspects that reflect this new paradigm and
Provides user's customized feed and as per his activity
Using a hybrid recommender system of content and
Collaborative method.

Abstract - **Content Aggregator is an information hub where a user can access information as per his interests. Content Aggregator targets renowned websites and extract the latest information. Users can access the latest information easily from Content Aggregator.**
There is the huge and rapid growth in the unstructured data every moment. The production and generation of data is predicted to be 44 times in 2020 as compared to the data in 2009. All these figures and statistical data are amazing and growing in exponential pattern. Such data is unstructured in nature which Means the data of different and heterogeneous formats. Web scraping is a term used to describe the use of a program or algorithm to extract and process large amounts of data from the web. The ability to scrape data from the web is a useful skill to have. Let's say you find data from the web, and there is no direct way to download it, web scraping using Python is a skill you can use to extract the data into a useful form that can be imported. The Beautiful Soup package is used to extract data from html files. Recommendation system compares the data collected from users and create a list of items recommended to the user. They are an alternative search algorithm because it helps users to find items and information that they would not find themselves. At present the problem of recommendation systems keeps to himself a lot of interest.

Keywords: Web Scraping, Hybrid Recommendation, Beautiful Soup

I. INTRODUCTION:

A content aggregator is an individual or organization that gathers Web content from different online sources for reuse or resale. There are two kinds of content aggregators: (1) those who simply gather material from various sources for their Web sites, and (2) those who gather and distribute content to suit their customer's needs.

.

II. RELATED WORK: -

A Dive into Web Scraper World (IEEE) HMR Institute of Technology Delhi by Deepak Kumar Mahto HMR Institute of Technology and Management, Delhi. We studied about Data Extraction Using Web Crawler, some legal issues and Designing Principles. This involves various methods and techniques in Web Scraping. Gaps Identified in our project by this paper are unable to resolve absolute URL and handling of redirect loops. [1] Information Extraction Using Web Usage Mining and Web Scraping (IEEE) University of Information Technology New Delhi by Sanjay Kumar Malik SAM Rizvi Extraction of useful data from discovery patterns using web mining. Conversion of unstructured data into a designated format. Gaps identified are Web scraping is limiting as you must know the html formatting, and we need to find a way around that.

[2]. A Hybrid Approach using Collaborative filtering and Content based Filtering for Recommender System by JonAtle Gulla and R. Cenk Erdur. News recommendation have specific challenges when compared to the other domains. From a technical point of view there are many different methods to build a recommender system. Thus, while general methods are used in news recommendation, researchers also need some new methods to make proper news recommendations. In this paper we present the different approaches to news recommender systems and the challenges of news recommendation. Gaps identified are Key challenge is predicting the future interests of users for better recommendations News items should be structured and machine readable.

[3] We all use Web Browser to extract the needed information from the Web Site, if you think this is the only way to access information from the internet then you are missing out on a huge range of available possibilities. Web Scraper is one of those possibilities, in which we are accessing the information on the internet using some programs and pre written libraries. Most websites do not offer the functionality to save a copy of the data which they display to your computer. The only option then is to manually copy and paste the data displayed by the website in your browser to a local file in your computer - a very tedious job which can take many hours or sometimes days to complete.

Over the last few years consumption of news articles has shifted more and more from the written versions towards the web. Internet devices like Desktop, Laptop or even a Mobile Phone became more powerful, with larger screens and connected to the Internet, have had a great influence on this paradigm change. A critical problem associated with online news is related to the fact that the large number of daily articles can be overwhelming to the users. Recommendation services can largely improve the efficiency and accuracy of acquired information. These systems are designed to filter critical news, key events and

Formatted: All caps

Formatted: List Bullet, Centered, Space Before: 0 pt, Numbered + Level: 1 + Numbering Style: I, II, III, … + Start at: 1 + Alignment: Right + Aligned at: 0.63 cm + Indent at: 1.27 cm, Border: Top: (No border), Bottom: (No border), Left: (No border), Right: (No border), Between : (No border), Bar : (No border)

meaningful items that might be of interest to a reader. Recommendation system model keeps the count of user interests and accordingly shows relevant information

~~II.~~III. TECHNOLOGY USED: -

Flask: - Flask (source code) is a Python web framework built with a small core and easy-to-extend philosophy. Flask is considered more Python than the Jingo web framework because in common situations the equivalent Flask web application is more explicit. Flask is also easy to get started with as a beginner because there is little boilerplate code for getting a simple app up and running.

Web Scraping: - Web scraping (web harvesting or web data extraction) is a computer software technique of extracting information from websites.HTML parsing is easy in Python, especially with the help of the Beautiful Soup library.

Beautiful Soup: Beautiful Soup is a Python package for parsing HTML and XML documents. It creates parse trees that is helpful to extract the data easily. There are mainly two ways to extract data from a website:

1. Use the API of the website (if it exists). For example, Facebook has the Facebook Graph API which allows retrieval of data posted on Facebook.
2. Access the HTML of the webpage and extract useful information/data from it. This technique is called web scraping or web harvesting or web data extraction.

~~III.~~IV. IMPLEMENTATION DETAIL

Step 1 Scraping raw data:

Our target websites include data across various fields such as sports, news, etc. To scrape such sites, we take the help of Beautiful Soup Library and Requests Package present in Python Library. A target site is requested and a beautiful soup object is created with the help of data request. Various beautiful soup methods are applied to filter data and acquire desired result. Output can be stored in various formats such as .csv, json format, directly into

A database. The stored data is displayed on aggregator site as per user's recommendations and content viewing. Step 2 Model selection:

Our proposed system for recommendation system will work on hybrid model which is the combination of collaborative filtering and content-based filtering. These model will be Machine learning based and use linear regression as learning algorithm. Consider an example where 5 users has given rating to some of the articles, each article has a particular set of attributes which shows what kind of article it is. Let's assume that attribute 1 represent sports news and attribute 2 represents Entertainment news taking example of article 1 which has attribute 1 value of

0.99 And attribute 2 value of 0.02 which mean article 1 is mostly a sports based article.

	User A	User B	User C	User D	User E	Attribute 1	Attribute 2
Article 1	5	5	5	0	0	0.99	0.02
Article 2	5	?	5	0	?	1.50	0.01
Article 3	?	5	4	?	1	1.00	0.1
Article 4	0	0	?	5	5	0.09	1.3
Article 5	1	0	0	5	4	0.2	1.05

Note: Here the '?' indicates that the user did not encounter the article yet.

Fig 3.1 Example of data model

Content based approach

Content based recommendation identifies the similar items to those that the target user has liked in the past.

In the proposed model the content-based approach will try to predict the rating of the article which is not encounter yet with the help of attributes of the article.

Collaborative filtering approach

Collaborative filtering identifies the similarity between two or group of users which have similar interests. In collaborative filtering the model will predict the attributes value of articles with the help of ratting of different usersAnd recommend those articles which are very similar to user interest

Hybrid model

The hybrid model is derived from the above mentioned two methods. Each methods have its own advantages and disadvantages, to make recommendation system more reliable we use hybrid model. Hybrid model will try to work like both approaches at the same time i.e. it will try to compute both the new ratting of article for the different users and the attribute of new article. The Hybrid model will be trained using linear regression, like other linear regression model our hybrid model will basically compute the error cost and try to minimize the cost, the cost function is also derived for both models to make hybrid model more reliable

Step 3 Algorithm:

r(i,j) = 1 if user j has rated article i (0 otherwise)

y(i,j) = rating by user j on article I ɵ(j) = parameter vector for user j x(i) = feature vector for article i Cost function:

Minimize x(1), . . . , x(n) and ɵ(1), . . . , ɵ(m) Simultaneously:

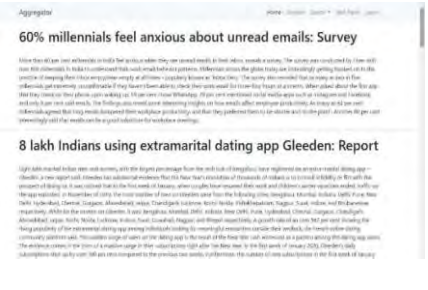

Fig 3.2 Cost function

Our goal is to minimize cost function these can be achieved by gradient descent by updating and x at every iteration.

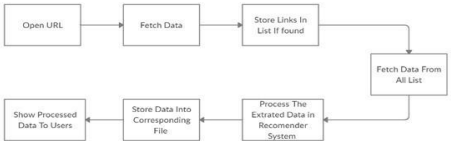

Fig 3.3 Weight update using gradient descent

Sample Code:-
Scraping Function on Target Site eg: FIFA World Rankings

From bs4 import Beautiful Soup import csv
Import requests def scrape ():
url="https://www.fifa.com/fifa-world- ranking/rankin-table/men/EON/wepAnan/ranking/men"f = csv.writer(opencsv/fifa rankings-men.csv', 'W'))
Html = BeautifulSoup(data.text, 'html.parser') x =html.find all(class='fi-t_ntext') f.writerow(['Rank', 'Name']) extracted_records = []

For i in x:
title =
i.text
record
= {
'title': title,
'rank': c
f.writerow([c,
title]])| c += 1
extracted_records.append (record)
Return (extracted records)

~~IV.~~ V. BLOCK DIAGRAM/FLOWCHART:

5.1 Block Diagram

The below fig 5.1 shows the principal component and function in news content aggregator and shows the flow of the process

$$x_k^{(i)} = x_k^{(i)} - \alpha\left(\sum_{j:r(i,j)=1}((\theta^{(j)})^T x^{(i)} - y^{(i,j)})\theta_k^{(j)} + \lambda x_k^{(i)}\right)$$

$$\theta_k^{(j)} = \theta_k^{(j)} - \alpha\left(\sum_{i:r(i,j)=1}((\theta^{(j)})^T x^{(i)} - y^{(i,j)})\theta_k^{(j)} + \lambda\theta_k^{(j)}\right)$$

Malaria Detection Using Deep Learning

Manjyotsingh Nanra, Niharika Chaturvedi, Vishal Nadar, Veena Kulkarni
Computer Engineering TCET
Mumbai
nanramanjyot@gmail.com, niharikachaturvedi42@gmail.com, vishalnadar98@gmail.com, Indiaveena.kulkarni@thakureducation.org

Abstract— **Malaria is mosquito-borne blood disease caused by parasites of the genus Plasmodium. According to the World Malaria Report 2016, an estimated 3.2 billion people in 95 countries and territories are at risk of being infected with malaria and developing disease, and 1.2 billion are at high risk (>1 in 1000 chance of getting malaria in a year). There were about 214 million cases of malaria globally in 2016 and about 438,000 malaria deaths. we construct a new image processing system for detection and quantification of plasmodium parasites in blood smear slide. Conventional diagnostic tool for malaria is the examination of stained blood cell of patient in microscope. The blood to be tested is placed in a slide and is observed under a microscope to count the number of infected RBC. The blood to be tested is placed in a slide and is observed under a microscope to count the number of infected RBC. Based on the guidelines from the WHO protocol, this procedure involves intensive examination of the blood smear at a 100X magnification, where people manually count red blood cells that contain parasites out of 5000 cells. An expert technician is involved in the examination of the slide with intense visual and mental concentration. This is tiresome and time- consuming process. Deep Learning models, or to be more specific, Convolutional Neural Networks (CNNs) have proven to be really effective in a wide variety of computer vision tasks. The proposed work is to develop automated system for detection of Malaria Parasites (MP) in cell images. This system is primarily based on Image processing of Cell Images acquired through digital microscope and classify it using Convolution Neural Network (CNN). This is to create an automatic system which will be able to detect and classify infected RBC cells. The classification of RBC will be entirely dependent on image processing and CNN. The image processing will have removal of impurities, noises and WBCs from image acquired through digital microscope and from remaining enhanced image, extract parasites. Then CNN will be used to identify species ofParasites.**

I. INTRODUCTION

Malaria is caused by protozoan parasites of the genus Plasmodium that are transmitted through the bites of infected female Anopheles mosquitoes and that infect the red blood cells. Most deaths occur among children in Africa, where a child dies almost every minute from malaria, and where malaria is a leading cause of childhood neuro- disability. According to the World Malaria Report 2016,anestimated 3.2 billion people in 95 countries and territories are at risk of being infected with malaria and developing disease, and 1.2 billion are at high risk (>1 in 1000 chance of getting malaria in a year). There were about 214 million cases of malaria globally in 2016 and about 438,000 malaria deaths. The burden was heaviest in the African region, where an estimated 92%2 of all malaria deaths occurred, and in children aged under 5 years, who accounted for more than two thirds of all deaths. Typical symptoms of malaria include fever, fatigue, headaches, and, in severe cases, seizures and coma, leading todeath.

II. LITERATUREREVIEW

H.A Mohammed reviewed various techniques for preprocessing. Deepa. A. Kureret al. [4], proposed a new approach for low-level image processing - SUSAN (Smallest Unvalued segment assimilating nucleus) Principle, which performs Edge and Corner detection. Image features based on color, texture and the geometry of the cells and parasites are generated, as well as features that make use of a priori knowledge of the classification problem and mimic features used by human technicians. A two-stage tree classifier distinguishes between true and false positives, and then diagnoses the four types of the infection. The algorithm detects the species of parasite with a sensitivity of 99% and a positive predictive value of 90-92% Daniel MaitethiaMemeu et al. [5] proposed a method for detection of plasmodium parasites from images of thin blood smears. The method is based on Artificial Neural Net-work (ANN) for testing the presence of plasmodium parasites in thin blood smear images. Pre-processing, features extraction are implemented and eventually diagnosis was made based on the features extracted from the images. Classification accuracy of 95.0% in detection of infected erythrocyte was achieved with respect to results obtained by expert microscopes. S. Kareem et al. [6] proposed a novel idea to identify the total number of red blood cells (RBCs) as well as their location in a Giemsa stained thin blood film images. The method utilizes basic knowledge on cell structure and brightness of the components due to Giemsa staining of the sample and detects and locates the RBCs in the image.Fordetection of Malaria, this study presented a simple approach based on the shape and size of each RBC by calculating its roundness using an appropriate threshold. The classification of malaria parasite is implemented using NCC that does not require training like the ANN.

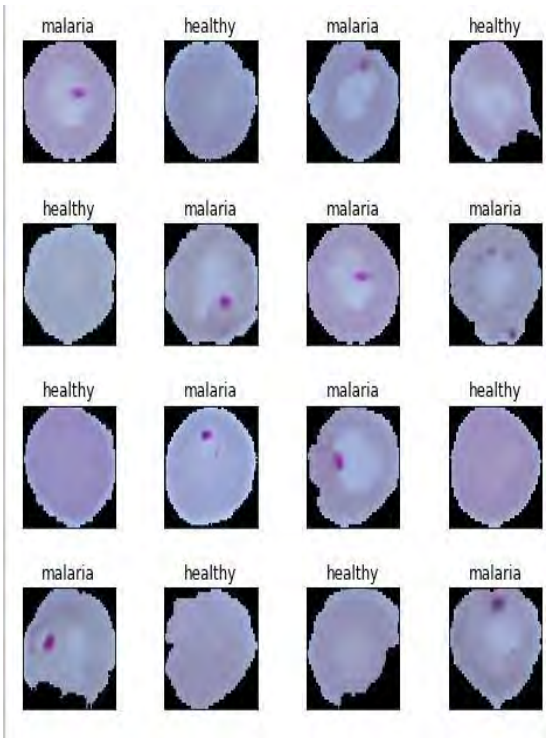
III. MOTIVATION

Conventional diagnostic tool for malaria is the examination of stained blood cell of patient in microscope. The blood to be tested is placed in a slide and is observed under a microscope to count the number of infected RBC. Based on the guidelines from the WHO protocol, this procedure involves intensive examination of the blood smear at a 100X magnification, where people manually count red blood cells that contain parasites out of 5000 cells. An expert technician is involved in the examination of the slide with intense visual and mental concentration. This is tiresome and time- consumingprocess.

IV. METHODOLOGY

A. ImageAcquisition

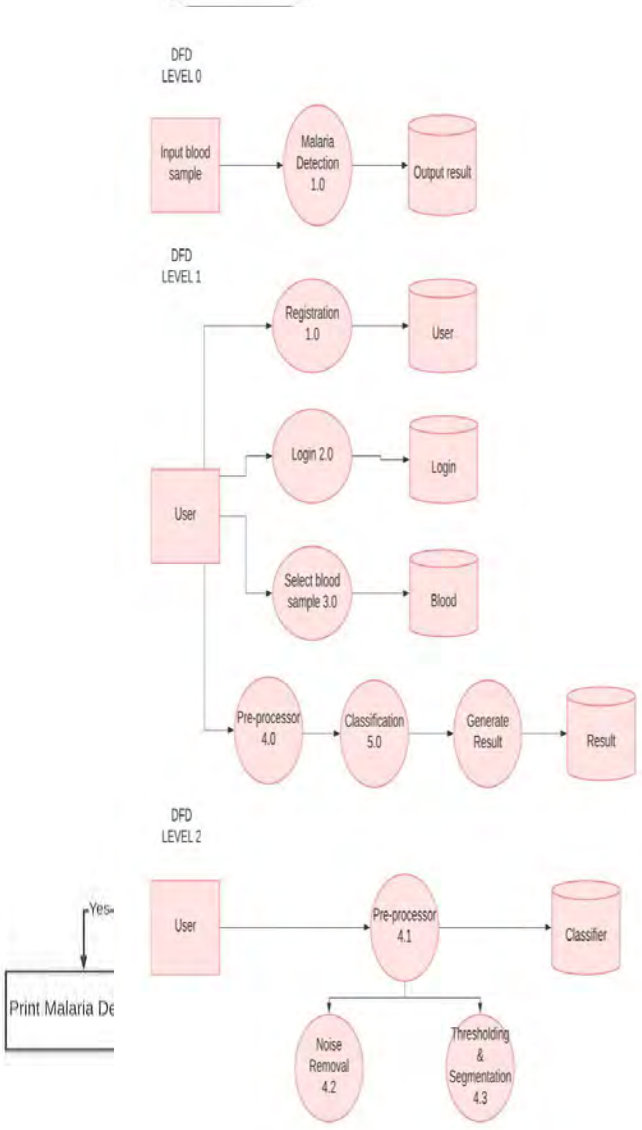
Images of segmented blood cells acquired from Kaggle[11] was used for training of our model. There are about 26000 images pre- classified into respective classes. The classes being Uninfected and Parasitized. Taking help of these datasets we build our model. Images are of followingformat



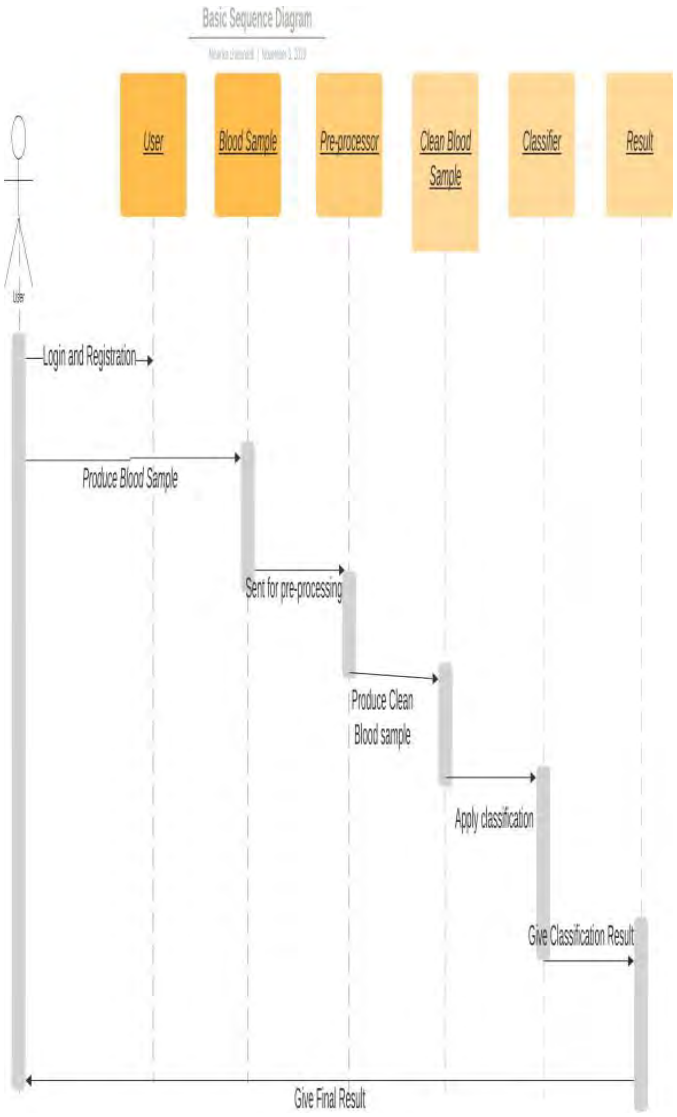
B. ProposedArchitecture

C. Flowchart

D. FunctionalModel



E. SequenceDiagram



V. APPLICATION OFPROJECT

Conventional diagnostic tool for malaria is the examination of stained blood cell of patient in microscope. The blood to be tested is placed in a slide and is observed under a microscope under 100x zoom to count the number of infected RBC. An expert technician is involved in the examination of the slide with intense visual and mental concentration. This is tiresome and time- consuming process. Hence by using image recognition along with machine learning it would become easy to detect malaria accurately and within less time, especially in areas with less resources or with less experiencedpeople.

ACKNOWLEDGMENT

We sincerely thank our guide Mrs. Veena Kulkarni for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. SheetalRathi, Dean Academic, Dr. R.R Sedamkar, the Principal, Dr. B. K. Mishra and the college management for their support

VI. RESULT AND ANALYSIS

A. Result

We were able to use image processing to get image in desired for. For malaria parasite detection we used Convolutional Neural Network (CNN). We were able to achieve accuracy of 95% with available dataset

B. FurtherWork

Further work needs to be done is to acquire dataset which isn't pre-processed and apply our algorithms on those datasets. Also, accuracy is to be improved so that this model can be used for practical purposes. It should also enable for early detection of malaria and detect various malaria parasite

Fake Product Review Detection and Classification Using Data Mining

Dr. Rekha Sharma, Anamika Prasad,Manvi Saxena, Akshit Vaghani
Department of Computer Engineering
Thakur College of Engineering and Technology
Mumbai, India
rekha.sharma@thakureducation.org, anamikaprasad.98@gmail.com, saxena.manvi11@gmail.com, akshit.vaghani7@gmail.com

Abstract— **any e-commerce website gets a bad reputation if they sell a product that has poor reviews; the user most often blames the e-commerce website rather than the manufacturers. These online reviews can change the customer's mind set. If these reviews are true, then they can help users select the appropriate product to meet their need. On the other hand, it can confuse the user if the reviews are manipulated or not true.Some review sites include some great audits by individuals within the item organization itself to provide false positive item reviews. It also happens that rival businesses generate false negative reviews to outperform their competitors. To eliminate this type of fake product review, we will create a system that detects fake reviews and eliminates all fake reviews using data mining techniques. Finally sentiment analysis is performed to classify positive and negative for actual reviews**

Keywords— Sentiment analysis, Prediction, Data Extraction

I. INTRDUCTION

Now-a-days an internet has become an essential thing, as it provides more facilities to its users. There are many social networking sites that offer users to share their views. As the technology of e-commerce is growing rapidly, the impact of online reviews increases. For consumers, reviewing becomes an essential way for them to gain more knowledge of product quality thus enabling them to make purchasing decisions. For business owners, the review seeks to improve and grow their businesses. Feedback from customer reviews is useful for product improvement. However, reviews may not always be provided truthfully and fake reviews are usually present. Business owners can pay someone to write a good review about their products or a bad review about their competitors' products. These fake reviews lead consumers to make wrong decisions about product quality. Therefore, it is important to detect fake reviews and is a challenging issue in both the industrial and academic sectors. People share their views about politics, social issues as well as various products. It is common today that a user watches reviews of that product online before purchasing anything. There are many sites that deal with these reviews. They

Provide ratings for products as well as show comparisons between different products. Some enterprises try to create fake reviews to influence customer behavior and increase their sales. But, how to identify those fake reviews is a difficult task for the customers. In today's competitive world it is essential for any enterprise to maintain its reputation in one market. Therefore it is necessary for both, namely to identify the enterprise and customer to the manipulated reviews. Traditional methods of data analysis have long been used to detect fake reviews. A review can be classified as either fake or real using either supervised or unproven teaching techniques. In this work we try the dataset and determine whether the review is real or fake.

II. OBJECTIVES

The contributions of the presented work are as follows:

- To implement best approach available for detection of fake reviews using opinion mining (sentiment analysis) techniques.
- To detect and flag fake reviews posted on ecommerce websites.
- To let users, know if each individual review is trust worthy or not for efficient use of money from user's side.
- To tell whether it is a 'false positive or false negative'
- Review with highest accuracy.
- To make a provision of removal of such reviews.

III. METHODOLOGY

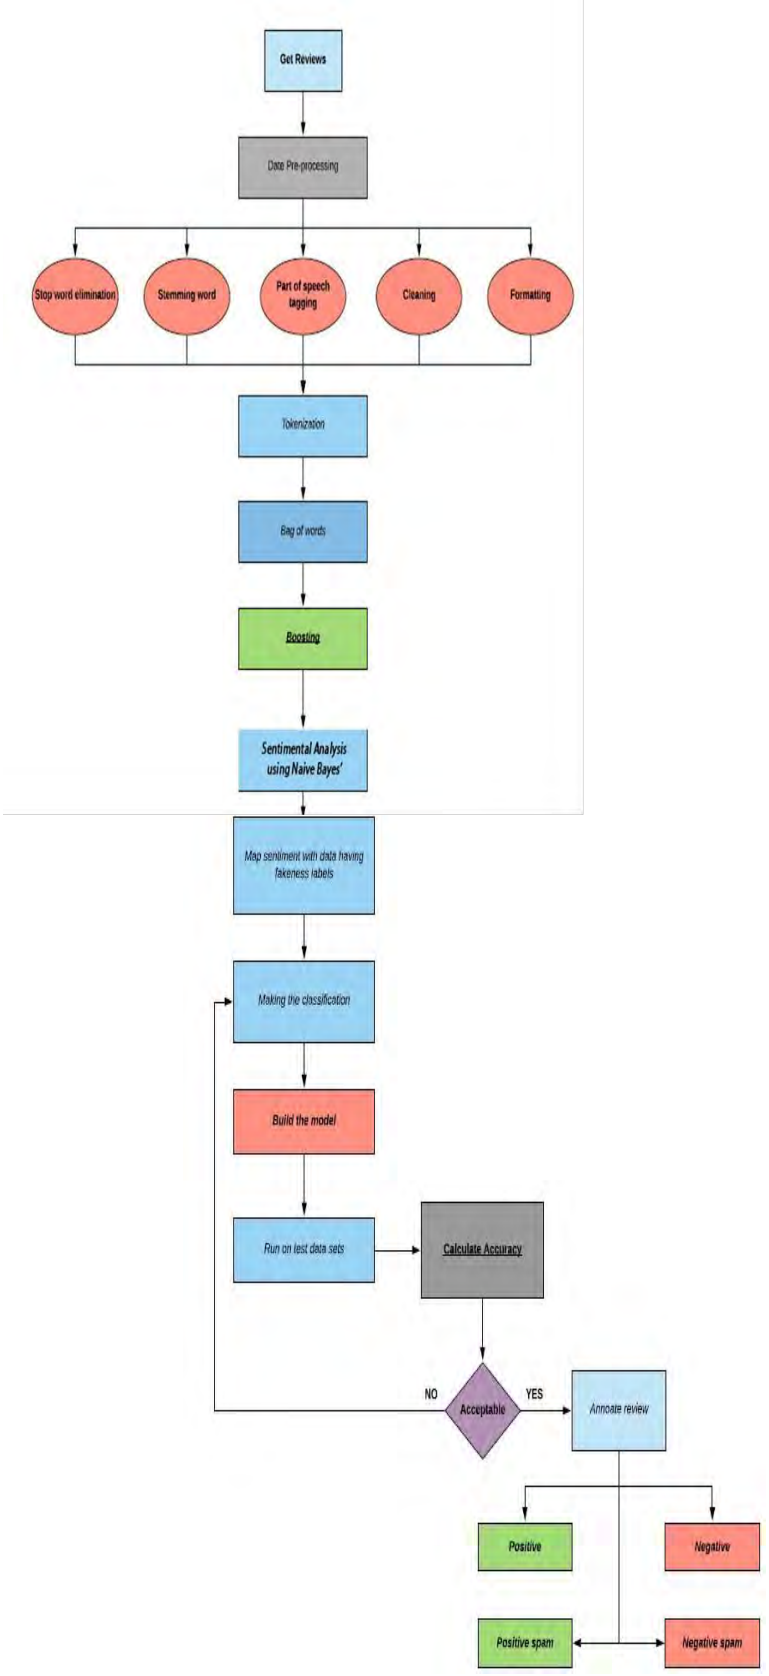
With our approach we aim to combine these 2 classifications and give a total of 4 classifications. The data preprocessing technique varies according to the dataset chosen. We use the methods like stop word elimination, part of speech tagging, tokenization. The use of algorithm also varies but all show varying accuracies. We have chosen Naïve Bayes' algorithm This is because it has better performance results. This approach is used in sentimental analysis so as to find whether the feedback is a positive or a negative one. Classification rules will be laid down, on the basis of the decision will be taken whether the review is fake or not.

Firstly, the most important aspect of the project is the data set. So the dataset is extracted by surfing over the internet. The dataset which best suits our interest is then selected. This dataset is then imported on the Machine Learning platform. This data is then distributed as 80% training and 20% test data. This data is the pre-processed using data cleaning methods like stemming word, stop word elimination, part of speech tagging etc. With this cleaned data, we train the classifier and then the

algorithm is applied. Naïve Bayes' algorithm is used for the sentimental analysis to achieve highest possible accuracy.

The proposed project work is under the Intelligent System Design and Development Domain which requires a detailed study of Natural language processing, Classification algorithms and Machine Learning.

The overall working of our project can be explained through the following abstract diagram.



A. Data Pre-processing

Data preprocessing is a data mining technique that involves transforming raw data into an understandable format. Real-world data are often incomplete, inconsistent and / or lacking in certain behaviors or trends, and are likely to include many errors. Data preprocessing ways include Stop word elimination, removal of URL, repeated characters, hash tags and usernames.

B. Training and Testing using Naïve Bayes algorithm

A Naïve Bayes classifier is an algorithm that uses Bayes' theorem to classify objects. Naïve Bayes classifiers assume strong, or naïve, independence between attributes of data points. Popular uses of naïve Bayes classifiers include spam filters, text analysis and medical diagnosis. These classifiers are widely used for machine learning because they are simple to implement.

C. Sentiment Analysis

Finally using Sentiment Analysis the result is obtained as positive or negative. The process of computationally identifying and categorizing opinions expressed in a piece of text, especially in order to determine whether the writer's attitude towards a particular topic, product, etc. is positive, negative, or neutral. Natural language processing (NLP) is used for this purpose. It is a subfield of linguistics, computer science, information engineering, and artificial intelligence concerned with the interactions between computers and human (natural) languages, in particular how to program computers to process and analyse large amounts of natural language data. To implement natural language processing in python Natural language toolkit(nltk) was used. NLTK is one of the leading platforms for working with human language data and Python. In the following project we have used nltk to make predictions, that is , given a product review, a computer can predict if its positive or negative based on the text. Also, various packages are imported from nltk for the pre-processing step.

D . Determine Fake or not

Further, for the fake, genuine review detection, reviews will be processed and analyzed on the following conditions.

- Does the review entered by the user contain any link which redirects them to other product page for brand promotion?
- Analyzing whether multiple review have come from the same user.
- Analyses whether same email account or same IP

Address are used for multiple reviews on same product

- Analyze whether the review contains more than 5 positive or negative words
- Examine the timing of reviews. See if there is a spike in the total number of reviews during a very short time frame.
- Look for overuse of "I" and "me" and a lot of verbs. Online reviews that frequently use "I" and "me" are more likely to be fake than those that don't -- possibly because when people are lying they try to make themselves sound credible by using personal pronouns. If the review posted by the user

satisfies most of the above specified conditions then it will be considered as spam/fake reviews. Once the review is detected as spam review or fake review, then user account will be blocked and review will be discarded.

IV. CONCLUSION

It is seen that sentiment analysis play vital role to make business decision about product/services. Sentiment Analysis not only encompasses concepts of text mining but also the concepts of information retrieval. Major challenges in Sentiment Analysis includes feature weighting which plays a crucial role for good classification. Also it is seen that soft computing techniques have not been extensively used in the literature. Thus, with the blend of Tokenization, Decision tree algorithm and Sentiment analysis, higher accuracy of results in short duration can be expected. After investigating various machine learning techniques to build classification models using different features sets obtained Precision rates.

- Analyzing whether multiple review have come from the same user.
- Analyses whether same email account or same IP

Address are used for multiple reviews on same product

- Analyze whether the review contains more than 5 positive or negative words
- Examine the timing of reviews. See if there is a spike in the total number of reviews during a very short time frame.
- Look for overuse of "I" and "me" and a lot of verbs. Online reviews that frequently use "I" and "me" are more likely to be fake than those that don't -- possibly because when people are lying they try to make themselves sound credible by using personal pronouns. If the review posted by the user

Satisfies most of the above specified conditions then it will be considered as spam/fake reviews. Once the review is detected as spam review or fake review, then user account will be blocked and review will be discarded

Based on this research study, improvements can still be made. For example, more attributes can be

considered such as the time stamp, tracing backwards the user ID and IP address. Furthermore, more instances can also be collected. Although there are numerous machine learning models for sports results prediction, better models with high accuracy rates are still worth exploring especially function based techniques.

V. FUTURE SCOPE

The project uses analyzed historical data and tries to predict the outcome and classify them. The major benefit of the project is that the result will be shown on the spot. The main aim of the project will be to increase the accuracy of the result so as to enhance the performance as compared to the previous approaches .The project can be further used at a greater level in the industry by using boosting technique while pre- processing. Moreover, the project allows us to check the odds and false negative so that they get a clear idea as to which reviews should be considered to be worked upon.to be worked upon. Worked upon The project has a number applications. False positive.

VI. ADVANTAGES

The algorithm could also be used at any kind of platform with any kind of review as well if it works efficiently and with a lot of accuracy. It could also be used by any type of company owner to get to know their rivals in the market who are trying to defame them. Also it would help them understand the reviews better classified as positive and negative. Not only comments or reviews, the model will be able analyze any type of statement and classify it as positive and negative.

VII. ACKNOWLEDGEMENT

We sincerely thank our guide Dr. Rekha Sharma for her guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work.

We thank the HOD, Dr. Sheetal Rathi, Dean Academic, Dr. R.R Sedamkar, the Principal, Dr.B. K. Mishra and the college management for their support.

Design and Development of Enhanced Plagiarism Checker

Rahul Pal,Deepak Shukla,Atul Singh,,Dr. Rekha Sharma Associate Professor
Computer Engineering Department
Thakur College of engineering and Technology
Mumbai, India

Abstract— **The plagiarism of technical journals, papers and other documents is a widespread and growing problem in the academics as well as research process. The traditional manual detection of this kind of plagiarism by human is hefty, not accurate, and overloading process. This project aims to create a plagiarism-detection system that can help academicians and researchers to make a better judgment of the work. There are currently many existing detection algorithms. Some of them have been studied and analyzed and compared. Based on this, the most suitable for our system has been chosen for the implementation. The proposed system checks plagiarism between text documents. Both Syntactic and Semantic similarity is calculated and the similarity result will be shown stating whether two sentences are similaror not.**

Keywords — Plagiarism detection. Levenshtein Algorithm

I. INTRODUCTION

Martins et al. define plagiarism as "the usage of work without crediting its authors". The easy and cheap access to enormous web content has turned plagiarism into a serious problem be it for researchers, publishers or educational institutions. One of the most common forms of plagiarism in academia is the textual plagiarism at document level, where documents are typically essays or reports andscientificpapers.Accordingtoarecentsurvey,16perc entofthe original articles published in leading surgical journals could be considered redundant publication. However, plagiarism applies not only to text documents but also to source-code as well. Source-code plagiarism can be defined as trying to pass off (parts of) source code writtenbysomeoneelseasone'sown(i.e.,withoutindicati ngwhich parts are copied from which author). In academic environment, source-codeplagiarismariseinprogrammingassignments.With the intention of achieving good grades with less or almost no effort, students often try to copy the assignments from their friends. Freshmenwhoplagiarizeintheircoursesaremorelikelyt ocontinue this malpractice in their later courses. Therefore this malpractice needstobecurbedatitsinitialstages. Theinstructor ofacoursecan receive a false feedback about the level of the course and performance of the students. This makes the problem of assignment plagiarismdetectionanimportanttask.It ishardtomanuallyinspect and (decide whether a submission is genuine or plagiarized) detect similar student submitted solutions in a large class. Though manual inspection is effective, it is laborious and time consuming. One possible way to address this is to seek the help of automated code comparison tools like Measure of Software Similarity (MOSS), JPlagwhichhelpinidentifyingsimilarsubmissionpairs. Mostofthe well-knownautomaticcodecomparisontoolsrelysolelyonthe text- based approach or use the features solely based on the property of the assignments at a syntactic level to detect plagiarism. However, boththeseapproachessuccumb tocodeobfuscation,whichisahuge obstacle toautomatic software plagiarism detection. Often students use clever techniques to obfuscate the code and evade from being detected.

II. RELATEDWORK

[1] Bradley Beth,A Comparison of Similarity Techniques for Detecting Source Code Plagiarism, The University of Texas at Austin, May 12,2014.

This paper addresses techniques applicable to the phrase "...structure and computer code..." in relation to computer science coursework. Got to know different techniques of source-code attacks. There is room for improvement in implementing document fingerprinting techniques over source code

[2] Zhan Su, Byung Ahn, Ki-Yol Eom, Min-Koo Kang,Plagiarism Detection

Using the Levenshtein Distance and Smith-Waterman Algorithm, IEEE INSPEC Accession Number: 10184600, 22 August 2016.

The original aim to determine whether Levenshtein distance is a good enough value for plagiarism checking results in a positive, Levenshtein distance is a good enough value for plagiarism. Informally,

the Levenshtein distance between two words is the minimumnumberofsinglecharactereditsrequiredtochangeaword into another word. There exists strategies to fool the algorithm but the strategies can be avoided by using severalrestrictions.

[3] A Machine Learning Based Tool for Source Code Plagiarism Detection, Upul Bandara, and GaminiWijayarathna,2014.

It gives several attributes to measure code similarity. This paper presents a new plagiarism detection method, which is based on machine learning techniques. We have trained and tested machine learning algorithms for detecting source code plagiarism. Most system will not work correctly, if programmers follow some coding standards and source code formatting tools specified in their projects.

III. PROBLEM DEFINITION

The objective of this project is to make a plagiarism checker software or tool which checks plagiarism between documents or betweendifferentsourcecodes.Andatlastthesimilarity percentage is computed with respect to syntactic and semantic similarities for documents and line wise checking for source codes and thus giving results whether the document is plagiarizedornot.

Inthiswork,ourfocusisonbuildingatoolpoweredbymachine learning algorithms, to detect plagiarism in programming assignments. We propose and use novel features that can alleviate the effect of code obfuscation and be able to detect the plagiarized student solutions. We use source code metrics as feature representations which can capture the variations observed in the code as belonging to three distinct themes: structure, syntax (syntax refer to the tokens that occur within basic blocks) andpresentation.

$$lev(i,j) = \begin{cases} \max(i,j), \min(i,j) = 0 \\ \min\begin{cases} lev(i-1,j)+1 \\ lev(i,j-1)+1 \\ lev(i-1,j-1)+eq(i,j) \end{cases}, \min(i,j) \neq 0 \end{cases}$$

IV. OBJECTIVES

- Detection Performance: The detection performance should be better than that of other tools, and we should be able to demonstrate this on a variety oftasks.

- Visualization: To be usable as plagiarism detection tool, it is important to show the locations of the similarities in each programpairorthesourceofotherfeatures.
Weshouldbeable to visualize the influence of certain features in the document pairs to make comparingeasier.

- Runtime Performance: Finding plagiarism in a set of source code documents should not take days, but preferably less than an hour. Besides the inconvenience for the user, slow performance makes evaluation of the tool and hyper parameter optimization harder. However, improvements in detection performance may justify a higherruntime.

V. METHODOLOGY

- *LevenshteinDistance*

Levenshtein distance is a measure of difference between two strings. Informally, the Levenshtein distance between two wordsistheminimumnumberofsinglecharactereditsrequired tochangeawordintoanotherword.Themeasurementwas first considered by Vladimir Levenshtein, and his name is used as the distance name. The distance may also be referred as edit distance, although the edit distance term actually refers to a largersetofstringdifferencemeasure,suchaslongestcommon subsequence (LCS) and Hamming distance. Formally defined, given two strings and its character set, the edit distance is the minimum-weight series of edit operations that transforms the first string into the second string. One of the simplest sets of editoperationsdefinedbyLevenshteinin1966are:insertion of a single symbol, deletion of a single symbol, and substitution of a single symbol. The original definition has a unit cost, so the Levenshtein distance is equal to the minimum number of steps to change the first string into the second string. This definition is referred as Levenshtein distance. The levenshtein distance between two strings a,b is given as lev(length(a),length(b))

Figure 1: Levenshtein Distance

Thakur college of Engineering and Technology
Mumbai, India
kodhanhsree@gmail.com, dolby14agarwal@gmail.com, anilyadav181997@gmail.com

Abstract—***The goal of the model proposed in this paper is to predict airline delays caused due to the major observed factors***
i.e. weather conditions, NAS(National aviation system), Airline and airport security using data mining and supervised machine learning algorithms. US domestic flight data and airline delay data from 2005 to 2015 were extracted and used to train the model. To overcome the effects of imbalanced training data, sampling techniques are applied. Decision trees, random forest and the XGBoost were implemented to build models which can predict delays of individual flights. Then, each of the algorithms' prediction accuracy and the receiver operating characteristic (ROC) curve were compared. In the prediction step, flight schedule and delay details were gathered and fed into the model. Using those data, the trained model performed a binary classification to predicted whether a scheduled flight will be delayed or on-time.

I. INTRODUCTION

According to the 'Bureau of Transportation Statistics (BTS)', approximately twenty percent of the entire scheduled commercial flights are delayed. Due to airline delays, airlines are costed multi-billion dollars per year and cause inconvenience to passengers. BTS has categorized airline delays into five main causes, which are air carrier, extreme weather, National Aviation System, late-arriving aircraft and security. All the factors mentioned above are closely related to other categories, indeed. For example, National Aviation System category can include delays due to the re-routing of flights by inclement weather. Besides, weather too is a factor affecting late-arriving aircraft although airlines won't report the causes as weather. By considering those facts, weather's percentage share accounts for about 40% of total delay minutes. Thus, study on the influence of inclement weather on airline delays is essential for efficient flight operations in relation with all the other factors. Furthermore, a decision support tool built on the study can inform passengers and airlines about delays in advance and help them reduce possible monetary losses. For this purpose, the classification model to predict delays of individual flights is proposed in this study to follow. On- time performance of flights has been an important research subject since the demand for air travel is ever increasing. Thus, several attempts were there to discover patterns in air traffic. Rebello and Balakrishnan have created variables indicative of the state of the NAS. And they predicted network-related delays of the future by studying the system- level dependencies among airports. Zonglei et al. have trained classification models to find how serious daily delays are at the hub-airport of China in the future. Contrastingly, Klein et al. have focused more on weather and provided a delay prediction model established on metric called Weather Impacted Traffic Index (WIFI) which measures the severity and the impact of weather. However little research exists that focuses on combined factors analysis of delay prediction of individual flight by utilizing machine learning. In this research, we have focused on arrival delays of individual flights using supervised machine learning algorithms. There are various reasons to explain why machine learning was tried. First of all, the volume of historical flight and delay data are too large to analyze analytically. Moreover, relationships between causal factors and delay or even correlations among factors are very complicated and highly nonlinear to test all hypothesis. Machine learning is able to develop models vigorously with huge amount of dataset and it has the ability to discover hidden patterns in the data. To summarize, machine learning is a clever method that can address problems in analytical analysis with big data. For predicting delays of individual flights, supervised machine learning algorithms were implemented with features including flight schedules and delay data at the origin and the destination airport. In order to increase the predictive capability, models were trained for individual origin-destination (OD) pair not for the entire National Airspace System (NAS) by capturing each airport's delay data. In the prediction step, flight schedule information combined with delay data was fed into the model to get the predictions on scheduled flights not yet flown. The paper is organized as follows: Section II provides brief explanation on methodologies used in this study and Section III describes how the model is built. In Section IV, classifiers' performance are investigated in terms of accuracy and ROC. Lastly, conclusions and future work are presented in Section V and they conclude the paper.

II. LITERATURE REVIEW

From the literature we reviewed, we found that this problem of flight delay prediction had different approaches by different people. The flight delay

prediction problem may be modeled by many methods, depending on the objectives of the researches. In this project we have approached the problem from machine learning perspective. Researches that study flight systems from machine learning perspective are

increasing. The methods commonly used include k-Nearest Neighbour, neural networks, SVM, fuzzy logic, and random forests. They were mainly used for classification and prediction.

Rebollo et al. applied random forests to predict delay innovation. They compared their approach with regression models to predict delay innovation in airports of the United States considering time horizons of 2, 4, 6 and 24 hours. Lu et al. compared the performance of Naïve Bayes, decision tree and Neural networks to predict delays in large datasets. They observed that decision trees had the best performance with confidence of 80%.

Lu et al. built a recommendation system to forecast delays at some airports due to propagation effects. Prediction was based on the k-Nearest Neighbour algorithm and used historical data to recognize similar situations in the past. The authors noticed fast response time and easy logical comprehension as the main advantages of their method. Khanmohammadi et al. created an adaptive network based on fuzzy inference system to predict delay innovations. The predictions were used as an input for a fuzzy decision making method to sequence arrivals at an International Airport in New York. of classifiers is dependent on the previous one and focuses on the previous one's errors. Samples that are incorrectly predicted in the previous classifiers are chosen more often or weighted more heavily when estimating a new classifier.

III. MOTIVATION

Flight delays have negative impacts, especially economic, for passengers, airlines and airports. Given the uncertainty of their occurrence, passengers usually plan to travel many hours before their appointments, increasing their trip costs, to ensure their arrival on time. On the other hand, airlines suffer penalties, fines and additional operation costs, such as crew and aircrafts retentions in airports. Furthermore, from the sustainability point of view, delays can also cause environmental damage by increasing fuel consumption and gas emissions. There is a known relationship between levels of delays and fares, aircraft sizes, flight frequency and complains about airline service. The estimation of flight delays can improve the tactical and operational decisions of airports and airlines managers and warn passengers, so they can conveniently rearrange their plans. It will be good experience to work with real data and practice skills related to statistics and machine learning. Also, it is interesting to discover more insights for airline industry.

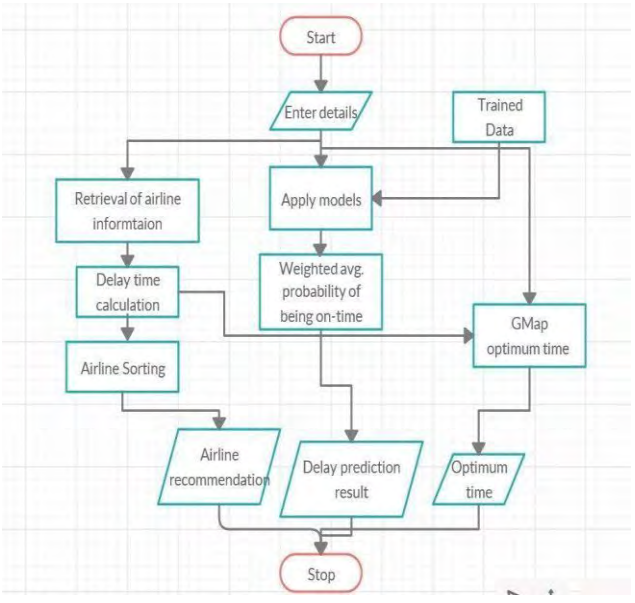
IV. METHODOLOGY

A. Supervised Learning Classifiers

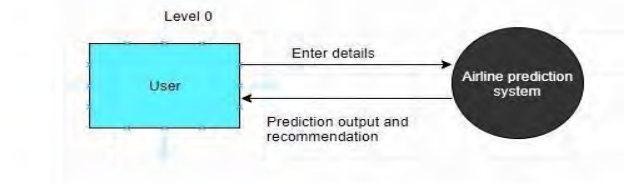
Random Forest (RF): Random forest is an ensemble of many individual decision trees. It builds a large collection of de-correlated trees which are noisy but unbiased, and averages them to reduce the variance. Random forest obtains a class vote from each tree, and then classifies a sample using majority vote. Let Cˆb(x) be the class prediction of the bth tree, then the class obtained from random forest, Cˆrf (x), is Cˆrf (x) = majority vote{Cˆb(x)}B

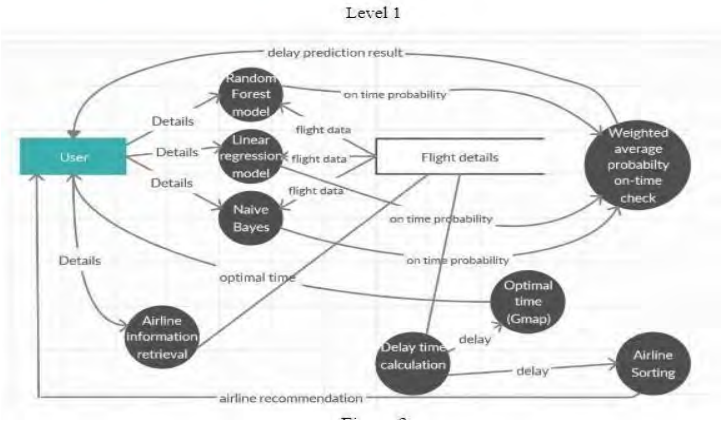
XGBoost: AdaBoost is a method of converting weak classifier into highly accurate prediction rule. It learns week learner on weighted example set sequentially and combines weak hypotheses linearly. Produced sequence

B. Flowchart

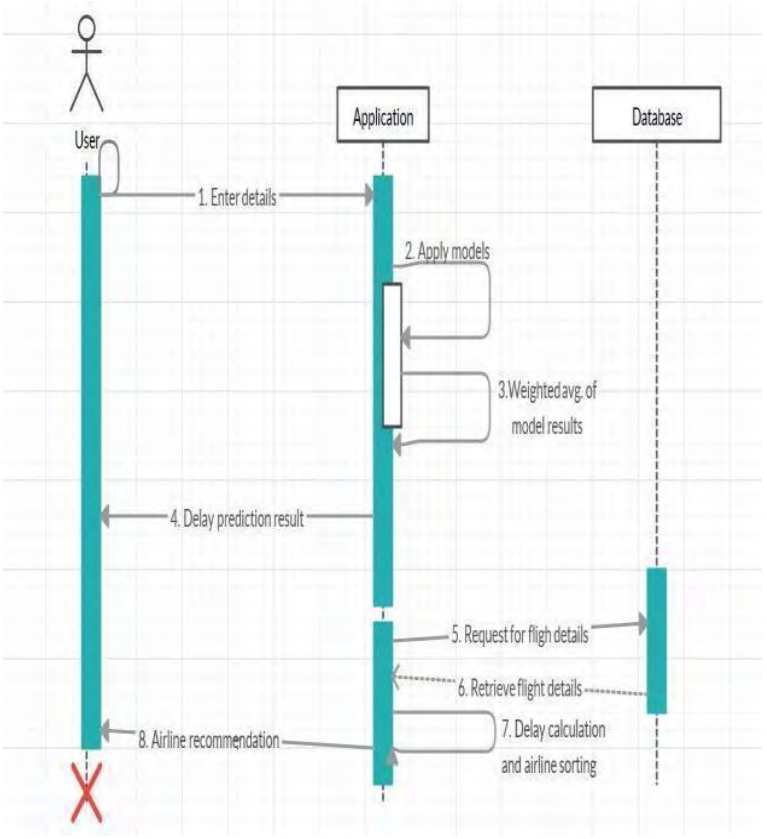


C. *Functional Model*





D. *Sequence Diagram*



V. APPLICATION OF PROJECT

Optimum Time Management: The proposed system is giving the percentage of the possibility of the flight getting delayed. The same system can be used to provide a specific time range where the possibility of the flight getting delayed is very low by considering the same attributes, the user can book their flight in that time range.

Travel Insurance: The system can be used by the Insurance Companies to get an estimate of the amount that will be used for settling the claims in advance. The claims can include travel delay, missing a connecting flight, baggage missing, etc.Hotel Management: The system can be used by the Hotel to check if a flight is delayed or not and sending the vehicles for pickup and drops accordingly. The hotel can obtain the itinerary details of the customers to schedule thepickup and drops.

VI. RESULT AND ANALYSIS

A. Result

We were able to use the random forest classifier to successfully classify the dataset that we had. We applied data preprocessing and cleaning techniques using Python to remove the unnecessary attributes. The
accuracy was 86% using Random Forest classifier.

B. Futher Work

Further work needs to be done so as to apply various other algorithms and take a weighted average of their accuracies since different algorithms work best on different datasets.

Abstract— ***Accurate color recognition models are a requirement for the growth of technology when concerned in dealing with Artificial Intelligence as well as in many industries whose interest lies in automated segregation of colors such as the publishing industry. In light of numerous such requirements and with the information of complexion of various images, machine learning calculations based on Manhattan distance can recognize the similarity of a new image as compared to the assigned dataset and characterize it into a particulargroup.***

There has been an extensive use of a color recognition model which can help various industries in streamlining their processes and reducing cost. Color recognition has a very wide uses ranging from science and technology to society. The project mainly focuses on building a system which can learn to classify images based on their colors. The system will learn from the dataset to classify new attributes using Machine Learning. The system will be focusing on effectively dealing with primary colors and will classify them based on majority color constituents of the image. The system evaluates the color histogram of the image and learns from the data set to classify it accurately. Integration of such a system with webcam can dynamically help the AI industry in achieving its goal.

Keywords— Histogram, OpenCV, Python, Color Recognition

I. INTRODUCTION

This undertaking centers around color recognition by K- Nearest Neighbors Machine Learning Classifier which is prepared by R, G, B Color Histogram. It can group Red, Green, Blue, White, Black, Violet, Orange, and Yellow colors. On the off chance that we need to characterize more colors or improve the precision for some critical applications we should chip away at the training data set or consider about other color highlights, for example, Color Moments or Color Correlogram.

We disengage the assignment into three obvious stages**:**

- **Training K-Nearest Neighbors Classifier:** Train KNN classifier by R, G, B Color Histogram esteems.

- **Feature Extraction:** Perform feature extraction for getting the R, G, B Color Histogram esteems of preparing pictures for trainingimages.

- **Classifying via Trained KNN:** Read Web Cam outline by outline, perform feature extraction on each edge and afterward arrange its mean shade via prepared KNNclassifier.

II. METHODOLOGY

The 2 main phenomena to understand basic Object Detection/Recognition Systems of Computer Vision and Machine Learning are:

1) Feature Extraction

We focus on a major to represent the points which seem of interest and then compare them with other such similar points in the image.

2) Classification

An algorithm that actualizes grouping, particularly in a solid implementation, is known as a classifier. The expression "classifier" now and then likewise alludes to the numerical function, executed by a grouping algorithm that maps input information to a classification.

Color Histogram

Color Histogram is a portrayal of the dissemination of colors in a picture. For advanced pictures, such as digital images a color histogram speaks to the quantity of pixels that have colors in every one of a fixed list of color ranges, that span across the picture's shading space, the arrangement of every single imaginable color. Color Histogram is the most broadly utilized method for extricating the color feature of a picture. It represents the picture from an alternate point of view. It represents the recurrence appropriation of shading canisters in an image. Itcheckscomparable pixels and store it. There are two sorts of color histogram viz. global color histogram and local color histogram. Color histogram is proposed as a worldwide color descriptor which break down each measurable color frequency in a picture. It is utilized to take care of the issues like change in translation, pivot and point of view. Local color histogram centers around the individual pieces of an image. Local color histograms consider the spatial distribution of pixel which is lost in global color histograms. Color histogram is anything but difficult to register towards little varieties in the picture so is significant in ordering and recovery of picture database. Aside from these focal points, it faces two significant disadvantages. To start with, overall and large spatial data isn't considered. Second

is that the histogram isn't powerful and extraordinary as two unique pictures with comparative color appropriation lead to comparable histograms, a similar view pictures with various presentation to light make varioushistograms.

Color Histogram for K NearestNeighbours (CHKNN)

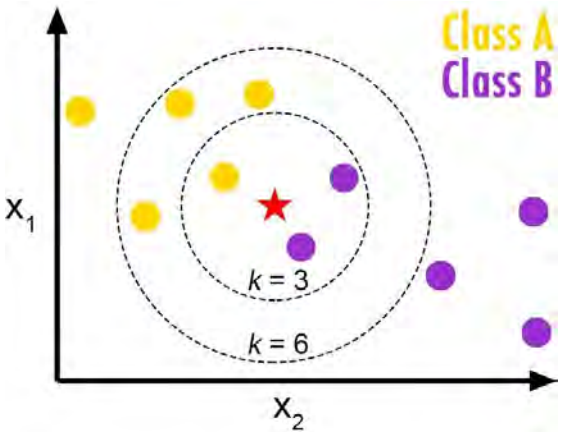
For a color pixel 2^{24} different colors are possible. The color histogram for K-Nearest neighbor (CHKNN) features of an image is presented. In this method one color in the common color palette which is more similar to a particular pixel color is considered to replace that pixel color. Same process was applied to each pixel color in order to classify all pixels in the image into k cluster. The K-Nearest Neighbor clustering algorithm is employed to categorize the pixels of all training images. The algorithm outputs the mean of all pixels in each cluster, which is set as the new initial value for further training. After these steps the color histogram is prepared. For kth color bin the CHKNN feature was defined as shown in Eq:

$$g_k = \frac{N_k}{N}$$

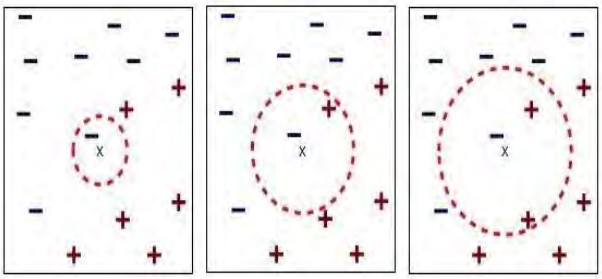
Where, N is total pixel numbers and N_k is the number of the pixels in the kth cluster. The method describes color feature with a small number of features and hence 16 groups of colors were evenly divided in the paper leading to effectively shorten image retrieval time and enhance retrieval performance. It is simple, easy to compute and noise resistant method. The method is robust to image size variance, displacement androtation.

K-Nearest Neighbors Algorithm

The k-nearest neighbors (KNN) algorithm is a straightforward, simple to-execute supervised ML algorithm that can be utilized to solve both classification and regression problems. K nearest neighbors is an algorithm that stores every single accessible case and groups new cases dependent on a likeness or similarity measure, for example, a separation function like Euclidean distance. K-nearest neighbor has been utilized in factual estimation and pattern recognition as of now as a non-parametric strategy. The K-nearest neighbor calculation accept that comparative things exist in closeness. At the end of the day, comparable things are close to eachother.



The thought behind k-Nearest Neighbor algorithm is



(a) 1-nearest neighbor (b) 2-nearest neighbor (c) 3-nearest neighbor

K-nearest neighbors of a record x are data points that have the k smallest distance to x

very direct. To group a new record, the framework finds the k nearest neighbors among the preparation or training archives, and uses the classes of the k nearest neighbors to weight the classification competitors. One of the downsides of KNN algorithm is its efficiency, as it needs to contrast a test report with all samples in the training set. Furthermore, the efficiency of this algorithm relies significantly upon two factors, that is, a reasonable similitude work, in other words a similarity function and a proper value for the parameter k in K nearestneighbor.

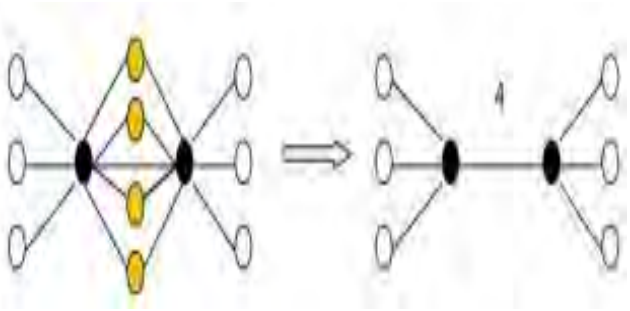
Improved k-Nearest Neighbor Classification algorithm

According to paper proposed by LeventErtoz, shared nearest neighbor method named SNN can be used to solve the problem of high-dimensional data which can be used in rapid recognition models such as real time color recognition models. The SNN core idea is that the similarity between two objects is defined based on Shared nearest neighbour. It is based on the following principle, if two points are similar to some of the same point, they are also similar, even directly similarity measure can't point out. The computation of SNN similarity between two point can be described as follows and Graphic is shown infigure.

Step 1: For each point, find out N nearest points for it and create its nearest neighbour list.

Step 2: If both two points appear in each other's nearest neighbour list, there is a link between them.

We build apoint link graph after we complete calculating link strength of every pair of linked points.
Step 3: The link strength of every pair of linked points is the number of shared neighbors.



Consider the above figure, each of the two black spots have eight nearest neighbors' interaction. The four of these nearest neighbors represented in yellow are Shared by the black dots. So, the SNN similarity between the two pointsis
4. Because SNN similarity is good on determining similarity between point and point, according to the SNN similarity we can successfully improve KNN classification algorithm to make it suitable for rapid recognition models.

3) PROPOSED WORK

We will likely recognize the color in still and dynamic images. We have thought of training the algorithm on several general color after which we read web cam frame by frame, perform feature extraction on each frame and then classify the mean color of it by trained K-Nearest Neighbor classifier. The objective is to first perform feature extraction for getting the R, G, B color Histogram of training images. The training images are mainly Black, Blue, Green, Orange, read, violet, white and yellow along with some other colors that are to be incorporated in the future. The goal is to set a connection between training images and new images captured through Webcam and color histogram seems to be the best guide.
The system tries to group the pixels based on the Euclidean distance. The Euclidean distance between any two points p and q is given by the length of the straight line connecting them. In Cartesian coordinates system if p having a space of points ($p1$, $p2$,..., pn) and q having a space of points ($q1$, $q2$,..., qn) are two points in Euclidean n-space, then the distance represented by d between p and q is given by the Pythagoreanformula

$$d(\mathbf{p},\mathbf{q}) = d(\mathbf{q},\mathbf{p}) = \sqrt{(q_1 - p_1)^2 + (q_2 - p_2)^2 + \cdots + (q_n -$$

$$= \sqrt{\sum_{i=1}^{n} (q_i - p_i)^2}.$$

After clustering we discover the color in some group of pixels and again perform the clustering on these groups to ultimately achieve the color of the image. For Real time

Web cam recognition each frame is considered as an image and is recognized independently.

4) CONCLUSION

With growing use of color recognition models such as in the distribution industry like publication media to reduce the cost of printing by segregating the images possessing majority components of similar color distribution, an accurate and efficient recognition model has to be developed. There is no denial that such a model can be widely used in monitoring changes and in advance fields like Artificial Intelligence. Though there are some tools available in the market, many of them are not accurate and stable. The main difference lies in those tools using a focal point to recognize the color, whereas our model considers the entire image frame and finds the color having the maximum distribution in the image. To give an edge to our recognition model, our project aims to also take into consideration some important factors like accuracy, stability, less response time, large variety of colors. All these important factors along with large training dataset assures that our model will be able to provide better results. It is very easy to integrate the model with different applications.
We have optimized the KNN algorithm as per our requirement of rapid color recognition to achieve better efficiency and accuracy. In this report, an intelligent system was developed based on machine learning and feature extraction to deal with the problem of color recognition in images. After investigating various machine learning algorithms to build recognition models using different features set obtained by feature extraction methods, we arrived at a conclusion of using K-Nearest Neighbor with improvement based on SNN (Similar Nearest Neighbor). There are still many factors affecting the recognition of color. First and foremost is the quality of training data. Other features include orientation, size and varying exposure of light. Theoretically, coverage of more features will result in a better accuracymodel.
Various improvements have been made for the system to support real time color recognition with less response time. For example, Large datasets are used carrying information of various colors. Although there are numerous machine learning models for recognition, better models with high accuracy are still worth exploring especially function based techniques. The system was successful in proving itself as a color recognition model and was able to recognize maximum color distribution in different images.

Review Paper On Image Forgery Detection

Lokesh Agrawal Heth Jain Dhruv Agrawal

Abstract **The arrival of sophisticated image editing software has made manipulating digital images' child's play. Today visual inspection can rarely distinguish between an authentic image and a forged one. Our confidence in the integrity of an imagehasbeenconstantlydwindling.Frommain-streammedia to various social media platforms, political campaigns, and the mass forwarded photos on instant messaging services, manipulated photos are on the rise. Revolutionary techniques have been devised to counterfeit the negative effects of these forged images. Here we review some of thesetechniques.**

KEYWORDS:-Gradient, image forgery, detectors, deep networks, copy- move

I. INTRODUCTION

For many years, human beings have used images or pictures to capture the reality around them or modify it to send the message they want to convey. This evolution has a before and after with the creation of photography. In today's age, there are a significant amount of computer crimes related to the illegal possession, distribution or modification of multimedia content. However,manipulationofimageshasbeengoingonforvarious years and is not exclusive to the current age. It was possible to manipulate through splices the negatives of the photographs, for example in Figure 1 the famous photo of Soviet dictator Iósif Stalin along with his commissioner for Internal Affairs, who disappears from the photo by order of Stalin after being executed in1940.

In earlier times, manipulation of images had a political, re- ligious, cultural motive but now this activity is mainly carried out for advertising or aesthetics. The ease of manipulating the images has become easy due to technological advances in mobile phones, computers, photo editing applications like Adobe Photoshop, Adobe Premiere, GIMP etc. Nowadays, image can also be manipulated on mobile phones using applications like Picsart , Snapseed ,etc. Due to the advent of Social Media, distribution of fake or manipulated images have become far more easier than ever.

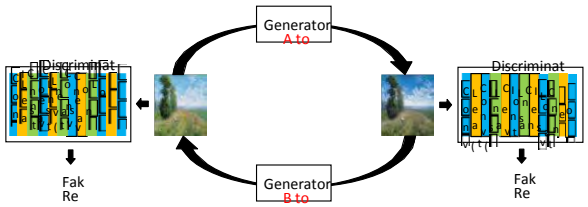

Figure 1: Cycle-GAN based image-to-image translation

InJuly2017,researchersfromthejournalCognitive Research
[2]usedadatasetof40scenes,30ofwhichweresubjectedto five different types of manipulation, including physi- callyplausible and implausible manipulations.707participants were showntoassesspeople'sabilitytodetectrealworldmanipulated scenes. The study found that only 60% of the people were able to detect the fake scenes and even then, only 45% of them were able to tell exactly where the altered content was. One of the main conclusions from their study was that if people cannot differentiate between real andfalsedetails in scenes, manipulations could often modify what we believe and remember.

Thereareanumberofimagetamperingtechniqueswhichare present which are used to manipulate or tamper the image. There are some valid reasons for tampering images such as marketing, promotional activities, etc. Unfortunately, the tools developed for these tasks are being used by some people to tamper the truth. In this paper, we take a look at some of the techniques which are used for detection of fakeimages.

This paper presents four algorithms; the first one is anError Level Analysis (ELA) algorithm, which can be used as an initial filter to detect the presence of splicing in an image. The second algorithm is a digital image authentication method based on the quadratic mean error of the Colour Filter Array (CFA)interpolationpatternestimatedfromtheanalyzedimage.
Thethirdalgorithmisaregionduplicationdetectionmethodfor images, which utilizes statistical image features in the frequency domain, viz., mean and variance. The primary motivation is to exploit the local

statistics of an image, using block-based mean and variance computations. The last algorithmusesanumberofdetectorstodetectfakeortampered images which are generated using Image to Image translation, based on generative adversarial networks (GANs). This manipulation technique is very dangerous as it allows one to modifycontextandsemanticsofimagesinaveryrealistic way. Therefore, we use methods based on CNN architecture, some based on ImageNet, etc. which we look further in thepaper.

*a) **1) GAN:-**:* As we know that image forgery and image manipulation is a big problem right now and due to advent of toolssuchasphotoshopeventhenon-expertuserscandoimage manipulation. There are many techniques for image manipulation but one of the most dangerous one is Image to imagetranslationusingGAN.Wewillreviewhowdetectors for imageforgerycanbeusedfordetectionoffakeimagesand how we can overcome this problem testing the cases in both ideal and compressedconditions.

Computer fares better when it comes to detect fake images which are not computer generated. Study shows that 62- 66% oftheimageswereclassifiedandtheusersfared worsethanthe computer. But when it comes to computer generated fake images, the trend is reversed. This may be attributed to the inability of current computer graphics tools to provide a good levelofphotorealism.Somepapersproposeto detectcomputergraphics images based on statistics extracted from their wavelet decomposition or from residual images while some papers rely on the different noise introduced by the recording device on traces of chromatic aberrations or traces of demosaicing filters. In face asymmetry is proposed as a discriminative feature to tell apart computer generated from natural faces. Only very recently, deep learning has been used for this task, and found to outperform preceding approaches. We analyze the performance of a number of learning- based methods in the detection of image-to-image translation. Our goal is to understand if, to which extent, and in which conditions, these attacks can be unveiled. Also to solve this problem, state-of-the-art methods taken form the image foren- sic literature, and on general purpose very deep convolution neural networks (CNN s) properly trained for this task are used.

In image to image translation, images from one domain are mapped to corresponding images in another domain. Using GAN based approach, results have been impressive. In most cases, the network is trained based on a large number of images but in some cases, the correspondences are not known a priori, and no images are available. So an alternate

training procedure is required.

Figure 2: Spot the fake.

Under the adversarial training paradigm, we have two actors: the image-to-image network (generator), and a support network (discriminator). The discriminator tries to tell apart real images from those created by the generator, while the Generator is trained to deceive the discriminator. Input image *A* is first transformed from its original domain*D A* to the output domain*DB* using generator A. Then, image is mapped back to the original domain *A* by generator B. In Fig.2 we show a sample result of this method

applied to satellite images. The image on the left is generated by the algorithm, while the other one is downloaded from Google Maps. At a first glance, no hints of a possible manipulation appear.

Figure 3: Examples of image-to-image translation; Left: Van Gogh or Monet? Right: summer or winter?

In this figure, original image is shown side by side with new versions obtained through a change of context: a different painting style (Van Gogh instead of Monet) or a different season (winter instead ofsummer).We compare a number of methods for the detection of image-to-image translation. Some are methods are:

- GANdiscriminator:
- Steganalysisfeatures:

1) Cozzolino2017:
2) Bayar2016
3) Rahmouni2017:

- DenseNet:

1) InceptionNetv3:
2) XceptionNet:

In order to train and validate the detectors, we need data sets of samples. For each category of detection methods, we use both the real and fake images. So, for example, the *apple2orange* subset includes all the original images of apples and oranges used to train the GAN, and the corresponding fakes (oranges and apples, respectively) generated by the GAN itself once trained.

Table I

SCENARIO 1: RESULTS ON THE ORIGINAL UNCOMPRESSED DATASET.

Accuracy	ap2or	ho2æb	win2sum	citysc.	facades	map2sat	Ukiyoe	Van Gogh	Cezanne	Monet	average
Steganalysis feat.	98.93	98.44	66.23	100.00	97.38	88.09	97.93	99.73	99.83	98.52	94.40
GAN discr.	69.84	90.77	52.31	99.87	98.38	90.44	66.19	96.01	98.97	84.16	83.58
Cozzolino2017	99.90	99.98	61.22	99.92	97.25	99.59	100.00	99.93	100.00	99.16	95.07
Bayar2016	99.26	99.77	50.36	76.02	89.75	79.70	77.23	99.00	98.70	88.89	84.86
Rahmouni2017	88.60	99.20	51.30	72.03	90.38	72.35	97.83	99.97	100.00	97.26	85.71
DenseNet	79.05	95.77	67.68	93.80	99.04	78.30	99.50	97.71	99.93	89.83	89.19
InceptionNet v3	84.95	94.78	58.76	99.41	93.99	70.54	99.80	98.77	99.87	89.89	89.09
XceptionNet	95.91	99.16	76.74	100.00	98.56	76.79	100.00	99.93	100.00	95.10	94.49
average	89.55	97.23	60.58	92.63	95.59	81.97	92.31	98.88	99.66	92.85	89.55

In Table I, for all considered techniques, we show the accuracy obtained for each type of manipulation, together with their average (last column) weighted by the number of sam- ples. Among the considered techniques, the highest average accuracy is obtained by Cozzolino2017. This shallow network provides near-perfect classification for all manipulations ex- cept winter2summer, for an average of 95.07%. However, the handcrafted features also provide very good results, as wellas XceptionNet, among the deep networks. In the last row of **Table I** we also report the average classification accuracy for each manipulation. This allows us to spot the mostchallenging cases, winter2summer and map2sat. On the opposite side, the manipulations most easily detected are horse2zebra, and some painting style transfer.

Table II

SCENARIO 2: RESULTS ON TWITTER-LIKE COMPRESSED IMAGES WITH TRAINING MISMATCH.

Accuracy	ap2or	ho2æb	win2sum	citysc.	facades	map2sat	Ukiyoe	Van Gogh	Cezanne	Monet	average
Steganalysis feat.	50.20	50.12	50.00	50.00	50.00	50.00	50.00	50.20	50.00	49.98	50.05
GAN discr.	50.15	55.24	49.91	50.50	50.38	50.27	48.24	48.90	49.04	47.88	50.19
Cozzolino2017	50.00	50.00	50.00	50.00	50.13	50.05	50.00	50.30	50.00	50.00	50.03
Bayar2016	64.55	81.40	50.05	50.62	84.50	54.15	54.93	89.90	97.37	70.57	67.42
Rahmouni2017	70.43	98.54	50.02	82.71	95.00	50.00	82.43	88.13	100.00	94.42	81.30
DenseNet	76.59	90.32	54.17	65.29	96.63	61.69	96.38	91.56	99.73	87.87	79.76
InceptionNet v3	83.85	86.92	52.67	98.66	93.99	60.00	95.81	93.52	99.57	88.45	85.44
XceptionNet	90.87	96.09	52.56	97.93	98.20	51.34	99.34	97.27	99.70	86.29	87.17
average	67.08	76.08	51.17	68.21	77.35	53.44	72.14	76.22	80.68	71.93	68.92

The good results of the former experiment should be taken with caution. In fact, it is very unlikely that the original fake image generated by a malevolent user is directly available. In **Table II** we show results in the presence of compression forthe very same detectors tested before, that is, the classifiers are still trained on original samples but tested on compressed ones. This simple routine operation impairs dramatically the performance of most detectors under comparison, especially techniques based on handcrafted features or shallow neural networks. Deep networks exhibit a higher robustness, espe- cially XceptionNet, with an accuracy of 87.17%, only 7% worse than the uncompressed case. This indicates that such networks do not rely only on textural micro patterns but also on other features, which survive compression.

Table III

SCENARIO 3: RESULTS ON TWITTER-LIKE COMPRESSED IMAGES.

Accuracy	ap2or	ho2æb	win2sum	citysc.	facades	map2sat	Ukiyoe	Van Gogh	Cezanne	Monet	average
Steganalysis feat.	79.39	90.02	56.66	92.17	73.62	69.39	65.83	95.30	94.73	80.89	81.09
GAN discr.	63.29	91.08	51.90	53.14	88.75	79.35	76.56	80.32	96.41	81.83	73.33
Cozzolino2017	79.57	89.82	53.74	86.81	62.88	89.64	67.67	98.80	99.93	87.33	82.62
Bayar2016	54.64	95.34	50.27	54.00	90.63	52.69	58.90	74.27	99.77	78.60	69.17
Rahmouni2017	84.96	98.35	54.30	57.60	91.88	54.93	96.83	99.63	99.77	89.72	80.97
DenseNet	78.27	93.44	66.94	97.83	98.19	80.45	97.54	98.53	99.57	83.95	88.51
InceptionNet v3	78.60	95.23	64.54	96.09	90.14	63.84	99.53	96.31	100.00	86.21	87.37
XceptionNet	93.52	93.77	67.07	95.11	99.22	67.97	99.66	95.18	99.97	84.02	89.03
average	76.53	93.38	58.18	79.09	86.91	69.78	82.81	92.29	98.77	84.07	81.51

In the last experiment we have considered a worst case, with mismatch between training and test set. When the goal is to detect fakes on social media, it is reasonable to train the classifiers directly on compressed images. The results obtained in this case are reported in **Table III**. The steganalytic features and Cozzolino2017 now perform reasonably well, but more than 10% points below the uncompressed case.

II. CONCLUSION OF GAN:-

From the following experiments, they say that the several detectors for image detection have performed very well on original images and some of them show impairments on compressed images. In the first table, they have shown that the experiments conducted in uncompressed original data have been very impressive. Cozzolino2017 provides near perfect classifications for all except win2sum. The next experiments performed by them is on compressed images. They have used Twitter like compressed images. In this, they performed 2 experiments. In the first experiment, they test the detectors on compressed images with training mismatch. It means that they have trained the detectors on original images but tested on the compressed ones. In this, deep networks have exhibited ahigher robustness, especially XceptionNet, with an accuracyof 87.17%.Inthelastexperiment,againXceptionNethassho wnthe best result. From the above three experiments, they say that test, durability is better preserved by deep networks, especially XceptionNet which keeps working reasonably well even in the presence of training-test mismatching.

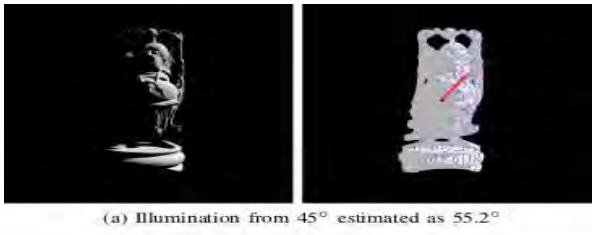
III. GRADIENT:-

Most of the methods for digital-image forensics are sta- tistical. For eg, the fixed pattern noise of a camera can be used to associate an image to a unique source device. Other methods analyze for example JPEG

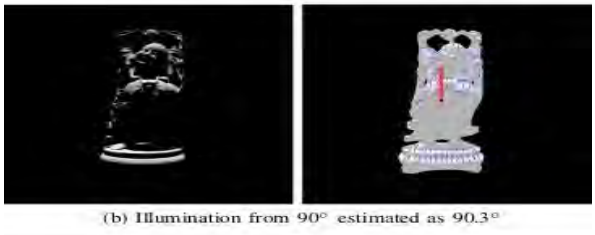
compression artifacts, traces of re sampling, or summarized noise statistics based on steganographic descriptors. Recent works perform similar tasks with

$$d\hat{I}(x,y) = \left(\frac{dI_x(x,y)}{\|dI(x,y)\|}, \frac{dI_y(x,y)}{\|dI(x,y)\|} \right)^{\mathrm{T}}$$

neural networks, e.g., to condition noise patterns on EXIF entries or to directly search for noise inconsistencies. However,it is still an open challenge to reliably apply statisti- cal methods to re compressed and down sampled data Physics- based methods are more resilient to re compression and down sampling. These methods search for physical inconsistencies in images to detect forgeries, like for example in the direction of incident light and the resulting shadows Estimation of the main illumination direction. Image intensity gradients for each masked person are computed and function as input for an estimation of the main light direction. The illumination information can be used as physics-based cue to expose spliced images. The two



(a) Illumination from 45° estimated as 55.2°



(b) Illumination from 90° estimated as 90.3°

(c) Illumination from 135° estimated as 128.6°

persons on the left origin from an image with different illumination as indicated by the estimated main light direction And object shading orthespectral distribution of light Natural objects are much less constrained, but Zheng and Chelappa pointed out that mean gradients still point towards the light source as long as the object is locally spherical.

Tofurthercharacterizethegradientvectorfield,ahistogra m of the gradient vectors is computed. The gradient directions are discretized into 72 bins, which corresponds to an angular resolution of 5 . The bins are collected in a histogram, and the sum of the histogram entries is normalized to 1 to accommodate for different object sizes of A and B. The mean of the normalized gradient vectors, i.e., the dominant lighting direction, is computedas

Where dI(x, y) denotes the magnitude-normalized gradient vectors, computed as

The normalization leads to the effect that only thedirection ofthevectoristakenintoaccount[31].Itcontributestoahi gh robustness to changes in albedo, and mitigates the need for intrinsic image decomposition for albedo neutralization. The mean in Eqn. 14 is used as the estimate for the dominant illuminant direction in the image plane they compute the dominant lighting directions a and b for two objects Aand

B. To quantify differences in illumination, they use the cosine dissimilarity LD,

$$L_D(\boldsymbol{a},\boldsymbol{b}) = 1 - \frac{(c(\boldsymbol{a},\boldsymbol{b}) + 1.0)}{2} \quad ,$$

where

$$c(\boldsymbol{a},\boldsymbol{b}) = \frac{\boldsymbol{a}^{\mathrm{T}} \cdot \boldsymbol{b}}{\|\boldsymbol{a}\| \cdot \|\boldsymbol{b}\|}$$

is the cosine of the angle between the two illuminant directions. This measure ranges from 0 to 1, with value 0for identical directions, and 1 for opposite directions. The proposed features, namely the differences in tilt LD, the divergenceoftiledestimatesDD,individualdifferences ofthe tiled estimates TD, and the correlation between the gradient histograms HD are used to quantify the dissimilarity of two lighting environment. This method being more robust than previous lighting based methods can be fully automated.They use the popular Mask R-CNN neural network to segment the image, which provides a coarse pixel-wise segmentation of object instances. Objects with an area below 1% of the image pixels are excluded from the analysis, since these consist of too fewpixels.

For splicing detection, they make the common assumptionthat objects from different images exhibit different lighting environments. Thus, the classification task is to determine whether two objects stem from the same image or from two different images.

Block size (pixels)	DA (%)	FPR_1 (%)	FPR_2 (%)
5 × 5	98.5186	6.2592	2.7709
10 × 10	98.4263	6.1293	2.3956
15 × 15	98.4092	6.1129	2.4251
20 × 20	98.4007	6.0382	2.8134
25 × 25	98.3770	6.0647	2.4074
30 × 30	98.3089	6.0184	2.4692
35 × 35	98.2972	5.9374	2.6008

Results of Gradient Based processing:

Dominant lighting conditions:
Themedianerrorforalllightdirectionsis20.Theothermethods performslightlyworsewithmedianerrorsforalllightdirections between 22 and 26 .

Fully automated splicing detection:

1) DSO-1 Dataset: Statistical methods perform betterthan the physics based methods because dataset contains images captured with frontal flash. However, after resizing and com- pressing the dataset, the performance of statistical methods drops significantly and their method performsbest.

2) OIS:The source images of thedataset

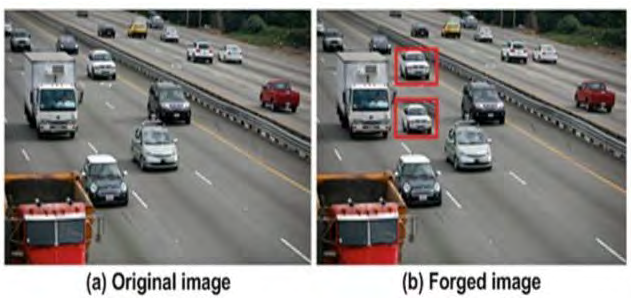
Stem from the publicly available OpenImages V4 dataset, which contains about nine million images annotated with image-level labels and bounding-boxes.only consider thesplic- ing of persons for manipulationdetection.

Inthiswork,theauthorsgaveahighlyresilientphysicsbased method that can be fully automated for comparing 2d lighting environments, which unlike previous lighting based methods can be applied to wider range of images. The method is based on four features computed on gradients of an object. The descriptor uses the whole object area instead of a single noisy area which contributes to its higher performance than previous methods.A simple logistic regression on the proposed features can be deployed to distinguish between objects from identical or different images. Fully automated segmentation and classification achieves an AUC of up to 0.774 onsplicedimages.

One of the most remarkable quality of this descriptor is that it remains unaffected by compression and resizing where statistics based methods fail and better than previous lighting based methods.

IV. COPY-MOVE FORGERY DETECTION EXPLOITING STATISTICAL IMAGEFEATURES:-

Many times attackers apply some post-processingoperations (such as blurring, edge smoothing, noise addition and filtering of the forged region, etc.) on the forged image, so that the manipulated regions seem natural.Here, we present a region duplication detection method for images, which utilizes statistical image features in thefrequency domain, viz., mean and variance [3]. The primary motivation is to exploit the local statistics of an image, using block-based mean and variance computations. The contribu- tion of each individual block with respect to the entire image, in terms of intensity, can be measured using the image mean, whereas the variation of individual pixel intensities within an image sub block, is indicated by the variance



V. CONCLUSION OF COPY-MOVE FORGERY DETECTION:-

Inthischapter,wepresentaregionduplicationforgerydetection methodutilizingmeanandvariancestatisticalfeatures.Thoseare simple yet powerful statistical image features and effective for forgery detection also. The presented

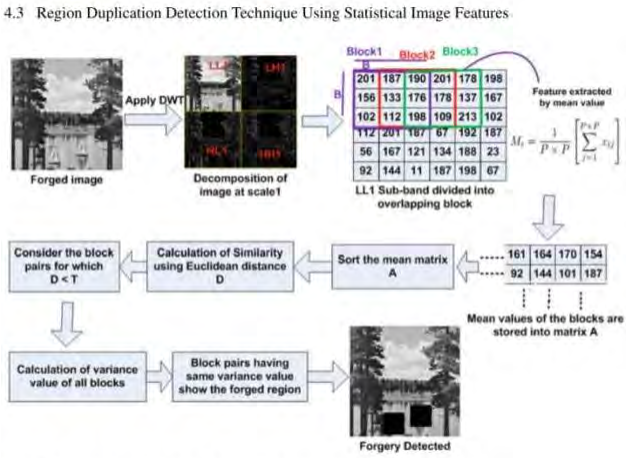


Fig. 4.2 Operational steps of the proposed algorithm

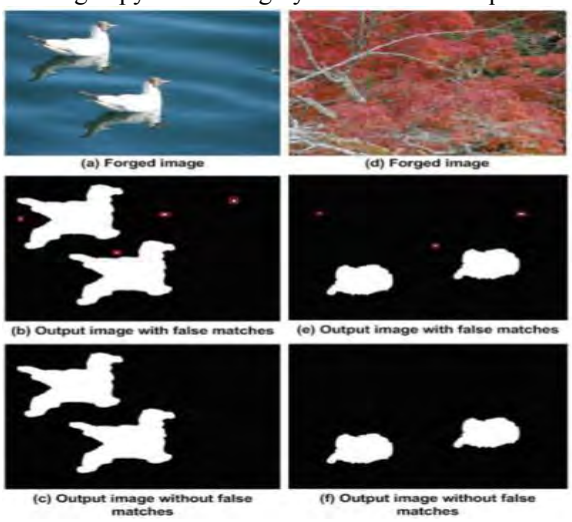
method operates by dividinganimageintopixelsub-blocksinthefrequencydomain, and also deals with the statistical features of all image blocks. The experimental results verify the efficacy of the method and show the supremacy of the technique over the existing copy- move forgery detection techniques.



VI. CONCLUSION:-

Wehavepresentedareviewoftheresearchcarriedoutinthearea of detection of fake or tampered images. Furthermore, a number of algorithms were discussed

which can be used to detect those images.Manipulatedimagesaremainlyfoundintwoforms: one intheiroriginalformandsecondintheircompressedformwh ich are shared on social media platforms like Twitter. We have seen three different algorithms used for detection. In this first one, deep network methods like XceptionNet has shown the best results throughout the three cases. Its performance is consistent across original manipulated image and on compressed manipulated image and also fares better when tested on compressed data but trained on original data. The gradient method uses a physics based approach. It can be fullyautomated for comparing 2D lighting environment which can be applied to a wide area unlike other lighting methods. Unlike detection methods for GAN which shows slightly different results for original and compressed images, gradient methods remain unaffected by compression and resizing. The last method is a statistical method which detects copy move forgery. The region duplication forgery detection algorithm using mathematical methodssuchasmeanandvariancewasused.Afteranalysis, the accuracyashighas98.51%wasrecorded.Theaccuracywas very high for the small blocks of pixels which went on to reduce marginallyasthesizeoftheblockincreased.Thesametrend was observed in the false positive rate which was recorded at 6.25% at the highest. Thus, it can be concluded that image forgery can be detected with high accuracy for small to medium block size image using the basics ofstatistics.

Predicting Customer Purchase Behavior on Black Friday

Devesh Varma , Angela Roy , Harsh Ramani , Abhishek Yadav
Third Year, Department of Computer Engineering
Thakur College of Engineering and Technology,
Mumbai, India

Abstract- **It is no surprise that businesses spend millions of dollars in carrying out market research before coming up with a new service or product. Despite that, it is important to recognize that the final product doesn't sell itself and actually requires the right marketing tools or personalized marketing to make itself visible to the potential consumers. With millions of buying options at our disposal, the behavior of this era's consumers keeps flickering, and it is important to advertise the right prod-uct to the right customer at the proper time.**

The project is built with to accurately predict how much will a user spend on a Black Friday sale given his de-tails. The data for our model is a sample of the transac-tions made in a retail store. We intend to know better the customer purchase behaviour against different products. Specifically, here the problem is a regression problem where we are trying to predict the dependent variable (the amount of purchase) with the help of the infor-mation contained in the other variables.

The features of customer like age, marital status, occu-pation, Current city, will help us accurately predict the amount he/she will spend on a Black Friday Sale. Root mean square Error (RMSE) is used for performance measure. RMSE is commonly used general purpose er-ror metric.

Key Terms- Black Friday, Shopping, Prediction, Multivariate Linear Regression

I. INTRODUCTION

A. Background

The term Black Friday is known to shoppers and retail-ers in the USA as both the day after the Thanksgiving holiday and one of the busiest shopping days of the year the day is characterized by high demand for retail goods. This makes stores to reduce the price on most of its products in order to attract customers due to increased competition. As a result, many stores offer highly pro-moted sales on Black Friday and open very early, such as at midnight, or may even start their sales at some time on Thanksgiving. Black Friday is not an official holiday, but some states observe "The Day after Thanksgiving" as a holiday for state government employees, some-times in lieu of another federal holiday, such as Colum-bus Day [1].

Black Friday has routinely been the busiest shopping day of the year in the United States since more than a decade [2].
With the use of recent development in Data Science and Machine Learning we can use the details of a person to find his purchase habits, predict his future purchases and use this to give personalized offers to them. This was not possible a few decades ago where the technology was not as advanced as it was today.

B. Problem Definition

Given a data of users such as Gender, Age, City loca-tion, Marital Status, Money spent and products bought, build a model to predict the amount of money he will be spending on a Black Friday sale. The main goal is to accurately predict the amount a person spends and the secondary goal is to predict the major factors influenc-ing his spending habits from the given data.

II. LITERATURE SURVEY

A. Machine Learning for Prediction

Machine learning is a subset of artificial intelligence (AI) which learns from experience with respect to some class of tasks, thereby improving its performace with experience. that provides system the ability to automat-ically learn and improve from experience without hav-ing someone programming it. The main goal of machine learning is to focus on the development of computer programs that can access data and use it learn for them-selves. The process of learning begins with observa-tions, facts, information or data, such as examples, di-rect experience, or instruction, in order to look for pat-terns in data and make better decisions in the future based on the examples that are given by the user.

The main goal is to allow the computers learn automati-cally without human intervention, help or assistance and adjust actions accordingly. Machine learning with the help of suitable algorithm enables analysis of large quantities of data. Although it generally gives faster and accurate results, it also requires addition resources such as CPU time and memory time to do the necessary pro-cessing and get accurate results [3].

Predictive analytics is a part of Machine Learning which is mainly driven by predictive modelling. It's more of an approach than a process. Predictive analytics and ma-chine learning go hand-in-hand; as predictive models typically include a machine learning algorithm. These models can be trained over time to respond to new data or values, delivering the results the business needs. Pre-dictive modelling largely overlaps with the field of ma-chine learning.

There are two types of predictive models. They are Classification models, that predict class membership, and Regression models that predict a number. These models are then made up of algorithms. The algorithms perform the statistical analysis, determining trends and patterns in data and predicting the values based upon them. Predictive analytics software solutions have built in algorithms that is used to make predictive models which help in predicting the most accurate value. The algorithms are defined as 'classifiers', identifying which set of categories data belongs to [4].

B. Multivariate Linear Regression Model

The goal of data analysis is to extract meaningful data or information from raw data with accurate estimation. One of the most important and common question con-cerning if there is statistical relationship between a re-sponse variable (Y) and explanatory variables (Xi). An option to answer this question is to employ regression analysis in order to *model* its relationship. Further it can be used to *predict* the response variable for any arbitrary set of explanatory variables.

Multivariate Regression is one of the simplest Machine Learning Algorithm. It comes under the class of Super-vised Learning Algorithms i.e, when we are provided with training dataset [5].

Multiple/Multivariate linear regression models the rela-tionship between two or more known variables and a re-sponse variable by fitting a linear equation to observed data. Every value of the independent variable/varia-bles x is associated with a value of the dependent varia-ble y.

Fig. 1 Structure of Input Dataset

The analysis of the Black Friday data set used in this paper includes 12 variables: Product_ID, Gen-der, Age, City_Category, Stay_In_Cur-rent_City_Years, Marital_Status, Product_Cate-gory_1 and Purchase.

This data set is cleaned from the original data set which contained 3 additional variables - Product_Cate-gory_2 and Product_Category_3. Product_Cate-gory_2 and Product_Category_3 contain missing obser-vations which are imputed as zero.

The Black Friday data set is further cleaned by stating the format of each variable. This included chang-ing Product_ID, Gender, Age, City_Category, Mari-tal_Status and Product_Category from character varia-bles to integers. These variables are nominal since they do not have order or a distance metric. 'Age' is ordinal because the age groups are increasing with actual age, but are not equally spaced.

Abstract**: Artificial Intelligence (A.I.) may be a multidisciplinary field whose goal is to automate activities that presently require human intelligence. Recent successes during AI. It includes computerized medical diagnosticians and systems that automatically customize hardware to particular user requirements. the main problem areas addressed during AI. It is often summarized as Perception, Manipulation, Reasoning, Communication, and Learning. Perception cares with building models of the physical world from sensory input (visual, audio, etc.). Manipulation cares with articulating appendages (e.g., mechanical arms, locomotion devices) so as to affect a desired state within the physical world. Reasoning cares with higher level cognitive functions like planning, drawing inferential conclusions from a world model, diagnosing, designing, etc. Communication treats the matter understanding and conveying information through the utilization of language. Finally, Learning treats the matter of automatically improving system performance over time supported the system's experience. Many important technical concepts have arisen from A.I. that unify these diverse problem areas which form the inspiration of the science. The system must automatically organize and utilize this information to unravel the precise problems that it encounters. This organization process is often generally characterized as an enquiry directed toward specific goals. The search is formed complex due to the necessity to work out the relevance of data and since of the frequent occurrence of uncertain and ambiguous data. Heuristics provide the A.I. system with a mechanism for focusing its attention and controlling its searching processes.**

Keywords: human intelligence, sensory input, arisen, articulating appendages.

I. INTRODUCTION

Artificial Intelligence is an approach to form a computer, a robot, or a product to think how smart human think. AI may be a study of how human brain think, learn, decide and work, when it tries to unravel problems. and eventually this study outputs intelligent software systems. The aim of AI is to enhance computer functions which are associated with human knowledge, for instance , reasoning, learning, and problem-solving.

The objectives of AI research are reasoning, knowledge representation, planning, learning, tongue processing, realization, and skill to maneuver and manipulate objects. There are long-term goals within the general intelligence sector. the normal problems (or goals) of AI research include reasoning, knowledge, planning, learning, tongue processing, perception, explain ability and therefore the ability to maneuver and manipulate objects. General intelligence is among the field's long-term goals.

Approaches include statistical methods, computational intelligence, and traditional symbolic AI. Many tools are utilized in AI, including versions of search and mathematical optimization, neural network sand methods supported statistics, probability and economics. The AI field draws upon computing , mathematics, psychology, linguistics, philosophy, neuroscience, artificial psychology and lots of others.

Approaches include statistical methods, computational intelligence, and traditional coding AI. During the AI research associated with search and mathematical optimization, artificial neural networks and methods supported statistics, probability, and economics, we use many tools. computing attracts AI within the field of science, mathematics, psychology, linguistics, philosophy then on.

Generally, A.I. systems function supported a knowledge domain of facts and rules that characterize the system's domain of proficiency. the weather of a knowledge domain contains independently valid (or a minimum of plausible) chunks of data . The necessarily adaptive organization of A.I. systems yields the need for A.I. computational Architectures. All knowledge utilized by the system must be represented within such an architecture. The acquisition and encoding of real-world knowledge into A.I. architecture comprises the subfield of data Engineering.

Use of machine intelligence to capture user interests and online behavior is very common now on the web. Whenever user visits a web site, in the background some intelligent algorithms execute to capture data about user’s interests and online behavior. The browsing history is analyzed by those systems and information is extracted from the data to make an intelligent guess to display advertisements of products that are of interest to the user.

II. ARTIFICIAL INTELLIGENCE RESEARCH AREAS

The working domain of AI is large in breadth and breadth. Therefore before proceeding further considers the prospering and customary research areas within the domain of AI are:-

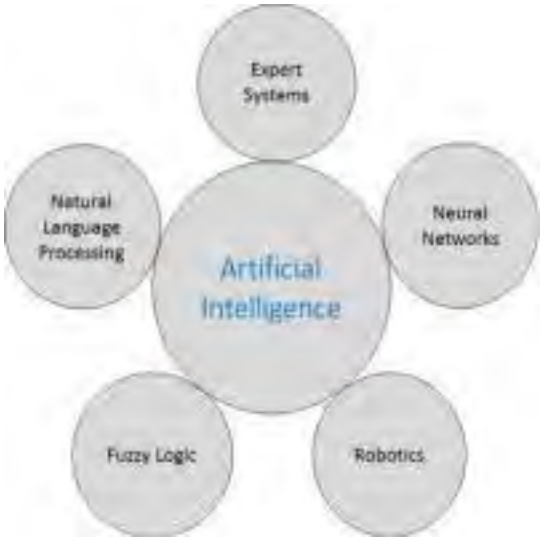

Figure 1: AI Research area

Expert System - In AI , an expert system are used for solving complex problems by reasoning about knowledge, represented primarily by if-then rules instead of by conventional procedural code. In general, an expert system may be a computing system that uses the decision-making capability of a person's expert.

Neural Networks - Neural networks are system of interconnected ? neurons? which exchange messages between each other. In machine learning artificial neural networks (ANNs) belongs to a family of model inspired by biological neural networks (the systema nervous of animals, present inside a brain) and are used for approximate functions or estimate a large number of inputs which are generally unknown.

Robotics - Robotics is a branch of Artificial Intelligence (AI), it is mainly composed of electrical engineering, mechanical engineering and computer science engineering for construction, designing and application of robots. Robotics is science of building or designing an application of robots. The aim of robotics is to style an efficient robot.

Fuzzy logic - symbolic logic was introduced in 1965 as a proposal of fuzzy pure mathematics . It is applied to varied fields, from AI to regulate theory. Fuzzy logic could also be a sort of many-valued logic during which truth table values of variable may be real between 0 and 1.

Natural Language Processing - Natural language processing (NLP) is a method of communicating with an intelligent system by using a natural language such as English. The input and output of NLP system is speech and transcription .

III. TYPES OF ARTIFICIAL INTELLIGENCE

A. Purely Reactive:

The most basic sorts of AI systems are purely reactive, and have the power neither to make memories nor to use past experiences to tell current decisions. Deep Blue, IBM's chess-playing supercomputer, which beat International Grandmaster Garry Kasparov within the late 1990s, is that the perfect example of this sort of machine.

Deep Blue can identify the pieces on a chess board and skills each moves. It can make predictions about what moves could be next for it and its opponent. And it can choose the foremost optimal moves from among the chances .

B. Limited memory:

machines can look into the past. Self-driving cars do some of this already. For example, they observe other cars' speed and direction. That cannot be wiped out a only one moment, but rather requires identifying specific objects and monitoring them over time. These observations are added to the self-driving cars' preprogrammed representations of the planet , which also include lane markings, traffic lights and other important elements, like curves within the road. They're included when the car decides when to vary lanes, to avoid isolating another driver or being hit by a close-by car.

C. Theory of mind:

We might stop here, and call now the important divide between the machines we've and therefore the machines we'll integrate the longer term . However, it's better to be more specific to debate the kinds of representations machines got to form, and what they have to be about.

Machines within the next, more advanced, class not only form representations about the planet , but also about other agents or entities within the world. In psychology, this is often called "theory of mind" – the understanding that folks , creatures and objects within the world can have thoughts and emotions that affect their own behavior.

IV. FEATURES OF AI

Artificial intelligence is so revolutionary, that some people consider it because the new age electricity. When Franklin first discovered electricity, it had been thought of as extremely profound- something that changed our lives forever. Scientists and researchers are regarding AI to be equally revolutionary-something which will transform the way most industries work.

- Eliminate dull and boring tasks
- Data ingestion
- Imitates human cognition
- Futuristic
- Prevent natural disasters
- Facial Recognition and Chatbots

V. PROS OF ARTIFICIAL INTELLIGENCE

- Minimal Human Intervention
- Faster and Accurate

VI. CONS OF ARTIFICIAL INTELLIGENCE

- This can prevent sympathizing with emotions for human contact, such as in being nurses. This can also reduce wisdom can understanding.
- This can prevent common sense occuring. Even if system is coded with common sense,it will be difficult for the sytem to get the common sense as that human can.
- Robots, with them replacing jobs, unemployment will increase.
- As seen partially with smartphones and other technology already, humans can become too dependent on AI and lose their mental capacities.
- If someone try to harm anyone using system that will lead to the destruction.
- AI as robots can take place of humans and enslaving us.

VII. FUTURE SCOPE

Artificial intelligent is a system which act like human. Basically it is not human but it will work like us..think like us react like us…

In future there will be time come when human don't need to work. System will teach the student with experimental things and in intelligent way so that student can understand the things properly.

Artificial Intelligence is to make replicate of human brain's capabilities so that the system start doing all those activities that the human is doing and in much less time. Trends of AI usage are changing day by day. Across the world, many companies are investing their energy, money and time in developing AI systems. However, it must be noted that business persons are not the only investors in AI technology. According to a report by The New Yorker, the government of China has been quite aggressive in using AI technology to control innovation in the near future.

VIII. CONCLUSION

Artificial Intelligence and therefore the technology are one side of the life that always interest and surprise us with the new ideas, topics, innovations, products etc. AI remains not implemented because the films representing it(i.e. intelligent robots), however there are many important tries to succeed in the extent and to compete in market, like sometimes the robots that they show in TV. Nevertheless, the hidden projects and therefore the development in industrial companies. At the end, we've been during this research through the AI definitions, brief history, applications of AI publicly , applications of AI in military, ethics of AI, and therefore the three rules of robotics. This is not the top of AI, there's more to return from it, who knows what the AI can do for us within the future, maybe it'll be a whole society of robots.

Interpretation of Models on the Onset of Diabetes using Machine Learning

Anshika Pandey , Sakshi Singh , Anand Khandare

Thakur College of Engineering & Technology, Mumbai.

anshikapandey603@gmail.com,sakshisaku3000@gmail.com , anandkhandare@thakureducation.org

Abstract-- **Diabetes mellitus is one of the most serioushealthchallengesfaced bytheworldtoday. Theobjectiveistodiagnosticallypredictwhetheror not a patient has diabetes, based on certain diagnostic parameters included in the dataset. Under the supervised learning, we have used Logistic Regression and Decision Tree. Using Decision Tree, the accuracy came out to be approximately 69%. In order to further test the accuracy, Logistic Regression predicted the accuracy to be 78%. The prediction is furtherdone and graphically represented through K-Meansand R-SquaredMethod.Thetesterrorandaccuracyfor logistic regression are then calculated using ConfusionMatrix.Theperformanceofclassifieris evaluated based on precision, recall, accuracy and is estimated over correct and incorrectinstances.**

Keywords-- Diabetes Mellitus, Machine Learning, Logistic Regression, Decision Tree, K-Means.

I. INTRODUCTION

Diabetes mellitus is a kind of metabolic diseases in which a person has high blood sugar. There are two general reasons for diabetes: 1- the body does not produce enough insulin. Only 5-10% of people with diabetes have this form of the disease (type1). With the help of insulin therapy and other treatments, even young children with type1 diabetescanlearntomanagetheirconditionandlive healthy. 2- Cells do not respond to the insulin that is produced (type2). Insulin is the most essential hormone that regulates uptake of glucose from the blood into most cells (not central nervous system cells).Thus,deficiencyofinsulinplaysacentralrole in all forms of diabetes mellitus. Type 2 diabetes mellitus is a complex disease of majorhealthImportance. This incidence is rapidly increasing in the developed countries. It is estimated by the year 2030, there will be 366 million people affected by Type 2 diabetes worldwide. Medical diagnostics is quite difficult task which is mostly done by expert doctors.Anexpertdoctorcommonlytakesdecisions by evaluating the current test results of a patient or compares the patient's results with other patients with the same condition by referring to the previous decisions.Thus, itisverydifficultforaphysicianto diagnose hepatitis. For this reason, in recent times, many machine learning and data mining techniques have been considered to design automatic diagnosis system fordiabetes.

Machine learning is an upcoming new technology with a wide range of applications. It has the potential to become one of the key components of intelligent information systems, inferred from large databases of recorded information that is to be applied as knowledge in various practical ways—such as being embedded in automatic processes, or useddirectlyforcommunicatingwithhumanexperts and for educational purposes. Most of the research work is directed towards the invention of new algorithms for learning, rather than towards gaining experience in applying existing techniques to real problems.

II. RELATEDWORK

Design of the prediction models for diabetes diagnosis has been an area of active research for the past decade. Most of the models found are based on clustering algorithms. In the proposed project the employed three techniques namely are: Regression algorithm, K-means clustering and Classification algorithm, for the classification of the patients suffering from diabetes mellitus. The performance

ForK-meansprovedtobebetterthanotherswhenall the similar symptoms were grouped into clusters using these algorithms. In recent times, a study conducted is intended to discover the hidden knowledge from a particular dataset to improve the quality of healthcare for the diabetic patients. This paper approaches to aim the diagnoses of diabetes by using Machine Learning and demonstrated the need for pre-processing and replacing missing values in the dataset. Through the learned training set, a better accuracy was achieved with lessertime. Hence, there is a requirement of a model that canbe developed that provides reliable, faster and cost effective methods to provide information related to the probability of patients suffering from diabetes. In the present work, an attempt is made to analyses the

diabetes parameters and to establish a probabilistic relation between them using Machine LearningModels.

III. PROPOSEDMETHODOLOGY

A. LogisticRegression

Logistic regression is an applied mathematics model that in its basic type uses a logistical operate to model a binary variable. In multivariate analysis, logistical regression (or logit regression) is estimating the parameters of a logistical model (a type of binary regression). Mathematically, abinary logisticalmodelincludesavariablewith2attainable values, like pass/fail that is portrayed by associate indicator variable, wherever the 2 values area unit labelled"0"and"1".Withinthelogisticalmodel,the log-odds (the exponent of the odds) for the worth labelled "1" may be a linear combination of 1 or a lot of freelance variables ("predictors"); the freelance variables will everbe a binary variable (two categories, coded by associate indicator variable) or a nonstop variable (any real value). The corresponding likelihood of the worth labelled "1" will vary between zero (certainly the worth "0")and one(certainlytheworth"1"),hencethelabelling;the operate that converts log-odds to likelihood is that the logistical operate, thence thename.

The equation utilized in logistical Regression is: p/1-

p = exp (b0 + b1x)

A. DecisionTrees

Decision tree is a tree structure that is within the type of a flow chart. It's used as a technique for classification and prediction with illustration exploitation nodes and internodes. The foundation and internal nodes area unit the take a look at casesThat area unit won't to separate the instances with totally different options. Internal nodes themselves area unit the results of attribute take a look at cases. Leaf nodes denote the category variable. Figure 1. Shows a sample call tree structure.

International Journal of information Mining & information Management method (IJDKP) Vol.5, No.1, Gregorian calendar month 2015 five Figure one. Sample call Tree Structure call tree provides a robust technique for classification and prediction in polygenic disorder designation drawback. Varied callalgorithmsareaunitonthemarkettoclassifythe information, together with ID3, C4.5, C5, J48, CART and CHAID. During this paper, J48 call tree algorithmic rule [10] has been chosen to determine themodel.Everynodeforthechoicetreeisfoundby scheming the very best info gain for all attributes associated if a particular attribute provides an unambiguous end result (explicit classification of sophistication attribute), the branch of this attribute is terminated and target worth is allottedthereto.

IV. FLOWCHART

The following fig. 1 depicts a general methodology or the flow of diabetes prediction system. We propose to predict whether a patient will suffer from diabetes or not in the future. In this process we will first collect a database of diabetes from hospitals or laboratories. Then we will be categorizing the collected data into diabetic patient and non-diabetic patient. We then extract the features from the dataset. From these features we select the attributes which are more responsible for diabetes in a patient. This stage is Feature selection. Later, we pre-process these features, to make it easier to process them and also to increase the accuracy. This dataset is then splatted into training dataset and testing dataset. The train-test split is of the ratio 70:30 which means that 70% of the data willbeourtrainingdataandtherest30%willbeour testing data. With the help of feature selection, we are able to get precise accuracy. This output is then evaluated using performance metrics. Machine learning models are used and the one with thebetter accuracy will be chosen to further train themodel.

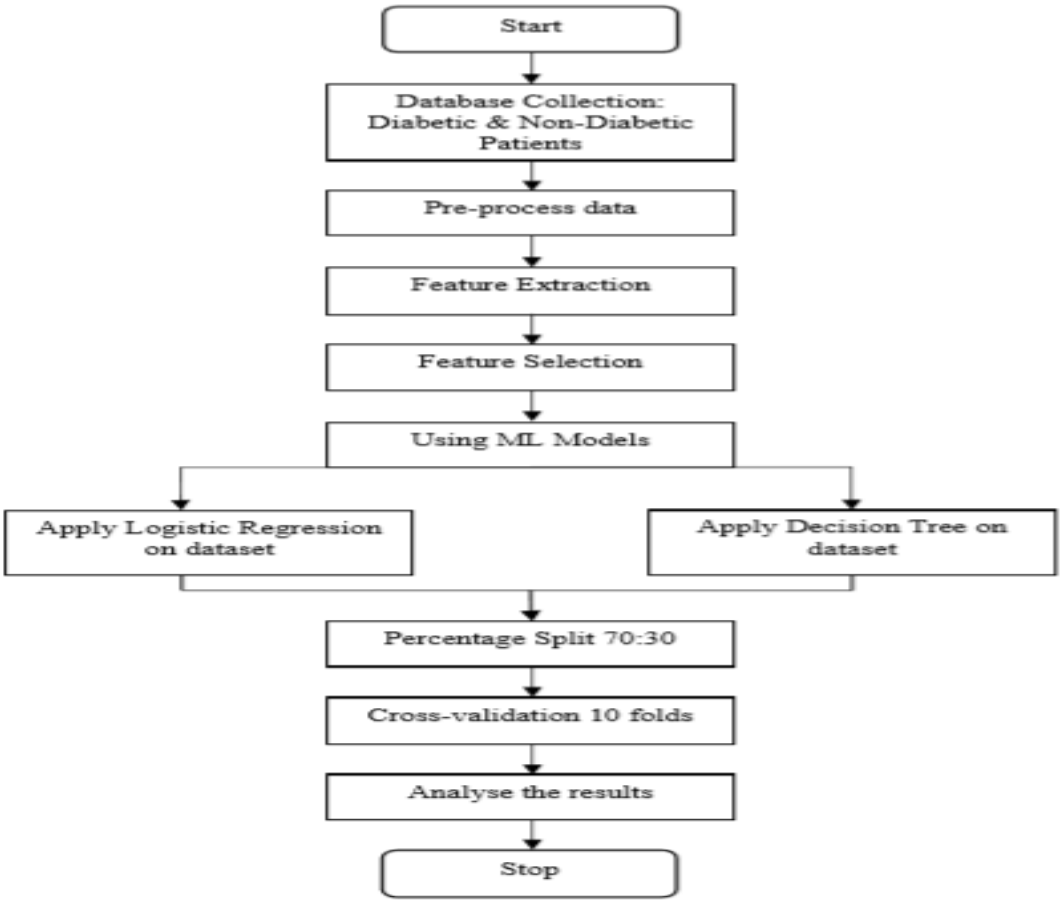

Fig 1. Flowchart of Diabetes Prediction System

IV. DATASET DESCRIPTION AND PRE- PROCESSING

The paper explores the aspect of DecisionTree and Logistic Regression as Data Mining techniques in determining diabetes in women. The classificationtypeofdataminingtechniquehasbeen applied to the Pima Indians Diabetes Dataset of National Institute of Diabetes and Digestive and KidneyDiseases.

TABLE 1

Dataset Description

Dataset	No. of Attributes	No. of Instances
Pima Indians Diabetes Database of National Institute of Diabetes and Digestive and Kidney Diseases	8	768

TABLE 2

Attribute Description

Attribute	Re-labeled values
1.Number of times Pregnant	Preg
2.Plasma Glucose concentration	Plas
3.Diastolic blood Pressure (mmHg)	Pres
4.Triceps skin fold thickness(mm)	Skin

8. Age (Years)	Age
9. Class Variable (0 or 1)	Class

4) Age(years)

5) Class Variable (nominal)-determines whether the person is suffering from diabetes or not.

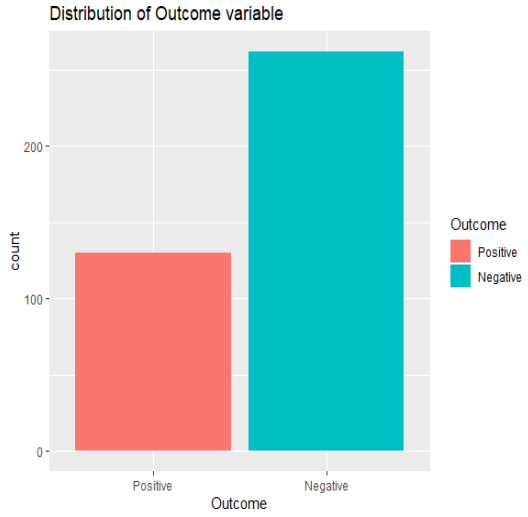

Fig. 2 distribution of the Outcome

VI. IMPLEMENTATION

In this paper two algorithms namely, J48 (decision tree algorithm) and Logistic Regression, have been used to create the model for diagnosis. The dataset was divided into training dataset and testing dataset by the cross-validation techniqueand percentage splittechnique.

10-fold cross validation is used to prepare training and testing dataset. After data pre-processing (CSV format), the Logistic algorithm is employedonthedatasetafterwhichdataaredivided into "tested-positive" or "tested-negative" dependingonthefinalresultofthedecisiontreethat is constructed. The algorithm is asfollows:

A. Algorithm

Input:

- Pima Indians Diabetes Dataset of National Institute of Diabetes and Digestive and Kidney Diseases dataset pre-processed in CSV format.Transformation steps include:
- Replacing missing values,and
- Normalization ofvalues.

The latter makes it easy to use the dataset, as the range of the variables are 0 and 1. The significant attributes obtained after execution are as follows:

1) Plasma glucoseconcentration
2) Body mass index (kg/m2)
3) Diabetes pedigreefunction

Output:

- J48 Decision Tree Predictive Model with leaf node either tested-positive or tested negative and Logistic Regression PredictionResults.

(1) The dataset is pre-processed. The further operations are performed on the datasetare:

(i) Replace Missing Valuesand

(ii) Normalization ofvalues.

(2) Processed dataset is passed through feature selection wherein certain attributes are deleted from thedataset.

(3) The final processed dataset is uploaded in csv file.

(4) The J48 Decision Tree and Logistic Regression algorithm areemployed.

(5) For purposes of the algorithms, Cross-Validation and Percentage Split techniques are applied for modelvalidation.

B. Software ApplicationApproach

With the advent of smartphones, patients are increasingly using mobile technology through automated text messages and various applications, or"apps,"tomonitortheirdiseasestates.In2010,an estimated 10.9 million people > 65 years of age and 215,000people<20yearsofageintheUnitedStates haddiabetes.

In the fast-paced and evolving world of technology, youngerpopulationsareoftenhighlyproficientwith and adaptable to smartphones. As a result, mobile apps for Apple iOS and Android operating systems have overwhelming popularity. More than 500 million Apple iOS and Android devices have been activated since2007.

In fig.3 the system architecture of diabetes prediction system is shown. We have trained diabetes dataset using Machine learning models. This software application is beneficial for both non- diabetic and diabetic patients. While training the model, age is one of the important factors for predicting diabetes. Hence this application can be used by any age group. For the people not suffering from diabetes (based on age, weight and height) can also use this application in order to predict if they will be prone to diabetes in the near future. The people suffering from diabetes can keep track of the factors such as blood pressure, insulin levels, glucose etc. on a daily basis. The application aims to prevent the onset of diabetes by forecasting the disease earlier and the precautions could be taken at an early stage.

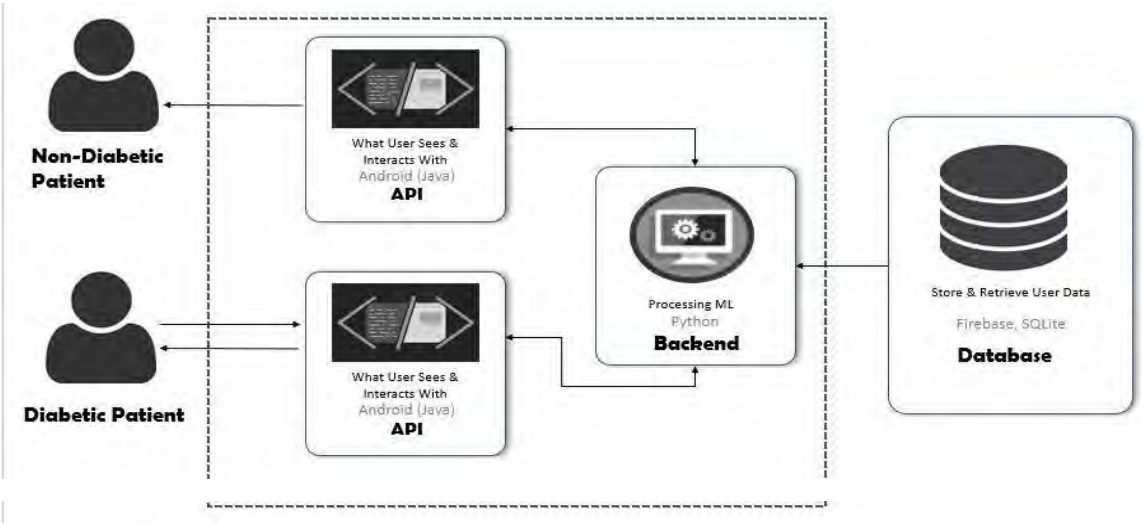

Figure. 3 System Architecture of Diabetes PredictionSystem

VII. RESULT ANDANALYSIS

A. LogisticRegression

1) Based on Percentage Split (70:30)Technique: Since a 70:30 percentage split was applied on the dataset 119 of the instances were used as the test dataset while the rest of were using for training the model. The logistic algorithm gives the following correctness results for the givendataset.

TABLE 3

Confusion Matrix and Statistics

	Prediction	
Actual	0	1
0	71	17
1	8	22

TABLE 4

Performance Measures from Logistic Regression

Accuracy	0.7881
95% CI	(0.7033,0.858)
No Information Rate	0.6695
P-Value[Acc>NIR]	0.003185
Kappa	0.4916
Mcnemar's Test P-Value	0.109599
Sensitivity	0.8987
Specificity	0.5641
Positive Pred Value	0.8068
Negative Pred Value	0.7333
Prevalence	0.6695
Detection Rate	0.6017
Detection Prevalence	0.7458
Balanced Accuracy	0.7314
'Positive' Class	0

4) Specificity (also called the true negative rate) measures the proportion of actual negatives that are correctlyidentified.

5) Mean Absolute Error: average of the absolute error between observed and predictedvalue.

6) Root Mean Squared Error: It measure of the differences between value (Sample and population values)predictedbyamodelor anestimatorandthe values actuallyobserved

7) Relative Absolute Error: It is the ratio of the absolute error of the measurement to the accepted measurement.

2. Terminologies of TestStatistics

1) Kappa Statistic: It is a metric that compares the Observed Accuracy with ExpectedAccuracy.

2) Mcnemar's Test P-Value: McNemar's Test [13] (sometimes also called "within-subjects chi-squared test") is a statistical test for paired nominal data. In context of machine learning models, we can use McNemar's Test to compare the predictiveaccuracy of the twomodels.

3) Sensitivity (also called the true positive rate, the recall, or probability of detection in some fields) measures the proportion of actual positives that are correctlyidentified.

TABLE 5

	Prediction	
Actual	0	1
0	233	5
1	29	74

Confusion Matrix of Logistic Regression

In the table, the values represent following:

a. Numberofcorrectoutcomethattheinstancetested

positive
2. Number of incorrect outcome that the instance testednegative
3. Number of incorrect outcome that the instance testedpositive
4. Number of correct outcome that the instance testednegative

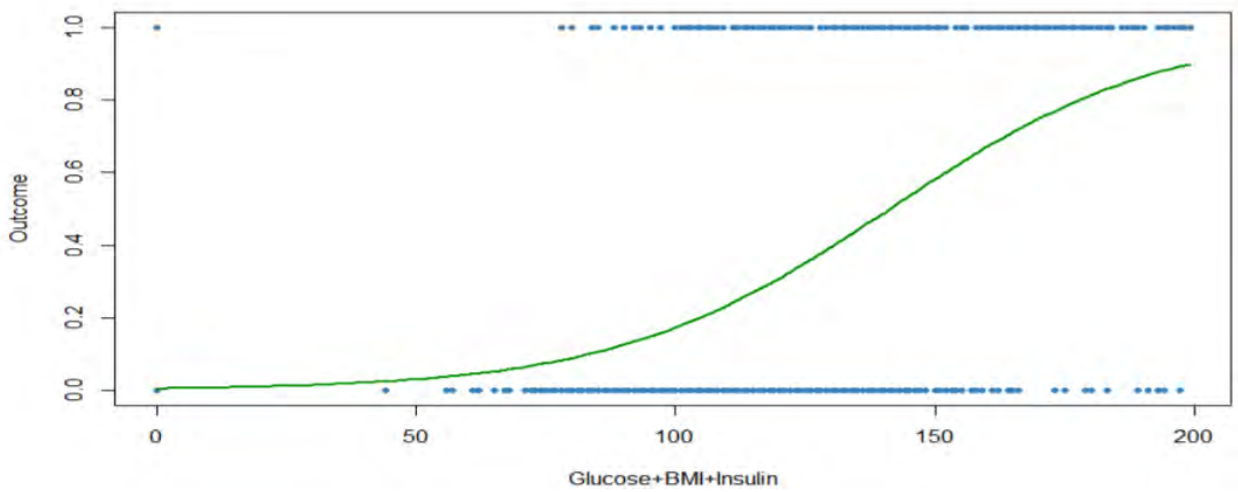

Figure. 4 Logistic Regression Curve

B. DecisionTree

Decision tree J48 implements Quinlan's C4.5 algorithm [5] for generating pruned tree. The tree generated can be used for classification of a patient that has being tested positive or negative for diabetes.Thedataminingtechniqueusesthethought ofinformationgain.Eachattributeofthedataisused to make a decision by splitting the data into smaller orsub-modules.

It examines normalized information gain (difference in entropy) that results from choosingan attribute as a split point. The highest normalized IG is used at the root of the decision tree. This procedure is repeated until the leaf node is created for the tree specifying the class attribute that is chosen. From the results obtained, both themethods have a

comparatively small difference in error rate, though the percentage split of 70:30 for Logistic Regression technique gives the least error rate compared to other two decision tree implementations. The machine learning models are efficient in the diagnosis of diabetes using the percentagesplitof70:30ofthedataset.Adeveloped model for diagnosis of diabetes will require more trainingdataforcreationandtestingwhichwouldbe more beneficial for our softwareapplication.

C. PerformanceAnalysis

Performanceofthemodelisbeingevaluatedon the basis of ROC curve. ROC Curve stands for Receiver Operating Characteristics Curve which is represented below in the fig, 7. The threshold value we took for analyzing the performance is0.5.

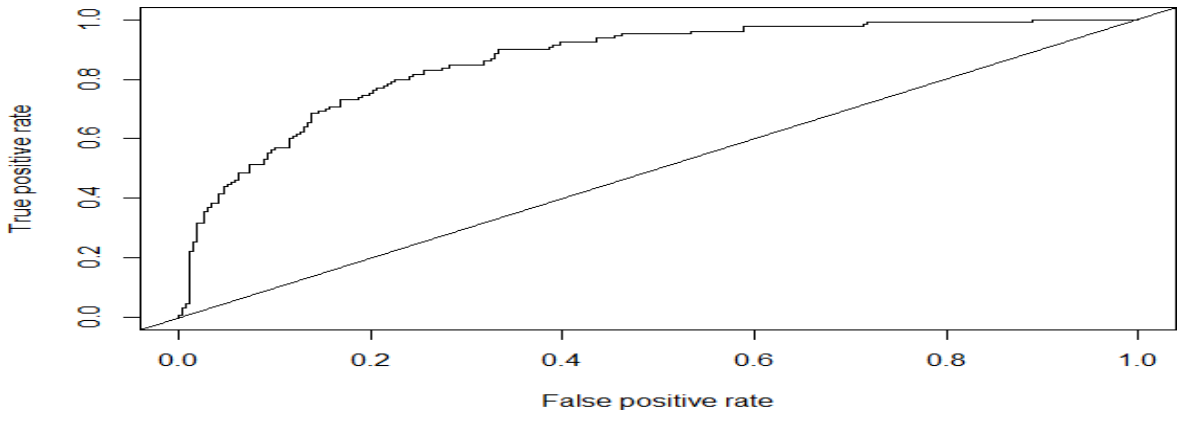

Fig.7 ROC Curve

By using both the supervised learning models, it is known that the Logistic regression model works better on classified or labelled data. The accuracy of the Logistic Regression came out to be 0.7884 whereas that of Decision Tree came out to be 0.6933. In fig. 6 we can easily predict that the Logistic Regression Model gives better performance and less error rate than Decision Tree. This result will be helpful in order to achieve good results for real time datasets.

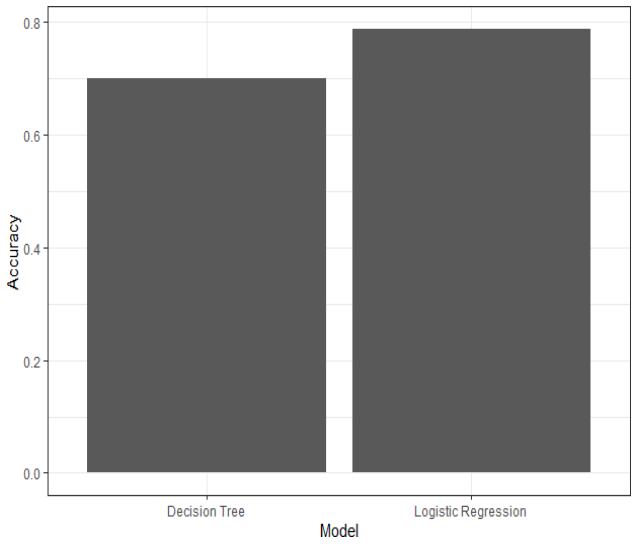

Fig. 6 Comparison of Model Accuracy

VIII. CONCLUSION

The automatic prediction of diabetes is an important real world medical problem. Detection of diabetes in its early stages is the successful key for treatment. This paper shows how the Data Mining techniques are used to model actual diagnosis of diabetes for local and systematic treatment, along with presenting related work in the field. Experimental results show the effectiveness of the projected model. The performance of thetechniques was investigated for the diabetes designation downside. Experimental results demonstrate the acceptableness of the projected model. In future,it's plannedtoassembleadditionaldatafromcompletely different locales everywhere the globe and build a additional precise and general discerning model for diabetes conclusion. Future study can likewise specialize in gathering data from a later period and see new potential prognostic parts to be incorporated. The work may be extended and improved for the automation of diabetesanalysis.

IX. FUTURESCOPE

There is so much to learn in this vast field of datascience.Inourproject,wehaveonlyfocusedon one set of population living in a particular region. Our aim is to expand our work on a city, where we would add more attributes responsible for diabetes. This would be a good estimation for the onset of diabetes. This would alert people and could take precautions beforehand. We aim to prepare a website where people would enter their details and would predict whether they would be prone to such disease called diabetes in the nearfuture.

palakfuria18@gmail.com , guptavaishnavi250@gmail.com , anand.khandare@thakureducation.org

ABSTRACT

Sentiment analysis is the interpretation and classification which categorize the feeling in diverse manner like positive, negative etc. allowing businesses to identify customer sentiment toward products, brands or services in online conversations and feedback. It is one of the most popular research field in natural language processing as it is widely studied in data mining, Web mining, and text mining. In fact, this research has spread beyond computer science to the management sciences and social sciences due to its importance to business world and society as a whole. Consider a sentence, *you're sosmart!* It sounds like a compliment However,consider the same sentence in the following context. *Wow, did you think you're so smart?* Now we are dealing with the same words but different emotions. Here sentiment analysis using NLP becomes complex to achieve accuracy .in this paper we discuss all the different method used for sentiment analysis and its use in real world.

KEYWORDS: -sentiment analysis, machine learning, NLP, social media, lexicon based approach, hybrid approach.

I. INTRODUCTION

Sentiment is an attitude, thought, or judgment which is prompted by feeling. Sentiment analysis [1-8], which is also known as opinion mining, is used to study people's sentiments towards certain entities. Web is a resourceful place in order to find sentiment information. From a user's perspective, people post their own content through various forums such as social media, micro-blogs, or social snetworking sites. From a researcher's perspective, many social media sites release their application programming interfaces (APIs) for data collection which is used by researchers, developers and analyst. For instance, Twitter uses three different versions of APIs available [9], which namely are the REST API, the Search API, and the Streaming API. With the REST API, this helps developers to find statistical data and user data; the Search API helps developers to query specific Twitter content, whereas the Streaming API is used to collect real time twitter content. Moreover, developers mix different APIs to create their own applications. Hence, sentiment analysis have a strong fundament with the support of massive data available online.

However, data online have several flaws that potentially disturb the process of sentiment analysis. The first flaw is that since people are able to freely post content online, the opinion quality cannot be guaranteed [10-12]. The second flaw is that the data online is not always true. The Stanford Sentiment 140 Tweet Corpus [13] is a dataset that has ground truth and is also available publicly. The corpus contains 1.6 million machine-tagged Twitter messages. Each message is tagged based on the emoticons (☺as positive, ☹as negative) discovered inside the message. Data is collected from Amazon [14], between February and April, 2014. The flaws faced have been overcome in the following two ways: First, each product review is inspected before it is be posted a. Second, each review has a rating on it that can be used as the ground truth. The rating is based on a star-scaled system, where 5 stars is the best rating and the worst rating has only 1 star.Social media has become one of the major root of information wrapping a wide scope of topics. It has become of the essential platform for exchanging the information. Social media also refers to the online interactive media resources which are posted on social media, it also advance personal engagement and community curation. A huge amount of multimedia data is generated in all type of social network per minute. With increasing demand of camera –equipped mobile terminals and social network platform (e.g. Twitter, Instagram, Facebook, We chat and Weibo), multimedia content including videos, document, images a main role in fetching information according to people's judgment and sentiments in social networks [35, 50, 94]. Sentiment analysis is no longer just a subject on natural language processing but it also have a connection with pattern recognition, computer vision and other issues in artificial intelligence. A variation of new idea have appeared in the promising area, specifically for visual sentiment analysis.

We will focus on various modes of sentimental analysis. A depth information of its different types of application in real world will be given and how it can help in grasping about various changes taking place in the current trends.

II. LITERATURE SURVEY

Minhoe Hur et al., 2016 [8] suggested a system to predict collection of Box-office depended on Sentiments of movie review. For this, they have used Viewer opinions as input variables. A three machine learning-based algorithms (artificial neural network, regression tree, and support vector regression) were used to get rough relationship between the box-office and its collection predictors.

Aurangzeb Khan, 2011 [19] suggested a rule-based technique. In this technique, SentiWordNet is used to get more specific than a pure lexicon-based technique

for sentiment analysis. The accuracy of the system is 86% at sentence level and 91% at document level.

Mudinas and Zhang, 2012 [22] suggested a hybrid technique which excels better in
performance than the lexicon. It also performs like leaning based technique. Hybrid Techniques is more substantial than lexicon technique and its performance is based on machine learning techniques. The overall accuracy of the system is 82.3%.

Lei Zhang et al., 2010 [18] suggested a ranking and extracting product attribute that was in opinion documents algorithm. Firstly, they had difficulty to determine the reviews given by the users by using a machine. And also to segregate them as positive and negative reviews. In order to overcome this, they used rule mining technique to for extracting product features.

Seven Rill et al., 2014 [13] suggested an application "PoliTwi" which shows an emerging political topics on Twitter by detecting it earlier and it gives the impact on concept-level sentiment analysis. For this, hashtags are used to decide the outcome of election in USA even prior to "Google Trends". Twitter API is used to analyse the collected data by using sentiment analyzing an algorithm

Monu Kumar and Dr. Manju Bala, 2016 [7] suggested that it is not easy to analyse the ample of unstructured data these days which are gathered from different social networking
sites like "Facebook, Wechat, Weibo, Instagram". That's why, they use Hadoop for intelligent analysis and cloud service for storage of big data. Cloud is used for Sentimental Analysis of Twitter.

Martin Wöllmer et al., 2013 [16] suggested a technique to analyze sentiments in Audio – Video context of a YouTube Movie. For this, they use Metacritic database as input to get user reviews. They assess the knowledge-based approach by applying data-based approach in-domain setting as well as in a cross-domain setting.

III. TYPES OF SENTIMENT ANALYSIS

Sentiment analysis presumes different forms, from models that focus on polarity (positive, negative, neutral) to those that detect feelings
and emotions (angry, happy, sad, etc), or even models that identify intentions (e.g. interested v. not interested).

3.1 FINE-GRAINED SENTIMENT ANALYSIS:

In business if polarity precision is important to you then you might consider in expanding your polarity categories to include:

- Very positive Positive
- Neutral Negative
- Very negative

3.2 EMOTION DETECTION:

Emotion detection focus on detecting emotions, like happiness, anger, sadness, and so on. Many emotion detection systems use lexicons (i.e. lists of words and the emotions they convey) or complex machine learning algorithms.

One of the drawbacks of using lexicons is that people express their feeling in different ways. Some words that typically express anger, like bad or kill(e.g. your customer support is killing me) might also express happiness (e.g. you are killing it).

3.3 ASPECT-BASED SENTIMENT ANALYSIS:

While analyzing the sentiment of a text or viewing the product review we always want to know what particular features or aspect do people mention are positive, negative or neutral way. That's where aspect-based sentiment analysis can help, for example in
this text: "The battery life of this smartwatch is
too short", an aspect-based classifier would beable to determine that the sentence expresses a negative opinion about the feature battery life.

3.4 MULTILINGUAL SENTIMENT ANALYSIS

Multilingual sentiment analysis can be difficult. It includes a lots of pre-processing and resources. Some of these resources are available online (e.g. sentiment lexicons), while others need to be created (e.g. translated corpora or noise detection algorithms), but you need to know how to code to use them.

Alternatively, a language in texts can be detected automatically, then train a custom sentiment analysis model to classify texts in the language of your choice.

IV. APPROACHES OF SENTIMENT ANALYSIS

Sentiment analysis uses different Natural Language Processing (NLP) methods and
algorithms, which we'll go over in more detail in this section.

Rule-based systems are used toperform sentiment analysis based on a set of instruction crafted rules.

Automatic systems rely on machinelearning techniques to learn from data.

Hybrid systems combine both rule-based and automatic approaches.

The machine learning-based approach uses a classification technique to categorize the text; it includes two sets of documents: training and a test set. The training set is used for learning to transform characteristics of a document, while the test set is used for inspecting how well the classifier performs.

The **lexicon-based** approach uses sentiment dictionary with opinion words and matches them with the data for determining polarity. There are three different techniques to construct a sentiment lexicon: manual construction, corpus-based methods and dictionary-based methods. The manual construction is the most difficult and time-consuming task. Corpus-based methods can produce opinion words with relatively high accuracy. Finally, in the dictionary-based techniques, the idea is to first collect a small set of opinion words manually with known orientations, and then to grow this set by searching in the WordNet dictionary for their synonyms and antonyms.

Finally, in the **hybrid approach**, the combination of both the machine learning and the lexicon-based approaches has the potential to better the sentiment classification performance.

SENTIMENT CLASSIFICATION APPROACHES		FEATURES/ TECNIQUES	ADVANTAGES AND LIMITATIONS
Machine learning	Bayesian Networks Naive Bayes Classification Maximum Entropy Neural Networks Support Vector Machine	Term presence and frequency Part of speech information Negations Opinion words and phrases	**ADVANTAGES** the ability to adapt and create trained models for specific purposes and contexts **LIMITATIONS** the low applicability to new data because it is necessary the availability of labeled data that could be costly or even prohibitive
Lexicon based	Dictionary based approach Novel Machine Learning Approach Corpus based approach Ensemble Approaches	Manual construction, Corpus-based Dictionary-based	**ADVANTAGES** wider term coverage **LIMITATIONS** finite number of words in the lexicons and the assignation of a fixed sentiment orientation and score to words
Hybrid	Machine learning Lexicon based	Sentiment lexicon constructed using public resources for initial sentiment detection Sentiment words as features in machine learning method	**ADVANTAGES** lexicon/learning symbiosis, the detection and measurement of sentiment at the concept level and the lesser sensitivity to changes in topic domain **LIMITATIONS** noisy reviews

Table 1. comparing different analysis approach

V. WORKING OF SENTIMENT ANALYSIS

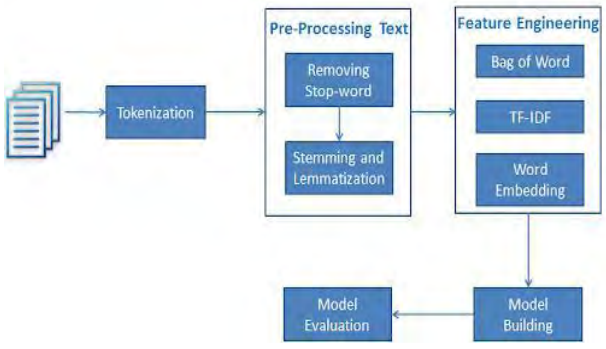

Fig1. Flow chart

The process of sentimental analysis include following steps:
Step1: training and predicting
In the process of training, model (dataset) is made to learn how to associate a particular set of input(text) to the output (tag) correspondingly based on the test sample used for training. Pair of feature vectors and tags are fed into algorithms by feature extractors to generate a model.

In the process of prediction, the feature extractor transforms the unseen text inputs into feature vectors. These feature vectors are fed to the model which generates prediction tags.

Step2: feature extraction
Text classifier in machine learning is of the most important step , transforming the vectorized text helps in finding similar word
representation with similar word meaning.Word embedding also known as word vectors is a new extraction technique, other common technique commonly used is bag-of-wordsakabag-of-ngrams

Step3: algorithm
Classifying the algorithm to be used is generally based on the statistical model like Naïve Bayes,
Logistic Regression, Support Vector Machines, or Neural Networks etc:

- Naïve Bayes: a family of probabilistic algorithms, Bayes's Theorem is used to predict the category of a text.
- Linear Regression: most commonly used algorithm in statistics which user a given set of features (x) to predict the values (y).
- Support Vector Machines: a non-probabilistic model which uses a representation of text sentiments are mapped to distinct regions within that space. New text are assigned similar category they're mapped to
- Deep Learning: a diverse set of algorithms that tries to mimic the human brain, by employing artificial neural networks in processing of data.

VI. ACCURACY AND CHALLENGES OF SENTIMENTAL ANALYSIS

6.1 ACCURACY:

Sentiment analysis is difficult due to things such as subjectivity, tone, lack of context, irony, and sarcasm. Not only the algorithms is a factor that is hard for doing sentimental analysis but also humans.According to Saif et al., human-agreement for Twitter sentiment analysis reaches a 0.655 value of Krippendorff's Alpha, which is a quiet exceptional of agreement but still far from great. According to our experience, custom machine learning models for sentiment analysis can reach 70–80% accuracy level with proper training, and sometimes it can even give higher result depending upon the on the domain and the scope of the problem. If one is interested in sentiment analysis, then they should check out the complete guide which goes through the basics of sentiment analysis, how does it work, it's challenges and applications, and share some useful resources.

6.2CHALLENEGES:

6.2.1SUBJECTIVITY AND TONE:

The detection of subjective and objective texts is just as essential as analysing their tone. However, so called *objective* texts does not contain explicit sentiments.

6.2.2 IRONY AND SARCASM:

People express their negative sentiments using positive words, which can be difficult for machines to detect the context without having a thorough understanding of the situation in which a feeling was expressed. This is what is called as irony and sarcasm.
For example, look at some possible answers to the question, *Did you enjoy your shopping experience with us?*
Yeah, sure. So smooth!
Not one, but many!

6.2.3 COMPARISONS:

Comparisons in sentiment analysis is another challenge which is worth tackling. Look at the texts below:

This product is second to none.
This is better than older tools.
This is much better than nothing.

6.2.4 EMOJIS:

According to Guibon et al. there are two types of emojis. *Western emojis* (e.g. :D) are encoded in only one or two characters, whereas *Easternemojis* (e.g. ¯_(ツ)_/¯) are a longercombination of characters of a vertical nature. Emojis play an important role in the sentiment of texts, particularly in tweets.

6.2.5 DEFINING NEUTRAL:

To define neutral is one more challenge to tackle in order to get accurate sentiment analysis. As in all problems, defining your categories -and, in this case, the *neutral* tag- is one of the almost important parts of the problem. The *neutral*, *positive*, or *negative* does matter when you trainsentiment analysis models. A good problem definition is a must as tagging data requires the tagging criteria.

VII. TOOLS USED FOR SENTIMENTAL ANALYSIS:

Sentimental analysis is a deep topic and not all beginners are comfortable using languages like R, python etc, there are number of blogs and forums available with tutorials of how to analyse but still it is easier to directly use application.

TOOLS FOR SENTIMENT ANALYSIS	TECNIQUES USED BY TOOLS
EMOTICONS	Emoticons contained in the text
LIWC	Dictionary and sentiment classified categories
SentiStrengh	LIEC dictionary with new features to strength and weak sentiments
Senti WordNet	Lexical dictionary and scores obtained by semi-machine learning approaches
SenticNet	Natural language processing approach for inferring the polarity at semantic level
Happiness Index	Affective Norms for English Words (ANEW) and scores
	for evaluating happiness in the text
AFINN	Affective Norms for English Words (ANEW) but more focused on the language used in microblogging platforms.
PANAS-t	Eleven-sentiment psychometric scale
Sentiment140	API that allows classifying tweets to polarity classes positive, negative and neutral.
NRC	Large set of human-provided words with their emotional tags.
EWGA	Entropy-weighted genetic algorithm
FRN	Feature relation network considering syntactic n-gram relations

Table 2. tools

VIII. APPLICATIONS

8.1 SOCIAL MEDIA MONITORING:

- It can be used to Analyse tweets and/or facebook posts to detect audience sentiment over a particular topic over a period of time.
- Control social media mentions of your brand
- Automatic route finding in social media to mention same team members
- Get deep insight of current social media trends.

8.2 BRAND MONITORING:

Not only brands have large amount of information available on social media, but all across internet. Instead of focusing specifically only on social media, they also use information from news, blogs, forums etc to analyse the brand status in the society and implement certain changes accordingly after studying the feedbacks.

8.3 MARKET RESEARCH:

sentiment analysis promotes all kinds of market research and competitive analysis. It helps in exploring and anticipating future trends and and also promotes competitive edge.

SENTIMENT ANALYSIS APPLICATIONS
BUSINESS
Consumers voice
Brand reputation
Online advertising: Blogger Centric Contextual Advertising Dissatisfaction oriented online advertising
On-line commerce
POLITIC
Voting advise applications
Clarification of politicians' positions
PUBLIC ACTIONS
Real-world events monitoring
Legal matters "blawgs"
Policy or government-regulation proposals
Intelligent transportation systems

Table 3, applications of sentimental analysis

IX. CONCLUSION

Sentiment analysis is a concept that can be applied to number of aspects from political analytics, product analytic, brand monitoring, market research etc. by incorporating this in the
current system we are able to increase the work with useful ends and more accuracy. It has moved beyond just being a topic of interest, it enables us to glean a new insight perspective, so that we can do work better and more productively.

In short, ample of efforts is been devoted to sentiment extraction of social media text. Although considerable amount of progress is been made in visual sentiment analysis but multimodal sentiment is still in its inception. Audio-only sentiment analysis is not usual because audio data is not self-dependent in social

networks, but they are incorporated with the videos. Therefore, the combination of audio-visual information is made for effective use for multimodal sentiment.

Movie Recommendation System Using R

Kartik Rawool, Anurag Tiwari & Suraj Jha

Thakur College of Engineering and Technology Mumbai, India

Abstract— **Recommendation systems have become ubiquitous today. With the advancements undertaken in the movie's domain in the past few decades, it becomes an arduous task to choose movies based on personalized preferences. Therefore, the need for a reliable system that recommends moviesto users becomes inevitable. Such a system takes into consideration a user's past viewing habits, tastes, personal fondness over a genre, actor, director, and latest trends in order to recommend movies to the person. In this paper, we highlight a user based collaborative filtering system that takes an input of three movies from a person based upon their preferences and recommends a list of ten movies which resemble the user's original choices. The filtering and recommendation is generated based upon ratings of several different users on many different movies. The system significantly enhances the user interface and gives a friendlier interface to interact with the application. It also plots and visualizes the data in order to build a more comprehensive understanding of the vast inclusive set of data working behind the application. In an attempt to connect and find similarities between different users, we explored the different similarity techniques which included Pearson, Jacquard and Cosine. Our application recommends ten movies to users based upon historical ratings and similarity between other users. In the final outcome, an interface in Shiny package in R studio was implemented through which the plots and movies output wasproduced.**

Keywords— Movie Recommender, User based Collaborative filtering, Recommendation model

I. INTRODUCTION

In today's rapid world, information overload has become a reality. Filtering out relevant content has become a hot research topic which has gained a lot of attention. [1] Movies are a pivotal source of entertainment. In presence of such diverse and varied content streaming on the internet on a seamless basis today, it becomes difficult to filter out content in a personalized format. On the other end, businesses and industries producing this content face problematic issues in reaching to the right kind of audience, in the absence of a marketing strategy. In order to ease out the selection of movies from a set of perplexing choices, the need and demand of a reliable recommendation engine becomes inevitable. It not only simplifies the selection mechanism for the users but also helps the businesses, industries as well as the creators to reach the right kind of audience. Providing related content which resembles a user's choices out of relevant and irrelevant collection of movies pertaining to his taste is the precise task of a recommendationengine.

Recommendation engines have become increasingly popular as they have been implemented at many different online platforms. The content of such platforms varies from movies, music, books and videos, to friends and stories on social media platforms, to products on e- commerce websites, to people on professional and dating websites, to search results returned on Google. [2

These systems are used to collect information from the user and to give him an insight into the related content according to his specific preferences. A wide variety of approaches have been used to provide recommendations. These incorporate collaborative filtering, content-based filtering and a hybrid approach. Different Algorithms and approaches are present to provide recommendations that use rating or content information; however collaborative filtering and content-based method suffer from the same limitations. Several researchers have tried to overcome these limitations by combining both collaborative filtering and content-based method and producing a hybrid approach that combines ratings as well as content information. Recommendation system will always remain an active search area for researchers.[3]

The table gives us conclusive data about how useful the recommendation engines are for the businesses as well. [4]

Netflix	2/3rd of the movies watched are recommended
Google News	recommendations generate 38% more click-troughs
Amazon	35% sales from recommendations
Choicestream	28% of the people would buy more music if they found what they liked

Table1. Companies benefit through recommendation system

II. RELATEDWORK

Inthissystem,wehadimplementedamovierecommender model in accordance with which we had referred several websites and implemented the concept in a very systematic and simplified manner. We had collected the required dataset from a website, titled group lens [5]. In order to process that data and apply various models for visualizing the data we underwent a pre-processing techniquewheretherelevantdatacontentwasfilteredout. Inabidtokeepitsimpleweused100,000ratingsand8570 movies with 706 users[6].

In this website we discovered that in a content-based model, we needed more specific and precise information about our user and therefore in a content-based model it was necessary to have a large dataset which in turn would make the system a bit more complex and inefficient. Hence, we make use of the collaborative learning model for recommending movies to a user since it is based on the similarity of the users who have the same preferences as that of another user [6].In this website it used genres for recommending movies. In order to do so, it first converted the genre into a binary matrix in a 0 and 1 format which was arising some number of limitations. So, we made the required changes and modified the model by using only the ratings parameter instead of genre which made the process more simplified. For creating the rating matrix we are using recommender lab function which is available in reshape2 package in R. We then convert itin the wide format rather than long format by cast () function which is in reshape2 package in R. It is also efficient to work with graphics packages lattice and ggplot2, as it makes it easy for creating plots to render comparisons of various data[7].

Now for analyzing the large amount of data it becomes tedious for computing with a greater number of variables, so we used Principal Component Analysis (PCA) for dimensionality reduction. It is used for converting the features i.e. the dimensions. This means restricting 3D to 2D or else 2D to 3D. For example, we are having 2 variables a and b, then we split into one more variable which implies that now, we are having 3 variables a, b, and c. Also, we add one more dimension to it. The function rind () is used to combine vectors/matrix since we are using it in rating mat and user select [8].

Now we implemented the technique of visualization of the dataset and by using knn algorithm to the rating matrix, we found out the further steps in our model to be continued [9].

III. PROPOSEDMETHODOLOGY

Architecture

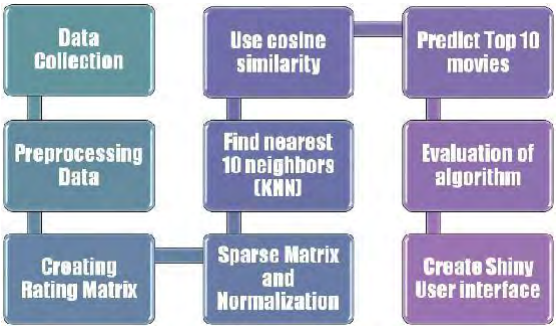

Fig 1: System Architecture

From the datasets, the ratings dataset was converted from the given data frame into a matrix data structure. This was done in order to apply our model later which required that the datasetshouldbepresentinmatrixformat.ThisMatrixisthen converted into a sparse matrix which nullified the ratings whose data was absent andmissing. We have a total of 100K ratings which include about 600+ users. We know that all the users have different opinions and perspectives. Also, each person rates his or her movies in a different way i.e. some users are stringent and critical while rating, whereas some are quite lenient. So, to bring everyone on the same ground we normalize the matrix. This weights the ratings about zero, which helps to compare different users and also gets the proper ratings of movies. We can see the normalized ratings being plotted in the following histogram. From the histogram we can infer that the greatest number of ratings areaverage.

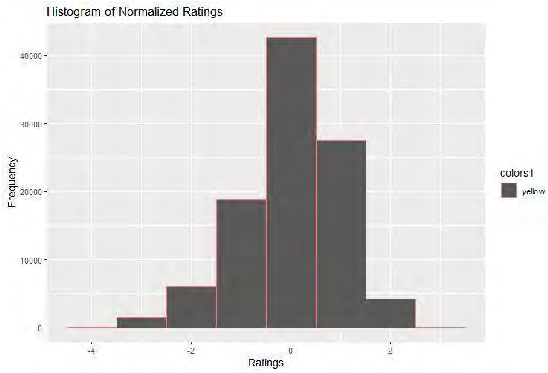

Figure 2: Histogram of Normalized Ratings

We further visualize our dataset using the
Package available in R studio and the plotted results are in the form of histograms and graphs which allow us to compare and give a deeper insight into the dataset which we are dealing with.

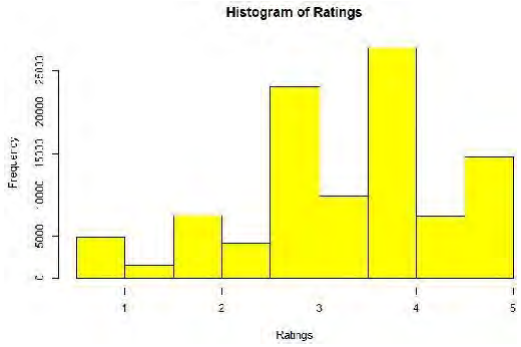

Figure 3: Histogram of Ratings

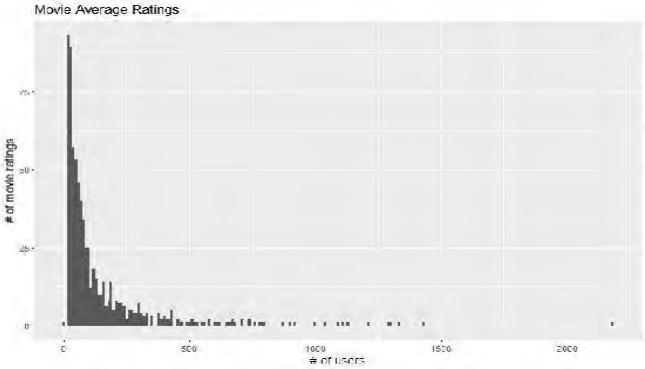

Figure 4: Average rating of movies

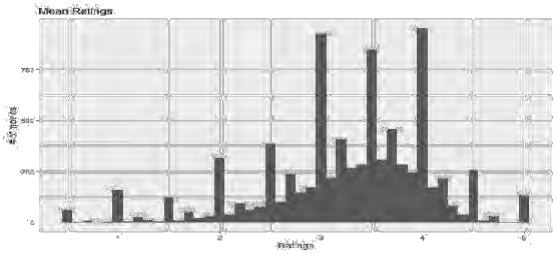

Figure 5: Mean distribution of ratings Once our ratings dataset is complete and ready for processing, we move on to the recommendation model. In this model we are going implement User Based Collaborative Filtering. For this filtering we need tofind users from the dataset who are similar to the person who is using our model. To find the users who have the same preferences, we use KNN algorithm. Through this algorithm we get n nearest neighbors. To get the most similar users we use and implement the similarity techniques. There are 3 types of similarity techniques available: 1. Jacquard 2. Cosine 3. Centered cosine or Pearson similarity. For our model we went ahead with cosine similarity. Higher the cosine similarity better is theselection.

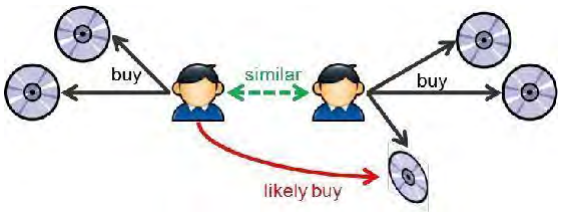
Figure 6: User Based Collaborative Filtering System [10]

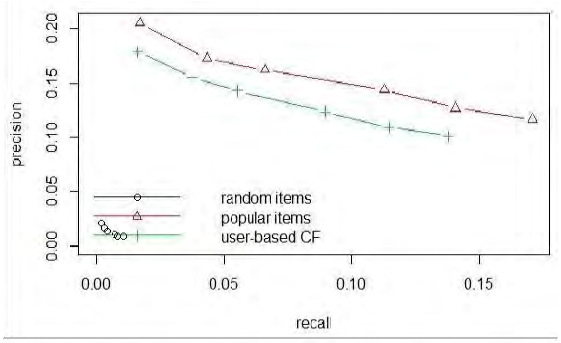


WewillbeusingRprogrammingtoimplementthemodel. So, we used the recommender lab package to use the UBCF model. With this model 10 movies are recommended to the user upon selection of three movies bytheuser.Therearevariouswaystorecommendamovie which include item based, collaborative, randomly or on popular basis but, when we performed the evaluation on the various models, and visualized it on ROC and precision-recall curve, we concluded after observing the curves that the UBCF and Popular are the best based on Area Under Curve. However, we are aiming to recommend on the basis of user's preferences. Hence, we narrowed down on the UBCFmodel.

$$\text{TPR (sensitivity)} = \frac{TP}{TP+FN}$$

$$\text{FPR (1-specificity)} = \frac{FP}{TN+FP}$$

Figure 7: ROC CURVE (RECEIVER OPERATING CHARACTERISTIC)



$$\text{Precision} = \frac{True\ Positive}{True\ Positive + False\ Positive}$$

$$\text{Recall} = \frac{True\ Positive}{True\ Positive + False\ Negative}$$

Figure 8: PRECISION RECALL CURVE

The following figure highlights and encompasses the algorithm that was undertaken in order to perform the User Based Collaborative Filtering on our model wherein each stage points to a pertinent step which was followed in the course of the entire implementation.

Figure 9: Working of the User Based Collaborative Filtering

After building the model we applied and implementedthe model in the Shiny web app available in the R Studio. Through this app we accept 3 movie preferences from the user and then display the 10 recommendations using the above model. Also, we display the average rating of the 3 movies out of 5. We also used the shiny app to display all the visualization results. Through this Shiny app wecan

Deploy the app on the web and then the app can be accessed by any user on the internet. This is all possible due to the Shinyapp.io website.

IV. IMPLEMENTATION

Software

The following code is the complete implementation which includes the server and user interface code in R studio.

```
#server.R
library(shiny)
library(ggplot2)
movies <- read.csv("E:/ANURAG/DATA SCIENCE/Final PROJECT/movies.csv", header = TRUE, stringsAsFactors=FALSE)
movies <- movies[with(movies, order(title)), ]
ratings <- read.csv("E:/ANURAG/DATA SCIENCE/Final PROJECT/ratings100K.csv", header = TRUE)
colors = c("red", "yellow", "green", "violet", "orange","blue", "pink", "cyan")
colors1 = c("yellow")
colors2 = c("red")

shinyServer(function(input, output) {

 # Text for the 3 boxes showing average scores

  formulaText1 <- reactive({
    paste(input$select)
  })
  formulaText2 <- reactive({
    paste(input$select2)
  })
  formulaText3 <- reactive({
    paste(input$select3)
  })

  output$movie1 <- renderText({
    formulaText1()
  })
  output$movie2 <- renderText({
    formulaText2()
  })
  output$movie3 <- renderText({
    formulaText3()
  })# Table containing recommendations
  output$table <- renderTable({

    # Filter for based on genre of selected movies to enhance recommendations
    cat1 <- subset(movies, title==input$select)

    cat2 <- subset(movies, title==input$select2)
    cat3 <- subset(movies, title==input$select3)

    # If genre contains 'Sci-Fi' then return sci-fi movies
    # If genre contains 'Children' then return children movies
    if (grepl("Sci-Fi", cat1$genres) | grepl("Sci-Fi", cat2$genres) | grepl("Sci-Fi", cat3$genres)) {
      movies2 <- (movies[grepl("Sci-Fi", movies$genres) , ])
    } else if (grepl("Children", cat1$genres) | grepl("Children", cat2$genres) | grepl("Children", cat3$genres)) {
      movies2 <- movies[grepl("Children", movies$genres), ]
    } else {
      movies2 <- movies[grepl(cat1$genre1, movies$genres)
                        | grepl(cat2$genre1, movies$genres)
                        | grepl(cat3$genre1, movies$genres), ]
    }

    movie_recommendation <- function(input,input2,input3){
      row_num <- which(movies2[,3] == input)

      row_num2 <- which(movies2[,3] == input2

V. RESULTS AND DISCUSSIONS

In this recommender model we found that for given input of three movies by user, a list of 10 similar movies which suit the tastes of the user are displayed. The main aim of the movie recommender system was to recommend movies to users according to different users rating on a particular movie. We had a set of users with their previous rating on a set of movies, and we predicted the rating that the user can give to a movie they have not previously rated.

Users of movie rentals prefer a movie recommendation that will match their 'taste' in movies and thus wish to invest their time into movies which are preferred by them. The movie rental businesses are eager to use analytics to solve this problem and gain revenues. Using our Movie Recommender System, a movie rental website can identify which movie the user will like the most and recommend similar titles which will increase their business and build customer loyalty. Collaborative Filtering approach was used in our project whereby the similarity of the ratings of the new user with that of the ratings of the other users were identified and recommendations were generated. With User Based Collaborative Filtering (UBCF) approach, the Cosine similarity of new user with other users was calculated and movies that users in the clusters liked were identified. The recommendation matched the similarity of ratings given as input.

VI. CONCLUSION AND FUTURE SCOPE

Through this project we were able to recommend movies to a user by receiving the user's preferences. Here we used based collaborative filtering for recommendation. We analysed different filtering models such as Item based Collaborative filtering, Popular and Random models. By plotting Receiver Operating Characteristic and Precision Recall Curve, we observed the AUC (Area under Curve) to conclude that UBCF is the best model to be used. For implementation of this model in R programming we took help of the Recommender Lab present. This package includes various functions to use the model we desired. For providing our users with proper experience we implemented a web app using Shiny in R Studio.

House Price Prediction Using R

Aayushi Sarda, Aunshuman Saha,Sarandeep Singh
Department of Computer Engineering
Thakur college of Engineering and Technology

Abstract— **This paper explores the question of how house are affected by housing characteristics (both internaland external). House prices increase each year, so there is a need for a system to predict pricing in the future. House price prediction favors the researcher to determine the sale price of a house and can help the customer to orchestrate the right time to purchase a house. The price of a home is usually based on three factors: location, product and timing. This study aims to predict house prices based on numerous factors. In normal case scenario, housing price index denotes the summarized price changes of residential estate houses. For a single familypriceprediction,itrequiresmoreaccuratemethod based on location, house kind, size, build year, local amenity, and other factors which could affect the house demand and supply. The housing market is one of the most competitive in terms of pricing and it tends to vary significantly based on varied factors, so it is one of the main areas to implement the process of machine learning tooptimize and predict the prices with the utmost accuracy. Thereforeinthisproject,weanalyzethevariousessential features while predicting housing prices with considerableaccuracy.**

Keywords—Machine Learning, Linear Regression, Decision tree, Multivariate regression, Data cleaning, R Shiny

I. INTRODUCTION

Predicting prices has been a contest for many researchers. Numerous engineers have tried to use various machine learning paradigms to form a model that can accurately calculate prices with only a minimum margin for error.

House Price Prediction is one such problem. These models take into account obvious parameters such as area of the house in squarefeet, no. of bedrooms, garage area, etc. Each of the features in our study is given a certain weight and that determines how important that feature is towards our desired prediction. This is called feature engineering. We have hundreds of different features to choose from, but one of the drawbacks of having a large number of parameters included is the heavy computations that result in making the regression model, and computing the prediction. We haveused the Iowa Housing Dataset for our project. Here, we have defined linear model data using decision tree model and multivariate model, using several features as its input, hence calculated the root mean squared error (RMS value) for the model. This project thus directs us to the application of machine learning algorithms in addition to other techniques to optimize the anticipated result.

II. METHODOLOGY

A. DATACOLLECTION:

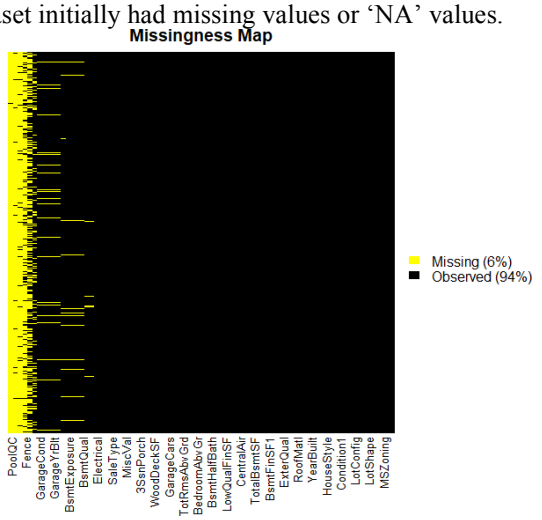
ThedatasetusedinthisprojectcomesfromtheIowahousing data taken from Kaggle. The dataset is in csv(comma separated values). It contains about 1460 entriesrepresenting the aggregate information about 80 features of homes from various suburbs located inIowa,USA.

Some of the features are:

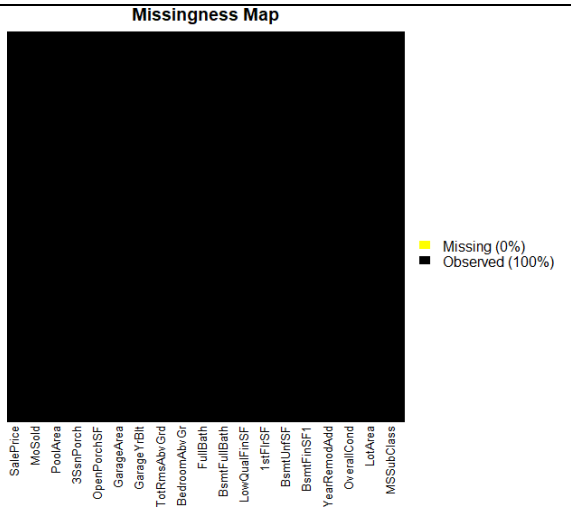
1. SalePrice - the property's sale price in dollars. This would be taken as the target variable to bepredicted.
2. OverallQual: Overall material and finishquality
3. GrLivArea: Above grade (ground) living area squarefeet
4. YearBuilt: Original constructiondate
5. GarageArea: Size of garage in squarefeet
6. FullBath: Full bathrooms abovegrade
7. TotRmsAbvGrd: Total rooms above grade (does not include bathrooms)
8. BedroomAbvGr: Bedrooms above grade (does NOT include basementbedrooms)
9. PoolArea: Pool area in squarefeet

B. DATACLEANING:

Data cleaning is the process of preparation of data for analysis by modifying or removing data that is incomplete, incorrect, duplicated, improperly formatted or irrelevant and then re-modelling, or removing the dirty or crude data.
The dataset initially had missing values or 'NA' values.



na.omit(data) function removes all those rows which have NA value.

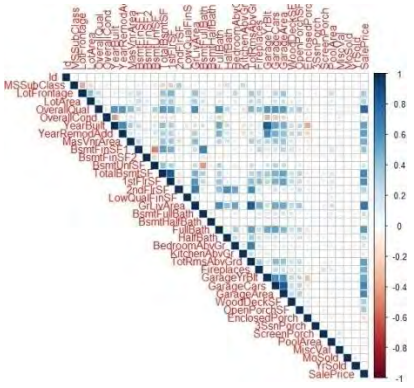


It returns a data table with just the rows where the specified columns have no missing value in any of them.

C. ANALYSINGDATA:

In order to see which columns are to be used for model fitting for Linear Regression and Decision Tree, we use a library called as 'corrplot'. It has a function called as corrplot which returns a graphical plot demonstrating the correlation between different variables of the dataset.

The variables showing a high positive correlation with the dependent variable are extracted for model fitting.



It is observed that the following variables showed the highest correlation:

- GarageArea
- GarageCars
- TotRmsAbvGrd
- FullBath
- GrLivArea
- TotalBsmtSF
- OverallQual
- YearBuilt
- Fireplaces

As a result, we use the above variables for our Linear Regression and Decision Tree model fitting.

SalePrice	OverallQual	YearBuilt	GrLivArea	TotRmsAbvGrd	GarageArea
208500	7	2003	1710	8	548
181500	6	1976	1262	6	460
223500	7	2001	1786	6	608
140000	7	1915	1717	7	642

D. APPLYINGMODEL:

Two machine learning models were used: Decision Tree and Multivariate Linear Regression

Multivariate **Linear Regression**:

In order to implement Multivariate Linear Regression, the lm() function is used.

Syntax of lm() function:

lm(formula, data, subset, weights, na.action, method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,
singular.ok = TRUE, contrasts = NULL,offset, …)

formula: It is a symbolic description of the model to be fitted.

data: This is the dataset being considered.

model, x, y, qr -the corresponding components of the fit are returned if TRUE

DECISION TREE:

In order to implement Decision Tree the library rpart is used.

rpart function is used which used to plot a decision tree.

rpart(formula, data, weights, subset, na.action = na.rpart, method, model = FALSE, x = FALSE, y = TRUE, parms,control, cost, …)

E. PERFORMANCE MEASURES OF THEMODELS:

MULTIVARIATE LINEAR REGRESSION:

The R-Squared value, also called as the coefficient of determination, is checked in linear regression which represents the proportion of the variance for a dependent variable (House Price) that's explained by independent variables.

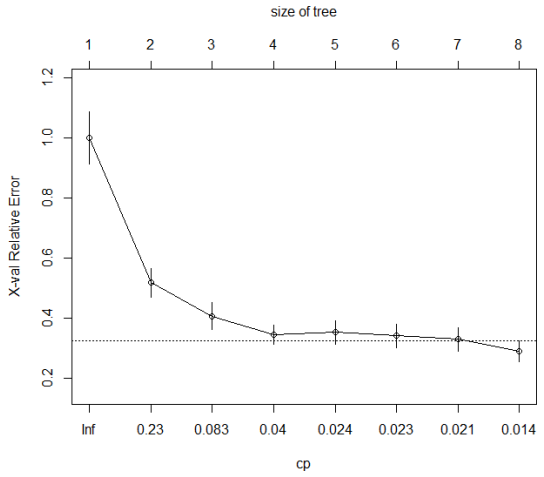
R-squared value measures how good our model has been fitted to the given training data. It evaluates the scattered data points around the fitted regression line. It is defined as the ratio of the variance explained by the model to the total variance. Higher R-squared values indicate that the difference between observed data and fitted values is small. R-squared is always measured between 0 and 100%.

The R-squared value of the linear regression model can be determined by using the summary(model) function which gives the residual error along with the R-squared value.

DECISION TREE:

For decision tree we use a plot function given as plotcp(model) which draws a line representing the highest cross validated error less than the minimum cross validated error plus the standard deviation of the tree.

Cross validation creates a number of partitions from the sample observations. These are called as validation sets and are obtained from the training data set. After fitting the model on training data, the performance is measured against each validation set and averaged. This average value gives a better assessment of how the model will perform to predict for observations



III. LITERATURESURVEY

A. HOUSE PRICE AFFECTINGFACTORS:

In the research paper that we referred [2] , R.A. Rahadi broadly classifies the house price affecting factors into 3 categories: physical conditions, concept andlocation.
Physical conditions include the properties of a house that can be perceived by human senses such as size, number of bedrooms, kitchen and garage availability, garden and area of land, age of the house [3] etc. Concept is a design scheme used by developers to attract buyers. These could include healthy and green environment, minimalist homeetc.
Location is one of the most important factors that affects the price of a house. The price of the house changes with respect to its proximity to public facilities such as schools, hospitals, malls, health centers, parksetc.

B. HEDONIC PRICING:

This is a price prediction model based on the hedonic price theory. The hedonic price theory assumes that the value of a property is the sum of all its attributes value [4]. For the implementation, hedonic pricing can be implemented using regression model. y = a.x1 + b.x2 + c.x3 +... + n.xi Where, y is the predicted price, and x1, x2, … xi are the attributes of a house. a, b, ... n are the correlation coefficients associated with each variable respectively for the determination of house prices. Sirmans, Macpherson and Zietz (2005) provide a study of 125 papers that use hedonic pricing model to estimate house prices in the past decade [5]. The paper gives a list of 20 attributes frequently used to specify hedonic pricing models. Our dataset contains 80 variables. The paper also discusses the effects of variables on the house prices. For example, number of bath-rooms is usually positively correlated to the final sale price. In our model we found that some variables such as garage area, pool size, the year in which the house was built, presence of a fireplace, the overall quality etc. had a very strong positive correlation with the sale price of thehouse.

IV. FLOWCHART

V. RESULT ANDDISCUSSION:

Accuracy:

TABLE 1

Expected SalePrice	Predicted SalePrice	Error Range
208500	255249.1	20-25%
181500	111691.8	
223500	344341.3	
140000	103489	
250000	239014.8	

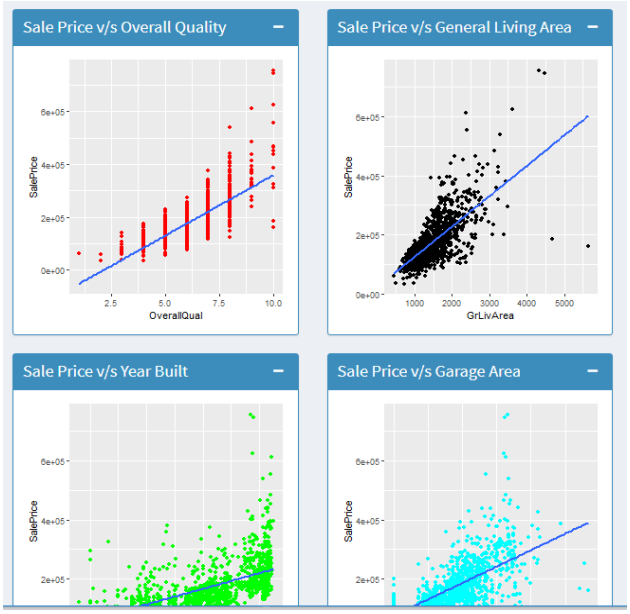
The error obtained when the values are predicted by multivariate linear regression is 20-25% (Table 1)

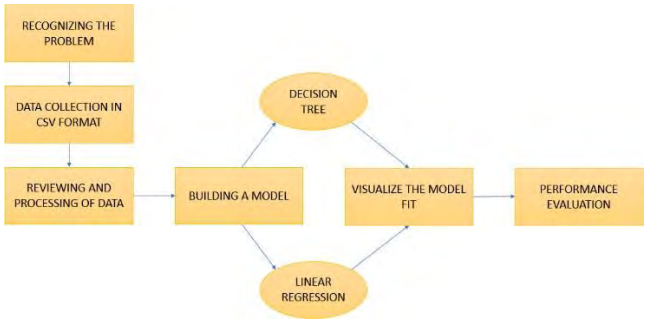
TABLE 2

Expected SalePrice	Predicted SalePrice	Error Range
208500	261186.8	15-20%
181500	125166.3	
223500	310979.5	
140000	189614.3	
250000	189614.3	

The error obtained when the values are predicted by decision tree is 15-20% (Table 2)

We implemented shiny web app in our project in order to make it a more user-friendly append we got the following results :





VI. CONCLUSION:

Real Estate is considered one of the most lucrative areas of investment. It can however be overwhelming for a beginner to understand the properties and features of a house which contribute to its value. Our goal was to create something that while being user friendly provides the operator with the necessary information in a clear concise manner to make an informed choice.

A Review on Dynamic Airline TicketPrice Prediction using Machine Learning

Anurag Tiwari,Janhavi Tawde
Department of Computer Engineering
Thakur College of Engineering and Technology, mumbai
anurag219tiwari@gmail.com,tawwjazz267@gmail.com

Abstract—— **this paper aims to review the dynamic pricingof anairlineticketforaflightonvariousroutes.Itproposesadata-drivenmodeltopredictthebesttimeforacustomertopurchase the tickets with the use of Machine Learning. The changing airfare is dependent upon various factors which are critically analyzed. This paper aims to study the factors which influence the fluctuations in the airfare prices and predict the prices of individualflights.**

Keywords—dynamic airfare, price prediction, machine learning

I. I. INTRODUCTION

Today, the airline corporations are using complex strategies and methods to assign airfare prices in a dynamic fashion. These strategies are taking into account several financial, marketing, commercial and social factors closely connected with the final airfare prices [3]. Any individual who has booked a flight ticket previously knows how unexpectedly and invariably the cost of a ticket can change. This is due to the fact that the airline companies use convoluted methods and mathematical models to assign the charges in a dynamic fashion. They use advanced strategies called Revenue Management or "yield management" to execute a distinctive valuing strategy [1]. The least expensive ticket experiences change in its value over a period of time. Conventional variables such as distance, fuel prices although play an important role, are no longer the only exclusive factors that dictate the pricing strategy. Elements related to economic, marketing and societal trends have played increasing rolesin imposing the dynamic prices. Due to the high complexity of the pricing models applied by the airlines, it is very difficult for a customer to purchase an air ticket at the lowestprice.

The Revenue management strategy aims to maximize the profit of the flight companies. It mainly works on time of purchase patterns and having the plane occupied as per their need. The time of purchase patterns indicate that the last- minute purchases will be expensive. The companies can dictate the occupancy of the seats in a flight by raising the cost on a flight which is filling fast in order to reduce sales and so, keeping some seats unoccupied for those last-minute expensive purchases. The intensity of optimizing the profits is huge which leads a consumer in paying more for a similar seat. According to a report, India's civil aviation industry is on a high-growth trajectory.

India aims to become the third- largest aviation market by 2020 and the largest by 2030. Indian domestic air traffic is expected to cross 100 million passengersbyFY2017,comparedto81millionpassengersin

A. Selecting a Template (Heading2)

First, confirm that you have the correct template for your paper size. This template has been tailored for output on the A4 paper size. If you are using US letter-sized paper, please close this file and download the Microsoft Word, Letter file.2015,asperCentreforAsiaPacificAviation(CAPA).Asth e workingclassofthecountryisexposedtoairtravelthesearch for the least expensive air ticket becomes inevitable.[1]Due to the high complexity of the pricing models applied by the airlines, it is very difficult a customer to purchase an air ticket in the lowest price, since the price changes dynamically.Forthisreason,severaltechniques[3],[4],able toprovidetherighttimetothebuyertopurchaseanairticket by predicting the airfare price, have been proposed recently. The majority of these methods are making use of sophisticated prediction models from the computational intelligenceresearchfieldknownasMachineLearning(ML). [3]Recent advances in Artificial Intelligence (AI) and Machine Learning (ML) make it possible to infer rules and model variations on airfare price based on a large number of features, often uncovering hidden relationships amongst the features automatically. To the best of our knowledge, all existing work leveraging machine learning approaches for airfare price prediction are based on: 1) proprietary datasets that are not publicly available [8] [9] and 2) transaction records data crawled from online travel booking sites like Kayak.com [10] [11] [12]. [4]

The issue with the latter is that the transaction records from eachonlinebookingsiteareasmallfractionofthetotalticket sales from the entire market, making the acquired data likely tobeskewed,andthus,notrepresentingthetruenatureofthe entire market.[4]

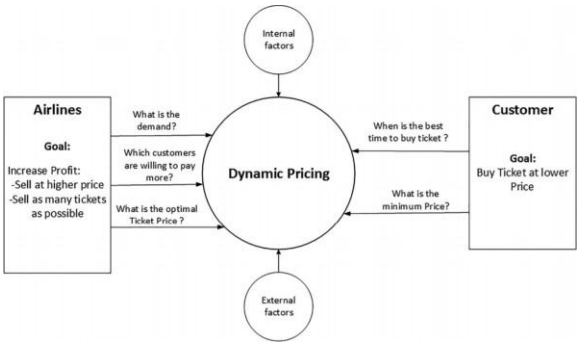
II. LITERATURESURVEY



There have been several studies conducted both at the airline and customer side but there has been no effort made to presentanoverviewoftheexistingwork.Theref ore,themain goal of this paper is to present a comprehensive literature review of existing

studies related to this topic which can be utilized by future researchers. Several issues havebeen

Discussed including data sources, features and various techniques employed for prediction. We believe that this is an important contribution for researchers who are aiming to work on this exciting area of research. [2]. One of the results ofourreviewindicatesthatexistingmodelsgenerall yrelyon limited number of features which are not effective enough in predicting ticket price. For example, customer side models generally utilize restricted features extracted from historical ticketpricedata,ticketpurchasedateanddepartured ate.Ina similarway,airlinessidemodelsarealsodevelopedb asedon limited internal factors such as seasonality, holidays, supply (number of available airlines and flights), fare class, availability of seats, recent market demand, flight distance and competitive moves by other airlines etc.[2]

Nowadays, social media sentiment analysis has become a good source of information. For example, social media data has been used for event prediction competitor intelligence, price prediction and tourist traffic flow prediction. A similar approach could be followed to extract useful social media information related to various external factors affecting airlines passenger demand and ticket price. For example, analysis of different twitter hash tags could give valuable information about the presence of an event at an origin/destination city, competitors' promotions, volume of tourist traffic flow, weather condition, economic activity etc. This in turns might allow us to predict the change in ticket price/demand. It is expected that a data mining model that utilizes information resulting from social media data would give better results than existing work in forecasting route demand and or ticket price. However, to the best of our knowledge, there is no existing work that utilizes social media data to predict route demand and or ticket price.

In this paper we have analyzed three different approaches [1][3][4]tothesameproblemofairlineticketpricepr ediction and have reviewed a fourth one [2]..

III. COLLECTINGDATA

There are hardly adequate research papers available discussing the various ticket pricing strategies that are implemented by several airlines and Online Travel agencies (OTA. This can be due to two reasons: first, ticket pricing strategies are highly business sensitive and remain proprietary of the owner company [2]. Most airlines prefer not to reveal their ticket pricing strategies because of competition with other airlines. Second, there is lack of publicly available datasets that could enable researchers to conduct their prediction effectively. As a result, researchers are obliged to rely on small datasets that are sometimes gathered using web scrapping programs. [2]

The three different approaches we studied have been classified as model 1, 2 and 3 and their data collection strategies are discussed.

1. Model 1

There were various sources of the data on the web which can be utilized for training the models. Websitesgiveinformationaboutthemultipleroutes,

Times, airlines and fare. To implement this data collection, a website "makemytrip.com" was selected and python is used for the implementation of the models and collection of the data [5].

a) Collection ofdata

The script extracts the information from thewebsite and creates a CSV file as output. This file contains the information with features and its details [13]. The following features are considered for the scarping ofdata

- Origin
- Destination
- DepartureDate
- DepartureTime
- ArrivalTime
- TotalFare
- Airways
- Taken Date

In this study, the focus was only on minimizing the airfare charges. Therefore, a single route was considered without return. This data is collected for one of the busiest routes in India (BOM to DEL) over a period of three months that is from February to April. For each flight data with all the features was collected manually.

b) Cleaning and preparing data

The collected data was preprocessed and cleaned in order to remove duplicate and null values from the datasets.

c) Analyzing data

Data Preparation was followed by analyzing the data,uncoveringthehiddentrendsandthenapplying various machine learning models. Days todeparture was calculated from the day the data was taken and the departure date. This was considered to bewithin therangeof45days.Thedayofdeparturewasfound to be a significant feature affecting the price. For example, the price of the airline ticket was cheaper onaweekdaythanaweekend.So,thetimehadbeen divided into four categories: morning, afternoon, evening,night.

2. Model2

Initially, the Greek Aegean Airlines [7] company and its flight, from Thessaloniki to Stuttgart, was selectedasthecasestudyoftheinvestigationforthis model. The current study consisted of four distinctivephases:

- the selection of the features of the flight that influence the airfareprices
- the collection of enough flights data which willbeusedtotrainandtesttheappliedML models,
- selection of the regression ML models being

compared
- ExperimentalevaluationoftheMLmodels.

During the phase of feature selection, the most informative features of a flight that determine the prices of the air tickets are decided. This phase was an extremely crucial phase as it defines theproblem under solving. For every flight the following features wereconsidered:

- F1: Feature 1 - departure time.
- F2: Feature 2 - arrivaltime.
- F3: Feature 3 - number of free luggage (0, 1 or 2).
- F4: Feature 4 - days left untildeparture.
- F5: Feature 5 - number of intermediatestops.
- F6: Feature 6 - holiday day (yes orno).
- F7: Feature 7 - overnight flight (yes orno).
- F8: Feature 8 - day ofweek.

The feature F4 indicates the number of days between the ticket purchase and the day of the flight.

In this study, the interest was focused on the prediction of a single airfare price without return. Forthesakeoftheexperimentsasetofflightstothe samedestination(fromThessalonikitoStuttgart)for the period between December and July, was collected. For each flight the eight features (F1:F8) were manually collected from the Web, 1814flights were recorded totally.

2. Model 3

In order to build the airline ticket price model at the market segment level, information about both the airline traffic and passenger volume for eachmarket segment is required. Therefore, two public datasets (DB1B and T-100) are used in our proposed framework. Data collected during 2018 are used to train and evaluate the proposed model. Table I summarizes the information of these two datasets. The United States Department of Transportation regularlyupdatesboththeDB1BandtheT-100.The DB1B dataset provides quarterly-aggregated information about the airline tickets in the United States from reporting carriers and consists of 10% randomly sampled ticket data from each reporting carrier. The information in DB1B is organized in three parts, namely “Coupon”, “Market”, and “Ticket. For our proposed framework, a subset of most related data are used, including the origin airport (ORIGIN), the destination airport (DEST), time of the itinerary (QUARTER), carrier information (REPORTING CARRIER), seat class (SEAT CLASS) (e.g., first, business, economic, etc.), total flight distance for a ticket (DISTANCE), airfare price (ITIN FARE), and the number of passengers in a ticket (PAX). Different fromDB1B, T-100 provides monthly domestic non-stopsegment data reported by both the domestic andinternational carriers.Itpresentsthenumberofpassengersofeach airline and each market segment by aircrafttype.

The selected features with their description which were chosen for this study are displayed in Table 2.

Entity	Availability	Data
Ticket	DB1B	fare price, total distance, and total number of passengers
Coupon	DB1B	market segment, time of theitinerary, carrier, and seatclass
Market Segment	DB1B&T-100	original airport, destination airport, and segment distance
Market Segment by carrier	T-100	number of passengers, and number of available seats by aircrafttype

Table 1 – Data entities and values

Feature Name	**Description**
Distance	Market distance between the origin and destination airports
Seat Class	Indicator for economy or premium seat type
Passenger Volume	Total number of passengers traveled between the origin and destination airports
Load Factor	The ratio of the total number of passengers to the total number of seats in a market
Competition Factor	The market HHI
LCC Presence	Indicator of LCC operating in the market
Crude Oil Price	Quarterly average of crude oil price
CPI	Quarterly average of Consumer Price Index
Quarter	Indicates the three-month period of the year

Table 2 – Feature Selection

III. MACHINE LEARNINGMODELS

1. Model 1

To develop the model for the flight pricepredictionmany conventional machine learning algorithms are evaluated. They are as follows: Linear regression, Decision tree [8], Random Forest Algorithm [9], K- Nearest neighbors [11], Multilayer Perceptron [10], Support Vector Machine (SVM) [12] and Gradient Boosting. All these models are implemented in the scikit learn. To evaluate the performance of this model, certain parameters are considered. They are as follows: R-squared value, Mean Absolute Error (MAE) and Mean Squared Error (MSE). The formulasforthesethreeparametersareasfollows:

$$R^2 = 1 - \frac{\sum_n^{t=1}(yi - \hat{yi})^2}{\sum_n^{t=1}(yi - \bar{yi})^2} \quad (1)$$

$$MAE = \frac{1}{n}\sum_{n}^{t=1}|yi - \hat{yi}| \quad (2)$$

$$MSE = \frac{1}{n}\sum_{n}^{t=1}(yi - \hat{yi})^2 \quad (3)$$

A. LinearRegression

Regression is a method of modeling a target valuebasedonpredictorsthatareindependent. Itismostlybasedonthenumberofindependent variables and the relationship between independent and dependent variables. Linear regression is a type of analysis where the numberofindependentvariablesisoneandthe relationship between the dependent and independent variables varylinearly.

$$y\ (pred) = b0 + b1 * x \quad (4)$$

A. Decision tree

The Decision tree calculation separates the informational collection into smallsubsets, at a similar same time it creates gradually. The entire informational collection is considered as the root initially. The characteristic qualities determine their dispersion. There are two primary characteristics in the decision tree calculation: Information Gain and Gina index. Information Gain is the proportion of change in entropy. Gina Index is a component that measures how frequently an arbitrarily picked component would be mistakenly distinguished. It implies a characteristic with a lower Gini index ought to beliked.

B. RandomForest

It is a supervised learning algorithm. The benefit of the random forest is, it very well may be utilized for both characterization and relapse issue which structure most of Current machine learning framework. Random forest forms numerous decision trees, what's more, adds them together to get an increasingly exact and stable expectationItisverysimpletodiscoverthe significance of each element on the expectation when contrasted with others in this calculation. [9]

C. K-NearestNeighbors

In regression techniques, the output obtainedisanaveragevalueofitsknearest neighbors. It is a non-parametric method like SVM. Using some values, the results are evaluated and the best performance value isobtained.

D. Multilayer perceptron(MLP)

It is the class of feed forward artificial neuralnetworks.Itincludestheinputlayer, output layer and the number of the hidden layers. The hidden layer gives the depth of the neural network. The setup includes 1 hidden layer, the number of neurons starts from 100 to 2000 with different intervals depending upon the required condition. To fire each neuron, it requires activation energy. The logistic sigmoid function is used as an activationfunction.

E. Gradientboosting

Itisanadditiveregressionmodelbyfitting simple function to current "pseudo" residuals sequentially by least-squares at eachiteration.ItusestheDecisiontreeasa basic estimator in scikit implementation. Starting from 10 to 1000 with the interval of 10 boosting stages are used with maximumnumbers

Thelossfunctionisanimportantparameter in the gradient boosting. It can be calculated with options: least squares regression, least absolute deviation, and quartile regression. The most important featureintheflightpricingpredictionisthe day is a holiday or not, the day is weekday or weekend and the difference between the days.

D. Support Vector Machine (SVM)

In the paper Support VectorMachine used as regression analysis that relays on kernel function considered as non-parametric technique [2]. The following kernels are used: Linear, Polynomial, Radial Basis Function [12]. As per the previous studies Random forest and the gradient boosting gives the maximum accuracy[11].

2. Model 2

Eight state of the art regression ML models [10], [12], [13], [14], [15] were selected for the current study and applied to the same data of flights. The MLmodelscomparedinthisworkarethefollowing:

- Multilayer Perceptron(MLP).
- Generalized Regression NeuralNetwork.
- Extreme Learning Machine(ELM).
- Random Forest RegressionTree.
- Regression Tree.
- Bagging RegressionTree.
- Regression SVM (Polynomial andLinear).
- Linear Regression (LR)

The 1814 flights collected in phase 2, were used in a 10-fold cross-validation procedure to train the aforementioned ML models. The performance indices used to compare the models are the prediction accuracy (% - MSE between the desired and predicted prices) and the time in seconds, needed to train each model.

IL Model	**onfiguration**
Multilayer Perceptron (MLP)	hidden layers 5 nodes each layer
Generalized Regression Neural Network	pread=1.0
Extreme Learning Machine	0 neurons
Random Forest Regression Tree	00 weak classifiers (decision trees)
Regression Tree	linParentSize=10 MinLeafSize=3 MaxNumSplits=45
Bagging Regression Tree	00 weak classifiers (decision trees)
Regression SVM (Polynomial)	rder=3
Regression SVM (Linear)	ochastic gradient descentsolver
Linear Regression	ual stochastic gradient descent solver

Table 3 – Models Configuration

3. Model 3

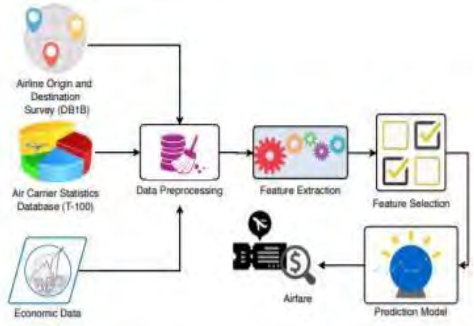


Fig 2 – Proposed Framework

For the experiments, samples of 16,577,497and 41,360,566 were collected from the 2018DB1B ticket table and coupon table, respectively. The T-100 dataset contains 329,426 samples. Several well-known machine learning models were tested as baselines to compare with theRF Model. In particular, LR, SVM, Multilayer Perceptron (MLPs), and XGBoost Tree were used for the evaluation.

For the SVM model, the radial basis function kernel is used, the tolerance for stopping criterion is set to 0.001, and the penalty parameter for the error term is set to 0.1. For the MLPs, three hidden layers are used with 30 neurons per layer. The Rectified Linear Unit (ReLU) is used as the activation function and Adam is the optimization function. The learning rate is set to 0.0001 with momentum enabled set to 0.9. For the XGBoost model, the number of estimators is set to 100 with a learning rate as 0.1, and max depth equals to 5. For the RF model, the number of estimators is also set to 100 with the minimum number of samples to split set to 2. To evaluate the proposed price prediction model, two popular metrics for regression analysis are used: the Root Mean Square Error (RMSE) and the Adjusted R Squared. RMSE calculates the differences between the observed values, y, and predicted values, y^. This difference for each data point is also called the residual. Thus, RMSE is calculated as follows:

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}$$

Where N is the total sample size. The lower the RMSE value is, the higher performance the regression model has. The Adjusted R Squared, (R2 adj), is usually used to explain how well the independent variables fit a curve or line. Adjusted R2 also adjusts for the number of variables in a model. The higher the Adjusted R Squared is, the better the result of regression is. It is calculated as follows:

$$R^2_{adj} = 1 - \left[\frac{(1-R^2)(N-1)}{N-p-1}\right]$$

where p is the number of predictors and R2 is:

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{N}(y_i - \bar{y})^2}$$

Here $\bar{y}$ is the mean value of y.

ML algorithms	R-squared	MAE	MSE
Random forest	0.67	0.08	0.04
Multilayer Perceptron	0.65	0.09	0.04
Gradient Boosting	0.47	0.13	0.06
Decision tree	0.45	0.09	0.06
K-nearest neighbour	0.38	0.14	0.07
SVM	0.19	0.15	0.08
AdaBoost	-0.12	0.21	0.11

Table 4 – Algorithm Evaluation

After evaluating the performance of the all machine learning models, further improvements were made usingacorrectpredictormodelforthebestresult.Two separated train models were developed by applying the trained datasets. Also the appropriate weights are assigned to them to get a better predictor model[16].

A. Stacked PredictionMode

The performance of machine learning models were evaluated critically. The study discovered that Random forest and Multilayer Perceptron, have better results compared to other models. Some weights are applied on the prediction results of these two models to get better prediction results.
This was a stacked predictionmodel.

B. Exhausted searchmethod:

This method found the optimal values for theta by running an exhausting search over a domain of finite interval from -n ton at the difference of a particular stepsize.

2. Model2

The influence of some critical features will be examined through a "one leave-out" rule. A 10- fold cross-validation procedure was applied to all the experiments and the mean performance of each model is presented in this section. The performance of all models for the case of the entire feature set (eight features) is presented in the table below, with the highest performed model being bold faced.

ML Model	**Accuracy(%)**	**Execution Time (sec)**
Multilayer Perceptron	80.28	20.88
Generalized Regression Neural Netwo	66.83	0.13
Extreme Learning Machine	68.68	0.05
Random For Regression T	85.91	5.50
Regression Tree	84.13	0.04
Bagging Regression Tree	**87.42**	17.05
Regression SVM (Polynomial)	77.00	1.23
Regression SVM (Linear)	49.40	0.34
Linear Regression	57.25	0.10

Table 5 – Results with all features

The following table highlights the changes inmodel when one leave-out rule was applied and some critical features were deliberately eliminated. The conclusive outcome on the model was as shown in thetable.

Feature Eliminated	Changes in Model	Conclusion
Departure and Arrival Time	Almost all models shown lower (up to 10%) prediction accuracy and greater execution time.	"departure time" and "arrival time" influence significantlythe Airfare prices.
"day of week"	all models were not affected as much as previously, except "Regression SVM" With Linear kernel.	"day of week" does not influence airfare prices
"overnight flight	The models perform similarly or even worse with the case of using all features. Only the "Multilayer Perceptron" and the "Regression SVM" with Linear Kernel seems to be affected significantly bythis Feature.	this feature is not related with the price of the air ticket,
holiday day	The "Bagging Regression Tree" outperforms all the models not only inthis experiment, but also all the modelsunder Different feature sets examinedpreviously.	The reminder models seem Not to be affected by the exclusion of "holiday day" feature.
number of intermediate stops	almost all models shown lower (up to 10%) prediction Accuracy and greater execution time.	Number of intermediate stopsinfluence Significantly the airfare prices.

Table 6 - Eliminated Features Conclusions

Concluding the previous study, one can claim that "Bagging Regression Tree", "Random Forest Regression Tree", "Regression Tree" and MLP modelsarethemoststablemodelsaccordingtotheir accuracy scores. In addition, as far as the execution time is concerned the best models are "Random Forest Regression Tree" and "Regressiontree".

3. Model 3

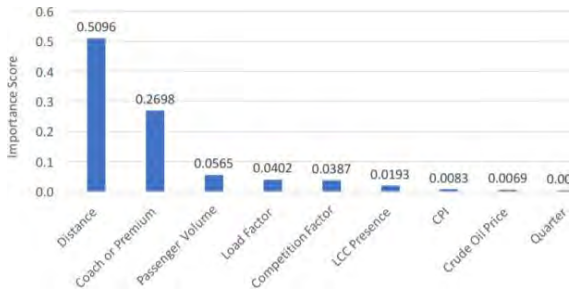

Figure 3_ - Importance of Feature generated by RF

In order to demonstrate the importance of each feature for airfare price prediction, the importance scores generated by the feature selection module were retrieved. The figure depicts the importance value for each feature. As shown in the figure, "Distance" and "Seat Class" (Economy or business) are the most important factors for airfare price estimation followed by "Passenger Volume", "Load factor", and "Competition Factor". Although the "CPI" and "Crude Oil Price" do not have very high importance scores, they can still help the model predict a more accurate estimation of the airfare price. However, based on the experiments, "Quarter" does not help the regressionmodel. Including the variable "Quarter" does not reduce the error during the training phase. Thus, it is automatically removed by the RF feature selection module.

The results comparing various regression models with feature selection and without feature selection areshowninthetable.Ascanbeseenfromthistable, LRandSVMhavethelowestperformancecompared to other ML methods with respect to the RMSE and R^2adjmetrics.Theperformanceofallofthemodels improves after applying feature selection, which illustrates the importance of this module. XGBoost performs better than MLP, SVM, and LR, but does not outperform RF for airfare price prediction. Therefore,weutilizeRFintheproposedframework, whichachievesthehighestperformancecomparedto other baselines for this dataset. Specifically, it reaches 62.753 and 0.869 RMSE and R^2 adj , respectively. In other words, it improves the R^2 adj by 40% compared to the LR model, which is extensively used in the previous studies for airfare pricepredictionAlthoughthelessimportantfactors may not contribute significantly to theperformance, theseresultsshowthattoachievethebestperforming model, one should include the "Load factor", "CompetitionFactor","CPI",and"CrudeOilPrice" as features. Consequently, the proposed framework utilizes all of these features to achieve the highest airfare price predictionperformance

Method	Without feature selection		With feature selection	
	RMSE	R^2 adj	RMSE	R^2 adj
LR	111.000	0.612	110.284	0.618
SVM	112.963	0.587	108.358	0.626
MLP	88.447	0.754	85.832	0.766
XGBoost	83.481	0.778	80.447	0.797
RF	66.584	0.858	62.753	0.869

Table 7 - Performance Comparison for different Regression Models with and without feature selection

V. CONCLUSION

This paper reported on a preliminary study in "airfare prices prediction". In the paper the overall survey for the dynamic price changes in the flight tickets is presented. The machine learning models which were reviewed in this paper utilized all different machine learning algorithms to be applied on different datasets as and where they were collected from.We observed that as the pricing models of the company are developedinordertomaximizetherevenuemanagement,the various features that influence the prices of the ticket are to beconsidered.Weobservedthatitisfeasibletopredictprices for flights based on historical data using machine learning. The experimental results show that ML models are a satisfactorytoolforpredictingairfareprices.Otherimportant factorsinairfarepredictionarethedatacollectionandfeature selectionfromwhichwedrewsomeusefulconclusions .From the experiments we concluded which features influence the airfare prediction at most. Apart from the features selected, there are other features that could improve the prediction accuracy.

Abstract. **Increasing on-chip integration with technology scaling in which more transistors are available on a chip than that can be simultaneously powered on will lead to the dark silicon era. Process variation gradu-ally impacts the performance (power, speed, frequency etc.) of system over its usage life. In this paper, by adapting the application allocation algorithm at the software layer, reduction of the impact of process varia-tion in multicore architecture is suggested and tested. Process variation causes core-to-core variations in power and frequency. To gain the maxi-mum performance within the power limits, best subset of cores should be selected from the available cores to run an application. When the power constraints are used as cost parameter, simulation of adaptive alloca-tion algorithm on sniper multicore simulator promises twice the better performance compared to conventional core allocation strategy.**

Keywords: Process Variations Dark Silicon E cient Application Mapping Sniper multicore simulator.

I. INTRODUCTION

Process variation [1] is naturally occurring variation in attributes of transistors, which results in measurable variance in the output performance and behavior of all circuit. We tried to execute processes in a way that it will choose cores based on its timing and maximum power constraints, which will be adaptive to the changes in the features of core like frequency. The basic idea here is to optimize the execution in such a way that the ine cient cores in the pool are turned o instead of the ones which are fast and which can give us better performance. This process of picking better cores out of available cores is called cherry picking [2].The focus of this paper is on exploiting process variations in dark silicon cores for performance improvement under a power budget so as to solve the problem of variation-aware core selection.

II. LITERATURE SURVEY

With the advancement of the technology, transistors are becoming faster and smaller, but transistor power consumption does not scales with the same level [3]. Due to supply voltage limits, power densities rapidly increase on the chip. So to prevent thermal emergencies ,a signi cant amount of on-chip resources needs to stay dark, This phenomenon is known in the literature as dark silicon [4, 5]

.Process variation and dark silicon are the most important factors impacting the performance of multicore systems in today's world.

2.1 Process variation

Mostly post-manufacturing tuning is used to reduce the impact of process vari-ation [6]. This conventional method often leads to system overdesign relative to their speci cation. Less leaky processing units are more energy e cient than their leakier counterparts at a given supply voltage and frequency. Algorithm suggested in this paper takes advantage of this observation, to shift the pro-cesses to execute on less leaky ones, maintaining performance while reducing total power consumption.

2.2 Cherry-picking: process variation aware core selection

Increased number of cores on a single chip led to dark silicon era, it refers to the amount of silicon that cannot be powered-on at the nominal operating volt-age for a given thermal design power (TDP) constraint. Certain cores of the system remain unpowered to avoid overheating. According to recent studies at 8 nm technology nodes, the amount of Dark Silicon may reach up to 50%-80% depending upon the processor architecture, cooling technology and application workloads. Some early work has been done in this eld which uses a heteroge-neous approach of using Hardware accelerators to get better performance out of the system [7]. When accounted for Process Variations, the approach becomes quite di cult.

III. PROPOSED WORK

An adaptive application allocation algorithm is proposed which can be used at any level of the core to application allocation. It uses two algorithms, one for estimation of execution cost and another for allocation of a particular core to a particular application so as to minimize the total cost of running these applica-tions. Input to these algorithms are application statistics, core frequencies and cost of running each application on di erent available cores. It rst gets the appli-cation statistics like maximum runtime allowed for each application to maintain the quality and minimum frequency requirements for each application. Minimum required frequency is stored as f_{min} for all i applications. It then estimates cost (here taken from sniper- runtime dynamics values) of using a particular core for a particular application based on estimation algorithm. Core frequencies are read and stored in f_{core} for all the j cores. It then checks whether a particular core can be used for a particular application by checking it against maximum runtime requirements. If it doesnt satisfy the constraints of the application then its cost is multiplied with a large value so that this particular core can never be used for this application. After all applications have been checked against all cores, it allocates a particular core to a particular application by using an allocation algorithm (Munkres allocation algorithm is used in this paper)[8]. It then displays the optimal mapping of each core with a certain application so that it results in a minimum cost. Pseudo code for estimation algorithm is as follows:

for i 1 to n do
for j 0 to n do

. for app
. for core
if (f_{min}[i] > f_{core}[j]) then
costmatrix[i][j] 1;
else
execute app[i] on core j.
Get execution time and cost
if execution time > timing constraint then
cost[i][j] 1 ;
else if power budget > max power constraint for chip then cost[i][j] 1 ;
else
update cost[i][j] to estimated cost value

Apply Allocation algorithm on cost matrix. Display output as one to one core allocation.

4 Adaptive Application Mapping Architecture

Fig.-1 shows the ow of data from one component to another in adaptive ap-plication allocation algorithm. Initially data was obtained from sniper using its test application FFT with di erent split radices. This data is stored in a text le and will be fed to two components namely allocator/manager and estima-tion engine. Estimation engine estimates minimum frequency requirements for each application and estimate the cost using previous cost values and actual cost which it gets from a component called Cores. It also saves the actual cost values in an array and text le. After estimating the cost, it scales it to an integer value which is then fed to allocator along with a minimum frequency requirements of each application. Allocator checks whether a particular core can be used for an application and if it cant be used then it multiplies the cost with a large number. It then uses an allocation algorithm (Munkres used in this case) which gives an optimal mapping i.e., a suitable core for each application which is fed to cores so that the mapped core can be used for the application it has been mapped with. Cores then output the actual cost values for the cores which are used for a particular value and send it to estimation engine so that these values can be used for estimation of costs in future.

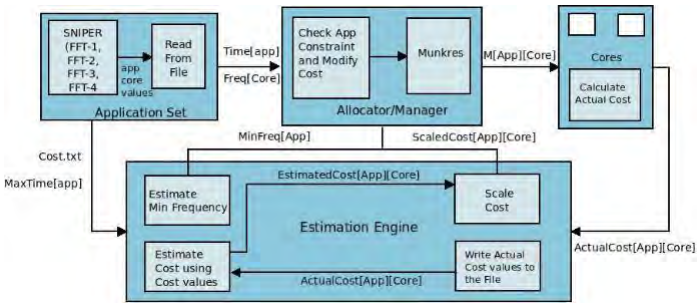

Fig. 1. Adaptive Application Mapping Architecture

IV. EXPERIMENTAL SETUP

A test application FFT of sniper simulator with di erent split radices are used as independent processes. Sniper is a parallel, high-speed multi-core simulator

[9]. These applications are compiled and then scheduled on di erent core fre-quencies like 2 GHz, 2.5 GHz, 3 Ghz and 3.66 GHz. The total execution time of an application to run on core, power leakage values and runtime dynamics are estimated with the help of McPAT framework [10] and stored in 2D cost matrix. This cost matrix is fed to allocation algorithm which gives an optimal mapping i.e., a suitable core for each application to

run. The timing analysis and the power analysis are manipulated which is shown in the Fig.2.

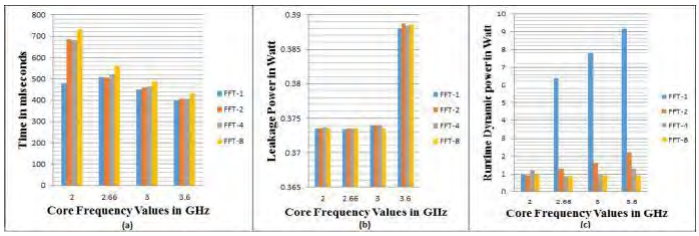

Fig. 2. (a) Total execution time for processes on di erent core frequencies (b) Leakage power values for processes on di erent core frequencies (c) Runtime Dynamic power values for processes on di erent core frequencies

Table 1. Cost matrix

Application	Core-1 (2 GHz)	Core-2 (2.66 GHz)	Core-3 (3 GHz)	Core-4 (3.66 GHz)
FFT-1	1.0035	6.36631	7.79809	9.1548
FFT-2	0.940722	1.31966	1.619870	2.1909
FFT-4	1.20623	0.916404	0.980522	1.2567
FFT-8	0.967971	0.898728	0.927073	3.9912

VII RESULTS AND ANALYSIS

This implementation is quite exible allowing the user to use di erent estimation parameters as per need. Here we have taken runtime dynamics as a parameter to estimate cost for running an application on a core. Table-2 given below contains di erent cost values when the input data, mentioned in section-5, was fed to adaptive allocation algorithm allocating cores in the manner given in the table and when same data fed to the simple allocation algorithm (if applications are randomly mapped on core available at that time).

Table 2. E ective cost by di erent method

Mapping of processes by Simple available core allocation method			Mapping of processes by Adaptive allocation method		
Application	Allocated Core	Cost	Application	Allocated Core	Cost
FFT-1	Core 1	7.294882	FFT-1	Core 1	4.506933
FFT-2	Core 2		FFT-2	Core 2	
FFT-4	Core 3		FFT-4	Core 3	
FFT-8	Core 4		FFT-8	Core 4	

Cost value taken by simple allocation is almost two times the value obtained when adaptive allocation algorithm is used. The results will be better if one of the highest costs is along the diagonal in the cost matrix because in that case simple allocation will take that cost. In some cases, simple allocation from available cores may result in lesser cost than the optimal mapping. This anomaly can be due to the fact that simple allocation overlooks the timing and frequency constraints of an application. Thus, if this algorithm is used then we can use the process exploitation to get better results and at the same time better cores can be used minimizing the overall cost of running a complete application.

V. CONCLUSIONS AND FUTURE WORK

Results of proposed work show that algorithm results in an optimum mapping of applications with given cores which helps us in achieving our goal of getting the overall minimum cost. This algorithm can be extended for dynamic cores which can operate in more than one frequency con gurations. This can also be used on a large scale once if it can be implemented on a chip level and thus can be used by wide variety of applications i.e. extending its scope from simple video coding to other applications which are a ected by process variation and dark silicon. Thus, if an application is able to select better core from a pool of available cores then it can e ectively reduce its running time and thus giving better results by consuming less power.

Abstract.**This paper proposes a solution on how to prevent fraud in current crowdfunding platforms using blockchain and smart contracts.Crowdfunding has some bad effects of an evil world. The main aim of this solution is to propose a solution that can reduce those effects. The key feature of Blockchain is that it maintains transparency among the nodes in the network. Blockchain-based smart contracts are contracts that can be partially or fully executed or enforced without human interaction. Since smart contracts are fundamentally conditional transfers of values, economic mechanisms designed in the game theory literature they can be implemented as smart contracts designed for crowdfunding websites where campaign managers can get approval based on their requirements. In this paper, we are proposing the methodology of how some key features of blockchain makes it efficient to implement crowdfunding.**

Keywords. Crowdfunding, Smart Contracts, Blockchain

I. INTRODUCTION

Crowdfunding is a method of raising capital through the collective effort of friends, family, customers, and individual investors. This approach taps into the collective efforts of a large pool of individuals—primarily online via social media and crowdfunding platform and leverage their networks for greater reach and exposure.

1.1 Benefits of Crowdfunding

From tapping into a wider investor pool to enjoying more flexible fundraising options, there are a number of benefits to crowdfunding over traditional methods. Here are just a few of the many possible advantages

Reach – By using a crowdfunding platform you have access to thousands of accredited investors who can see, interact with, and share your fundraising campaign.

Presentation – By creating a crowdfunding campaign, you go through the invaluable process of looking at your business from the top level—its history, traction, offerings, addressable market, value proposition, and more—and boiling it down into a polished, easily digestible package.

PR & Marketing – From launch to close, you can share and promote your campaign through social media, email newsletters, and other online marketing tactics. As you and other media outlets cover the progress of your fundraise, you can double down by steering traffic to your website and other company resources.

Validation of Concept – Presenting your concept or business to the masses affords an excellent opportunity to validate and refine your offering. As potential investors begin to express interest and ask questions, you'll quickly see if there's something missing that would make them more likely to buy in.

Efficiency – One of the best things about online crowdfunding is its ability to centralize and streamline your fundraising efforts. By building a single, comprehensive profile to which we can funnel all our prospects and potential investors, we eliminate the need to pursue each of them individually.

1.2 Problem Statement

"Nicole Carpenter"[7] have stated that current crowdsourcing platforms are at high risk by malicious campaign creators who may raise money in the name of a project and inappropriately misuse funds for their private use reason for the same,this is due to lack of transparency between investors and campaign managers.Our main aim is to create a platform which maintains transparency on how campaign manager will use the raised funds.Blockchain will help us to forecome the problem of transparency between investors and campaign manager.

Under the current structure, the ultimate amount raised for a crowdfunding campaign is almost never the actual amount raised. That's because middlemen clogg the funding pipeline, giving rise to the phenomenon of a middleman.Blockchain technology automated processes, from smart contracts to security features and more, do not call for additional fees, nor does the technology distinguish between these services. Ultimately, this provides the opportunity for the technology to be a cheaper, one-stop platform that could replace most, if not all, of the intermediaries

siphoning money from crowdfunding campaigns under the current structures.

"CJ Cornell" and "Charles Luzar" [9] have mentioned the possible frauds on crowdfunding platform "Backer Fraud" when backer submits campaign to withhold the funds or to claim the refund."Broker/Portal Fraud" where campaign operators themselves may engage in fraud, or enable fraud."Backer Creator Fraud" where creators contributed to their own campaigns either directly or through surrogates.

1.3 Objective

- Our main objective is to create a web based solution for crowdfunding using blockchain.So that it can be easily accessed by the end user.
- Identify the possible frauds, vulnerabilities of currently implemented crowdfunding solutions.
- Provide more secure solution to the user by preventing above specified frauds to occur.

1.4 Scope

Although there are many problems and frauds related to crowdfunding But our scope is limited to few major section of any crowdfunded project

- **Preempted Fraud**-In "Preempted Fraud," a suspicious crowdfunding campaign is shut down by the platform before any money changed hands. The policing is often done by members of the site (many who are just observers as opposed to contributors).
- **Attempted Fraud**-Attempted fraud could take place due to a campaign using IP that they did not own, or similar misrepresentations. While these deliberate attempts often are 'preempted' or 'stillborn', several campaigns have been launched that have used copyrighted IP or have disputable claims.
- **Perceived Fraud**-In these cases, accusations of fraud often come when the 'perks and rewards' are significantly delayed. Rewards-based crowdfunding has spawned a new category called 'pre-order' or 'pretail' crowdfunding – where backers get claim to an early version of the new product they are backing as a perk in exchange for contributing to the project.

II. REVIEW OF LITERATURE

2.1 Papers/Findings

1. **The paper titled "Exploring Blockchain for Alternative Finance" stated that[1]:**
   This paper was based on the variety of research on crowdfunding and its impact on society and economy.They created a work group to explore blockchain for alternative finance.Their main aim was to enable different target groups of the sector, namely crowdfunding platforms, investors, startups, SMEs, and policymakers to understand, deploy and support blockchain empowered use cases.The basis of their research were qualitative interviews with market and technology experts and SMEs, who were experienced in blockchain based products/services. Based on their outcomes, they complemented the practical perspectives from a research, legal and technological point of view.They did research keeping in mind - technical aspect,particality ,legal aspect.They stated that blockchain can be a solution to various security issues like confidentiality , fraud and trust.
2. **The paper titled Funding Community Projects with Smart Contracts on Blockchain[2] stated that :**

   The main aim of this paper was to demonstrate free riding problem in civic crowdfunding i.e people can still take advantage of projects without investing in it.This could be a reason for no investment in the campaign.Hence they suggested a way to implement incentive mechanism with cryptocurrency like Ether.They also stated that as blockchain is distributed the interaction between the agent and the smart contract will be guaranteed to be recorded in the blockchain.Since each agent in the blockchain is identified only by its public key, mechanisms deployed as smart contracts are vulnerable to Sybil attacks. And as Solidity programming language and the Ethereum execution environment are still in infancy, several work-arounds are needed to deal with floating points, buffer over/under flows, reentrant code etc.

3. **The paper titled "Equity Crowdfunding Based on the Blockchain? – A Delphi Study [3]" stated that :** The purpose of the study was to conclude that equity crowdfunding using blockchain has potential to close the gap faced by startups.They divided this study into two

parts first expert based delphi survey and ten market driving forces and checking how they influence the equity crowdfunding if

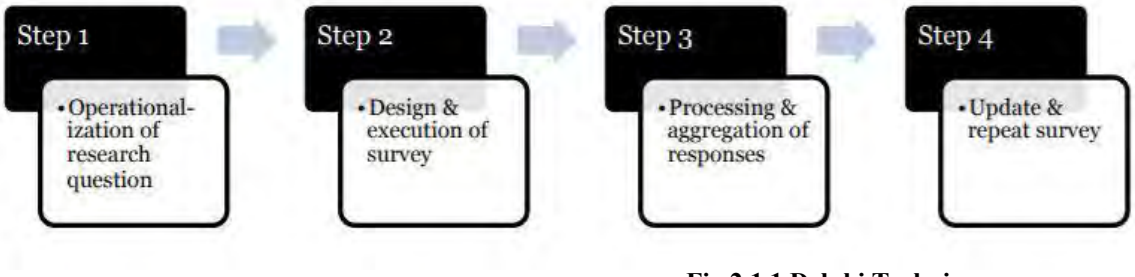

Fig 2.1.1 Delphi Technique

Fig 2.1.1 illustrates classic delphi techniques,which starts with operationalization of research question based on literature review and expert opinions that can be evaluated by further experts.Then, a survey is designed and executed with a pilot round beforehand. After conducting the first round, anonymous responses are processed and statistically aggregated for the next round. This controlled feedback allows experts to reassess their initial judgements. The whole process is repeated until a previously determined stopping criterion is reached.The result of study showed that out of 10 driving forces, 6 had positive influence on equity crowdfunding.And hence experts agreed that blockchain has positive influence on equity crowdfunding.

4. **The paper titled "Analysis and outlook of applications of blockchain technology to equity crowdfunding in China.[4]" stated that :**

This paper was specifically for crowdfunding in china.They reviewed different papers and already implemented applications to conclude if blockchain can be used in equity crowdfunding or not. They wanted to allow anyone with a good startup idea to create campaign.They stated that implementing the solution with blockchain will provide low barrier entry points,low cost and high speed transaction as compared to traditional application.Their main aim was to maintain transparency and fight money laundering.As the reward to the investor,they offer equity or bond like shares.They have also mentioned some problem that is faced in implementing equity crowdfunding "Registration of shares - the location of investors can be drastically different" , "Difficulty in confirmation of shareholder's rights "."Registration cost management- different location different cost". Blockchain for equity is still on paper,there are many technical and legal issues to be resolved.

5. **Whirl White paper "Inspiring a Whirlwind of Good[5]" stated that :**

This is a whitepaper on an application called WHIRL "Pay-it-forward" which an crowdfunding project based on blockchain.The most interesting aspect in their application is that whenever someone creates a campaign, they will get karma points depending on the amount you contribute. A person can create

campaign only when they have some karma points i.e they have contributed to some campaign.As there can be lots of campaign this application only focuses on limited campaign at a time combined with karma points.And their unique point is that they use different dozen of cryptocurrencies hence this project can be used globally.

They are tackling two problems first "Many campaign closes unfunded" and secondly backers loses interest when they don't get their rewards.To solve first they have limited campaign at a time and only people long listed on different cryptocurrencies can back a project.And they give karma points in reward.

6. **The paper titled "The Application of Blockchain Technology in Crowdfunding:**

Towards Financial Inclusion via Technology" [6] stated that :

This paper is on crowdfunding in Malaysia, which is the first country in south asia to implement it.They stated that "Crowdfunding is a practice of funding a project or venture by raising small amounts of money from a large number of people via the internet". According to paper crowdfunding can be a different financial source for startups ,entrepreneur .Blockchain could bring crowdfunding to the next level by providing not only data security but also efficiency and affordability.Building awareness is most important in crowdfunding.Creating roadshows,conferences are necessary in empowering underprivileged groups.They tried to create engagement with private sectors and also created shariah - complaint crowdfunding to encourage crowdfunding in muslim countries.

III. PROPOSED SOLUTION

Author "Conny Weber and Christin Friedrich"[1] and " Praphul Chandra, Amit Ranjan, Jaywardhan Sawale, Lakshmi Rajsekhar,Gaurang Singh, and Hrishi Wadki" [3] have concluded that the blockchain has good influence on crowdfunding and can be beneficial for society and economy of the country if implemented properly.We can conclude that providing incentives to the investor is a great aspect in crowdfunding. "Analysis and outlook of applications of blockchain technology to equity crowdfunding in China" [2] and "Inspiring a Whirlwind of Good " [5] have implemented different ways of providing incentives to the investor.But we find that giving ether as incentives will be more beneficial for investor than giving karma points."Aishath Muneeza,Nur Aishah Arshad,Asma' Tajul Arifin" [6] have stated how malaysia has implemented crowdfunding using blockchain ,how creating awareness about crowdfunding is important and that needs support of financial banks also.

An important aspect in crowdfunding is security and management of the money funded by the investors,hence we will be using Blockchain to maintain transparency between investor and campaign creator.The investors will have all the right to decide if the campaign creator can withdraw the money that have invested or not after threshold reached.

We are using ethereum as it is public blockchain network that allows anyone to get connected to the network.No node in ethereum will have special rights like in other type of network.Ethereum uses proof of Stake.While PoW depends on computing power to mine blocks, PoS depends on a node's stake (typically the amount of currency a user holds) in the system. The more stake a user controls, the more authority they have over validation.Hence this is more suitable for crowdfunding as it gives more priority to higher investors.

3.1 Methodology

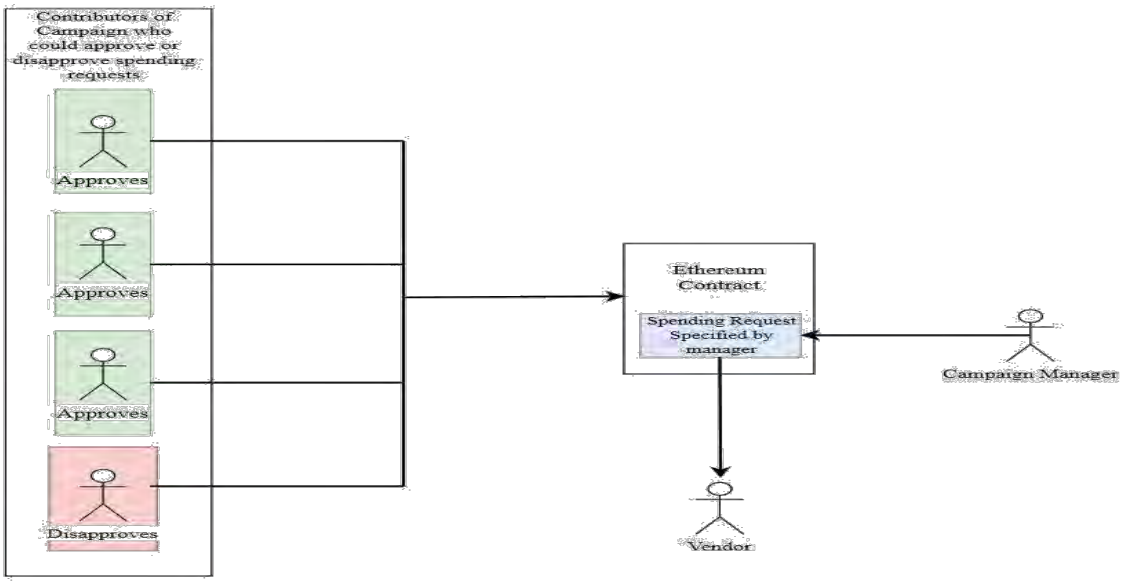

Fig 3.1.1:The Solution Architecture

Fig 3.1.1 illustrates that manager of the campaign will create a spending request on an Ethereum smart contract contributors will approve the spending request on platform.

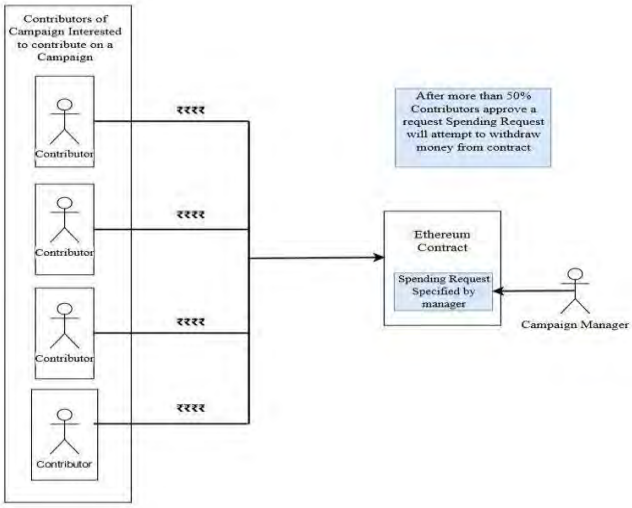

Fig 3.1.2: An Approval Module

In Fig 3.1.2 green color represents approval of backers as YES and red color as NO and depending on approval results the contributors will contribute accordingly. The money will be given to vendor and vendor will provide the requirements to campaign creators. Contributors in return will get some credits or offers as they contributed towards the campaign In this way campaign creators cannot fake their requirements and use it for their personal use This way campaign would be successful and technological world will be benefited from the innovations created by campaigns.

End User Diagram

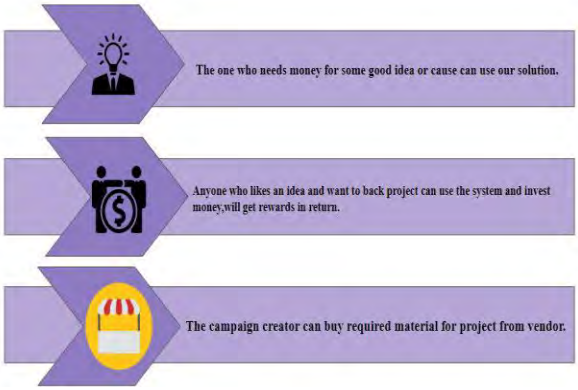

Fig: 3.1.3: Users of the system

Fig no 3.1.3 illustrates all the users of the application i.e campaign manager,investors and vendor.These have to be connected to the blockchain,to get connected they can register using application.

Use Case Diagram

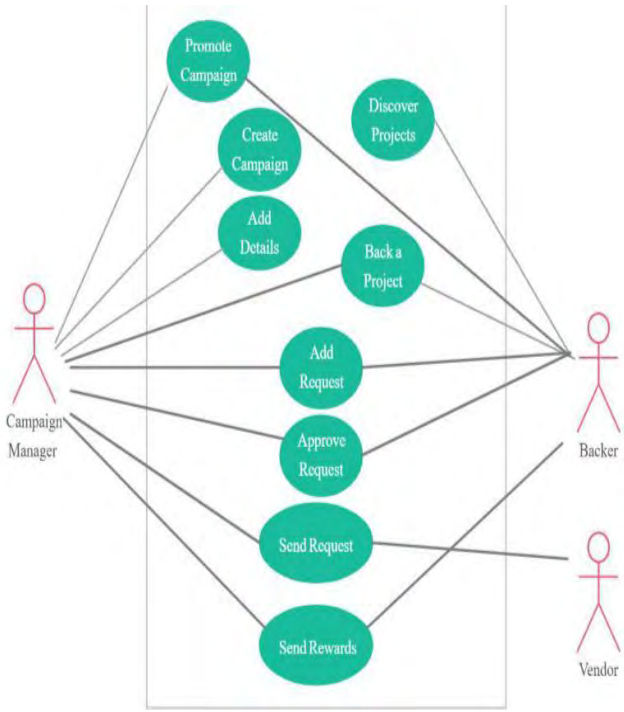

Fig 3.1.4 Use case diagram

Fig 3.1.4 shows the use case diagram of the application which illustrates the involvement of different end user in activities.Example for a campaign manager to add request there must be some investors.

IV. IMPLEMENTATION AND RESULTS

A web based application is developed for our solution and to handle block chain side of our application we have used solidity programming language, for end users to interact with our smart contract we have used React JS as our front end and to provide an interfacing between front end and block chain web.js is used as a translation layer.

4.1 Rinkeby

Rinkeby provides us with an Ethereum testnet it is used by developers to test their written smart contracts. Currency on Rinkeby testnet is valueless. Rinkeby uses Proof of Work. We have used Rinkeby test network to

make sure that all transactions are working in perfect manner when they will be deployed to an actual ethereum network, at that time there should not be a risk involved of users losing their cryptocurrency which possess an actual value.

4.2 MetaMask

MetaMask is a browser extension which enables us to run decentralized applications (dApps) without being part of the Ethereum network as a Ethereum node. Instead it connects to another ethereum node called Infura and run smart contracts on that node. MetaMask manages Ethereum wallet, which contains Ethers of a user, and allow us to send and receive through a decentralized application of interest.

4.3 Pages of application

These are some prototype design of our crowdfunding solution on blockchain, it contains a series of webpages that a normal end user will use to interact with an instance of a contract deployed on rinkeby test network.

Campaign Display page

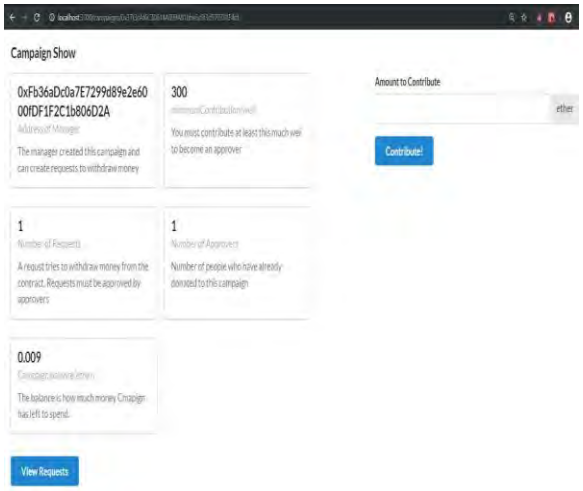

Fig: 4.3.1 View Campaign page

The new campaign has been added to the application and Fig 4.3.1 displays that campaign,on this page users can see what the campaign is about and various details about campaign like minimum contributions required, number of requests and number of approvers who have approved for this campaign. Users could also contribute to that campaign on this page. To view all requests that campaign manager has requested view requests button can be clicked.

Requests page

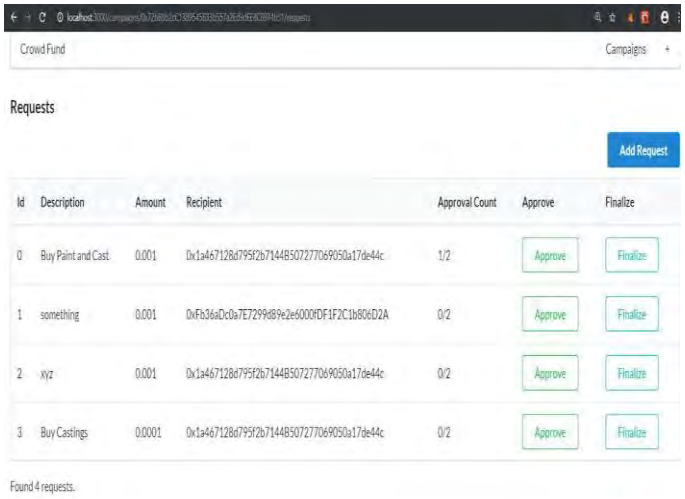

Fig: 4.3.2 View Requests page

Fig 4.3.2 shows how users could view all the requests created by campaign manager, also they can approve the particular request but only if they have contributed to that campaign that request can only be finalized by campaign manager only and only if percentage of requests to campaign contributors is greater than 50%.

4.4 Etherscan

Etherscan is a blockchain explorer for Ethereum and enables us to search the Ethereum blockchain for transactions, addresses, tokens, prices and other activities that take place on Ethereum or on Rinkeby test network. We are using Etherscan to confirm details of what is published on Rinkeby test network.

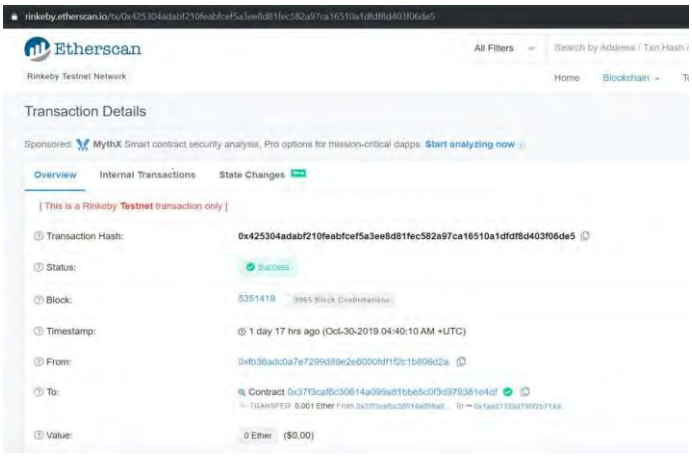

Fig 4.4.1 Details of a Transaction on Etherscan

Fig 4.4.1 shows transaction details on etherscan we can search details about any transaction by simply entering its hash no matter how old a transaction is we could verify that transaction on etherscan till we have its hash.Ether scan shows the following details:

- Status of a transaction weather it was successful or not.
- Block number of that transaction on Blockchain.
- Timestamp when it was mined, From whom this transaction was sent its Public address.
- To whom this transaction was intended to.
- Gas used for processing of this transaction.
- Nonce Position of the block in Blockchain.

All the above Transaction details ensures transparency as its publicly available and these details further cannot be modified.

V. CONCLUSION

The execution environment for Blockchain based Smart Contracts is the peer-to-peer network of thousands of geographically distributed nodes which maintain a copy of the blockchain (distributed ledger).In a blockchain each node/agent is identified by its public key, for testing environments Rinkeby network could be used to create demo users for a network, Ethereum and solidity programming has to be used for creation of smart contracts which will interact with our blockchain network.Later the application will be hosted on AWS EC2 and smart contract will be hosted on the main ethereum network, any person on the blockchain can access the application.The application will be beneficial for society, people will get single platform to showcase their innovative ideas,people who needs money in some crisis can also use this app.Donator can trust this solution as campaign creator won't be able to use money other than the cause.

Abstract. **Wireless Sensor Network is used in various application such as hospital, environment monitoring, experiments. It is also used in bat-tlefield for target tracking. If it is deployed in hostile environment in military application then nodes can be captured and data can be up-dated. WSN is equipped with low battery, storage and computational power. Hence, how to ensure the security of wireless sensor network un-der limited resources has become a key problem. This paper starts with application of WSN, summarizes security threats and analyses various key management and security schemes.**

Keywords: wireless sensor network security, issues, key management, pairwise key generation

I. INTRODUCTION

A wireless sensor network (WSN) is a group of spatially distributed autonomous devices i.e. sensors. It can be used to monitor physical or environmental con-ditions such as sound, temperature, vibration, pressure, motion or pollutants

[14]. Military application such as battlefield surveillance [12], is the main moti-vation for the development of wireless sensor networks. However, wireless sensor networks are now used in many application areas, including industrial process monitoring and control, machine health monitoring, environment and habitat monitoring, healthcare applications, traffic control, and home automation [3]. Wireless sensor networks have emerged as a dominant technology in the current decade. WSNs are becoming popular now a days because of its applications. Al-ready many companies have started developing commercial applications. At the same time they have posed numerous unique challenges to researchers. Wireless sensor networks are generally composed of hundreds or even thousands of tiny sensor nodes, which are constrained in many aspects like memory capacity, pro-cessing power and most importantly energy or battery power. Most of the time sensor nodes do not have access to renewable energy resources. The overall cost of a WSN is also required to be relatively lower. Moreover when we look at the applications of WSNs, there are many applications areas, e.g., battlefield aware-ness, traffic monitoring system etc in which security of information remains as an important issue. Providing security to a WSN is a non-trivial problem [26]. Security mechanisms which are applicable to wired or other ad-hoc networks are not suitable for WSNs [12]. There are many reasons behind it and we discuss those in the subsequent sections. There are many challenges in sensor networks. In this paper we focus on different security issues. Wireless sensor network ap-plications include wildlife monitoring, manufacturing machinery performance monitoring, building safety, earthquake monitoring, and military applications. A major benefit of these systems is that they perform in-network processing to reduce large streams of raw data into useful aggregated information. Protecting it all is critical. Because sensor networks pose unique challenges, traditional se-curity techniques used in traditional networks cannot be applied directly [18]. Several key challenges need to be addressed in wireless sensor network. First, to make sensor networks economically viable as sensor devices are equipped with limited energy, computation and communication capabilities. Second, sensors are often deployed in accessible areas where physical attack possibility increases. And third, sensor networks interact closely with their physical environments and with people, posing new security problems [15]. Hence, existing security schemes are inadequate, and new schemes/ideas are required for security. Here, we out-line security issues in WSNs, followed by schemes for sensor network security and suggest future work for research. We cover several important security challenges, including key establishment, secrecy and authentication.

1.1 WSN ARCHITECTURE

Layerd Architechture: A layered architecture shown in 1consist of a single powerful base station and sensor nodes layers around it correspond to the nodes that have the same hop-count to the BS. Layered architectures are used in-

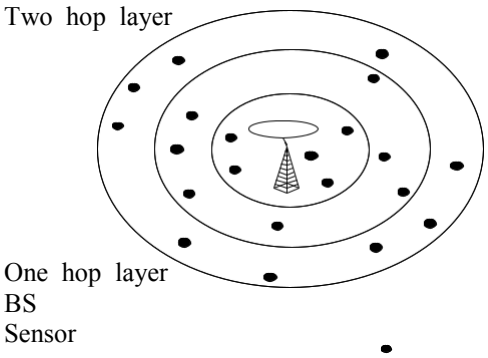

Fig. 1. Layered Architecture of WSN.

building wireless backbones. The advantage is that each node is involved only in short distance.

Clustered Architechture: Clustered architecture organizes the sensor nodes into clusters. As depicted in figure 2, each cluster is governed by a cluster-head. Nodes send data to cluster head and then only heads send messages to a Base Station. This is Suitable for data fusion and it is Self-organizing.

While analyzing security schemes we need to understand WSN limitations. Lim-

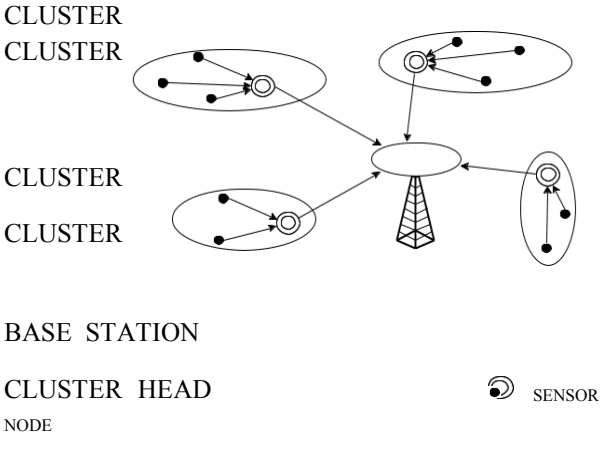

Fig. 2. Clustered Architecture of WSN.

itations of WSNs are as follows. Computational Power[3]: Symmetric and asym-metric cryptographic schemes are available for WSNs security but each schemes have their own advantages and limitation. Resilience of asymmetric schemes is good but it requires high computation and sensor nodes are equipped with very low computational power. At the same time it requires more power that symmet-ric schemes. High computations power drains battery of sensor node. Hence these issues need to be consider while proposing and implementing security mechanism for WSNs.

II. ISSUES/ATTACKES

In Wireless Sensor Networks hackers/intruders can gain access to data collected by nodes. They can get access remotely to nodes. Once they get access to node, attackers read/modify data depending on type of attack. In passive type of at-tack, attacker collects data and analysis characteristic of data flow. In active type of attacks, attackers modify data for his own benefit. Comparatively pas-sive type of attacks are difficult to detect but can be protected by encrypting the contents. Encryption protects data but because of limited resources, we need to be very careful while selecting and implementing encryption algorithms.

The term Security is mainly comprises of authentication, confidentiality and in-tegrity. Authentication allows a sensor node to ensure the identity of the peer node with which it is communicating. It rejects messages coming from attackers or any other send if they fail to prove identity. Confidentiality is making in-formation inaccessible to unauthorized user. Only authorize user can get access to data. In symmetric encryption techniques same key is used to encrypt and decrypt. Cipher text is transmitted to receiver and on receiving side cipher text will be decrypted by secret key. Integrity is used to check that the received data is not altered. Message contents can be modified by attackers. If node compro-mised then data integrity is violates [6]. In addition to this we should know one more term i.e. availability. It allows authorize user to access data from anywhere and anytime as per request. Below section focuses on key management, node capturing, and addition on new node in network.

III. ANALYSIS OF SECURITY SCHEMES

Key management schemes are the core of the secure communications. Config-uring a secure sensor network is a non-trivial task due to resource constrained sensors. As we have seen, existing key management schemes for the WSN are not able to achieve security and efficiency requirement. To address weakness of existing schemes and to achieve security and efficiency requirement we propose key establishment scheme based on pairwise key approach. Pairwise key concept assures highest resilience for WSNs. This chapter deals with key management and establishment schemes, in which we explain schemes in detail. Considering security, key management is very important and complex in wireless sensor net-work. Wireless Sensor Networks dynamic structure increase the difficulty of key management. Various key distribution schemes have been proposed to establish pairwise key between nodes in the literature. Each scheme has its weakness

and cannot simultaneously achieve both security and efficiency requirements of wire-less sensor network. This section deals with the work carried out on various key management schemes for WSNs.

3.1 Key-Management Scheme by Eschenauer and Gligor

In [21], key distribution consists of three phases, 1. Key pre-distribution, 2. Dis-covery of Shared key, and 3. establishment of Path key. The key pre-distribution phase [21] of this scheme consists of five off-line steps, after key pre-distribution phase every node has to discover shared key with its neighbors. During net-work initialization in the operational environment the shared-key discovery phase takes place, where every node discovers its neighbors in wireless communication range with which it shares keys. In path-key establishment phase path-key is assigned to selected pairs of sensor nodes in communication range. Since all the keys are randomly selected from the same key pool, it is quite possible that two neighboring nodes have some overlapped keys. If common key in two sensors identified, sensors can use it as their pairwise key directly. Otherwise, a path key establishment procedure is imitated which generates a path-key between the two communicating nodes under some other intermediate node's participation. This scheme addresses security issues but power consumption, computational speed have to consider for effective implementation.

3.2 Random Key Pre-distribution Schemes

Chan [20] proposed improved scheme based on [21]. This scheme is also known as q-composite scheme. Any two neighboring sensor nodes find a single common key from their key rings to establish a secure link in the key setup phase. [20] Proposes a modification to the basic scheme where q common keys ($q \geq 2$) are needed, instead of just one. By increasing the amount of key overlap required for key-setup, the resilience of the network against node capture increases. If the amount overlap of required key increases, it becomes exponentially harder for an attacker with a given key set to break a link. However, to preserve the given probability p (probability that two neighbor nodes can set up a secure link during the key-setup phase) of two nodes sharing sufficient keys to establish a secure link, it is necessary to reduce the size of the key pool | S |. When size of pool gets reduced then attacker will get access to gain a larger sample of S by breaking fewer nodes. These two factors results in an optimal amount of key overlap. High level of resilience against node capture can be achieved using the q-composite keys scheme when number of captured nodes are small. If large numbers of sensors nodes have been compromised, the q-composite keys schemes tend to reveal larger fractions of the network to the adversary. If q increased it becomes difficult for an adversary to obtain small amounts of initial information from the network if he able to capture small number of initial node. In other words, the adversary needs to capture more sensors in [20] than in [21] to crack the same fraction of communications between noncaptured nodes.

3.3 Enhanced Pairwise Key Establishment Scheme for WSN

In [21] and [20] the communication pairwise keys between sensors use the preloaded keys directly. Once some nodes are captured, the adversary may crack other nodes or even the entire network. In [21], [20] and [13] high resilience and full network connectivity cannot be achieved. Due to the heavy key storage overhead of each sensor, these schemes cannot be used for a large-scale WSN. To over-come these problems [18] proposed Enhanced pairwise key establishment scheme (called as pairwise key scheme), to achieve security and efficiency requirement of WSNs. In this scheme two type of keys, set up key and pairwise key are used. We have focused on unique pairwise key generation for WSN. If adversary captured a node and exposed pairwise keys then he cannot use captured keys to find keys of other nodes because pairwise key calculated by pair of node are not repeated and can be used by respective pair only. This technique provides highest resilience, full network connectivity and low communication overhead.

3.4 Scheme based on RSA & ECC

Faleh Alfaleh and other researchers have studied and compared two popular cryptographic schemes and found it useful as compared to other cryptosystems [6]. Among all asymmetric algorithms RSA is secure and reliable algorithm. In addition to this elliptic curve cryptography (ECC) algorithm can also be used. No doubt that RSA is more secure that ECC but considering resource constrained nature of WSNs and when we apply various evaluation criteria it is clear that ECC is suitable for WSNs. The computation cost, less memory, low bandwidth and running time of cryptographic operations must be managed to increase the efficiency of WSN.

3.5 Session Key Establishment Scheme

In WSNs gateway is used to access information collected by sensor nodes. For secure communication session key needs to be exchanged between communi-cating nodes. [7] Proposed key agreement scheme. To login in the system and establishes a secure connection with the sensor node via gateway node the user makes use of his biometric feature. It restrict the password guessing attack and forgery attack. Work is verified using BAN-logic to ensure the restriction of mu-tual authentication, and replay attack. In BAN-logic participating parties while communication undergo the verification of the transmitted message. An authen-ticated user and sensor agree upon shared session key. Agreement of key is done when scheme is executed and user is verified. With the adoptability of AVISPA, which is a suitable formal security method to prove this scheme resists all the security attributes. Results shows that, this scheme defends most of attacks and communication cost is average which needs to be improved.

3.6 Mixed Public and Secret-key Cryptography

Most of the researchers recommend symmetric cryptographic methods for mak-ing Wireless Sensor Networks secure. In WSNs, key management plays an impor-tant role in security. It has to be analyzed, verified, how the given security scheme affects security when we try to keep low battery consumption, low bandwidth and high computational speed. As per literature survey it has been observed that symmetric schemes are preferred but they are not optimal at every time. Asym-metric schemes are comparatively secure but reduce performance of nodes which affects whole network. As proposed in [2] symmetric and asymmetric methods can be used by for WSNs security. In this scheme MAC is used to generate digital signature. Evaluation shows that proposed scheme gives maximum connectivity, but only if the neighbor discovery phase is long enough. It also provides good resilience after initialization phase.

IV. ANALYSIS OF SCHEMES

This section gives the overview of various schemes proposed/implementated for Wireless Sensor Network Security. Schemes considered for security are mainly based on key management concept. Table 1 shows details of various schemes and impact.

Table 1. Comparison of WSNs schemes

Protocol/Scheme	Resilience	Remark
KM Scheme by Eschenauer and Gligor[21]	High	Scheme enables key revocation but power consumption need to be reviewed.
q-composite Scheme[20]	High	The q-composite keys scheme offers greater resilience against node capture when the number of nodes captured is small.
Enhanced Pairwise Key Establishment Scheme[18]	High	Communication overhead can be reduced to improve power consumption.
SKG Protocol[1]	Good	If base station compromised then network can be compromised
RSA & ECC[6]	High	ECC better that RSA. The computation cost, less memory, low bandwidth must be managed to in-

		crease the efficiency of WSN.
Session Key Establishment Scheme[7]	Good	Results shows that, this scheme defends most of at-tacks and communication cost is average which needs to be improved.
An Efficient Key Distribu-tion Mechanism[5]	High	Memory usage and communication overhead is high which have to be address in resource constrained WSNs.
Mixed Public and Secret-key Cryptography[2]	High	In this scheme MAC is used to generate digital sig-nature.
Energy-Efficient Key Man-agement Protocols[4]	High	Scheme is efficient only for low new node addition and authentication rate.

V. CONCLUSION

In this paper we have studied WSNs architecture, its advantages, application, challenges and few methods to implement WSNs effectively. While developing system for any field/area to address problem, resource constrained nature of WSNs need to be considered. Most challenging task to design application/system with low power, communication limitation and computational capability. Lim-ited battery and processing capability restricts researchers in making highly se-cure network. If we want to achieve higher level of security then such application may consume more power. Providing security in wireless sensor network is a non trivial task. Various schemes have been proposed in literature to address problem like security, effective utilization of power, speedy computation/processing with easy implementation. To make WSNs secure key management scheme must be simple and flexible. Most of the key management schemes are based on the ran-dom key pre-distribution concept. After analyzing schemes we can conclude that, each scheme has its weakness and can not simultaneously achieve both security and efficiency requirements of wireless sensor networks. Considering current ad-vances WSNs need schemes which will deliver desirable outcome.

Security Issues On Cloud Computing

Akram.H.Shaikh Research Scholar , B.B.Meshram Professor
Department of Computer Engineering and Information Technology
Veermata Jijabai Technological Institute, Matunga, Mumbai
ahshaikh_p18@ce.vjti.ac.in , bbmeshram@ce.vjti.ac.in

Cloud computing has now become a necessary enterprise architectural component irrespective of the company size. Cloud solutions like AWS by Amazon, Google cloud by Google, Azure by Microsoft, etc. are providing plans at very competitive rates, thereby making it easier for companies to deploy virtual machines of any size, any capacity and any kind of processing & security requirements. But generally, the architectural security layers are very generic and do not cater to the company specific security requirements. Cloud Computing Services like Software as a Service (SAAS), Platform as a Service (PAAS) and Infrastructure as a Service (IAAS) are delivery model which provides software, application platform and infrastructure recourses to consumer. While providing these services cloud computing is facing security and privacy issues there is need to find security issues

This Paper describe broad literature survey on cloud security issues, layer wise classification of each issues like threats, vulnerabilities and solutions present in literature

Keyword: Cloud Computing, SAAS, PAAS, IAAS, Vulnerabilities attack

I. INTRODUCTION

During the last decade, the internet has known a great invasion that has totally changed the world. This rapid evolution has made access to the Internet an easy task with the advent of different devices like cellular phones, laptops, tablets and others that connected to the virtual world anywhere and at any time. In other hand, multitenant architecture, virtualization, remote access, the ubiquity of broadband networks and the establishment of universal standards of interoperability between software's. All of these elements had been a good step for the emergence of cloud computing in the world of distributed systems as a successor of cloud computing.

However, with all of these benefits, there are still a number of barriers, that effect the widespread adoption of cloud computing, and the most important one is security. The cloud computing system is based on the trust, what makes security and confidentiality the major issues. These and other security issues whether on the technical or on the legal plan decrease the confidence of cloud computing and its adoption. In this paper covers an overview about security issues in cloud computing.

II. CLOUD COMPUTING MODEL

According to the National Institute of Standards and Technology (NIST), cloud computing is defined as a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. This cloud model promotes availability and it is composed of three service models, deployed in four deployment models, and offers five characteristics [1] as shown in Fig

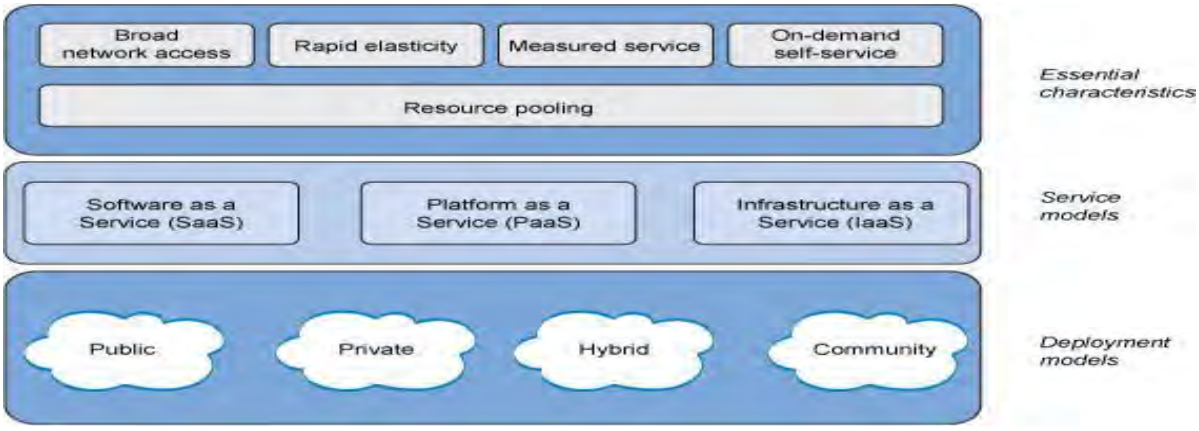

Fig: 2.1-Cloud computing services

2.1 Service Models

1] Software as a service (SaaS) The capability provided to the client is to utilize the supplier's applications running on a cloud foundation and open from different customer devices through a thin customer interface, for example, internet browser. in other words, in this model, a total application is offered to the client as a service on request.. A good example of this would be using a Web browser to view email as provided by Microsoft, Yahoo, or Google [1].

2] Platform as a service (PaaS) here the consumer can deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages and tools supported by the provider. The consumer does not manage or control the underlying cloud infrastructure including network, servers, operating systems, or storage, but has control over the deployed applications and possibly application hosting environment configurations [1].

3].Infrastructure as a service (IaaS) the consumer can provision processing, storage, networks, and other fundamental computing resources and he is able to deploy and run arbitrary software, which can operating systems and applications. The consumer does not manage or control the underlying cloud infrastructure, but has control over operating systems; storage, deployed applications, and possibly limited control of select networking components [1].

2.2. Deployment Models

1. Public: the cloud infrastructure is available to the public or a large industry group and, it is owned by an organization selling cloud services.

2. Private: the cloud infrastructure operated solely for an organization. It may be managed by the organization

3. Community: the cloud infrastructure is shared by several organizations and supports a specific community that has shared concerns. It is managed by organizations or a third party and may exist on premise or off premise.

4. Hybrid: the cloud infrastructure is a composition of two or more

2.3 Essential characteristics

1. On-demand self-service: A consumer can unilaterally provision computing capabilities, such as server time and network storage, as needed automatically.

2. Broad network access: all services in cloud computing are available through the network and accessed by different devices such as desktop computer, mobile phones, smart phones and tablet devices...

3. Resource pooling: the provider's computing resources are pooled to serve multiple consumers using a multi-tenant model, with different physical and virtual resources dynamically assigned and reassigned according to consumer demand.

4. Rapid elasticity: resources can be elastically provisioned and released. The user is free to purchase additional resources and opportunities in any quantity and at any time.

5. Measured service: Cloud systems automatically control and optimize resource use by leveraging a metering capability (pay-per-use basis) at some level of abstraction appropriate to the type of service (e.g., storage, processing, bandwidth, and active user accounts).

III. CLOUD SECURITY

3.1 Security Issues on SAAS , PAAS and IAAS

This Section discusses about Security issues on SAAS, PAAS, and IAAS

3.1.1 Software-as-a-Service (SaaS) Security Issues

SaaS provides application services on demand such as email, conferencing software, and business applications such as ERP, CRM, and SCM [3]. SaaS users have less control over security among the three fundamental delivery models in the cloud. The adoption of SaaS applications may raise some security concerns.

1. **Application security**

These applications are typically delivered via the Internet through a Web browser. However, flaws in web applications may create vulnerabilities for the SaaS applications. Attackers have been using the web to compromise user's computers and perform malicious activities such as steal sensitive data. [3]. The Open Web Application Security Project (OWASP) has identified the ten most critical web applications security threats [4]. There are more

security issues, but it is a good start for securing web applications.

2. Multi-tenancy

SaaS applications can be grouped into maturity models that are determined by the following characteristics: scalability, configurability via metadata, and multi-tenancy [3]. In multi-tenancy, a single instance serves all customers. This approach enables more efficient use of the resources but scalability is limited. Since data from multiple tenants is likely to be stored in the same database, the risk of data leakage between these tenants is high. Security policies are needed to ensure that customer's data are kept separate from other customers [2].

IV. DATA SECURITY

Information security is a typical worry for any innovation, yet it turns into a significant test when SaaS clients need to depend on their suppliers for legitimate security [2]. In SaaS, authoritative information is regularly prepared in plaintext and put away in the cloud. The SaaS supplier is the one liable for the security of the information while is being handled and put away [3]

V. ACCESSIBILITY

Getting to applications over the web by means of internet browser makes access from any system device, including open PC and cell phones. In any case, it likewise opens the support of extra security dangers. The Cloud Security Alliance [5] has discharged a report that portrays the present condition of versatile registering and the top dangers here, for example, data taking versatile malware, unreliable systems (WiFi), and vulnerabilities found in the network OS and authority applications, uncertain commercial centers, and nearness based hacking

3.1.2 Platform-as-a-Service (PaaS) Security Issues

PaaS facilitates deployment of cloud-based applications without the cost of buying and maintaining the underlying hardware and software layers [2]. Same as SaaS, PaaS also brings data security issues and other challenges that are described as follows:

1. Third-party relationships

Moreover, PaaS does not only offer conventional programming languages, but also does it offer third-party web services mechanism such as mashups. Mashups merge more than one source element into a single integrated unit. Thus, PaaS models also succeed to security issues related to mashups such as data and network security [2]. Also, PaaS users have to depend on both the security of web-hosted development tools and third-party services.

2. Underlying infrastructure security

In PaaS, developers do not usually have access to the underlying layers, so providers are responsible for securing the underlying infrastructure as well as the applications services [2]. Even when developers are in control of the security of their applications, they do not have the assurance that the development environment tools provided by a PaaS provider are secure.

3.1.3 Infrastructure-as-a-Service (IaaS) Security Issues

IaaS provides a group of resources such as servers, storage, networks, and other computing resources in the form of virtualized systems, which are accessed through the Internet [1]. Users are entitled to run any software with full control and management on the resources allocated to them. IaaS providers must undertake a substantial effort to secure their systems in order to minimize these threats that result from creation, communication, monitoring, modification, and mobility. Here is some of the security issues associated to IaaS.

1. Virtualization

Virtualization enables clients to make duplicate, share, relocate, and move back virtual machines, which may enable them to run an assortment of utilizations [1]. In any case, it likewise presents new open doors for assailants in view of the additional layer that must be verified [2]. Virtual machine security becomes as significant as physical machine security, and any defect in it is possible that one may influence the other. Virtualized situations are defenseless against a wide range of assaults for ordinary frameworks; be that as it may, security is a more noteworthy test as virtualization includes more purposes of section and more interconnection multifaceted nature. In contrast to physical servers, VMs have two limits: physical and virtual [7].

2. Virtual Machine Monitor

The Virtual Machine Monitor (VMM) or hypervisor is liable for virtual machines detachment; hence, if the

VMM is undermined, its virtual machines may conceivably be undermined too. The VMM is a low-level programming that controls and screens its virtual machines, so as any conventional programming it involves security defects [1].

3. Virtual Networks

System segments are shared by various inhabitants because of asset pooling. As referenced previously, sharing assets enables assailants to dispatch cross-occupant assaults. The most secure path is to snare each VM with its host by utilizing devoted physical channels. Nonetheless, most hypervisors utilize virtual systems to interface VMs to convey all the more legitimately and effectively. For example, most virtualization stages, for example, Xen give two different ways to arrange virtual systems: spanned and steered, yet these procedures increment the likelihood to play out certain assaults, for example, sniffing and parodying virtual system [2].

VI. VULNERABILITIES THREATS AND SOLUTIONS FOR CLOUD SECURITY

Table 1 Shows Vulnerabilities Threats and Solutions for the Respective layers of the cloud.

Table 1: Layer wise Threats Vulnerabilities and Solutions

S.N	Delivery Model	Threats	Vulnerabilities	Solution or Defense Mechanism
1	SAAS PASS IAAS	Account or service Hijacking	Insecure interfaces and APIs	1.Identity and Access Management Guidance [10] 2.Dynamic credential[11]
2	SAAS PASS IAAS	Data leakage	1.Data-related vulnerabilities 2.Vulnerabilities in Virtual Machines 3.Vulnerabilities in Virtual Machine Images 4.Vulnerabilities in Virtual Networks	FRS techniques [12] Digital Signatures [13] Encryption [14] Homomorphic encryption [14]
3	SAAS PASS IAAS	Denial of Service	1.Insecure interfaces and APIs 2.Unlimited allocation of resources	Cloud providers can force policies to offer limited computational Resources 1.Filtering tree 2. Trace-back and filter system
4	SAAS	Customer-data Manipulation	Insecure interfaces and APIs	Web application scanners [15]
5	IAAS	VM escape	Vulnerabilities in Hypervisors	HyperSafe [16] TCCP (Trusted Cloud Computing

				Platform) [17]
6	IAAS	Malicious VM creation	Vulnerabilities in Virtual Machine Images	Mirage [18]
7	IAAS	Insecure VM migration	Vulnerabilities in Virtual Machines	PALM [19] VNSS [20]
8	IAAS	Sniffing/Spoofing virtual networks	Vulnerabilities in Virtual Networks	Virtual network framework based on Xen network modes: "bridged" and "routed" [21]

4.1 Threats: Account or service hijacking

Due to Insecure interfaces and APIs vulnerability in SAAS, PAAS, IAAS Account or service Hijacking Attack is made, the possible solutions for which are 1.Identity and Access Management Guidance [10] 2.Dynamic credential [11] as detailed below.

A record theft can be performed by various ways, for example, social building and powerless accreditations. In the event that an aggressor accesses a client's qualification, he can perform noxious exercises, for example, get to delicate information, control information, and divert any exchange [8].

4.1.1 Vulnerabilities: Insecure interfaces and APIs

Cloud providers present services that can be used through APIs (. The security of the cloud depends upon the security of these interfaces [8]. Some problems are:

1. powerless accreditations
2. Insufficient authorization checks
3. Insufficient input-data validation

4.1.2 Countermeasures for Account or service hijacking

Below are the solutions of account or service hijacking

1. Identity and Access Management Guidance: Cloud Security Alliance (CSA) is a non-benefit association that advances the utilization of best practices so as to give security in cloud situations. CSA has given an Identity and Access Management Guidance [10] which gives a rundown of prescribed best rehearsed to guarantee personalities and secure access the executives. This report incorporates centralized directory, access management, identity management, role-based access control, user access certifications, privileged user and access management, separation of duties, and identity and access reporting.

2.Dynamic Credentials: [11] presents a algorithm to make dynamic accreditations for mobile cloud computing frameworks. The dynamic qualification changes its worth once a client changes its area or when he has traded a specific number of information parcels.

4.2. Threats: Data leakage

Due to Data-related vulnerabilities in Virtual Machines, Vulnerabilities in Virtual Machine Images Vulnerabilities in Virtual Networks on SAAS, PAAS, IAAS data leakage attack is made, the possible solutions for which are FRS techniques [12],Digital Signatures [13],Encryption [14],Homomorphic encryption [14]

Data leakage happens when the data gets into the wrong hands while it is being transferred, stored, audited or processed [8].

4.2.1Vulnerabilities

Here are some vulnerabilities in Data leakage

1. Unlimited allocation of resources-

Inaccurate modeling of resource usage can lead to overbooking or over-provisioning [2].

2. Data-related vulnerabilities:

Here in this Type of Vulnerabilities Data can be collocated with unknown owners, Incomplete data

cannot be completely removed, Data backup done by untrusted user

Data deduplication: a technique that stores only a copy of redundant data which may be not secured

3. Vulnerabilities in Virtual Machine Images

A. Uncontrolled placement of VM images in public repositories [7]

4. Vulnerabilities in Virtual Machines

1. Possible covert channels in the collocation of VMs
2. Unrestricted allocation and deallocation of resources with VMs [2]
3. Uncontrolled Migration - VMs can be migrated from one server to another server due to fault tolerance, load balance, or hardware maintenance
4. Uncontrolled snapshots – VMs can be copied in order to provide flexibility, which may lead to data leakage
5. Uncontrolled rollback could lead to reset vulnerabilities

4.2.2 Countermeasures for: Data Leakage

There are mainly three solutions for Data leakage attack which are listed below.

1. Fragmentation-redundancy-scattering (FRS) technique [12]: This method means to give interruption resilience and, in result, secure storage. This method comprises in first separating delicate information into irrelevant parts, so any piece doesn't have any noteworthy data independent from anyone else. At that point, pieces are dissipated in a repetitive style crosswise over various locales of the disseminated framework.

2. Digital Signatures: [13] proposes to verify information utilizing computerized signature with RSA calculation while information is being moved over the Internet. They guaranteed that RSA is the most conspicuous calculation, and it very well may be utilized to secure information in cloud situations

3. Homomorphic encryption: The three fundamental activities for cloud information are move, store, and procedure. Encryption strategies can be utilized to verify information while it is being moved all through the cloud or put away in the supplier's premises. Cloud suppliers need to unscramble figure information so as to process it, which raises protection concerns. In [14], they propose a technique dependent on the utilization of completely homomorphic encryption to the security of mists. Completely homomorphic encryption permits performing subjective calculation on figure writings without being unscrambled. Current homomorphic encryption plans bolster predetermined number of homomorphic tasks, for example, expansion and duplication.

4.3 Threat: Denial of Service

Due to the Vulnerabilities in insecure interface and APIs and unlimited resource allocation denial of service attack is made the possible solution for which is filtering tree and trace back filtering system

It is possible that a malicious user will take all the possible resources. Thus, the system cannot satisfy any request from other legitimate users due to resources being unavailable.

4.3.1 Vulnerabilities

Here are some Vulnerabilities of denial service

1. Insecure interfaces and APIs

Cloud providers offer services that can be accessed through APIs (SOAP, XML/JSON). The security of the cloud depends upon the security of these interfaces [16]. Some problems are:

A. Weak credential

B. Insufficient authorization checks

C. Insufficient input-data validation

2. Unlimited allocation of resources- Inaccurate modeling of resource usage can lead to overbooking or over-provisioning

4.3.2 Countermeasures for Threat: Denial of Service (Denial-of-Service Prevention Mechanisms)

There are two possible solutions which are filtering tree and trace back filtering system which are listed below

1. **A filtering tree** that goes about as an assistance intermediary inside a Service Oriented Architecture (SOA) model is displayed. The creators inspect the uncertainties in institutionalized cloud APIs and how these can be misused in provisioning, the board and checking of administrations. They propose adding a mark reference component to each SOAP solicitation to guarantee that it originates from a genuine source. Twofold marks are created utilizing hashed qualities of each SOAP envelope, for example, the quantity of youngster or header components. The customer IP address is kept in the message header alongside a riddle that is put away as a component of the WSDL record. The proposed framework needs to examine every bundle exclusively, which can prompt a bottleneck in DDoS circumstances.

2. **A trace-back and filter system is proposed** to protect the cloud from DDoS attacks. SOA trace-back is used by adding a tag to SOA packets to record the route taken. This system cannot identify the source of attack, because the tag is only added to the packet once it is relatively close to the server. The tests used in the paper do not consider spoofed IP addresses or the fact that an attacker is likely to make use of zombie machines

4.4 Threat: Customer Data Manipulation

Due to Data-related vulnerabilities in insecure interfaces and APIs on SAAS Customer Data Manipulation attack is made, the possible solutions for which are Web application scanners [15]

Users attack web applications by manipulating data sent from their application component to the server's application. For example, SQL injection, command injection, insecure direct object references, and cross-site scripting

4.4.1 Vulnerabilities

Vulnerabilities of Customer Data manipulation is Insecure interfaces and APIs

1 Insecure interfaces and APIs

Cloud providers present services that can be used through APIs

4.4.2 Countermeasures for Threat: Customer Data Manipulation

Here is the possible solution for customer data manipulation

1. **Web application scanners**: Web applications can be an easy target because they are exposed to the public including potential attackers. Web application scanners [15] is a program which scans web applications through the web front-end in order to identify security vulnerabilities. There are also other web application security tools such as web application firewall. Web application firewall routes all web traffic through the web application firewall which inspects specific threats.

4.5. Threat: VM Escape

Due to Data-related vulnerabilities in Vulnerabilities in Hypervisors on IAAS VM Escape attack is made, the possible solutions for which are Hyper Safe [16] TCCP (Trusted Cloud Computing Platform) [17]

It is designed to exploit the hypervisor in order to take control of the underlying infrastructure [1]

4.5.1 Vulnerabilities in Hypervisors

1. Complex hypervisor code [1]

2. Flexible configuration of VMs or hypervisors to meet organization needs can be exploited

4.5.2. Countermeasures for Threat: VM Escape

1. Hyper Safe [16]: It is a methodology that gives hypervisor control-stream trustworthiness. Hyper's Safe will probably ensure type hypervisors utilizing two procedures: non-by acceptable memory lockdown which shields compose shielded memory pages from being adjusted, and limited pointed ordering that changes over control information into pointer records. So as to assess the adequacy of this methodology, they have led four kinds of assaults, for example, adjust the hypervisor code, execute the infused code, alter the page table, and alter from an arrival table. They inferred that Hyper Safe effectively anticipated every one of these assaults, and that the presentation overhead is low.

2.**Trusted Cloud Computing Platform**: TCCP [17] enables suppliers to offer shut box execution conditions, and enables clients to decide whether nature is secure before propelling their VMs. The TCCP includes two basic components: a trusted virtual machine monitors (TVMM) and a trusted coordinator (TC). The TC deals with a lot of confided in hubs that run TVMMs, and it is kept up yet a confided in outsider. The TC partakes during the time

spent propelling or moving a VM, which confirms that a VM is running in a confided in stage.

4.6. Threat: Malicious Virtual Machine Creation

Due to Virtual Machine Images vulnerability on IAAS Malicious Virtual Machine Creation attack is made, the possible solutions for which is Mirage [18]

An attacker who creates a legitimate account can make a VM image containing malicious code such as a Trojan horse and store it in the provider storehouse [1].

4.6.1 Vulnerabilities in Virtual Machine Images

1.Uncontrolled placement of VM images in public repositories [7]

2. VM images are not able to be patched since they are dormant artifacts

4.6.2. Countermeasures for Malicious Virtual Machine Creation

1.Mirage: In [18], the authors suggest a virtual machine image management system in a cloud computing atmosphere. This technique includes security features: access control framework, image filters, a provenance tracking, and repository maintenance services.

4.7. Threats: Insecure Virtual Machine Migration

Due to vulnerabilities in Virtual Machine on IAAS Insecure Virtual Machine Migration attack is made, the

possible solutions for which are Protection Aegis for Live Migration of VMs [19] and VNSS [20]

Live migration of virtual machines exposes the contents of the VM state files to the network. An attacker can do the

following actions:

1. Access data illegally during migration [2]

2. Transfer a VM to an untrusted host [2] Create and migrate several VM causing disruptions or DoS

4.7.1 Vulnerabilities in Virtual Machines

Uncontrolled snapshots – VMs can be copied in order to provide flexibility, which may lead to data leakage

4.7.2 Countermeasures for Threat: Insecure Virtual Machine Migration

Here are the possible solutions for Insecure Virtual Machine Migration

1. Protection Aegis for Live Migration of VMs (PALM): [19] proposes a secure live migration framework that jam uprightness and security insurance during and after movement. The model of the framework was executed dependent on Xen and GNU Linux, and the consequences of the assessment demonstrated that this plan just includes slight personal time and relocation time because of encryption and unscrambling.

2.VNSS: [20] proposes a security framework that customizes security policies for each virtual machine, and it

provides continuous protection thorough virtual machine live migration. They implemented a prototype system

based on Xen hypervisors using stateful firewall technologies and user space tools such as ip tables, xm commands

program and conntrack-tools..

4.8. Threat: Sniffing/Spoofing virtual networks

Due to vulnerabilities in Virtual Networks on IAAS Sniffing/Spoofing virtual networks attack is made, the possible solutions for which is Virtual Network Security [21]

A malicious VM can listen to the virtual network or even use ARP spoofing to redirect packets from/to other VMs.

4.8.1 Vulnerabilities in Virtual Networks

Sharing of virtual bridges by several virtual machines [21]

4.8.2 Countermeasures for Threats: Sniffing/Spoofing virtual networks

Here is the list of possible solutions for Sniffing/Spoofing virtual networks

1. Virtual Network Security: Wu and et al [21] presents a virtual network framework that secures the communication among virtual machines. This system depends on Xen which offers two design modes for virtual systems: "spanned and directed" The virtual system model is made out of three layers: steering layers, firewall, and shared systems, which can counteract VMs from sniffing and caricaturing. An assessment of this methodology was not performed when this production was distributed.

VII. CONCLUSION

As described in the paper, however, there are exciting advantages and benefits of cloud computing, there are yet several security problems that reduce his adoption. Traditional methods of security cannot solve all kind of cloud environment security problems because it is a complex architecture composed of a combination of different technologies. Therefore, thinking about new security methods and policies to include in cloud architecture is a necessity today.

Signature Based Data Sharing Over the Cloud

Priti Rumao[1] , Mamta Meena[2] and Samidha Kurle[3]
[1,2,3] Computer Engineering Department,
Atharva College of Engineering, Malad West,
Mumbai- 400095, India

Abstract. **Cloud computing, which is subscription based service, mainly focuses on data sharing from any place, anywhere. So when data sharing amongst multiple participants come into the picture, it faces multiple issues associated with data integrity, efficiency and privacy of data owner. The ring signature is inspiring concept to model authenticate and anonymous data sharing system. The basic functionality of ring signature is to furnish signer's privacy and us-er's anonymity. Still the process of certificate verification remains a bottleneck which doesn't allow this system to be more scalable. Hence, the ID based ring signature can be used as alter-native solution for this. The concept of forward security has been added further to make ID based ring signature more secure, because even if a key has been compromised, all previously generated signatures remain valid. In this signature based data sharing over cloud system, for-ward secure ID-based ring signature is further enhanced by adding weil pairing: It keeps even shorter keys secure, it also requires less processing power and time. This property is essential to build large scale data sharing system. So here efficient and tangible application of this system has been provided.**

Keywords: Authentication, data sharing, cloud computing, forward security

I. INTRODUCTION

1.1 Overview

Recent trends in technology, generates huge amount of data. Cloud computing is flourishing technology with many characteristics, amongst which data storage and data sharing provides number of benefits to both i.e. individuals as well as society. Now-a-days cloud is mostly used for data storage and data sharing. Through cloud computing, huge number of participants gains large number of data. But many partic-ipants may lead to compromising data integrity, efficiency and privacy. So to over-come issues related to above mentioned key features, Rivest, Shamir and Tauman proposed a concept of ring signature[2]. But in case of ring signatures, need of certifi-cates validity verification and management was important, which leads to spending much more cost on it. The concept of Identity-Based (Id-Based) cryptosystem [3] introduced by Shamir to overcome certificates verification and management issues. In this, for each user the public key can be easily computed from data related to this user's publicly known identity. From its master secret for users, a private key genera-tor (PKG) then generates private keysfor users. This property avoids the need of certificates and accompanies an innate public key to each user within the system.Id-Based system, eliminates the need of certificates verification, hence saves communi-cation and computational cost.When combining ring signature with Id-based system, the outcome has much more advantages than certificates based ring signature system. In case of traditional certificate-based ring signature, verifier has to validate each and every certificate of the members (users) present in the ring. Once certificate validation is done, then verifier will verify message and user's signature. For Id-based ring sig-nature, entire certificate validation process is eliminated. Here verifier just has to verify identity of the user and message-signature pair of user. Since certificate valida-tion process has been eliminated, it saves hugely time and computation cost. This system is most beneficial to organizations having huge data and many more users. The first ever ID-based ring signature scheme was proposed in 2002 by Zhang and Kim [4]. Other proposed existing ID-based ring signature schemes include [5], [6], [7], [8], [9], [10], [11], [12].

For data sharing, more users can be added to ring. More members are added to provide more protection. But by increasing number of users, probability of key expo-sure also increases. So if one private key of the signer is compromised then all gener-ated signatures of that particular signer becomes valueless i.e. future signatures are no validated and previously issued signatures cannot be trusted. Hence when a key leak-age is acknowledged, key revocation mechanisms must be invoked immediately to prevent the generation of any signature using the compromised secret key. Still, this does not solve the problem of past signatures which has been forged.

Hence, to conserve the validity of past signatures even if current signature is com-promised, new concept of forward secure signature has been introduced by Anderson [13], and the solutions were developed by Bellare and Miner [14].The basic idea in-troduced by Bellare and Miner is: Total validity time (T) of public key is divided into smaller time

slots. Even if during current time slot a key is compromised, then for adversary it is difficult to find out previous or next keys. Huang et al. [1] combine Id-based ring signature with forward security to generate robust solution. In this, in case of ring signature, importance of forward security is highlighted and robust algorithm has been designed. It is first solid design of forward secure Id- based ring signature and under the standard RSA assumption, its security has been tested (proved) in ran-dom oracle model. Still it is always possible to reduce cost with respect to time con-sumption.

Andre Weil introduced the notion of weil pairing in 1940. This concept was mainly designed to attack elliptic curve cryptography (ECC) system [15].Sakai et al. [16] showed that weil pairing can be used for key exchange. Boneh et. al. [17] developed identity-based encryption scheme which has chosen cipher text security in the random oracle model, in which encryption is done by modified Elgamal and decryption is done by modified weil pairing computation.

So, to summarize, signature based data sharing over cloud makes use of advantages of all three techniques, namely, Id based ring signature, forward security and weil pairing to develop robust solution.

1.2 Contribution

In this paper, a new notion called signature based data sharing over cloud has been proposed, which proves its importance for building cost effective authentic and anon-ymous system to mainly save time consumption for data sharing system.

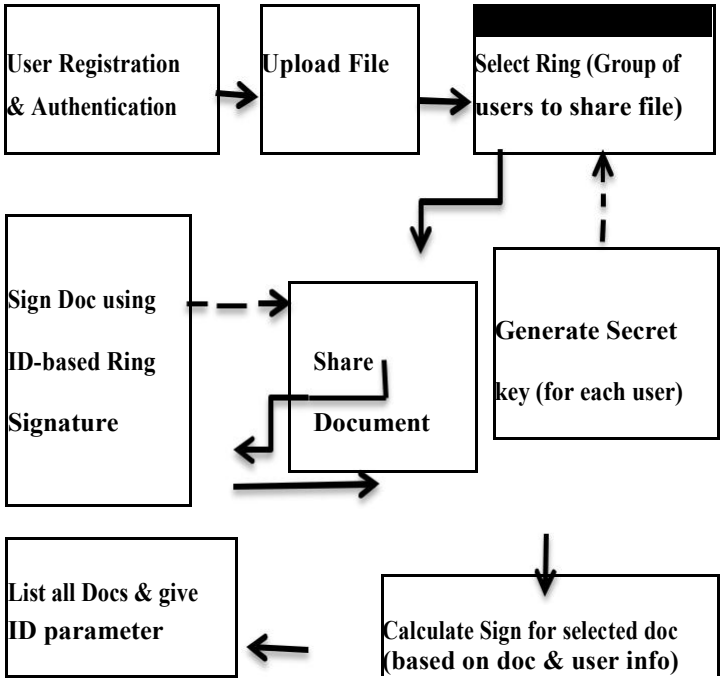
The system presents concrete solution for Id based ring signature with forward security and weil pairing to make it more robust.

Practical implementation of the system is possible:

- Since it uses Id based ring signature scheme, so cost of certificate validation has been removed.
- Secret key size is small. Key update process is easy but generates needed result.
- Use of weil pairing further reduces time consumption but enhances security process.

II. PROPOSED SYSTEM

Signature based data sharing over cloud architecture proposed an efficient data sharing system in cloud environment which supports data authentication and anonym-ity of signer. The workflow of proposed system is shown in figure 2.1. In this, basi-cally first data owner registers and authenticates users into the system. Currently sys-tem is single owner multi users system. Once registration and authentication is done, owner uploads file to the system. Once file has been uploaded to the system, owner selects group of users with whom, document (data) has to be shared and generate their secret key for the ring. While sharing the document, using id-based ring signature scheme, the document has been signed and shared. User will be able to see all the shared documents. While downloading the document, previously calculated signature and signature of selected document has been verified. Once signature verification is successful document will be downloaded.



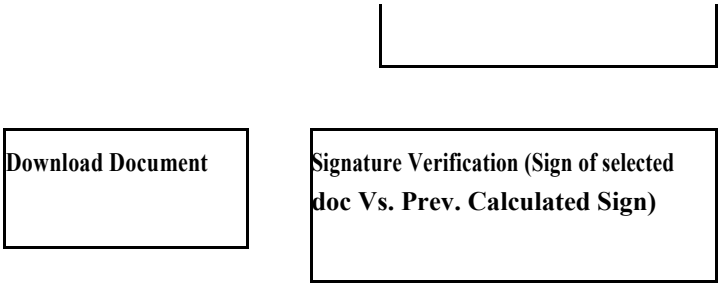


Fig 2.1: Proposed system of Signature based data sharing over cloud

The following steps show the workflow of the proposed system:

Step 1: User registers into the system: At this stage concept of forward security has been added. Here for public id i.e. Username total validity period of a year is as-signed. That entire year has been divided into time slots, during which secret key i.e. password of user will remain valid. One day prior to end of current time slot, system will request for change of password. At the end of the time slot unless and until pass-word has been changed, system won't allow users' login. At the end of the public key validity, user simply has to register and authenticate into the system. (Refer figure 2.2).

Fig 2.2: User Registration

Step 2: Data owner uploads file to be shared into the system (Refer figure 2.3).

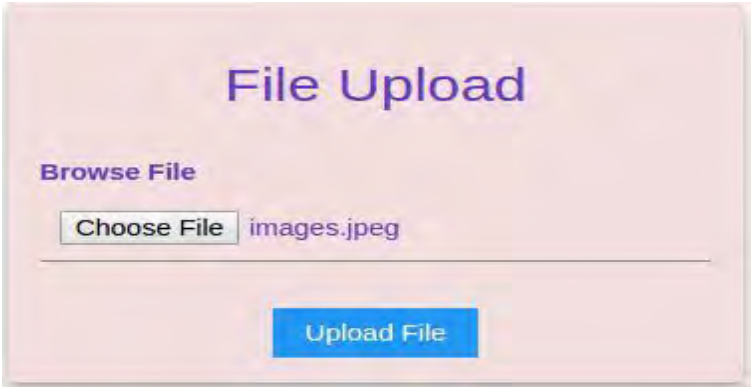

Fig 2.3: Upload File

Step 3: Data owner selects group of users (ring) to share selected file: Here using the concept of weil pairing ring (group) signature has been generated and to download the document, this signature with document and user's certain information has been send to selected users (Refer figure 2.4).

Fig 2.4: Users Selection to share data

Step 4: Data owner share documents amongst selected group of users: When doc-ument is shared, that time, based on all the keys of selected users and document in-formation, one signature for that document has been generated (Refer figure 2.5).7

Fig 2.5: File sharing done.

Step 5: All the shared document has been shared with all the users in list format (Refer figure 2.6).

Fig 2.6: Shared data

Step 6: To download the document, first based on the document and user infor-mation, signature has been generated and then signature of currently selected document and previously generated signature associated with that document has been compared.

Step 7: Once both the signatures are matched, then document will be downloaded for that particular user: Here only if signature is matched, then only user will be able to download the document or else user is not allowed to access that particular document (Refer figure 2.7).

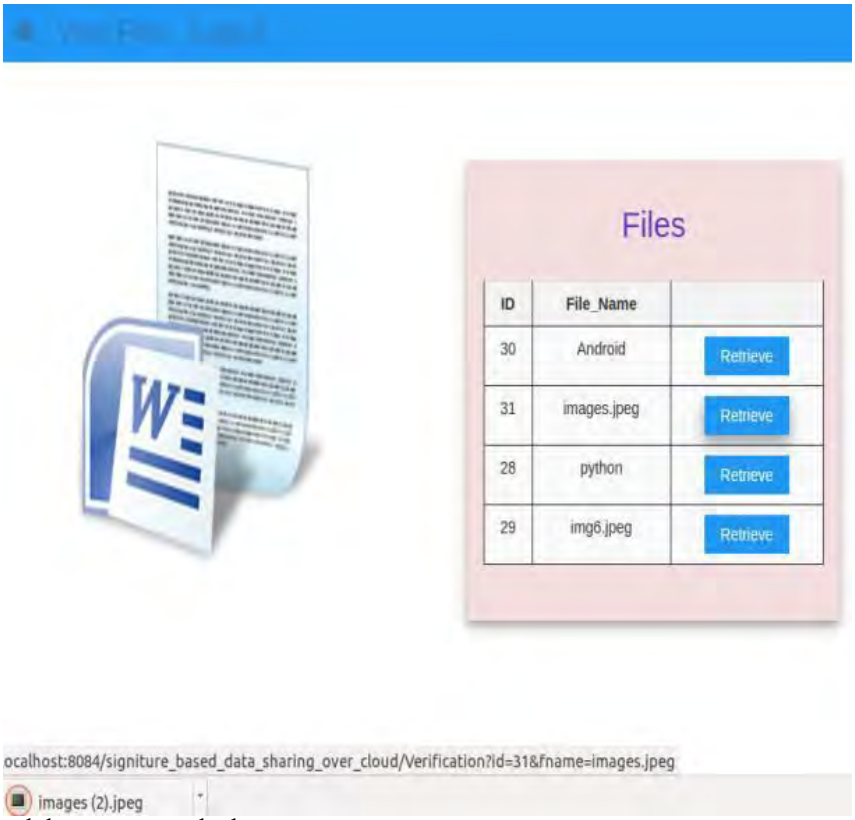

Fig 2.7: Download data once matched.

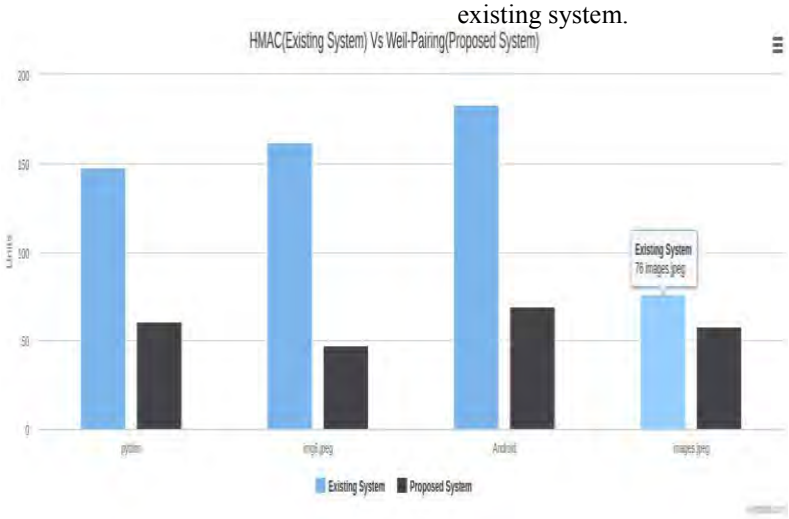
III. COMPARATIVE ANALYSIS

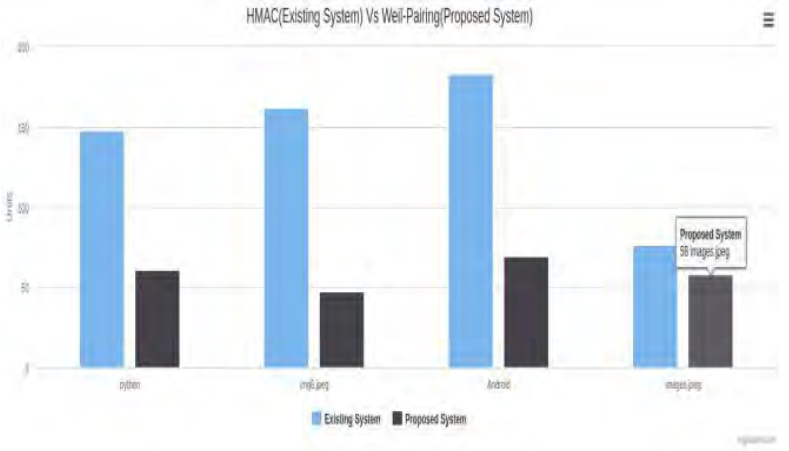
In this section, analysis of proposed system with respect to exiting system has been done. This analysis has been done on the basis of execution time parameter. The existing forward secure id- based ring signature system [1] is based on two different schemes namely, forward security and id- based ring

signature, whereas proposed system is combination of weil pairing, forward security and id- based ring signature. Proposed system supports and implements the concept of pairing, whereas existing system avoids pairing concept altogether.

The results, comparing existing system and proposed system has been shown in fig 3.1 (a) & (b). It can be seen that document retrieving time for existing system is high when compared with proposed system. So is can be said that proposed system provide cost efficient solution than the existing system.



(a)



(b)

Fig. 3.1 (a) (b): Graphical representation for time required to retrieve documents between existing and proposed system

IV. CONCLUSION

In this paper, to fulfill the ever growing need of data sharing, a new scheme called signature based data sharing over cloud has been proposed. It combines id- based ring signature with forward security and weil pairing. This scheme provides anonymity, authentication as well as reduce execution time parameter. With the help of weil pairing, proposed system becomes more efficient. This scheme will be very useful in many practical applications where authentication and user's anonymity plays an important role. The proposed scheme currently focuses on re-ducing execution time parameter. Providing more security features and still reducing cost re-garding time and space parameter will be the open problem and future research work.

Driver Activity Monitoring using MobileNets

Garima Tripathi, Deval Srivastav, Saim Shaikh, Priyank Shah
Dept. of Information Technology
Fr. Conceicao Rodrigues College of Engineering,
Mumbai,Maharashtra,India
garima@frcrce.ac.in

Abstract: **This paper presents a method to monitor the driver's activity and continuously look for red flags such as distracted driving, overuse of mobile phones while driving, drowsiness, sleeping. This is achieved by using a camera based system and the mobilenet neural network which has been trained on our self- made dataset.**

Keywords: Computer Vision, Machine Learning, Activity Monitoring, MobileNets, Image Processing.

I. Introduction

In our current world as driving technology continues to grow the driving effort required decreases. Our drivers become more and more careless resulting in loss of life in many circumstances. The proposed system aims to solve this problem by developing a system to monitor driver's activity and warn him when necessary. The method involves deploying a neural network trained on categories such as talking or texting on the phone talking to co passengers, operating the radio and drinking water. In our paper we have extensively tested performance of different neural networks[1] such as resnet-50[2] , inception[3] and also mobile nets[7]. Throughout the development our focus has been on how close we can get to real life conditions so our network will receive the images from an IR camera allowing our system to perform during night time. Our system can be easily fitted to any existing vehicle very easily and will be intuitive to use. The system will also be equipped with sensors to detect, rash driving and will consist of security features such as fencing, fingerprint authentication to prevent thieving of the vehicle.

In this domain lots of research has been done it can be concluded that the most popular vision methods include detecting driver inattention using head pose eye gaze estimation or simply checking eye closure rate. Measures such as EEG, electrocardiogram, etc. Our paper will discuss these methods and other techniques that have been used in the next section.

The paper has been organized in the following manner, the next section will discuss related work in the given domain in depth after which we will present our method of approaching this condition and finally we will discuss all the results we have obtained from the proposed system.

II. Literature Survey

According to the research conducted by us it can be concluded that the most popular methods to solve this problem involve either driver biological measures, driver physical measures, driving performance measures or some kind of a hybrid measure[3].

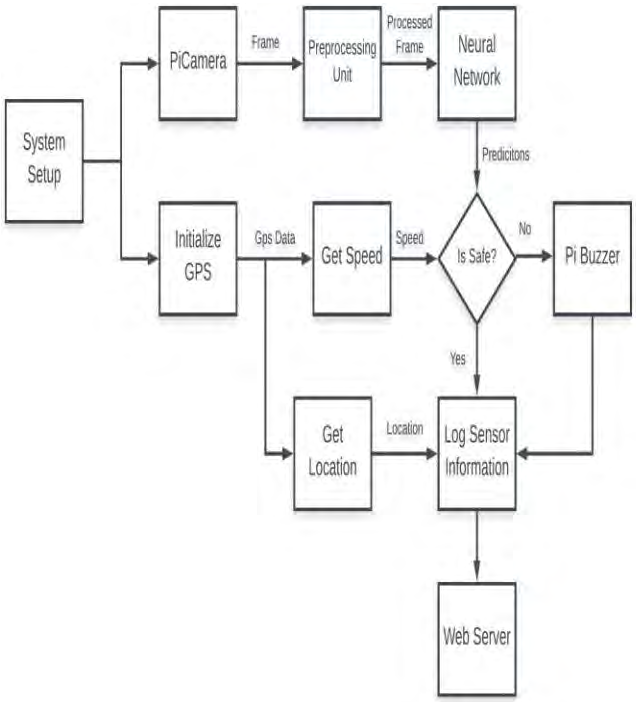
Driver biological measures include biological signals like EEG, electrocardiogram (ECG), electro-oculography (EOG). These signals are collected through electrodes in contact with the skin and then analysed for fatigue and drowsiness. Physical measures involve eye closure detection and blink frequency, face position, driver gaze to detect inattention.

Driver performance measures involve various measures such as steering angle and other driving criterion. Most research that has been done in the related field has been focused on detecting driver inattention using eye gaze tracking and head pose estimation. These methods rely only on head and eye movement to detect inattention whereas in real life a driver can be distracted doing various tasks that cannot be detected by head movement alone. It has been observed that current driver monitoring systems employ statistical machine learning methods to detect driver distraction and work on a limited dataset .Some Research has been done on applying deep learning technologies to solve this problem but such systems cannot be deployed in a vehicle in a cost effective manner nor do they work in night time conditions[4][5].

III. Proposed Method

Figure 1 describes the entire workflow of the project right from the hardware setup to the user interface. The Pi camera is mounted on an appropriate position in the dashboard of the vehicle. It is then connected to the camera port on the Raspberry Pi. The SM808 GSM +GPS module is connected to the Raspberry Pi via USB TO RS232 serial port. The GPS antenna is connected to the module and placed outside the

vehicle with a clear view of the sky Connect the Raspberry Pi to a portable power supply via the micro USB port. The Pi camera records footage and send the frames to the Preprocessing Unit .The footage is recorded at a resolution of 640*480 at 25 frames per second. For the night time footage the Pi Camera is aided by 2 IR bulbs which help provide clear frames even in pitch black conditions. The frames received from the Pi Camera are processed .The frames are first flipped



and then are resized to the size of 224*224 as the network takes an input of 224*224 images.

Fig.1: Implementation flowchart

TABLE 1
DATASET STATISTICS

Sr.no	Class	Count(day +night)
1.	Safe Driving	5000
2.	Talking on phone	5000
3.	Texting on phone	5000
4.	Drinking	5000
5.	Sleeping	5000
7.	Yawning	5000

A. Mobilenet

Mobilenet[7] is a neural network that was developed by google to perform on low powered devices lacking graphical GPUs that are known to accelerate neural network performance. MobileNets are small, low-latency, low-power models parameterized to meet the resource constraints of a variety of use cases, one of those use case devices can also be deploying it on a raspberry pi which we intend to do.

A standard convolution both filters and combines inputs into a new set of outputs in one step, but in a case of mobilenets it first uses depth wise convolution that applies a single filter to each input channel. The point wise convolution then applies a 1X1 convolution to combine the outputs the depth wise convolution. The depth wise separable convolution splits this into two layers, a separate layer for filtering and a separate layer for combining. This factorization has the effect of drastically reducing computation and model size, this modification allows mobilenet to be faster than its other counterparts.

For our application we have employed a mobilenet v2 , its the second iteration of mobilenets and now it along with the depth wise separable blocks it also uses bottleneck residual layers and also adds a 1 x 1 expansion whose purpose is to expand the number of channels in the data before it goes to the next block. In the proposed system we have used mobilenet v2 as its much more better than its older version, mobilenet was trained on a self made dataset of driver's performing distracted activities.

Fig. 2. Dataset samples for night

Fig. 3. Dataset samples for day

In the above pictures we can see the dataset samples from night and from day. The images are in order of Sleeping, Talking on the phone, Drinking, Texting, Yawning,

B. Training

This section will discuss how we trained our model on the above dataset. We have used transfer learning to

train our neural network as we have used model of mobilenet v2 and only trained the last few layers to get best results and quicker training times.

We used a 50%,20%, 30% split for training validation, testing respectively for our model. To further simulate real world conditions we added data augmentation to our model.This allows our model to perform better in difficult scenarios like low lighting wrong camera alignment etc. After experimenting and testing with a lot of different kind of augmentations we found the following augmentations gave us best results were random zoom that generates extra images that are zoomed in randomly upto 20%. In the same way we added random crop upto 20% and also random brightness for varied conditions. Augmentations effectively increases the size of our dataset and also makes sure the model works better in unknown conditions.

We trained our model on a computer with a 1070 ti.Our model was trained for 4000 steps which took 3hrs to validate accuracy of 95.6%.

IV. Results

In this section we will discuss about the results we have received after implementing the system. Our model received 95.6 percent accuracy in our validation test dataset and along with training mobilenets we also trained an inception v2 model and resenet-50 and vgg-16 model to compare the performance we received on the raspberry pi. These results are an average of all the 5 runs done on the same raspberry pi. Thus after looking at the results we can come at a conclusion that the mobilenet is the most ideal neural net model for our use case.

TABLE 2
Comparison of different models

Sr.no	Model name	CPU usage		FPS	Accuracy
1.	Inception V2	90%		1	98%
2.	Mobilenet V2	66%		6	95%
3.	Resnet-50	91%		2	97%
4.	VGG60	93%		1	96%

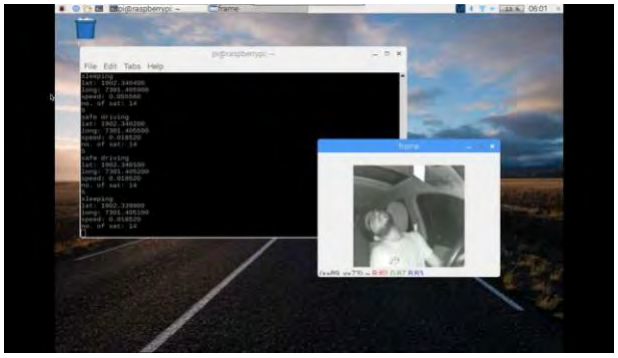


Fig. 4. Raspberry Pi screen

Although the model works as its intended to it was noticed by us that its very dependent on the driver who is driving and to remove that factor from the results we must record the dataset with a multitude of drivers.

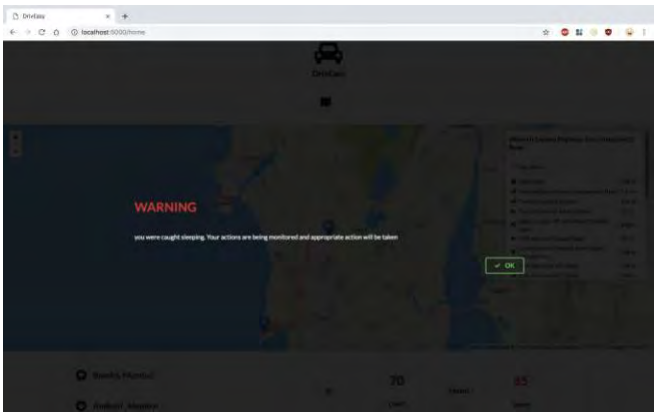

Fig.5 Web site screen for offense

V. Conclusion and Future Scope

On successful implementation the system will provide a robust and efficient method to monitor driver activities and thus prevent accidents that occur due to distracted driving, overuse of mobile phones while driving, texting on phone, drowsiness, sleeping etc. When such a system is in place it will enforce the drivers to be more careful and drive responsibly which will prevent loss of lives and will promote a safer driving experience for other drivers on the road

Once applied over a large number of vehicles the system can also be used to create a network of vehicles to share important information. In the future this network will be able to collect huge amounts of data and this data can be used to plan routes better. More over since we have deployed a hardware platform more and more features can be added in due time. Features such as facial recognition for authentication and various kinds of analysis can be done using the data of our platform. The algorithm in the proposed system relies on a neural network to detect driver's activity which performs well but an object detection approach can be used to detect specific distracting objects which will theoretically perform even better than standard neural net approaches.

Abstract.-**The Proxy Mobile IPv6 (PMIPv6) is a network-based mobility man-agement protocol which counts on MIPv6 signaling and reuse home agent's ac-tivity through a proxy mobility agent in a localized network. In any type of wireless communication, handover delay should be as less as possible. Tremendous work has been done to minimize the handover delay in PMIPv6 and many solutions have been proposed by the many researchers. Almost all of the solu-tions have one thing in common that the authentication information of the MN should be sent to new MAG in advance and to send information to new MAG, it is mandatory to anticipate the new MAG. This paper proposes an algorithm to predict new MAG and also provides the results achieved by simulating the pro-posed algorithm on NS-2.29.**

Keywords:- Pmipv6, Mobile node, AAA server, MAG

I. INTRODUCTION

In the current period of wireless technology, mobility is gaining popularity for enabling users to access resources while roaming. There are mainly two models which provide mobility by the use of mobile IP: Network Based Mobility Management & Host Based Mobility Management. In Network based mobility management, the func-tions related to mobility management reside only in network entities and it does not need involvement of MN in the signaling or management of their movement. That means, MN remains completely unaware of its mobility. On the other hand, active participation of MN is needed in host based mobility management. Therefore, an additional software stack should be installed in MN. Thus, host based mobility management requires updating current mobile node to fit into the network whereas there is no such requirement in network based mobility mangement. For this reason, InternetEngineering Task Force (IETF) has standardized Proxy Mobile IPv6 (PMIPv6) as the network based mobility management protocol.

In PMIPv6, the mobile node is privileged to roam within that localized network provided by the PMIPv6 domain. Thus, the network administrator may have overall knowledge-set of complete network, also the resources/assets are made gettable at every PoAs and their adjoining PoAs as well. In PMIPv6, there are three network entity which take care of functions related to mobility management: Local Mobility Anchor (LMA), Mobile Access Gateway (MAG) & Authentication, Authorization, and Accounting (AAA) Server. To use the network, MN needs to get registered to LMA and then MN can access network through MAG. While moving in the network, MN may get disconnected from current MAG and get connected to the new MAG. Each time, when MN gets connected to MAG, it verifies authentication of MN fom LMA which increases hand over delay significantly.To reduce hand over delay, many researchers have proposed that current MAG should send authentication information of MN to new MAG. This is possible when new MAG should be known to current MAG. This paper focuses on the implementa-tion of algorithm that predicts new MAG with the help of MN movement. This paper also presents results ach

PMIPv6 has three main entities: LMA, AAA server & MAG. The LMA maintains the information to reach MNs and all the packets sent to or sent from MN has to pass through LMA only. In PMIPv6, the function of mobile access gateway is to do the mobility management functions and it is installed in the link to which the MN gets attached. When MAG gets MN's router solicitation message in its area, MAG verifies MN's legitimacy using MN's policy profile which is maintained at AAA server.

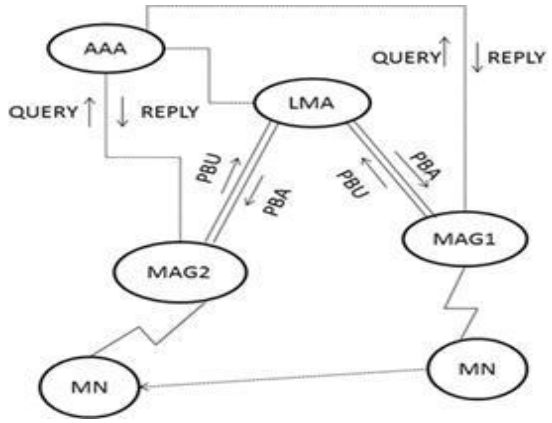

Fig. 1. Working of PMIPv

To use PMIPv6 network, MN first needs to get registered to LMA. Router solicita-tion message of MN is received by MAG. MN should include MN-ID in router solici-tation message. After receiving this message by MAG, to know LMA address, MAG uses Query Message to ask AAA server about the LMA address of MN.

When the QUERY message is received at AAA server, AAA server searches for the policy profile of the MN using MN-ID present in QUERY message. If the policy profile is not found at AAA server that means MN is not allowed to use network. If the policy profile is found at AAA server, AAA server needs to send the REPLY message carrying LMA address of MN to MAG.

When the REPLY message is received at MAG, MAG gets LMA address present in the REPLY message. After this MAG needs to create Proxy Binding Updates mes-sage and send it to the LMA to notify LMA about reachability state of MN.

When LMA receive PBU, it creates bi-directional tunnel between itself and MAG. After this, it creates message named Proxy Binding Acknowledgement which carries the MN's address prefix.

MAG sends Router Advertisement message after receiving PBA from LMA. When MN receives Router Advertisement message, it will be finally able to communicate in the network.

II. LITERATURE REVIEW

Academic and industries have done widespread research work to reduce Hand off delay in host based mobility management protocols and network based mobility man-agement protocol.

D.Johnson et al proposed MIPv6 which describes functioning of MIPv6. MIPv6 is host based mobility model in which each mobile node is always identified by its home address, regardless of its current point of attachment to the Internet [1]. Mobile IPv6 allows a MN to be connected to the Internet while travelling from one Access point to another, a process is called as handover. During handover, there is a time period when the MN cannot communicate to the internet due to various operations such as link switching, IP protocol tasks, movement detection, new Care of Address configuration, and Binding Update etc. Above mentioned handover delay as a result of typical Mo-bile IPv6 operations is mostly not tolerable to real-time traffic.

To reduce this handover delay R. Kodali et al. has proposed Fast Handover for Mobile IPv6. In this various factors are focused to reduce handover delay such as how to enable a MN to send packets as soon as it finds a new subnet link and how to deliv-er packets to a MN as soon as it becomes reachable [2].

H. Soliman et al also proposed Hierarchical Mobile IPv6 Mobility Management in which handover delay has been reduced in HPMIPv6 by introducing one more level in hierarchy and one more MIPv6 node called as Mobility Anchor Point [3].

Similarly, in network based mobility management, several works have been per-formed to minimize handover delay. V. Deverapalli et al. proposed a network based mobility management protocol namely "Proxy Mobile IPv6". Proxy Mobile IPv6 protocol is intended for providing network-based IP mobility management support to

a mobile node, which does not require the participation of the MN in IP mobility re-lated operations. Local Mobility Anchor (LMA) and the Mobile Access Gateway (MAG) are the core functional entities in the PMIPv6. In PMIPv6, AAA server can be used to store policy profile of MNs to keep track of genuine MN [5].

Ming-Chin Chuang et al. proposed FH-PMIPv6, defines predictive handoff mode in which the next MAG is informed about the handover information in advance. Both the phases authentication and registration are performed simultaneously to decrease handoff delay, in FHPMIP [9].

Ahmad Rasemy et al. have combined handoff with route optimization (O-PMIPv6) into their proposed protocol called Optimized Proxy MobileIPv6. Optimized signaling cost, network utilization and handover delay, the performance of PMIPv6 and F-PMIPv6 is improved by the proposed protocol [10].

Geumsan Jo et al. have proposed method in which an MN movement history is maintained at Local Mobility Anchor (LMA) and proposed method compares the current location of the MN with the prior location and using which anticipate the nMAG [12].

III. PROPOSED METHODOLOGY

As discussed earlier, to reduce handover delay in PMIPv6, many researchers have proposed that current MAG must send authentication information of MN to new MAG. Now, each MAG is surrounded by many other MAGs. It means that, current MAG should be able to predict the new MAG. Following is the algorithm proposed here to predict the new MAG.

In this work, the area around current MAG is divided into eight different parts. Once the MN is about to go out of coverage area of current MAG, the MAG will find out the current location of MN using GPS. Upon knowing current location of MN, MAG can find out the nearest MAG to the MN using following Haversian formula.

$a = \sin^2(\Delta\varphi/2) + \cos\varphi1 \cdot \cos\varphi2 \cdot \sin^2(\Delta\lambda/2)$

$c = 2 \cdot \text{atan2}(\sqrt{a}, \sqrt{(1-a)})$

$d = R \cdot c$

where φ is latitude, λ is longitude, R is earth's radius (mean radius = 6,371km);

Pseudo JavaScript Code :

```
var R = 6371000; // metres

var φ1 = latitude1.toRadians();

var φ2 = latitude2.toRadians();

var Δφ = (latitude2-latitude1).toRadians();

var Δλ = (longitude2-longitude1).toRadians();

var a = Math.sin(Δφ/2) * Math.sin(Δφ/2) +

Math.cos(φ1) * Math.cos(φ2) *

Math.sin(Δλ/2) * Math.sin(Δλ/2);

var c = 2 * Math.atan2(Math.sqrt(a), Math.sqrt(1-a));

var d = R * c;
```

As the proposed methodology has been simulated in the NS-2.29, following formu-la is used to find out distance between MAG and current location of MN.

$= \sqrt{(\ 1 -\ 2)2 + (\ 1 -\ 2)2}$

Where, (X1,Y1) and (X2,Y2) are locations of MN and MAGs respectively.

Following is the pseudo code for finding the nearest MAG to MN current location.

```
if(dist >threshold && mniflag==0)

{

for(i=0;i<n;i++)

{

dx=xpos-amxpos[i];

dy=ypos-amypos[i];

dxs=dx*dx;

dys=dy*dy;

dist=dxs+dys;

if(dist<min)

{

min=dist;

mini=i+2;

}

}

mniflag=1;

}
```

Where, dist is the distance of MN from current MN,

Threshold is used to decide whether MN is likely to leave coverage area or not, xpos is x coordinate of MN, amxpos is the array which contains the MAG addresse

5 RESULT & ANALYSIS

For simulation, one AAA server, one LMA, nine MAGs, one corresponding node (CN) & one MN are considered and CN needs to send data to MN.

Topology is simu-lated in such a way that MN will get connected to MAG which is surrounded by 8 other MAGs. When MN is about to get disconnected from current MAG, current MAG uses above proposed methodology to predict the next MAG. Table 1 shows the configuration of other necessary parameters for the simulation:

Simulation tool	NS-2.29
Simulation time	20sec
Number of LMAs	1
Number of MAGs	9

Table 1. Simulation Parameters

Packet size	1000 bytes
Routing protocol	PMIPv6 with AAA
Traffic type	CBR
Destination of MN	Each time, different destination is set

The correctness of proposed methodology is evaluated on the basis of predicted new MAG and actual new MAG. The TCL script is run again and again with new destination of MN so that each time, the new MAG for MN should be different. Each time, readings of predicted new MAG and actual new MAG are noted down. The readings, in which the predicted new MAG and actual new MAG are same, show that the prediction was correct whereas the readings, in which the predicted new MAG is not same as actual new MAG, show that the prediction was not correct. To evaluate the correctness of proposed methodology following formula was used.

Where, CPr is number of correct predication got and TPr is total number of predictions taken.

In all, total 500 times code was run with different destinations. Out of which 437 times the predications were correct and 63 times predictions were incorrect. So, ac-cording to the formula mentioned above, the percentage of correctness of proposed methodology is 84.7%.

Handoff delay also was observed for correct predictions and incorrect predictions. Handoff delay is nothing but the time difference between the time at which the MN got disconnected from current MAG and connected to new MAG. Following figure explains the handoff delay.

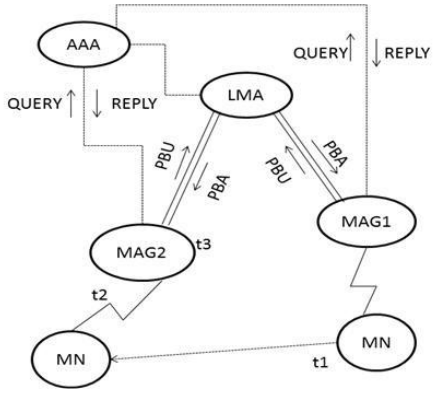

fig. 2. Handoff delay

In the above fig, t1 is the time at which MN got disconnected from current MAG (MAG1), at time t2, MN discovered the new MAG (MAG2). Though MN discovered

Situation	Handoff Delay
Without Prediction	8.044ms
Correct Prediction	**4.024ms**
Incorrect Predictions	8.044ms

new MAG, MN cannot use the network until new MAG receives PBA from LMA. At time t3, MAG2 receives PBA from LMA and at t3, MN now can use the network. So, handoff delay, in this case can be given as follows.

Handoff delay = t3-t1;

Following table shows the handoff delay observed in various situations.

Table 2. Handover Delay

The table shows that three scenarios were observed. First one, when prediction algorithm is not used, handoff delay found in this scenario is 8.044ms. Second scenario, when prediction algorithm is

used and predicted MAG was the same as of new MAG, in this scenario the handoff delay observed was 4.024ms (almost half of the previous case). In third scenario, the predicted MAG was not same as new MAG to which MN got connected. In this case also handoff delay observed was 8.044ms. Moreover, to find correctness of implemented algorithm, the code is run against 200 distinct desti-nation addresses and out of 200 runs, 184 times, the predicted address, found to be correct. This allowed us to conclude that the correctness of algorithm is 92%.

6.CONCLUSION

The PMIPv6 is one of the promising network based mobility management algo-rithm. However, the handover delay is the place where this algorithm can be opti-mized more and made more prominent. Many research works have been done in this field, to reduce handoff delay of PMIPv6. The back bone of reducing handoff delay is to send authentication information of MN to new MAG. This requires prediction of new MAG to which MN is going to connect. This paper proposed an algorithm to predict the new MAG and also presented the result achieved. It is observed that use of prediction algorithm leads to reduction in handoff delay to almost half. Moreover, to find correctness of prediction algorithm, the algorithm is run 200 times with distinct destination addresses of MN. The correctness of algorithm is found to be 92%.

umraans@gmail.com,deepali.vora@vit.edu.in,anuragabhishek@gmail.com

Abstract — **Facial recognition system is used widely to identify and verify the person's face from image or video source. With the continuous expansion of the surveillance system, surveillance cameras not only bring convenience, but also produce a massive amount of monitoring data, which poses huge challenges to storage, analytics and retrieval. The smart monitoring system equipped with intelligent video analytics technology can monitor as well as pre-alarm abnormal events or behaviors. Here, propose system will detect the intruder and inform the security within seconds. The NVIDIA Jetson Nano board will be used to compute Convolutional Neural Network algorithm for the facial recognition process. The basic idea will be to use this system where a database can be stored of the existing faces. The system will then take the data from the surveillance camera and run facial recognition algorithm on it. It will match all the faces with the ones already stored in the database and if it finds any face which is new, it will send an alert to the security personnel. This will help to increase the security of the place where there are many people gathered at a time for example schools, colleges, universities, etc.**

Keywords—Facial Recognition, Biometric, NVIDIA Jetson Nano, Surveillance

I. INTRODUCTION

Traditional video surveillance can only provide simple functions such as video capture and storage. It cannot automatically alarm for any intruders. In order to find any intrusion in real time, monitor personnel need to constantly observe the video. In this case, the monitor faces dozens of surveillance video images, which is easy to fatigue. It may not be able to respond in time to intrusion due to lack of concentration, and loose key information in the video. [1]
In addition, because a large amount of surveillance data, video needs to be stored for months or years, it will result in a large storage cost. Therefore, the intelligent video surveillance system is urgently needed to assist the monitoring personnel to use the intelligent detection technology to process, analyze and understand the video signal while retaining the original video key information, andautomatically detect the target and location information without manual intervention. [1]
In the event of an intruder, an alarm is issued in time to effectively assist the monitoring personnel. The traditional moving target detection method can only detect frames with moving targets, but cannot understand the semantic content in the video. With the development of deep learning, advanced target detection, semantic understanding, and instance segmentation techniques are emerging, which realizes the semantic understanding of video content and improves the accuracy. In recent years, with the advancement of video analysis technology, intelligent video surveillance systems have developed rapidly, and a large number of representative technical achievements and applications have emerged. [2] With the help of embedded video analysis algorithms, the intelligent surveillance camera can identify the abnormal behavior of the monitoring site without manual intervention. Typical anomalous behaviors include entering and leaving an area, moving quickly, gathering, and so on.
The Intelligent Video Analytics Model (IVAM) also known as Human Object Detection Model will be used. The block diagram below shows how the model process flows.

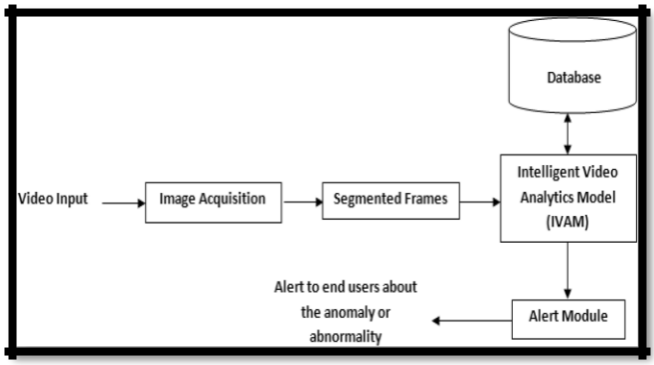

Fig 1 (IVAM Block Diagram)

Fig. 1.1 shows the model for proposed surveillance system. The basic flows runs as, first the data is fed as video input. From the video input the image will be acquired and each frame will be segmented. The IVAM will be applied on the segmented frames. In this step the feature extraction will be done. The data from the database will be matched to the output from IVAM. If it doesn't match then the alert will be triggered to notify the security personnel. Once the intruder is detected the image of the intruder will be snapshot along with the timeframe and will be saved in the database as evidence. [3]

II. LITERATURE SURVEY

Video monitoring and analysis for facial recognition problem has been studied by many researchers and different techniques/ approaches have been suggested in the Table 1.

III. PROPOSED SYSTEM

To address the above issues in facial recognition, we propose a better surveillance system using NVIDIA Jetson Nano instead of Raspberry Pi. Jetson Nano have much higher AI performance than Raspberry Pi. It has higher RAM and GPU which provides faster results compared to the Raspberry Pi. Jetson Nano board runs multiple neural networks simultaneously hence it provides accurate results

in much less time. The proposed system will be a much better surveillance system which will run on the Jetson Nano. The proposed system will be evaluated on the basis of efficiency, accuracy and runtime. The OpenCV library will be used on the Jetson Nano to run the system. Fig. 2 shows the process flow for the facial recognition system. The video input will be fed to system.

Face Detection: First the system will detect all the faces from the video feed. Here the Multi Task CNN algorithm will be used. This algorithm runs 3 neural networks. The first network will detect the face by scaling the image to a particular size. Jetson Nano supports DeepStream SDK and samples. These will be help in face detection.

Face Alignment: The second neural network will align the face and add a padding to the faces which are partially outside the screen/ bounding box. The third network will provide the final result i.e. the aligned face.

Feature Extraction: FastICA algorithm to be used. It will add the geometric feature to the face for independent component analysis.

Feature Matching: Again the Multi Task CNN algorithm will be used to match the features with the existing ones in the database.

Results: Finally, if the features doesn't match then the alarm is triggered to the security.

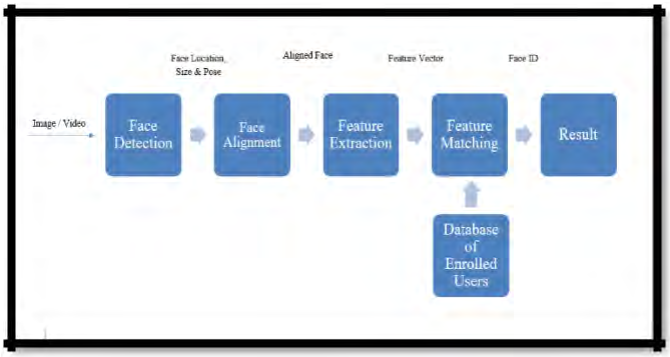

Fig 2 (Block Diagram of Proposed System)

The proposed system uses Jetson Nano board by Nvidia which will provide better performance as compared to the traditional Raspberry Pi boards. Following table shows the comparative study between the Jetson Nano board and Raspberry Pi board based on 13 parameters.

Table 2 shows that Jetson Nano has higher AI performance which is useful will applying deep learning algorithms and which will give a better edge at running the proposed surveillance system. The high powered CPU, GPU and RAM also helps in faster computations of complex algorithms as well as it helps to run multiple neural networks simultaneously. The video output of the Jetson Nano has 4K resolution thus providing clear image. The only constraint which goes against the proposed hardware is the price of the
hardware but given the specifications and computation power it is worth the money.

Table 2 (Comparative Study)

	Jetson Nano Dev Board	Raspberry Pi 3A+	Raspberry Pi 3B+
AI Performance	472 GFLOPS	21.5 GFLOPs (est*)	21.4 GFLOPs (est*)
CPU	1.4 GHz 64-bit Quad-Core ARM Cortex-A57 MPCore	1.4 GHz 64-bit Quad-core ARM Cortex-A53	1.4 GHz 64-bit quad-core ARM Cortex-A53
GPU	128-Core Nvidia Maxwell	Broadcom VideoCore IV	Broadcom VideoCore IV
RAM	4GB LPDDR4	512MB LPDDR2 SDRAM	1GB LPDDR2 SDRAM
GPIO Header	40-pin	40-pin	40-pin
Board Dimensions	100 X 79mm	65 X 56mm	85 x 56mm
Wireless	None	Dual-band 802.11ac wireless LAN, Bluetooth 4.2/BLE	Dual-band 802.11ac wireless LAN, Bluetooth 4.2
Ports	4x USB 3.0, wired ethernet 10/100/1000Mbps	1 USB 2.0	4 USB 2.0, Wired Ethernet up to 330 Mbps
Multimedia	2160p30 (H.264)	1080p30 (H.264)	1080p30 (H.264)
Video Output	HDMI, Display Port (4K)	HDMI, Display Serial Interface (DSI)	HDMI, Display Serial Interface (DSI)
Camera Serial Interface	YES	YES	YES
M.2 Key E Slot	YES	NO	NO
Price	$99	~$25	~$35

IV. CONCLUSION

The above proposed surveillance system for the facial recognition promises a much efficient and highly accurate in giving the results. The use of the Jetson Nano will be critical in the performance of the entire system. Due to the use of Jetson Nano, the entire process will run much faster and multiple neural networks will run simultaneously. Moreover the use of Multi Task CNN algorithm for face detection, alignment and feature matching will also provide much better results One of the major advantages of the proposed system is that Jetson Nano uses the same CUDA and OpenCV libraries along with its own Jetpack SDK's. Along with these, Nvidia's TensorRT will also help for high performance deep learning inference. So using the existing libraries it will be much easier to design an efficient system which will work much faster and more accurately.

Table 1 (Literature Survey)

Authors	Abstract	Algorithms	Inference from Existing System
Kyu Beom Lee, Hyu Soung Shin [1]	Proposes a new process of ODTS by combining deep learning-based object detection network and object tracking algorithm and it shows dynamic information of an object for a specific object class can be obtained and utilized.	R-CNN, Object Tracking Algorithm	This system adds CADA that discriminates every cycle based on dynamic information of the car objects. As a result of experimenting with the image containing each accident, it was possible to detect the accidents within 10 seconds.
Ishani Mondal, Sombuddha Chatterjee [2]	This paper proposes face recognition involves a large number of challenges when it comes to deal with the visual analysis. Thus, this development or approach plays a significant role in security applications such as legal documents identification, identification of terrorists in public places.	CNN Algorithm	The proposed method has been used in real-time, runs perfectly on the standard benchmark dataset as well as the custom dataset prepared by us. The Performance has been better compared to the traditional approaches just because of the deeper architecture of the convolutional neural networks.
Liyun Zhuang, Yepeng Guan [3]	A novel method based on deep learning to solve the adverse impact imposed by illumination variation in the face recognition is proposed in this paper.	Log-Gabor Algorithm, LBP Algorithm	Experimental results have shown that the proposed method has superior performance in face recognition by comparing with some state-of-the-arts.
Yun Xia Liu, Yang Yang, Aijun Shi, Peng Jigang [4]	This paper proposes a method based on Mask R-CNN for intelligent monitoring of indoor surveillance video.	R-CNN Algorithm	It uses advanced target detection and instance segmentation technology in deep learning to realize the semantic understanding of video content, which not only effectively retains
Authors	**Abstract**	**Algorithms**	**Inference from Existing System**
			the key information in the original video.
M. Ali et. al. [5]	In this paper, an edge-based system for deep learning is proposed for efficient and large-scale video stream analytics. Using the infrastructure, an object recognition scenario was implemented.	CNN Algorithm	Results on an object recognition scenario show 71% efficiency gain in the throughput of the system by employing a combination of edge, in-transit and cloud resources when compared to a cloudy-only approach.

Yi Shan [6]	This paper proposes Deep learning algorithms, such as CNN could provide high accuracy for great number of applications including ADAS and video surveillance analytics. Considering processing speed and energy efficiency, FPGA is a good hardware to construct customized CNN solution.	CNN Algorithm	This system processes 16 channels of continuous input video with the resolution of 1080p. Two functionalities could be easily switched by just clicking a button in this live demo: one ADAS system for vehicle, non-motorized vehicle, and pedestrian detection, tracking, and attributes analytics; and the other video surveillance system for face detection and recognition. The FPGA used is Xilinx MPSoC ZU9, and the whole board including this FPGA only cost about 50 Watts with Peak performance at 5.6 TOPS.
A. Balasundaram, C. Chellappan [7]	The main objective of this paper is to design and implement a novel intelligent video analytical model as a human object detection method for surveillance video.	Intelligent Video Analytics Algorithm	It is found and concluded that the IVA model outperforms most of the existing approaches in terms of object detection and classification with less error. From the results, it is observed that the IVA model has achieved 99.77% and 98.19% accuracy in correctly classifying the normal and abnormal frames from benchmark dataset and custom dataset, respectively. Similarly, 0.23% and 2.03% of normal and abnormal frames are classified incorrectly from benchmark dataset and custom dataset, respectively.
Abdulkadir Sengur, Zahid Akhtar, Yaman Akbulut [8]	Face recognition systems are now being used at industrial level throughout the world. Despite the great advances, counteracting face spoofing attacks has yet proven to be a challenging task. Therefore, in this paper, as a first step we have investigated two well-adopted CNN models for face PAD without any fine-tuning.	CNN Algorithm	Investigation of two well-adopted CNN models for face PAD without any fine-tuning, which is contrary to the prior studies. Experimental results on two publicly available databases are presented. The future work includes a comprehensive analysis of several state-of-the-art deep learning models for face PAD.
Camille Bailas, Mark Marsden,	In the early age, smart city applications were relying on a cloud centric approach. Thus, in this paper it is explored that video analytics at the edge using a Dell	Crowd Density, ResNet50,	The algorithm can process more than one frame per second where most CCTVs only capture one image per second which make them suitable for near real-time crowd

Dian Zhang [9]	Edge Gateway 5000. They can process more than one frame per second where most CCTVs only capture one image per second.	Crowd Counting	monitoring. However, with the algorithm complexity increasing, the size of the frame highly impacts the performance. It can increase by a factor of 5 the processing time at the
Authors	**Abstract**	**Algorithms**	**Inference from Existing System**
			edge. Carefully choosing the input size is important as a good trade-off between the model accuracy and the runtime performance can be found saving up to 30% time.
Xiujie Qu, Tianbo Wei, Cheng Peng [10]	With the advent of the era of big data, deep learning theory has been rapidly developed and applied, especially in the field of image recognition. Based on the principle of CNN, a method of realizing face recognition on FPGA is presented in this paper.	CNN Algorithm	The speed of face recognition system is 400FPS, the recognition rate is 99.25%, and what's more, it has good robustness, which means it can complete the recognition function under most light conditions. Compared with the existing results, the indicators of the system have been significantly improved.
Milena Napiorkowska, David Petit, Paula Marti [11]	Detection of objects in images has been long used in computer vision applications in fields such as surveillance or robotics. This paper shows how one of the networks developed for the ImageNet challenge can be applied to satellite imagery for object detection using three examples: roads, palm trees and cars.	VGG Algorithm	Results show that our approach is good at finding objects that might have different colours and slightly varying shapes, which cannot be achieved as easily using more common techniques in remote sensing such as Random Forest or Support Vector Machine.
Muhammed Usman Yaseen, Ashiq Anjum, Omer Rana [12]	A system to perform video analytics is proposed using a dynamically tuned convolutional network. Videos are fetched from cloud storage, preprocessed, and a model for supporting classification is developed on these video streams using cloud-based infrastructure. A key focus in this paper is on tuning hyper-parameters associated with the deep learning algorithm used to construct	Video Analytics Algorithm	Numerous experiments on the testing dataset proved that the system is accurate with an accuracy of 0.97 as well as precise with a precision of 0.96, respectively. The system is also capable of coping with varying number of nodes and large volumes of data. The time required to analyse the video data depicted an increasing trend with the increasing amount of video data to be analyzed in the cloud. The

	the model.		analysis time is directly reliant on the amount of data being analyzed.
Xukan Ran, Haoling Chen, Xiaodan Zhu [13]	In this work, they developed a measurement-driven frame-work, Deep Decision, that chooses where and which deep learning model to run based on application requirements such as accuracy, frame rate, energy, and network data usage.	CNN Algorithm	Results suggest that Deep-Decision can make smart decisions under variable network conditions, in contrast to previous approaches which neglect to tune the video bitrates and resolution and do not consider the impact of latency on accuracy. It doesn't include object tracking to reduce the frequency of running deep Learning, generalizing the algorithm for a larger set of edge devices, and customizing the algorithm for different categories of input videos.
Ali Elmahmudi, Hassan Ugail [14]	In this paper, the use of deep learning approach for face recognition using partial face data is studied. Based on the popular CNN and using the VGGF model for extracting features from face, two different classifiers namely the cosine similarity and the linear support	VGG Face Model, CNN Algorithm	Experimental results validate that the cheek, nose, forehead and mouth have low recognition rates. On the other hand for top half of the face, right or left half and for ¾ of the face the recognition rates reach 100%. In addition, the Cosine similarity measure greatly improves
Authors	**Abstract**	**Algorithms**	**Inference from Existing System**
	vector machine for classification were utilized.		the performance of the classification when compared to the SVM.
Onur Can Kurban, Ahmet Bilgic [15]	In face recognition systems, variables such as direction of light, facial expression and reflection makes identification difficult. With biometric fusion, both safe and high performance results can be achieved	VGG Face Model	The results show that the S gesture can be used for authentication with this method. These two biometrics are fused as a score level by sum rule to increase both safety and robustness.
Khalid Tahboub, David Guera, Amy Reibman [16]	In this paper, a two-stage quality-adaptive convolutional neural network to address the problem of a changing video data-rate is proposed.	CNN Algorithm	Experimental results demonstrated that when adaptive data-rate streaming is used our proposed quality adaptive approach reduces the miss rate compared to the

			baseline detector.
Poonam Sharma, R. N. Yadav, K.V. Arya [17]	Proposed algorithm is a face recognition algorithm from video using generalized mean Deep Learning Neural Network. The performance of the proposed algorithm is tested on two most commonly used databases, i.e. PaSC and YouTube databases.	CNN Algorithm	The results proved that the proposed algorithm is better in terms of identification accuracy.
Atika Burney, Tahir Q, Syed [18]	In this paper, it is shown that the mid-level descriptors of the groups can be used to classify crowd videos and also similar accuracy can be obtained if the whole crowd is considered as a single entity.	CNN Algorithm	Results shows the additional tasks of identifying groups, computing their features and then combining them to define the crowd can be reduced to single step of computing the features of the crowd.

Secure Data Aggregation and data Transmission using HMAC Protocol in Cluster base Wireless Sensor Network

Abstract— **Wireless Sensor network (WSN) facing many issues in due implementation in vulnerable environments. Various researchers has already defined a systems for data transmission with WSN, still such system having high data loss issues, maximum packet delay as well as packet overhead during the data transmission. Different parameters has to consider to improve such losses like cluster network generation, data aggregation, secure data encryption and data transmission using distribution approach produces effective outcome and eliminate such issues. Moreover implementation with cluster network and selection a cluster head (CH) based on trust which produces much effective results and provides flexibility to system. This is research we proposed secure data transmission in cluster network and investigate the Quality of Service (QoS) parameters of entire execution. Initially we create different clusters with collaboration of multi sensor nodes while each node consist individual battery power as energy. According to highest energy we calculate the trust and such node defined as CH, Data Aggregation (DA) and Broadcast Tree Construction (BTC) two different techniques have been used for eliminate network lifetime or cut generation in system. In partial experiment analysis system shows improve QoS parameters like Throughput, delay, packet overhead etc respectively. It also enhance the network life because of proposed energy conservation approach.**

Keywords - Cluster Network, WSN, Data aggregation, Broadcast Tree Construction, QoS.

I. INTRODUCTION

In this era, the dagger development of mobile computing expedients that primarily embody laptops, personal digital assistants (PDAs), as well as hand-held digital devices, is driven by a revolutionary change in the computing world. Security approaches to eliminate different network attacks like wormhole attack [1] in untrusted environment. To identify intruder or threats from large traffic defined in [2]. Computing will not simply place trust within the power provided by private computers, and the idea of gift computing often arises and becomes one within the applied science society at every research hotspots [3]. Throughout this environments a path behalf of the two hosts might contains steps through one or extra nodes inside the painter. an important draw back in associate degree passing mobile ad-hoc network is finding and maintaining routes since host quality can cause topology changes [4]. Several routing algorithms for MANETs are proposed inside the writings which they differ inside the painter. New routes square measure set up and existing ones square measure modified. Basically MANET networks square portion extra susceptible to suffer from the hateful performances. This paper we proposed an wormhole attack detection and prevention approach using secure mechanism of detection such malicious behaviour. This paper we proposed an various attack detection and prevention approach using secure mechanism of detection in malicious behaviour [5] and investigate the proposed experimental analysis.

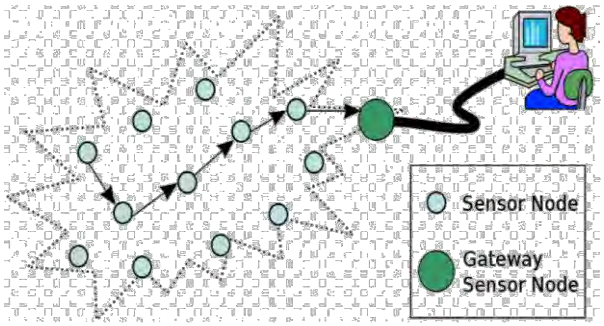

Figure 1 : Representation of a wireless sensor network [6]

The above figure 1 shows basic WSN view in sensor network, which is basically similar to wireless ad hoc networks in the intelligence that they rely on wireless connectivity and unstructured establishment of networks so that sensor data can be ecstatic wirelessly.

II. RELATED WORK

Yashpal sinh Gohil et. al. [1] proposed a true Link verifies whether or not there's an immediate Use truelink to link a node to its adjacent neighbor. The main disadvantage is that TrueLink only works on IEEE 802.11 devices that are backward compatible with an update to the computer code. An approach to trip time (RTT) is emerging to beat the problems of further hardware exploitation. The RTT is that the time taken to deliver RREQ to a supply node and to collect RREP from endpoint. A node should calculate the RTT between its neighboring nodes and itself. The malicious nodes are priced higher for RTT than different nodes. This method will determine the supply of its real and misbehavior neighbors. This detection technique is efficient only in the case of hidden attacks.

Vikaskumar Upadhyay and Rajesh Shukla [2] describes Numerous methods are planned to be used to identify wormhole attacks using a leash method for the packets. Packet leash is the technique that guards against wormhole attack. The leashes are either spatially or temporally categorized. All nodes inside the network should have data from their own position and stable synchronized clock in spatial leashes. This requires its own current location when a sender sends the data packet and UTC accepts wormhole nodes. Directional data are exchanged between source and destination during this technique. Destination by scrutiny will find the wormhole the Received signal from malicious nodes and gave directional info. The relation to the wormhole is observed if the supply signals and intermediate nodes are distinct.

Amit Kumar and Sayar Singh Shekhawat [3] describes, in Authors have criteria of contact that are primarily focused on a paradigm of research to ensure safe communication. Another such assault is a wormhole attack, in which two or many nodes are often flustered together to gain knowledge calculation and communication. A wormhole compromised network is illustrated during this post, and the research model can be used for secure communication within the network being targeted. The network model is designed to identify the secure communication node, so that connectivity is maximized. Additionally, in mostly mobile network based attack, the writers address a way of generating the safe path. The model eventually provided the optimized parameter for reconciliation communication. Results show the improved performance of model in terms of the communication throughput and reduced the loss.

Ashish Kumar Jain and Ravindra Verma [4] authors To search for aggressive or legitimate nodes inside the network, build calculative confidence values for the nodes. Authors propose a way to defend against victimizing wormhole attack combination of parameters such as energy, connection range and node buffer length. A node's confidence value is calculated backed by these parameters. This node confidence value is then compared with the threshold value of network faith. This comparison was supported and one can find out if The selected node is either malicious or valid, or is not. The planned methodology consists of two phases: first, the analysis of the network parameter and the calculation of the threshold, and second, the implementation of the protection on the routing protocol that prevails. Results area unit assessed by expanding the AODV protocol as well as evaluating the efficiency of the proposed routing protocol and matching it to the insecure AODV. The performance of the proposed confidence-based approach, based primarily on defense, is cost-effective and reasonable against comparative findings wormhole attacks in MANET.

Rajan Patel Anal Patel, Nimisha Patel [5] this Survey is The different techniques used to identify authors of wormhole attacks suggest an approach for the identification and prevention of wormhole attacks. A projected defensive approach against wormhole attack based primarily on the Hash-based Compression Function (HCF) that is really mistreatment of any secure hash operates to chip a hash field for the RREQ packet and the projected approach looks terribly promising compared to other proposed solutions in literature.

Dhruva Patel et. al. [7] system describes various safety hazards which affect different levels of safety. Because of its simplicity and self-routing nature, MANET is responsive to various threats, and various attacks can breach separate layers within the network. There are numerous attacks and each attack has its own impact on different layers since some can only affect a single layer of the network while others can hit other layers, i.e. depending on the nature of the intrusion on how it reacts. Wormhole assault is now a network layer intrusion capable of crippling the communication network entirely. all the attacks.

Juhi Biswas et. al. [8] system present AODV With the implementation of the MANET and Wormhole Attack Detection and Prevention (WADP) technique on this revamped AODV, the routing protocol is modified to detect and prevent wormhole attacks in real world. So that fraudulent nodes are found within the network and the false positive limitation

node authentication function is eliminated. Simulation tests also indicate that node authentication does not eradicate false positives although it helps to chart the actual location of the hole jointly and could be a relatively double test for hole attack detection. This algorithmic rule doesn't use any special hardware for police work wormhole attack.

Kapil Raghuwanshi et. al. [9] take Initiative to eliminate or minimize the impact of a hole assault by offering a solution within the initial route setup point that could sense the presence of a void. Such resolution is based on the hop count analysis approach, i.e. hop count is used as a parameter for characteristic shapes involving tunnel space. Hop counts are evaluated to detect hostile nodes. Simulation of the planned work is completed in many node and traffic situations in the presence of a wormhole attack. The simulation results The predicted strategy demonstrates superior performance as PDR and attendance decreases however, in fact, "normal end-to-end gap" rises. It has been noticed within the analyzed state of affairs that the MAODV has a superior performance than AODV. Modified AODV is ideal for wormhole attack identification and bar detection. This strengthens the insecure circumstances of the packet distribution level, with a borderline reduction in turnout and a reasonable raise in end-to-end delay.

System [10] Throw light on a weak wormhole attack, during which two or more malicious nodes type a tunnel as a relay mechanism into the packets themselves. Such an attack may result in the packets sent being selectively diverted, fabricated and changed. During this paper AN identity is planned on the side of the clusters to shield the network from hole attacks based primarily on the signature theme. The designed theme need not transmit any credentials between nodes, thereby overhead calculations. Cluster During which cluster heads area unit selected in such a way that they cannot be harmful, specifically focused architecture is employed. This style works in 3 steps. The effects of the simulation indicate the improved performance of the theme in terms of throughput, packet delivery ratio and end-to-end delay.

According to [11] proposed protocol is based on Neighbourhood overhearing and frequent analysis of key and different tables and expected procedure information was found to be safe and a few region assault units are checked on it. Wormhole assault is observed by nodes being overheard. The results show that M-AODV has been strengthened in terms of the packet transmission magnitude relationship and the latency has therefore been lowered further, however the overhead amount has been raised. M-AODV jointly improves network reliability and stability. Thus, the planned protocol is proven to be protected in simulations alongside wormhole and blachole attacks.

Luo It. Al. [15] Fixes problems with WSN because every node is created to handle all the information from a forward-looking and network management-friendly, autonomous system to all levels, from the appliance layer to the appliance layer. This works very well, especially thanks to the algorithms developed with the short-shortcut WSN, they do not create simplicity and completeness when trying to implement widely and widely distributed different and low-energy WSNs at the same time.

Gante et al. [16] for example announce good organization of SDWSNs to boost potency and Overcome the inherent difficulties of common WSNs. The management theme is predicated on a Base Station Design for WSNs with Associated Integrated Controllers. The controller creates forwarding rules that area units stored in flow tables from location knowledge acquired through the localization technique processed in the layer layer application layer of the design.

Olivier et. al. [17] projected gradable design referred to as software package outlined Clustered detector It is believed that multiple base stations network (SDCSN) are used as controllers which additionally play the role of cluster head. Clusters of large nodes are divided into clusters, and each has a cluster head. The cluster head controls and coordinates the detector nodes in each cluster, and the knowledge processed in each cluster is diverted to the cluster head.

Oliveira et al. [18] style associated implement associate design supported Even within the framework many controllers in WSN referred to as Tiny-SDN supports Tiny-OS with a style structure consisting of SDN-enabled detector nodes and SDN controller node. This fixes issues such as in-band management, high communication delays and restricted power offers.

Tootoonchian et. a. OpenTM [19] projected associate very Put a little effort into this technique or work for new techniques observation SDN-based WSNs associated remains an exposed analysis space. Freshly but, work has been conferred on a network mensuration design supported SDN for observation of WSN data like routing path per-packet, the ratio each Link and hence the delay in each ointment-hop configuration.

East-West Apis modify supervisors that area unit within the similar dominion or neighbouring dominions to express with one another [20]. it's vital to say here that SDN isn't concerning SDNs have been shown to have the ability to change network management and allow innovation through network programmability, rather than enhancing network performance.

The challenges to think about once integration a quality management theme contains management

the impact of nodes coming In the network and therefore the nodes perform network functions, implement functions, and different network attributes on QoS. A number of solutions and process steps have been provided by Zhou et al to stop the problems associated with the SDN controller nodes and offer WSN efforts. [21].

III. PROPOSED SYSTEM DEISGN

Figure 1 describes the cluster creation process and transmission between source and destination node. At the end of each TS network nodes verifies sensed data and broadcast messages to nodes within given Cluster Distance (CD) for cluster creation. Cluster creation uses the Relay Node (RN) and CD to group the sensor in same cluster. Upon accepting the broadcasted message each node verifies the value of RN. If its value is within RN it stores in its memory and compares CD with each node's distance. If the distance between nodes is same or less to CD and sensed value is within given RN then those group of nodes forms a cluster. The nodes NID which are related they will not broadcast message for cluster creation. Nodes which are not participate in cluster creation process based on *RN* and *CD*.

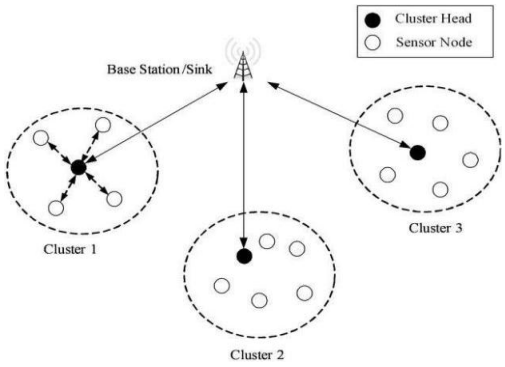

Figure 2: Proposed system cluster scenario

IV. CLUSTER HEAD SELECTION :

Input: Cluster set with nodes.
Output: Ch selection with remaining sensor node.
Step 1: select all nodes as initial population.
Step 2: Select evaluation set
Step 3: Apply crossover on similar power nodes.
Step 4: Apply mutation on each sensor node.
Step 5: Apply fitness on all nodes power
Step 6: select best node using rout let wheel selection.
Step 7: Check GA evaluations
Step 8: Select final max energy node as CH node.

V. DATA TRANSMISSION USING BTC :

A dynamic cluster it will be designed when the goal reaches several cluster boundaries. A difficult role problem is how the device identifies the situation, particularly in a fully distributed environment, when the goal reaches the boundaries. We use boundary nodes to solve this problem in a fully distributed way.

The following assumptions are taken in order to design the proposed algorithm.

In this work we have carried out an algorithm which is wormhole attack identification has been through in a cluster based network creation manner to eliminate the wormhole attacks. Basically AODV routing protocol is utilized as the fundamental network topology. A multi-layer method is used to determine if a node is participating in a wormhole attack. Introduces the layered approach to decrease the capacity of dispensation on respective cluster heads. Due to safety point of view, this also decreases the risk of a cluster head should be hacked by attacker.
The complete network is separated in clusters sets illustrated in figure 1. Sometimes clusters might be corresponded or separate. Every cluster contains a single cluster head as well as number of cluster member nodes. Member nodes forward on the data only to the cluster head when any nodes want to send data to Cluster Head (CH). The CH is responsible for forward on the collective data to all its other cluster members. The CH is selected enthusiastically and preserves the routing information.
Input: Primary source node *Sender_node*, Destination node *Dest_node*, Group of nearest nodes Neigh_node *[],* node id as *N_id,* node energy *N_eng;*
Output: From source to destination way based on the given algorithm.
Step 1: initially system select the *Sender_node* and *Dest_node* on dynamically
Step 2: select the packet or file f for info broadcast.
Step 3: if (*file or data* ! =null)
Step 4: read each byte *bytes* form *file or data* when reach null
Step 5: send data, initialize *cost_filed_1, cost_filed_2, parent_filed_1, parent_fileld_2*
Step 6: while (nd[i] when reach NULL)
cost_filed_1=node[i]_eng
parent_filed_1= node[i]_id
cost_filed_2 =node[i+1].eng
parent_filed_2= node[i+1] _id
Step 7: if (*cost_filed_1> cost_filed_2*)
cost_filed_2=null
parent_filed_2=null
Else
parent_filed_1= parent_filed_2
cost_filed_1= cost_filed_2;
parent_filed_2=null
cost_filed_2=null
Step 8: end of while loop
Step 9: reiteration till when extent at the sink node

VI. RESULTS AND DISCUSSION

After In this section we present experiment analysis using log file, Once simulation has finished it will create trace file at background, which contains all information of node communication as well as other log information. we have created a database of 5 text files which contains reading of 5 ms each till 25 ms as our simulation time is 25 ms. After that, we read the text file in a program created for the trace in Netbeans IDE 8.2. We got readings of various events in Netbeans from which we have plotted the graph of various parameters such as Drop rate(DR),Throughput and Packet Delivery Ratio(PDR) calculate d according to equation (1), (2) and (3) respectively. The evaluation has done with various WSN as well as cluster network existing protocol [12] [13] [14].

Table 1. The simulation parameters has used which is described in below table

Parameter	Values
Simulator	NS-allinone 2.35
Simulation time	25 sec
Channel Type	Wireless Channel
Propagation Model	Two Ray Ground
Standard	MAC/802.11
Simulation Size	1000 *1500
Max packet Length	1000
Ad hoc routing	AODV
Traffic	CBR

Table 2: shows the basic difference between the proposed and existing WSN.

Parameters	**WSN [21]**	**Proposed (cluster base with AODV)**
Data Aggregation	No	Yes
Data Security	Yes (selective)	Yes
Energy Conservation	No	Yes
Packet Loss	High	Low
End to End delay	High	Low
Packet Overhead	High	Low

1. Drop Rate:
It is defined as the number of packet lost per number of packet sent. The smallest amount value of drop rate states superior performance of the protocol.

$$Drop\ Rate = \sum_{i=0}^{n}\left(\frac{packet\ received\ [i \dots n]}{sent\ packet\ [i \dots n]}\right)$$

2. Throughput:
It is defined as the total number of packets supplied over the entire simulation era.
This is a mix of TCP's total number of packets and the total number of packets sent.
The higher throughput value means higher performance of the protocol.

$$Throughput = \left(\frac{\sum_{i=0}^{k} received\ packet[TCP]}{\sum_{i=0}^{l} sent\ packet[TCP]}\right) * 100$$

3. Packet Delivery Ratio (PDR):
The PDR is defined as the ratio of the data packet numbers to the number of packets produced through the network. The higher value of the packet distribution ratios represents greater efficiency of the protocol.

$$PDR = \sum_{i=0}^{n}\left(\frac{packet\ received\ [TCP]}{packet\ sent\ [TCP]}\right) * 100$$

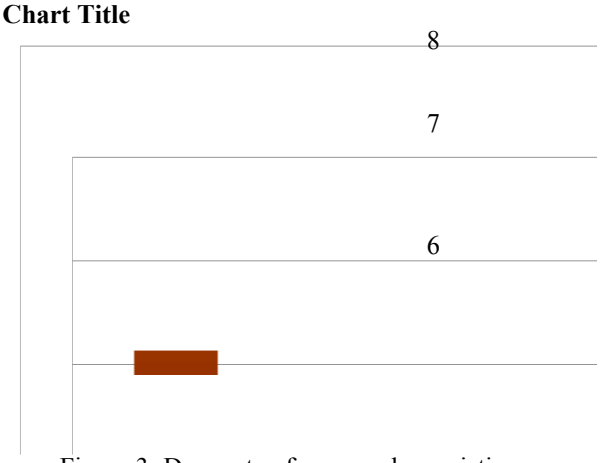

Figure 3: Drop rate of proposed vs existing

This figure 3 will provide the drop rate overall simulation during the communication with other protocols. The above graph has calculated based on various experiment analyses in NS2 environment. All defined protocols has used with different number of nodes in cluster network. The graph shows minimum packet drop rates of proposed AODV than other protocols.

Figure 4: Throughput of proposed vs existing
96
This figure 4 will provide the throughput of system during the communication with other protocols. Throughput s the most vital parameter the measure the QoS of any network. Similar as first experiment .tr files has95 utilized for evaluate the throughput for all protocols. This figure also shows our approach produces highest throughput than all three protocols.

Chart Title

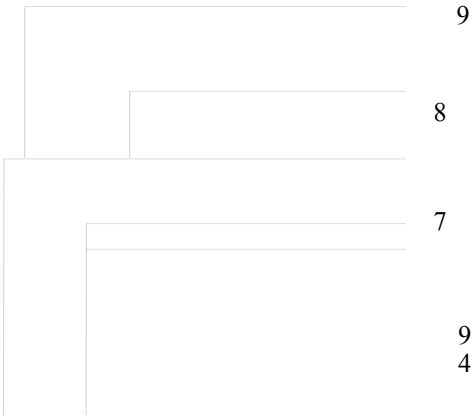

Figure 5: Network lifetime of proposed vs existing

This figure 5 will provide the how system will increased the actual time percentage of simulation due to proposed energy6 conservation protocol. Network lifetime has calculated based on after applying the energy conservation protocol, conservation s the technique during the data transmission eliminate unnecessary energy utilization by in Seconds

This proposes an aggregation of the HMAC and data in WSN. The CHs are initially chosen based on the connectivity of the node, which acts as a Data Aggregator. The proposed techniques$_3$provide the ad hoc network with greater security and also prevent different types of network attacks. It supports in the direction of escalations the packet delivery ratio (PDR) as well as decreases the network directly above by cultivating the enactment of the respective routing protocol. In the future, for faster detection of wormhole nodes, it will also need to modify the table entries in the receiver node. And also improved the security of the wireless ad hoc network. By means of set up such effective approach to prevent various kin fog network attacks with new defined algorithm. It also exposure and elimination of wormhole attack throughout data communication. The proposed Techniques offer greater security for various types of ad hoc networks and also deter network assaults. This facilitates the elevation of the packet distribution ratio (PDR) and reduces the overhead network by encouraging the enactment of the respective routing protocol. To get the detection of wormhole nodes faster, the table entries at the receiver node need to be improved in future plan as well. And the security of ad hoc wireless networks is also improved. By applying such an effective approach, the kin fog network will deter various attacks with new defined algorithm.

VII. CONCLUSION

sensor, receiver as well as internal nodes respectively. In proposed system BTC has
used for best path selection as well as energy conservation protocol.

Abstract. **VANETs have gained great focus among the researchers since last few decades. The areas of great interest are the types of routing, and quality of service (Qos). The main challenge is to find the ways to counter the continuous-ly changing VANETs topologies and its high speed nature, and then determin-ing which routing protocols are best suited for a particular transmission type; and which ones provide more consistent and stable routing performances. Rout-ing in networking is one of the key factors in determining how effective and ef-ficient data packets can be transmitted within a network environment. As the topology is consistently ever-changing a reliable communication with needed QoS is of utmost importance. QoS with respect to routing protocol is a domain which demands improvement. Great efforts have and are still being made to improve the routing capabilities of the protocols in existence to en-hance QoS mechanisms in routing protocols. The simulation results indicate that the proposed approach can lead to improvements in terms of QoS metrics like Throughput, Packet Delivery Ratio, end to end delay, Energy Consumption & Residual energy.**

Keywords: VANETs, Qos, Throughput, Packet Delivery Ratio, end to end de-lay, Energy Consumption & Residual energy.

I. INTRODUCTION

Traffic safety is a major challenge recognized by the major players in the automo-tive industry and by many governments. According to which annually thousands of road accidents are reported in any country. Traffic accidents are most of the day's results of the driver's failure to access quickly and properly the driving condi-tions. Normally drivers have imperfect information about road situations, speed and position of vehicles around them and typically are compelled to form decisions like breaking and lane changing without the benefit of whole data. "The need for commu-nication when the deployment of any fixed infrastructure is impossible and therefore the advancement of computer and wireless communication technologies, led to the event of Mobile Ad-hoc Networks (MANETs)" [1]. Vehicular Ad-hoc Networks as a subset of Mobile Ad-hoc Networks which provide data exchange via Vehicle-to-Vehicle (V2V), Vehicle to Roadsides (V2R) and Vehicle to Infrastructure (V2I) communications and a car which takes part in such a network is equipped with a WLAN and cellular communication device [2]. VANETs is additionally defined as a wireless communication technology which is additionally ready to enhance driving safety and velocity by exchanging real-time transportation information, and "it should upon implementation, collect and distribute safety information to massively re-duce the amount of accidents by warning drivers about the danger before they real-ly face it" [3]. In addition, VANETs also are ready to minimize incidents and improve traffic conditions by providing vehicles, drivers and passengers with information about the road condition. VANET has its own unique characteristics in compari-son with other sorts of MANETs, the unique characteristics of VANET include: pre-dictable mobility, lack of powers constraints, variable network density, Rapid changes in network topology, High computational ability and large scale networking [4]. Safety services information such as traffic accidents and road congestion which are sensitive to reliable and real-time communication should be broadcasted immedi-ately. Data transmission in such environment is critical and has got to be distributed in multiple paths to enhance the end-to-end delay. Some stale routes are generated in the routing table which leads to unnecessary routing overhead causing frequent link fail-ures as well as route discoveries. Therefore the discovered route between couple of vehicles should be as stable as possible to satisfy QoS requirements [5]. The intermit-tent nature and short-live of these algorithms, make the created clusters to

provide scalability with lower communication overhead [5]. Rapid change in topology, owing to time varying vehicle densities and other factors; both external and internal, makes preserving a route very difficult and this in turn incurs high routing overheads as well as low throughput [6]. A cluster on demand minimum spanning tree with primsalgo-rithm has been proposed in [7] for VANET. In this approach the vehicles has been clustered by accounting the intra-cluster QoS. An extended Kruskal algorithm has been proposed in [8] to support QoS.

Thus, we aims to develop a QoS Enabled Data Dissemination using Kruskal's algo-rithm to provide efficient data dissemination (QoS-EDDKA) and quality of service in VANET. This approach constructs the clusters aid of minimum spanning trees in every road segments by considering the intra cluster QoS. Each spanning tree will have a cluster head that is responsible to collects or disseminates the data from the leaf nodes and to other coordinator nodes and vice versa

II. RELATED WORK

A bee communications inspired QoS routing scheme to improve the network throughput and to reduce packet loss in vehicular ad hoc network (VANET) environ-ment has been proposed in [9]. Their scheme was inspired by the natural bee commu-nications paradigm. The routing scheme is inspired by the bee's foraging behavior in the nature. Control messages are exchanged within all nodes in the cluster to ensure a reliable and stable connection. However this may contributes to overhead problem in routing.

In [10], the authors present Cross layer based vehicular routing model (CL-RVR), to facilitate reliable routing in VANETs, which would cater to QoS requirements for desired applications by combining the parameters from physical and network layers. Their simulation results show that their proposed scheme can improve the packet delivery rate and reduce link failure ratio in routing in VANETs

A cluster-based routing protocol for urban Vehicular Ad Hoc Networks (VANETs) using Optimized Link State Routing (OLSR) was presented in [11]. In their model OLSR, MultiPoint Relays (MPRs) used for routing, are selected at each node using neighbors' reachability resulting in a high percentage of MPRs.

In [12], the authors present a link prediction algorithm as an addition to the AQRV protocol that selects the best routing path in urban vehicle environments to predict the duration of availability of the present path. This methodology expects to anticipate a connection breakdown before its incidence and directing the data packets through a substitute route.A QoS Enabled Data Dissemination using Kruskal's algorithm to provide efficient data dissemination and quality of service in Hierarchical VANET [13].

III. SYSTEM MODEL

The proposed system model consists of n number of vehicles, Road Side Unit (RSU). Every vehicle can communicate with other vehicles and also with RSU. QoS provisioning often needs negotiation between host and network, call admission con-trol, resource reservation, and priority scheduling of packets [14]. A communication link between the nodes will be exist if they present in their communication range The vehicles present within the radius of the intersection point are not allowed to form the clusters. Figure 1 shows the Clustering of Vehicles in VANETs with the proposed technique. The vehicles which are away from that region can form and join the clus-ters. It has been assumed that if the road contains any of the Road side unit then it will act as the cluster head for that region. Vehicle clustering represents a management scheme in which the adjacent vehicles are gathered into a group known as a cluster. Each cluster has one active node plays the role of a CH. CH is selected to control and manage the cluster activities. All the other nodes in each cluster are entitled cluster members. These members are usually belonging to one cluster or in some cases it belonged to multiple clusters. The cluster head (CH) can communicate with the clus-ter member (CM) as well as with the other cluster heads.

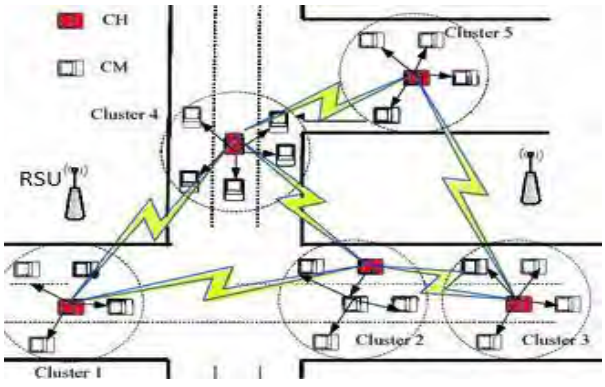

Fig. 1. Clustering of Vehicles in VANETs.

The number of clusters can be formed on a road segment can be determined by us-ing following equation Here l is the length of the road segment measured in meters; TR is the Inter-cluster communication range of the nodes. According to this the Road has been segmented and the cluster head has been selected in each segmented road. Figure 2 shows the segmentation of road in the

proposed approach. The clusters will be formed for the nodes which are travelling on the same direction.

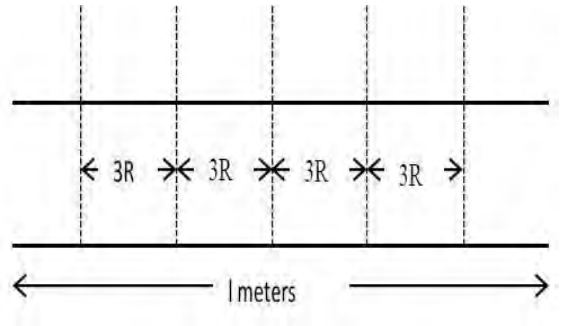

Fig. 2. Segmentation of Road.

The node stability has been computed based on the Time to Live (TTL) and the ac-celeration of the vehicle

Where D is the distance between the node and the road segment, S is the speed of the node.The stability of the node can be given as follows

Where size of the queue is the present size of queue at node i, length of the queue is the queue length between the node i and j.

The probability density function (pdf) has been calculated for every node relied upon the NS value.

$$\frac{}{\sqrt{=}} \quad (\ -)[\text{—}]$$

Here μ is the mean of the NS value gotten from the nodes in the road segment, σ is the standard deviation valued to the particular mean.

The signal to interference ratio between a node i and node j can be given as follows

Vehicle pseudo ID	Temporary public/private key pair	Pairwise key

$$\frac{}{\sum}$$

Here, N is the number of channels available between the node I and node j, ptx is the transmitted power between the two nodes i and j. Prj,k is the measured received power at the node j on the channel k.

The weight for each link based on NS and can be given as follows

Initially the VANET Topology was created by SUMO 30.0.0 & MOVE.jar in the Ubuntu 14.04 LTS. The vehicle (CM) which wants to send the message communicat-ed to the corresponding cluster head for transmitting the message by sending group information request. In order to provide data security within the message digital sig-nature was attached by using ECDSA algorithm accordingly it generates the Private and public key and also it encrypt the data. The road side unit (RSU) holds both Pri-vate and public key information. Every vehicle which send group information request message was encrypted by private key of his own with certificate attached as shown in table 1.

Vehicle ID	Message ID	Message	Timestamp	Certificate

Table 1. Frame format for group information request messagThis message is signed by public key of RSU and it forward to trusted authority (TA). TA decrypt this message and check certificate of vehicle from its database. If its valid then it sends verification message to RSU. TA assigns Pseudo ID to vehicles and temporary Public and Private Key pair. TA sends this Pseudo ID, temporary pub-lic and private key pair this message is encrypted by permanent public key of vehicle as shown in table 2.

Vehicle ID	Pseudo ID	Temporary public/private key pair	Timestamp

Table 2. Trusted authority table.

In this way all the vehicles gets authenticated and RSU form cluster of vehicles and also it select group leader (GL) or cluster head (CH) and assign group ID .The format of it is as shown in table 3.

Vehicle pseudo ID	Pseudo ID	Temporary public/private key pair	GL/GM

Table 3. RSU vehicle information table

Cluster head (CH) or group leader (GL) maintains table of vehicles in group and which has vehicles Pseudo ID and their Temporary Public and Private Key pair as shown in table 4.Cluster head then Broadcast this message to all vehicles encrypted by group key.

Table 4. Cluster head table

IV. ALGORITHMIC STEPS

Start:

Algorithm packet Scheduler (Graph T){

Set priority queue Q which composed of all the edges of G

Remove all the Successive tree links for node(Vertex V) to first trust node. R <- Total no of removes links

Best candidate <- b

Run BFS Algorithm from v in a radius

// Problem description : Hierarchical Vanet Packet Scheduler For every vertex V in V[G]:

If nodes other than b on disconnected main tree: Candidates <- nearest Candidate nodes into tree list Best weight =infinity

For each node g in the candidate list: Hg <- Hop count from g to the sink Dg <- Degree of node g

If (Dg+Hg)< Best weight:
Best weight=Dg+Hg
Best candidate <-g
Connect node V to Best candidate in shortest path.

In our work we Run BFS Algorithm from v in a radius to from the minimum span-ning tree in which best weight considered as infinity, nearest candidate with minimum weight is added to tree list. For each node g in the candidate list Hop count (Hg) from g to the sink and Degree of node g (Dg) is calculated .If sum of Hop count (Hg) and Degree of node g (Dg)is less than then the Best weight is modified as Dg+Hg and node g is considered as best candidate. Connect node V to Best candidate in shortest path.

V. SIMULATION RESULTS

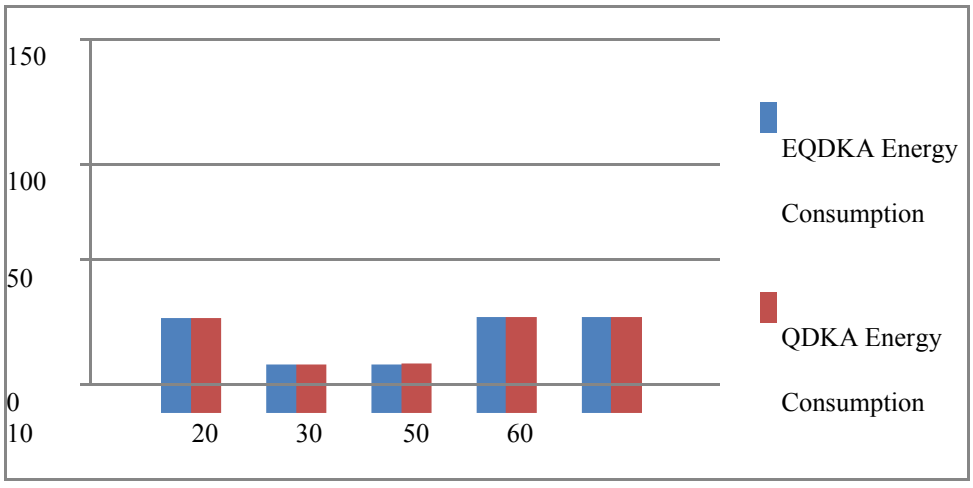

Fig. 11. Comparative Analysis of QDKA & Proposed EQDKA algorithm on Energy Consumption with respect to number of nodes.

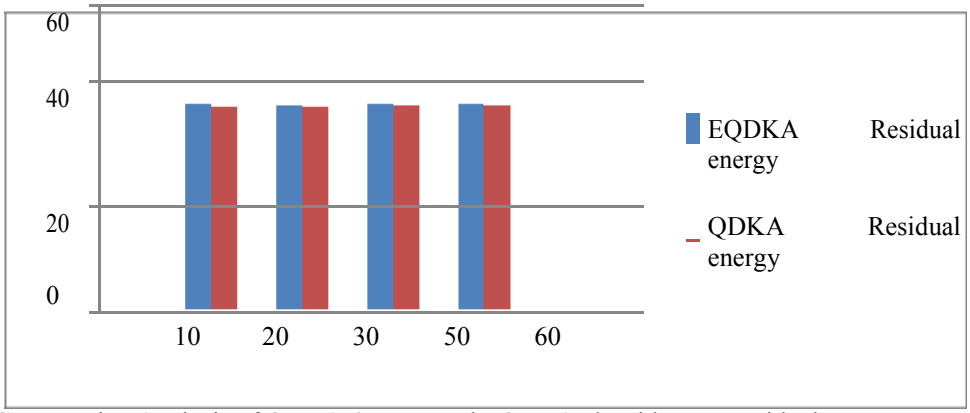

Fig. 12. Comparative Analysis of QDKA & Proposed EQDKA algorithm on Residual energy with respect to number of nodes.

VI. CONCULSION

Through the stimulation results obtained from NS2 as shown in fig. 3 to fig. 12 we can conclude that by using proposed EQDKA algorithm Qos have been improved with respect to Throughput, Packet Delivery Ratio, end to end delay, Energy Con-sumption & Residual energy.

A Comprehensive Study and Possible Solutions on Hostel Management System

Lakshmi K. Jha, Harshali P. Patil
Department of Computer Engineering
Thakur College of Engineering and Technology,
Mumbai University
lakshmijha19@gmail.com, harshali.patil9@gmail.com

Abstract—**The ongoing manual hostel management system demands a lot of paper work and calculation & therefore may be imprecise, which leads to inconsistency and inaccuracy in maintenance of data. The information stored on the paper can be lost, stolen or destroyed, under any circumstances. Thus, the presentsystemtakeslotoftimecausinginconveniencetohostel ler and employees. Due to this manual behaviour, it become complicated to add, update, delete or view the data. Also, if number of hostellers increases drastically, then to preserve detailed record of every student is extremely difficult. Therefore, thekeyintentionofthispaperistargetedforCollegeHostelwhich integrates allocated room report, unallocated room report, transaction management, maintaining the decorum of the hosteller&giveplatformforplacementstobeexcellentlycontrol. The paper proposed management of hostel in computerized system. The system is equipped with some special features for serving hostel admin. Each record will generate a unique identity and it can be searched by a unique ID. The warden will have a bettercontroloverthefunctionalitieslikecomplaintmanagement and tracking time using RFID. This will turn down efforts of warden & provide better service to thehostellers.**

Keywords— Hostel management, Active RFID, complaints management, Online hostel system, Hostel placements.

I. INTRODUCTION

21st century is the century of knowledge. Educational institutions and hostels are the two sides of a coin. Thus, the number of hostels is also widely increasing for providing the home like atmosphere to accommodate the students. And real time chaos occurs for the persons who are searching for the hostels and software or online applications are not usuallycast offinthiscontext.Furtherthepersonswhoreallywantstoserve at hostels places finding difficulty to get jobs. This paper proposesthesystemwhichwillovercometheproblems likeAllot different students to the different hostels. -Vacate the students for the hostels. -Control the status of the feepayment.
-Manage the details of the students & amend the student records. Hostel infrastructure Mess creation and management RegisteredstudentsMeritlistsRoomandmessallotmentMess billcalculationFinesandPayrollandgivingopportunityforjob seeker for laundry, rector, electrician, carpenter, Messmanger, etc.

II. LITERATURESURVEY

"Tracking Student Movement Single Active RFID" illustrated a model for tracking movements of students by using SMOSA which comprises of two graphical user interface (GUI) that standalone,onlineuseranddatastorage;database.Thissystem supervised two tasks: attendance system and tracking system by use of RFID[1]-[5].

In 2017, "Solving Hostel Student Issues Using Mobile Application"waproposedtosolvethehostelstudentproblem like food, water, security, & electricity issues in digital environment. In this system, one can send the message to the hostel management via mail or whatsapp messages and these messages will substantiate by hostel management. The paper depicts web-based application is better to use instead of using paper [6],[7].

Indocon micro engineers limited established a hostel management software having distinct features such as modifyingtechnology,income/revenuemanagement,cohesive web booking engine and interfaces to all engagement channel [8].

For further examine, we examined the College Hostel Management Software developed by Initio which covers six modules like the hostel module, the transport module, the librarymodule,theregister/storemodule,thequerym oduleandthe visitors tracking module. It bids information on the building, rooms and students [9],[10].

ThepaperbyC.Prom&Rosyproposesasystemwhichin dulge hotelier with mobile technology era. It shows an android application named ALICE which is divided into categories of SPA,housekeeping,front-desk,concierge,roomservice,valet- travel & TV & appliance. The aim of the system is to create fluid 2-way communication with the hotelier to improved hospitality. The hotelier can directly communicate with this android app to control the requirement like controlling the temperature of a/c, requesting for room service. This systemis programmedtoactonpredefinedthings.Byselectingas ervice, an alert message will be sent to management, where further action is taken[11],[12].

Thepaperby'MaryShalin'proposesanandroidapplica tionfor hostel Out pass form, which allow a student to be able to fill form in an elegant way rather than doing it manually. The application makes generation of a completed form to get an Out-pass form in a simplest way. This reduces a lot of human efforts and also use of paper to a small-extent. The paper aims to give effective result in case of emergency situations, when the student might not be able to contact parents or wait for an approval due to several reasons. This will result in less time consumption&aneasywaytokeeptrackofoutpassreco rdof student with mentioned time[13]-[15].

III. PROPOSEDSYSTEM

This paper defines managing a hostel. The research work described in this write-up is marginals to educational institutions. The aim is to provide solution of the problems of traditional method of managing hostel facility. The systems appeal to attempt hostel services related to administrator, management and student of the hostel. It self-operates the administrative processes and turn down the stress associated withhuntingforinformationonastudentorafacilityina stack ofregisters.Itispeculiarlyprogrammetocentrallyalloc ateand maintain accommodation spaces in a typical student's hostel. Theuserofthesystemcanupdatethedataofallthosestud ents who have left the hostel, and check the profile of newly come on the tip of finger. The student staying in the hostel will be registered with an ID number allocated at the time of room allocation. The generation of the bills is automated and is directly issue in the form of notification to thestudent.

The system has a unique approach to trace information andanother perspective of the system is for job hunting process. This feature will provide a platform for workers to seek jobs. The module will be categorized as laundry men, rector, mess staff&in-charge,electricianandacarpenter.Thiswillleadthe system to follow up the efficiency, which will automatically decreasetheunemploymentbyprovidinganareatoactu pon.

Nextaspectofthepaperhighlightsthedigitaleraofinno vating an online application by trim back the paper. This will bring a solutionfortheissuefacedbythestudentsstayinginthe hostel.
Issuecanbemessproblem,electricityproblem,waterp roblem, food problem, furniture problem, security problem, medical service problem & internet facility problem. To handle the mention issues, this module will invent an automated application to fire complaint, give suggestions and feedbackto thepanel.

LaststageincorporatesuseofRFIDtags.Thelightisthr ownin trackingtheincomingandoutgoingactivitiesusingthe tagand receiver. It will enhance security and record is maintained. In addition, it drives an even-flow operation in accessing and retrieving data in a polished way and hence resulting in saving a lot of human effort and time.

Table I: Functionality of modules

Sr. No	Modules	Modules Functionality	Processing
1.	Registration	Entering details of hosteller.	User profile.

2.	Room Allotment	Authenticate a user & allotting room.	Hosteller details with Registration number& Roomno.
3.	Fee Management	Fee details accesses by administrator.	Fetching data of payment & generating Receipt.
4.	Complaint Management	Offline text message of units.	Complaint ID & Actions taken.
5.	RFID Tracking	Senses incoming and outgoing time.	Communicates with the tag & receives Information.
6.	Offline Notification	Providing timely information to parents	Alert message.
7.	Job Hunting	Job related to hostel	Checking availability of workers.

The work of each module is as follows:report generation which is decisive in data handling, which makeproposedsystemmorereliable,morerobustandefficient. Thisapproachwillcoordinateusingacentraldatabasetohandle the complexness of student's hostel management and administrativefunctions.*Registration:* Once the hosteller installs the application, then they would be asked to register themselveswiththeirdetails.Thiswillbestoredinthe database and a unique serial number isgenerated.*Room Allotment:* This section provides an online criterion for the admission to hostels. Hostel accommodation can be provided based on the availability of rooms. The administrator will preserve the records of room vacancies & wipe out particular record from the datastore. Details like number of rooms in each hostel, number of members accommodate in eachroom.

A. *Fee Management:* The system handles the monotonous task calculating hostel fees in easierway inhaling faster access. For every accommodation, software allows administrators entrust with fare that hosteller needs to pay and gives them payroll for the same.

B. *Complaint Management:* The module will work with anapproachtomakecomplaintorsomesuggestionor feedbacks to be easier to coordinate, monitor, track and resolve issues put on by the hosteller in order to increase the performance of the management & aiming for bestimprovements.

C. *RFID Tracking:* Hosteller incoming and outgoing time will be recorded using RFID smart labels. When thehostellerIDcardwillbeswipedagainstthereader, information will be matched in existing system of the datastore & time will bemarked.

D. *Offline Notification:* An alert message of the above module will make acount.

E. *Job Hunting:* Job seekers will have an opportunity to search jobs in this platform. They will be able to identify job, analyse requirement & apply accordingly. The background process will check availability of workers & notify them for thesame.

The flow of this system is as follows:

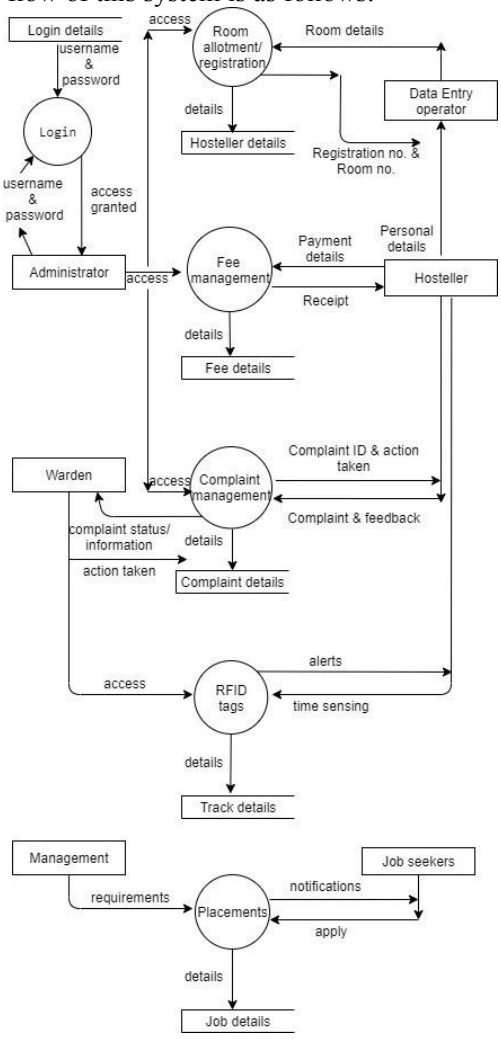

Fig. 1 Flow of proposed system

IV. CONCLUSION

Thepaperproposedauser-friendlyapproachforstudentHostel. The paper roots

on the requirements specifications of the hosteller with the analysis of the previous system, scope to the flexibilityof enhancement in future work. The system will ease all the members using this approach, to manage and automate overall processing of any largehostel.The idea highlights on managing hostel rooms, hosteller records,&roomallocationprocessetc.Theschemeap proaches flexible recommendation and can be reform according to the individualneeds.

***Abstract*— the combination of present day data technologies into modern farming has just added to yieldincrementsinthemostrecentdecades. These days,thedevelopingInternetof Things(IoT) alongside WirelessSensor Networks(WSNs)with their minimal effort sensors and entertainers empowernovelapplicationsandnewopendoors for aprogressivelyexact,webpageexplicit,and supportable agribusiness with regards to Smart Farming. Right now, present an all-encompassinghorticultural checking framework, its structure, anditsbuildingusage. Theframeworkbasically centers around in-situ appraisal of the leaf territory record(LAI),asignificantharvestparameter.Also, we present true difficulties and encounters picked upindifferentarrangements. Atlast,first outcomes are exemplarily exhibited so as to quickly address the capability of ourframework.**

KEYWORDS: IOT- INTERNETOFTHINGS

I. INTRODUCTION

Farm Monitoring using cloud network aims to increase overall development of agriculture filed. It aims to replace the traditional techniques with new wireless sensor technology. Farm Monitoring is a system that connects digital technology with traditional systems of agriculture. Thissystemwillenhancethe communication and sharing experiences between farmers and experts and others interested in this technology.Thissystemisdesignedtodevelopasmart farming system that uses advantages of cutting edge technologies such as IoT, wireless sensor network and cloud computing to help farmers to enhance the way of farming is done. Using [1] sensors like temperature, humidity, moisture etc. are used to collect information about the field and help farmers to take precise decisions on insights and recommendations based on thecollecteddata. Agricultureisoneofthemost important sectors of Indian Economy. Indian agricultural sector accounts for 18 % of India's gross domesticproduct(GDP)andprovidesemploymentto50% ofthecountrys' workforce.EstimationofCrop Yield during the cropping season plays an important role for planners and policymakers for decision making. It is one of the critical parts as it depends on different factors weather, soil and crop Management. Weather plays one of the important role for plant growth and development, soil is important for plants to get nutrients while crop management is important for planning the planting time and application of different management practices for better crop yield. Different approaches had been reported for estimating crop growth and development based on statistical and mathematical based models. In this study the authors have tried decision tree and random forest based Machine Learning approaches to estimate crop yield. DecisionSupportSystemfor Agro-technology Transfer (DSSAT) simulation model is used to estimate crop yield for the period from 1981 to 2025. The datasetsfrom India MeteorologicalDepartment (IMD) from 1981 to 2016 and National Oceanic and AtmosphericAdministration(NOAA)RCP4.5climatic variables from 2017 to 2025 were used in the current study. Wecanprovideadecisionsystemthatisableto learn from the input variable and predict the plant growth and development in real time. Our result indicates that there is (R2 = 0.67) and RMSE of 281 kg/ha from data predicted from random forest andCrop Yield Estimation. The studymakesuseof MODIS data from Earth Observing System satellites namelyTerra(EOS AM-1)& Aqua(EOSPM-1)from NASA. Thestudyvalidatesthepredictedyieldby comparing their values with NDVI values. High NDVI valuesmeansmorevegetationandmoreyield.Hence, itcanbesaidthatdecisiontreesandrandomforests can be used in forecasting the crop yield. FarmMonitoringusingcloudnetworksystemisused to generate decisions on irrigation using real time data. Farm Monitoring using cloud network proposed will help farmers to plan an irrigation schedule in his farm according to the collected data. Proper scheduling of irrigation and fertilization is very important for proper developmentofcropsaswellasfarmers. This [2]system will collect the data as per climatic conditionfromfieldsalongwithweatherdatafrom web repositories and this data can be used to take several

effective decisions for increasing the production of crops. Farm Monitoring using Cloud Network system used cloud and big data functionalities to store and retrieve data from anywhere, with the help of repositories and datasets. Cloud

And Big Data concepts are used separately to predicttheproductionofyields. Thissystemcollects data through sensors and stores this data in cloud databasethroughinternet. Thenusingthebigdata predictiveanalysistechniquestoanalyzeandpredict the crops production.

The result of the experiment is evaluated by the average error rate of 10-fold cross validation of each data set for 10 runs. 5-fold cross validation is a process which divides the data set into 4 blocks. 4 blocks are merged for training data and the rest block for the testingdata. Tableshowstheaccuracyofclassifying abalone data set, horse-colic data set and soybean data set. Wetesteverydatasetforfourtimesandthen calculate the average accuracy. Every time we randomly choose the training data and testing data. Using the training data to generate the decision tree classifier and then classify the testing data.

Accuracy	Jowar	Bajra	Soybean
Test 1	25.17	55.56	41.28
test 2	30.20	67.65	34.49
test 3	29.43	70.32	11.13
Test 4	27.59	69.26	14.25
Avg.Accuracy	28.10	65.70	25.29

Thissystemisproposedtofulfillthe gapbetween farmers and technology in agriculture. It helps farmers to understand the requirements to grow the crops in critical seasons and avoid financial losses caused to them. It will be helpful to the farmers of different geographicalregions.The[3] proposedsystemcontains facilities such as collecting real time data that will help farmerstomakeprecisedecisions. Theproposed system is cost effective as the entire process is softwaremanagedandsensormonitored. Thissystem will help in improving better yieldWeather data from the meteorological department can be used along with the sensed data to predict more information about the future which will help farmer planaccordinglyandimprovehislivelihood.

The proposed system will store all the information in a centralized [4]cloud, which will be available to all usersatalltime.Managementofalldatarelatedto land, location, area; soil and land characteristics through centralized decision support systems. Management of all data related to land, location, area; soil and land characteristics through centralized decision support systems.

The proposed system will manage all data related to land, location, soil through centralized decision support systems. Proposed system will eliminate farmer's limitations about technical knowledge and resources. It will provide farmer's to use agriculture resources efficiently.

Agriculture plays a crucial role in India's economy and around 70% of people earn their income through it and alsoprovideslargeemploymentopportunities. The technological advancement has led to remarkable achievementsindeveloping Agriculturalbased software applications to get faster information. But, many farmers are still applying the traditional methods of farming and hence the result of productivity becomesverylow. Agriculturepredictionprocessfor organic and inorganic farms is an open issue and it depends upon weather, soil fertility, water, seasons and commodity prices, etc. Soil fertility factor is paramount important to maintain the crop growth and increase theproduction.Thesoilfertilitylevelshelp the farmers to identify the deficiencies in the soil, namely nutrient content, soil type, pH value, EC (Electrical Conductivity) value and soil texture and to choosetherightcropstoincreasetheproduction.In this work, as a novelty, the soil fertility level is predictedbyanalyzingthe VirudhunagarDistrictSoil information and recommendations are offered for crop selectionandsowingbyusingC5.0: Advanced Decision Tree(ADT)classifieralgorithm.Usingthis technique,anAndroidbasedmobilephoneapplications named as Design of Smart Information System (DSIS) applicationhasbeendeveloped. Theproposed application activates the Global Positioning System (GPS) to identify the user location.The performance of proposedmodelisanalysedanditiscomparedwith the existing classification model for agricultural data. Agriculture is the backbone of India's economy. It also provides large employment opportunities to the people. Nowadays, the cropcultivation becomes very low since many farmers are still following the traditional farming methods. So the farmers, governments, agricultural scientists and the researchers are exploring new methods to get high yield from the farmland. Government of India is concentrating on the agriculture industry by handling several activities to increasethecropproductivity(VincyaandValarmathi, In

India, the primary nutrients (Nitrogen, Phosphorous, and Potassium)areverydeficient intheagriculturalsoil. So, it is mandatory to take necessary action for overcomingthedeficiency byapplyingthecorrect requirement of fertilizers for the crop. Soil health is the combination of physical, chemical and biological activitiesofsoil. Theessentialgoalofanytechnology with respect to agriculture is to make the better crop production with many

Immediate and sustainable benefits (AthmajaandHanumanthappa,2016). Farmers are not only harvesting the crops and vegetables,buttheyalsoharvestthemassiveamount ofdata. Therefore,thereisaneedofbigdataanalytics to analyze the same. It works with large datasets and problematical processing is done by database management applications or traditional data processing tools. MapReduce is used to access the big data sets with a parallel distributed algorithm and it is implemented with a programming model. It performs two operations:oneisMap()andanotherisReduce(). Map()takescareaboutfilteringandsortingthedata and Reduce () concentrates on summarizing the data (BhargaviandJyothi,2011).Dataminingdiscovers theunknowninformationfromthedataset. Thesoil nutrient information, soil composition and soil characteristics are required for determining the soil fertilitylevel. Also,themeasureofsoilfertility indicatesthedeficienciesthatneedtotaketreatment are based on the soil test.

II. RELATED WORK

Thesimulationmodelsplayaverysignificant rolein the development of the agro-ecological and socio-economic conditions. Several applications are in use, based on data mining algorithms in the agriculture field.Decision Support Systems (DSS) are used to generate data for agriculture management systems viz., the pest management, farm management and crop managementsystem. Theperformanceofthese systemsislow.Hence,theutilizationofIoT based advanced techniques could improve the process of farmer decisions about crop fertilization.

Many authors have done their research using data miningtechniqueswithsmallinstances. Thedecision support system model, related to soil water balance, consider several factors as soil type, weather, canal network,andcroptype(Oadetal.,2009).Gholapetal. (2012) used Decision Tree algorithm for predicting soil fertility. Author collectedthedatasetfromthe privatesoiltestinglaboratory,Puneandusedselection andboostingtechniquestotunetheperformanceofthe J48 algorithm. Ad boost is one of the boosting techniquesusedinthisresearch

Theypredictedthe soilfertilitylevelandclassifiedasverylow,veryhigh, low, high, moderate, andmoderatelyhigh. Further, they improvedtheaccuracylevel as 96.73% after applyingselectionandboostingalgorithm.Preethaiet al. proposed new approach for soil classificationand predicted various factors with the help of decision support system.

Theauthormonitoredtheagriculturalactivitieswith thehelpofthisnewdecisionsupportsystem. Their study isinvolved with the CoimbatoreDistrict dataset and by using enhanced C4.5 algorithm, fast decision support process is achieved. In addition, they have conveniently learned important information on pest and disease control through mobile phone. For rural formers, mobile multimedia agricultural advisory system based call centre provides the required information

III. LITERATURE REVIEW

Farm Monitoring using Cloud Network system used cloud and big data functionalities to store and retrieve data from anywhere, with the help of repositories and datasets.CloudandBigData conceptsare used separatelytopredicttheproductionofyields. This systemcollectsdatathroughsensorsandstoresthis dataincloud[5] databasethroughinternet. Thenusing the big data predictive analysis techniques to analyze and predict the crops production. Cloud database is used as it is an efficient and well defined application. Cloud based system integrated aims at follows: Cloud database is used to store and share the crop information's. Itgives smartness with flexibility, predictability, scalability and optimization. It provides information for farmers in an economical and reasonable cost Withregardstoarablecultivating,IoT frameworkscan possibly give new bits of knowledge and give a state- of-the-art situational mindfulness with an a lot more significant level of spatio-transient granularity of checking[6]. Theybolsterthecomprehensionof elements impacting crop development and yields, which is exceptionally critical for a feasible agribusiness. Throughsite-explicitadministration,IoT frameworks help to fundamentally spare homestead assets and, in this manner, increment ranch yield. Moreover, IoT-based harvest observing additionally improves yield displaying and the nature of yield expectations. By and large, the rising computerized upheaval,especiallyIoT combinationintopresentday

agriculture,isakeyempoweringagentthatpermitstorobot ize numerous procedures and bolster them with important extra data.

SincethepremiseoftheIoT anchorfromyieldsto ranchers is sensor-based information gathering, sensor gadgets and their in-situ sending is major for the achievement of Smart Farm-ing. Such gadgets run from little, ease, and asset obliged sensors to complex high-precision sensor stages that could be over the top expensive. For a huge scale crop moni-toring, for the most part numerous sensors are required. Henceforth, from a financial viewpoint, the cost of individual sensors is vital for the arrivalon venture (RoI). In Wireless Sensor Net-works (WSNs), such modest gadgets are ordinarily utilized for en-vironmental detectingofgenuinelyquantifiableparameters. These are remotely interconnected and intended for enormousscaleandlonghaularrangements. Asthey are dominatingly battery-driven, they are in like manner profoundly asset compelled. In this way, singular sensors have constrained detecting exactness that is remunerated by the enormous number of working together gadgets consistently gathering ecologicaldata. Also,ground-basedWSNscanbe supplemented by remote detecting that depends on airbornesymbolism. Thisistypicallyobtainedby satellites or as of late by rambles and, among others, is utilized to determine data about harvest development. This is especially advantageous to estimateWSN-situated in-situ data to significantly bigger regions.

IV. EXPECTED OUTCOME

Saves time by allowing you to always keep track of critical operations via a smartphone or tablet no matter where you are or the time of day. Increases efficiency by reducing the risk of unwanted downtime and interruptions. Increases security since the system alerts users of unexpected events and unwelcome visitors. Reduces the risk of environmental effects because you canimmediatelyseewhensomethinggoeswrong. A robust, easy-to-use system tailored to the specific needs and prerequisites of farms.

Easy to install and easy to expand and customise to the special conditions at your farm. Can also be supplemented with other types of monitoring, such as mobile cameras and special detectors, e.g. at the diesel tank, along fences and to monitor temperatures in differentlocations. Thisenablesyoutogatherall critical information for your operations in a single system. You can monitor everything from a smart, user-friendly app on your smartphone or tablet.An affordable, flexible monitoring system that can be adapted to any type of farm.

IoT basedfarmingsystemcanproveveryhelpfulto farmers since over as well as irrigation is not good for farming.Thresholdvaluesforclimaticconditionslikehum idity, temperature, moisture can be fixed based on the environmental conditions of that particular region. This system will generate irrigation schedule based on the real time sensed data from field and data from the weatherrepository. Thissystemcanrecommend farmers weather or not there is a need for irrigation.

IoT servesasapowerful,reliable,andcosteffective technology tto implement idea of “” that aims to empowerment of farmers with advanced connectivity through web services, measurement of environment factors like soil moisture, temperature, humidity and implementingcloudcomputingalongwithrealtimemonit oring

Abstract— **Currently about 70-85% of total irrigation of agriculture inIndia isdone through borewell and tubewellsi.e.viathegroundwater. Groundwaterishard waterwhichhas ahigh concentrationofminerals,andofthesecalcium salts arethemosttroublesome.Oneofthemain element which isfound inabundant and which ismainly responsible for causing hardness is calcium carbonate.**

Thesemetalsand hardness causingagents are harmfulofhumanhealthas wellas foragriculture. Althoughtheeffectisnotthatprominent, soitis ignoredmostof thetime. Butona longrun ithasa veryhugeimpactonthefieldofthecropandthe overall agriculture.

Thisproblem ofhardwatercanberesolvedby reducingthe concentrationofthesemetalsand salts by electro-magneticwater softener.Thiswater softenerisnotaburdentothepocketas itis affordable for the farmers. It operates at a frequencyof15kHzandpoweredbya 5-9voltage powersupply.This refinedwaterwillincreasethe fieldtoagreatextend.

Keywords—Calcium Carbonate,ReverseOsmosis.

I. INTRODUCTION

Withthecurrenteconomicalconditionand unstable market,thecategoryofpeoplethatsufferthemost arefarmers.Theyworkhardday in-dayouttoearn fortheirlivelihoodandintheendtheyarejustableto managefoodfortheirfamilyandsavesomepenny forfuture.Variousthingscanbedonetoimprove thisconditionoffarmersandoneof themistohelp andimprovethefieldoftheircultivation withno muchburnedontheirpockets.

Whenwe lookatthe parametersandthe possible reasonsfortheyield tobenot that significant,soone ofthefactor onwhichitcandependon agreat extendistheconditionandquality ofwaterwhichis being used for agriculture. In India mainly, agricultureisdonewiththe helpofgroundwaterfor mostof theperiodinayearandinthemonthsof monsoonthe farmersdependonrainasasourceof water fortheircrops.

Theproblem withgroundwater isthatitcontainslots of metals,saltsandhardnesscausingagents.This issueis ignoredtoagreatestextendwhenit comesto farming,butthesesaltsand hardnesscausingagents arenot goodforagricultureandit hinders thegrowth ofcroptoagreatextend.If thehardnessisremoved sotheoutcomeoftheagriculturewillbe more than expectedandconditionoffarmerswillbeimprove a andextend.

Ifthe hardness isremovedtheoutcomewillchange drastically,sotheproblemarisesishow toremove hardnessand saltofthewater atcheapandaffordable way.Therearevariousfiltersthatuse chemicaland electro-chemicalmethodstoremovehardnessof the waterduringitsbeingusedandthey arevery expensive. Thereisa oldtheorywhich saysthat whenhardwaterispassed throughastrongmagnetic fieldtheCaCO3elementscombinetogethertoform asinglemolecule.

Withthehelpof abovetheoryweuseelectro-magneticmethodto removehardnessandmakeit evenmore-betterforagriculture.This processesis goingtobeachievedby creatinganstrong electromagneticfieldandthewaterwillbe passed throughthisfieldwhichwillhelptoreduce the hardness andwaterwillbebetterforuse.Notonly combiningthehardnesscausing agentswillsolvethe problem but even filteringoutheseimpuritiesis equallyimportant.

Thisprojectusestheconceptofextractingdataabout theconditionofwaterof particularlocationand dependingonthatvaluetheamountofhardnessfrom thewaterwillberemoved.Thisprocesswillnotcreate anunnecessary stressonthecircuitand itcanworkin proper condition ofalongtime.Thiscircuitwillbe connectedwithafiltertoremovetheimpuritiesfrom thewatermakingitsconditionbetterthanbefore.

II. LITERATUREREVIEW

[1] EvaluatingGroundWaterQuality andSuitability forIrrigation.ApplWaterScience.By DianaAnoubam Sharma,Madhuri S. Rishi, TirumaleshKeesari.Explains how thelevelof impuritiesreducestheyieldofthefarm.Butthe gapishowtoremovetheimpuritiesofthewater.

B. Algorithm/Circuit

Theprojectwillusecolitiscrystaloscillatorwhichuses aLCtankcircuitto produceafeedback.Thecapacitor dividergeneratesapositivefeedbackto generatean oscillationwave.This tankcircuitwillgeneratean oscillator frequencyof26kHzwhichisrequiredfor combiningCaCO3 moleculestogether.Crystalis connectedinparallelwith resistors andcapacitorbiased junction.Thepowersupplywillbegivenby Adriano dependinguponthe locationofuse.Thecircuitdiagram isshownbelowwhichshows alltheconnection.

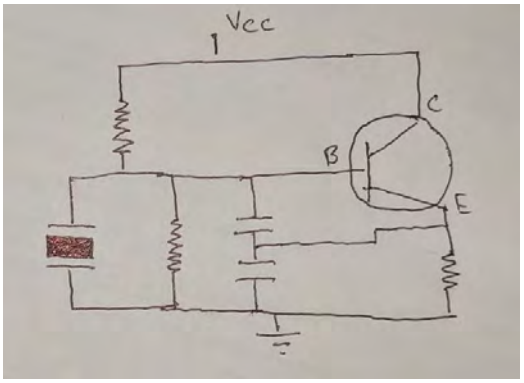

Figure2:ColpittsOscillatorCircuit

C. Applications

Thisprojectwillbeusedbyfarmersto reducethe hardnesscausingagentsfromthegroundwater.This will improve cultivation of farm as hardness is the waterisoneof themainhindranceforcultivation.

Farmerswillgetan overallpositivereturn fromthis project.

D. Advantages

Themainadvantageof thisprojectisthatthehardness causingagentsfromthegroundwateris removedand waterisfreefromimpurities.The projectwill helpthe farmersto getabetteryieldandbetterreturnsfortheir cultivation.

E. Methodology

Inourprojectwearegoingto useagileprocessmodel becauseitisincrementalaswellasiterativeinnature andit canadopt changesquickly.

Agile methodology isa practice that promotes continuous iterationof development and testingthroughoutthesoftwaredevelopmentlifecycle of theproject. AgileMethodsbreaktheproductinto smallincrementalbuilds.Thesebuildsare providedin iterations.Eachiterationtypicallylastsfromaboutone tothreeweeks.Everyiterationinvolvescrossfunctional teamsworkingsimultaneously onvariousareaslike– Planning,RequirementsAnalysis,Design, Coding, Unit Testing andAcceptanceTesting.

We aregoingto divideourprojectintodifferentphases andgoingtoworkonthephasessimultaneously so that the project can be done within stipulated time with properefficiency.Wearegoing to useAgile methodologybecauseitcanadoptchangesquicklyand if therewillbebuginthecodethenwecanfixthebug simultaneouslywhiletheprojectisgoingon.We can check our project and can make the decision accordingly.Whenwe aredone withparticularphase thenwecantestthesamephasesimultaneously.

F. Objectives

Todeterminetheagentsthatcause hardnessinwater.

Implementasystemtoremovethis hardness andincreasethefieldof agriculture.

Implementdatamining forremovalof hardnessinthewaterdependinguponthe location forwhichtheprojectisbeing used.

Theprojectwillrequireverylesspowerto operateanditwillnotbeaburdenforthe farmer

Theprojectwillnothaveanyadverse effecton farmoronenvironment.

Filteroutttheimpuritiesfromthe water andmake itinthebeststate inwhichit canbeuse

V. FUTURESCOPE

The project will use date set for all the location available from respective government websites. This datasetwill helptodeterminethe hardnesspresentin groundwaterat allthepossiblelocations.Thisproject willbeableto setthevoltagevalueforallthelocation withoutanyextrainformation.Thewayofreducingthe timecomplexity fromtraversingthousandsofrecordsin thedatabasewillbesolvedby findingmostappropriate algorithmdependingonthedataset.

VI. ACKNOLEDGEMENT

WesincerelythankourguideMs.PrachiJanraofor her guidanceandconstantsupportandalsofor the stickto ourbacks.We alsothankstheproject coordinatorsforarrangingthe necessaryfacilitiesto carry outtheprojectwork.

We thank theHOD,Dr.SheetalRathi,DeanAcademic, Dr.R.RSedamkar,thePrincipal,Dr.B.K.Mishraand thecollegemanagementfortheirsupport

Abstract— **Thisapplicationis amobilityserviceprovider. An application that matches passengers withrickshaws, via websitesandmobileapps.Itisoftenhardto findarickshawin Mumbaiwhenneededthe most.Thisapplicationmatchesyou witha rickshawwillingtotakeyoutoyourdesireddestination. Toorderarickshaw,itisnecessarytoownasmartphoneand to register within the mobile application by entering your name,e-mailaddress,a cellphonenumber.Globalpositioning systeminthesmartphoneisusedtodeterminethelocationso thepassengerdoesnothaveto knowtheexactpickupaddress. The ride order appears on thenearest driver's smartphone applicationand he/shecanacceptorrejectthe ride.The applicationaimsto bridgethegap betweenrickshawsand passengers andprovidesthemwithaplatform tofindfares easily, without thefear ofconvoluted interfaces likeOlaor Uberwhichoften scarethedrivers.**

The app does not interfere withthe payment system of rickshawdrivers,making iteasyforanyrickshawdriverto adaptunlikeothermobilityserviceproviderswhich restrictthe driversto followthecompanyprotocols.Thispaperdescribes theapplication,itsdevelopment,andits technical implementation.

Keywords—Mumbai, Mobility Service Provider, Global PositioningSystem,Rickshaw,Smartphones.

I. INTRODUCTION

Itisverydifficulttofindanauto rideinMumbaiwhen neededthe most.Thisprojectfocusesonsolvingthis issue. Basically,itis anapplicationthatconnectspassengerswith Rickshawdrivers.

To order an auto rickshaw, it isnecessaryto own a smartphoneandtoregisterwithinthe mobileapplicationby enteringyourname,e-mailaddress,acellphone number. Globalpositioningsysteminthesmartphoneisused to determinethelocation sothepassenger doesnothaveto knowtheexactpickupaddress.Theride orderappearsonthe nearestdriver'ssmartphoneapplicationandhe/shecanacce pt orrejecttheride.

The app does not aim to interfere with the payment systemofrickshawdrivers,makingiteasyforany rickshaw driverto adaptunlikeothermobilityserviceproviderswhich restrictthedriverstofollow thecompanyprotocol.

Generally, wefocusonsavingpeople'svaluabletime, promotethe useofsustainabletransport,optimisetrafficand givingthe autorickshawdriversacomparativelymoreuser friendlyUI,freedomtouse

traditionalmethods andan opportunitytooptimisemonthlyprofit.

II. MOTIVATION

Withover110,000autorickshawdriverscatering toaround2 millionMumbaikarsondaily basis,wearestillfacingan immenseproblemoftransportinthecity.There hasbeenan exponentialincreaseinthe riseofgiantlikeOlaandUber especiallyinMumbaibutthisproblemisunsolved. This motivatesus tobringinasolutiontooptimizeetheuse of publictransportoralready existingfacilitywhichcould eventuallycontributeto thesolvationoftrafficproblemsin Mumbai.

III. PROBLEMDEFINITION

Giants likeOlaorUber recentlycameupwithOlaAuto andUberAutobutbecauseof theirbyzantinebusiness models,it becameworse.

The majorproblemsfacedbytheautorickshawdrivers includedhighcommissionrates,complexUI, usageofonline paymentmethods.It turnedoutthatthey made20%more profit goingthetraditionalway.

Bymakingthisapplication,weaim tosolvealltheabove problems andalsofocusonreducingthewastageoftimethat goesinvainfindingrides.

IV. OBJECTIVESOFTHEPROJECT

Ourmainobjectiveofbuildingthisapplicationistoact asbridgebetweenthe autorickshawdrivers inMumbaiand users tooptimisethe ridesatthe timeofrushhourandalso ensuring thateveryuserisableto gettherideontimeand everydriverisabletogetrideaccordingtohispreference.

Overall,objectivesofthisprojectareto:

- PromoteSustainableUrbanTransport
- Createamulti-lingualapplicationwithasimpleruser-interface
- Createanapplicationsupportingtraditionalpayment methods
- Optimizetraffic

V. SCOPEOFTHEPROJECT

Having110, 00Autorickshawdrivers and200,000 auto commentatorsoneverydaybasis.Withthesehugenumbers, itissignificantthatwehave agiganticmarkettotargetand thisapplicationhasacommendablescopeandweareveryOptimisticaftertheresponse thisideagot in themarket analysissurvey.

VI. APPLICATIONOFPROJECT

- These arethemajorapplicationsinclude:
- PrivateAutorickshawService
- SharedAutorickshawService
- 200,000Commentators: Offices,Schools,Colleges, Workers, Hawkers,etc.
- VirtualAutoRickshawService
- TrafficOptimization

VII. MARKETANALYSISSURVEY

AMarketAnalysisof about80 autorickshawdriverswas doneenquiringaboutthefollowingquestions:

- Areyouanownerorauto-rickshawisonRent?
- Areainwhichyou drivemostly
- Type ofdriver: Ola,Uber,Share,Private
- According aSurvey,most ofthepassengerstravel by Ola/Uberbecauseof therejectionsby auto-drivers.Whatexactlyistheproblemfacedby auto-drivers?
- Accordingtoyouwhatisthemajorproblemfaced byOla/UberAuto-rickshawdrivers.(Thisquestion is only applicable if Ola/Uber driver. If normal driver,put NA)
- Howmanyhoursadaydoyoudrive?
- Howmanyhoursyouwastefindingaride?
- Howmanyhoursyouwastefindingaride?
- Ifthere existsa solution toalltheproblems you discussed you pay on a monthly basis. May be aroundRs.500orhow muchyoucouldaffordtopay monthly?

Accordingtothe survey,56.2%ofauto-rickshawdrivers rentedtherickshawwhiletheother43.8%were theowners

Whilethehighestpercentvotedtheyfacedproblemswith paymentsystemsofOla/UmberAuto, alarge proportionvoted theydidn't understandtheconvoluted userinterfaces

VIII. PROPOSED WORK

The perceptionsofauto-rickshawsandtheirdriversamongst the middleclasses,media,consumerorganizations,and policymakersarelargely negative.Thevehiclesareseenas polluting,unsafe,and asignificantcauseofcongestion,and the drivers as greedy.Auto-rickshawsare perceivedasan intrusion into o r d e r e d u r b a n space, to b e t a m e d a n d controlledwithstrictpoliciesand punitivepenalties. Policymakingrelatedtoauto-rickshawsis dysfunctional–it doesnotadequatelyaccountfortheperspectiveofdrivers norforthefactthatthey provideа much-valued,cost-effective transportation service. While the concernsregardingovercharging,for example,onthepartofauto- rickshaw users, are understandable, policymaking has focusedlargelyon enforcingcompliancewithregulations, whichdo notreflectoperatingconditions.Auto-rickshaw numbersareseverely restrictedtocontrolpollutionand mitigatecongestion;private motorvehiclesare not,despite their rapidgrowth.

Awiderangeofpolicy responsesandtechnological advancementsare necessarytorespondtothecriticismsand negativeperceptions regardingauto-rickshawsandtheir impacts,toimproveservicequalityforauto-rickshaw users, andtoadvancethewelfareofauto-rickshawdrivers(note that theseobjectivesarenot antitheticaltoeachother,butare mutuallysupporting).Thisisparticularly necessaryifthe auto-rickshaw is to compete against new entrants in the publictransportmarketwhoutilizesmartphonetechnology tolinkpassengerswithindividualdrivers whodrivecarsor smallvans,whichare,unlike auto-rickshaws,notexposedto dustandweatherand areoftenair-conditioned.Thesenew competitors,suchasOlaandUber,are increasinglyavailable inurbanIndiaandoffermorecomfortableservice for above auto-rickshaw rates.Fixedpricesalsoremovehagglingand theperceptionofover-chargingandindividualgreedfrom thetransaction.The entranceofthesecompetitorsprovides auto-rickshawdriverswithampleincentiveto improvethe servicetheyofferto passengers.However,theirabilitytodo thislargelydependsuponpolicyreforms andavailabilityof technologies, which must address the economic factors drivingtheperceivedovercharging andgeneraldysfunction inthe auto-rickshawsector.These reformsneedtobebased onarecognitionofthedriver'sperspective,and thedaily reality of auto-rickshaw operation, which is one of long hours,highcostto revenueratios,andlimitedopportunities foreconomic mobility.Drivingan auto-rickshawprovidesa wagethat isunlikelytoplacethedriverandhisfamily above thepovertyline. Restrictive permitregimes, permit price inflation, and thenecessityof purchasing permits on the blackmarketmakeowning anauto-rickshaw impossibleor extremelydifficult,withmanypurchasesendingindefault andrepossession.

A platform that iseasyto understand for arickshaw driverwithalmostno formaleducationandconvenienttoa commuter whoisalways inahurrytogetarickshawis needed.Platformthatdoesnotburdenthe already limited economicmobilityofthedriver.Aplatformthatmakesuse

ofmoderndaytechnologiessuchasUPIandGPSforfinding customersaccordingtoconvenienceofthe driveraswellas finding rickshaws according to needs of the customer without charginghefty chargestoeither.

B. Softwarerequirements

1. Android Studio 3.5.2: Android Studio is the integrated development environment for Google'sAndroidoperating systemdesigned specificallyforAndroiddevelopment.
2. Java virtual machine (JVM): JVM is a virtual machinethat enablesa computer torun Java programs aswellasprogramswritteninother languagesthatare compiledtoJavabytecode.
3. JRE: 1.8.0_202-release-1483-b03amd64
4. OpenJDK64-Bit ServerVMbyJetBrains
5. Windows Operating System: Windows operating systemistheOS platformrequiredforthe deployment oftheproject.
6. Google Firebase: Firebase is a Backend-as-a-Service —BaaS,app-developmentplatformon Google Cloud Platform. Primarily used for cloudcomputing,database management,user authenticationandhosting.
7. Google Realtime Database: Realtime Database is Firebase'soriginaldatabaseused forrealtime updatesonusers andrickshawdrivers

X. TECHNOLOGY

A. Java

Javais ageneral-purposeprogramming languagethat is class-based,object-oriented,anddesignedtohaveasfew implementationdependenciesaspossible. It isintended to letapplicationdeveloperswriteonce,runanywhere,meaning that compiledJavacodecanrunonallplatformsthatsupport Javawithouttheneedforrecompilation.Javaapplications aretypicallycompiledtobytecodethatcanrunonanyJavavirtual machine(JVM) regardless of the underlyingcomputer architecture. ThesyntaxofJavais similar toCandC++, but it has fewerlow-levelfacilities than either of them. As of 2019, Java was one of the mostpopular programming languages in useaccording toGitHub,particularly forclient-serverweb applications,withareported 9milliondevelopers.

JavawasoriginallydevelopedbyJamesGosling atSunMicrosystems(whichhassincebeenacquiredbyOracle)and released in 1995 as a core component of Sun Microsystems'Java platform. The original andreferenceimplementationJava compilers, virtual machines, andclasslibrarieswereoriginallyreleased bySun underproprietarylicenses.AsofMay 2007,incompliancewiththe specifications of theJava Community Process, Sun hadrelicensedmostofitsJavatechnologiesundertheGNU Pluginforapplets).

On,releasedonSeptember25,2018;Oraclereleasedfor thelegacyJAva8LTSthelastfreepublicupdateinJanuary 2019forcommercialuse,while itwillotherwisestillsupport Java 8withpublicupdatesforpersonaluseuptoatleast December2020.Oracle(andothers)highly recommend uninstallingolderversionsofJavabecauseofseriousrisks duetounresolvedsecurityissues.SinceJava9(and10and 12)isno longersupported,Oracleadvisesitusersto immediatelytransitiontoJava 11(Java13isalsoa non-LTS option).

General Public License. Meanwhile, others have developed alternative implementations of these Sun technologies, such as the GNU Compiler for Java (bytecode compiler), GNU
Class path (standard libraries), and Iced Tea-Web (browser)The latest versions are Java 13, released in September 2019,
and Java 11, a currently supported long-term support (LTS)

IX.REQUIREMENTSPECIFICATIONS

A. HardwareRequirements

XI. CONCLUSION

Thisundertakinghadafundamentalobjectivetobuildup a model capable ofhandling tremendous influx of client bookings inrealtimeaswellasstoringthe dataforfurther analysis. It wasconceivabletopresumethatthelevel of achievementofthe cinematographicincomeexpectationis veryunique dependentonthe typologyoftheneedyvariable utilizedintheinvestigation.The exactmodelshowedgreat measurableoutcomeswhenthe reliantvariablewastwofold and interim. Nonetheless, in what respects themulticlass expectation, theoutcomes wereexceptionallyalong way fromthe realworld,contrarilyaffectingthemodel.Wehave studied variousresearchpapersrelatedtorecognitionmodel.

Wehaveoptimizedthe Euclideandistancealgorithmas per our requirement to achieve better efficiency and accuracy.Inthis

report,anintelligentsystemwasdeveloped basedonmachinelearning andfeatureextractiontodeal with theproblem ofrickshawactivity.

Basedonwhatwehaveresearched,improvementscan be made for the existing systems to support real time bookingswithlessresponsetime.

Weaimedoncreatingadesperatelyneededintherealm ofrickshawsinMumbai,this modelcanbefurther extrapolatedtoothermetropolitancitieslikeDelhi and Bangaloreas rickshawsare deployedineverylargecityin India thereforeleavingascopeforlargeexpansion.Witha businessmodel tobolsterthisarrangement,anall-round product canbebuilt.

XII.ACKNOWLEDGMENT

Wesincerely thankourguideMrs.JesalkumariVaroliafor herguidanceandconstantsupportandalsoforthestickto ourbacks.Wealsothanktheprojectcoordinatorsfor arranging thenecessaryfacilitiestocarry outtheproject work.
We thanktheHOD,Dr. SheetalRathi,DeanAcademic,Dr.
R.R Sedamkar,thePrincipal,Dr.B. K. Mishraandthe collegemanagementfortheirsupport.

Abstract—**theamountofwaterrequiredby aplant depends upon number of factors, which include plant'sspecies,soiltype,weatherand variousother microparameters.In general,bestwaytowatermost plantsisby applyingenoughto moistentheplant's entirerootsystem,and then lettingthesoildryout slightlybeforewateringagain.A soilmoisturesensor canbeusedtocheckthesoilnearplantroots andwater them accordingly.But,plantscanreceivewater naturally through rainandaswe know, toomuch water canbeasharmful astoolittle water tothe plants. Inthisprojectweareplanningtobuildan automatic wateringsystemwhichnot onlymeasure soilmoisturebutalso check theweatherdependingon whichitmakesdecisionto watertheplant.Tocheck theweatherwewillbeusingawebbased API which willcommunicatewithourAdrianomicrocontroller. If,in nearfuturethereischanceofrainfallthesystem willrefrainfromwateringthe plantsregardlessofsoil moisturestatus.Thisprojectwillhelp reducethe humaneffortrequiredandalso decreasewater consumption,whilemaintaining the healthof the plants.**

I. INTRODUCTION

Nowadaysthereis scarcityofwateralloverthe world, especiallyinIndiadue tolowgroundwatertableand irregularrainfallmostofthewatergetswastedin drainage.Thusthereisa needofmoreefficientand cheapalternativetotraditionalformofwateringthe plants.

Automatedplantwateringsystemestimateandmeasure theexistingplantandthensuppliesdesiredamountof waterneededbythatplant.Itis minimizingtheexcess wateruseaswellas keepingplantshealthy.Thissystem Savestimeandis accurate.Atplaceslikesocietiesand Buildinggardenswecan implementan automatic wateringsystemwhich is easyandaccurateforthe growthofplants.Thiswillminimizethehuman interventionandwillalso savetime.

To demonstratebuildingandenhancingofexisting automaticplantwateringsystems,weexploitavailable technologieswehavesuchas afreewebhostingand Freecloud todevelopsucha system.Webelievethatour Proposedsystemcanbeappliedtodifferenttypesof plants.

II. BACKGROUND

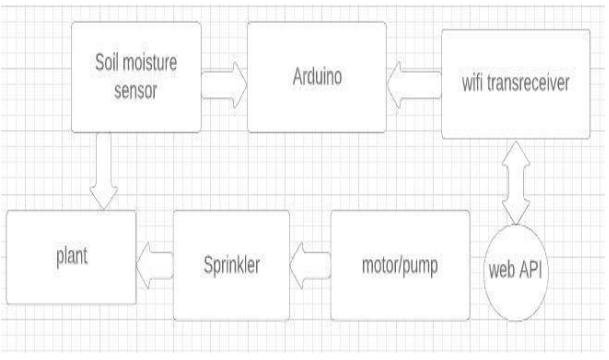
FuzzylogicNaturallanguage(likemostotheractivities inlifeandindeedtheuniverse)is noteasilytranslated Intotheabsolutetermsof0and1. (Whethereverythingis ultimately describableinbinarytermsis a philosophical Questionworthpursuing,but inpracticemuchdatawe mightwanttofeedacomputerisinsomestatein Betweenand so,frequently,aretheresultsofcomputing.) Itmayhelptoseefuzzylogicas thewayreasoning really worksandbinaryorBooleanlogicis simplya special caseofit.

InternetofThings(IoT)is a systemofinterrelated computingdevices,mechanicalanddigitalmachines, objects,animalsorpeoplethatareprovidedwithunique identifiers(UIDs)andtheabilitytotransferdataovera networkwithoutrequiringhuman-to-humanorhuman-to-computerinteraction

EmbeddedSystemiscombinationofcomputer hardware and softwarewhichis designedfora specific function.Industrialmachines,agriculturalandprocess industrydevices,automobiles,medicalequipment, cameras,householdappliances,airplanes,vending machinesandtoysaswellas mobiledevicesareall possiblelocationsforanembeddedsystem. Embedded systemtechnology reducesthecostand sizeofelectronic circuitforprojectdevelopments.

III. PROPOSEDIDEA

Figure1: Blockdiagram



Ourprojectis basedonthreefunctionalmodel.First functionis tomeasurethemoisturecontent insoil. Secondis tokeeptrackofweatherconditionsbytheuse of realtimedatafromopensourceWeatherAPI.Lastly analysesboththedata,comparetopre-setvaluesforthe givenplantanddecidewhethertostartthemotorfor watersupply.Thecompletesystemiscontrolledby Adrianoboardwhichis programmedusingAdrianoIDE software.

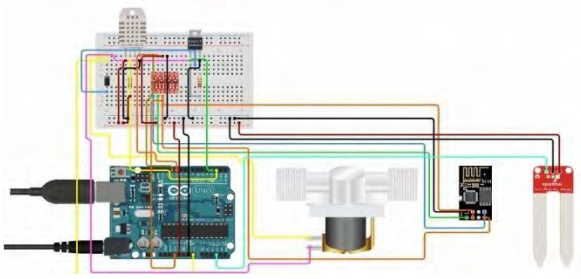


Figure2: PictorialRepresentationof System

A.Detectingsoilmoisturecontent:
Themeasurementofwatercontent inthe soilis achieved byusageof soilmoisturesensorwhichsendsan alertto themicrocontrollerwhen the soilmoisturedropsbelow Thresholdlevel.

B.GatheringWeatherdata
To tracktheweatherconditionsofnearfutureweuse openweathermapAPI whichis an opensourceweather APIthatprovidesdata inJSON formattothe microcontrollerineveryten minutesusingWi-FiTransceiver.Thisdata includesmeantemperature, probabilityof shower,airhumidity andwindspeed.

Automaticwateringandrecordingdata
Basedon theanalysisandcomparisonofcollecteddata withcertainpresetrequirementsandfuzzylogic Algorithmthe systemdeterminestheappropriate conditionstostartthemotorandwatertheplants

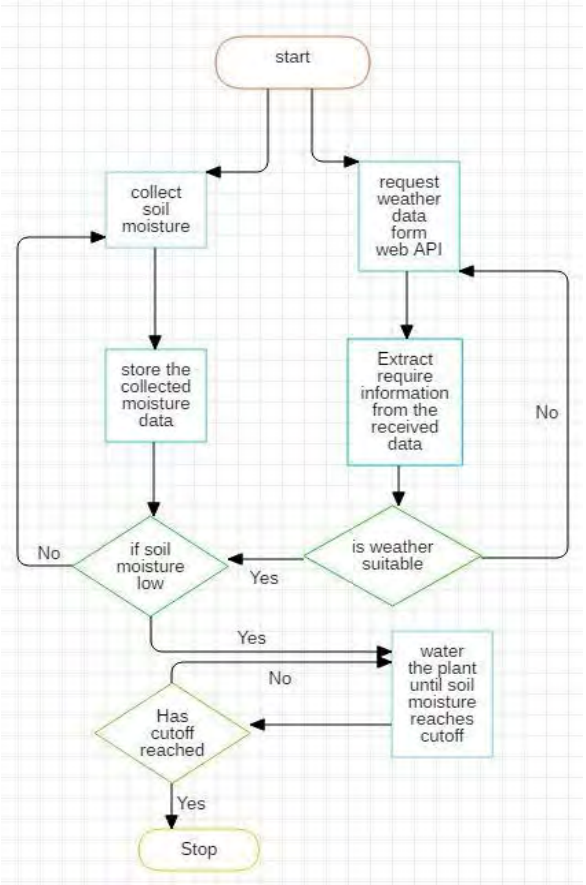

Figure3: FlowchartofAutomaticWateringSystem

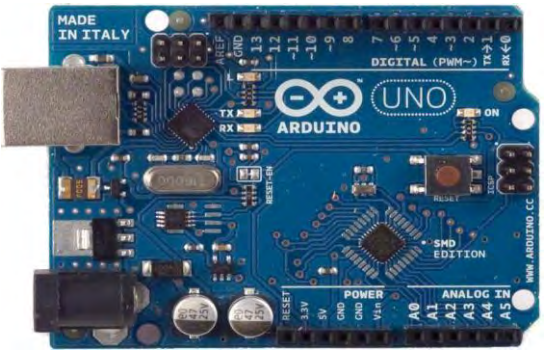
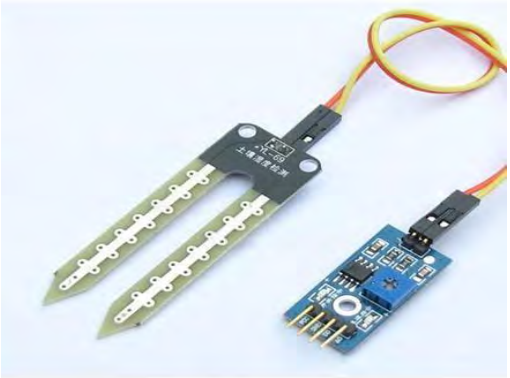
IV. COMPONENTS USEDFORSYSTEM

1. Adriano Uno: This microprocessor is used to gathercollecteddatafromadjoining modulesandtakesdecisiontostartwatering.



2.Soil MoistureSensor:Soilmoisture sensorwillbe used to measuremoisturecontent inthesoil.



3. ESP8266-01 (Wi-Fi Transreciever):Tran'sreceiverwill be usedtocollectdatafromopenweathermap.org APItogetreal-timeweatherreports.

4. Relay: Themainoperationofthisdeviceis tomakeorbreakcontactwiththehelpofa signalwithoutanyhumaninvolvementinorder ToswitchitONorOFF.Wewillbeusingthisto Controlthemotortopumpwater.

5. Water pump:DCpoweredpumpsuse direct current frommotor, battery, or solar power to move fluid in a variety of ways.

6. SDcardmodule:Thismodulewillbe usedtocollectdata intheSDcardforfuture analysis.

V.RESULTANDANALYSIS

Duringtheprocessoftestingwehaveachievedpositive resultsfromthisproject.Itwasfound thatourplants wereabletogrowwithoutdehydrationwhilstusing limitedwater.Although,furtheroptimizationcan be Donetoourfuzzyruleset.ThedatastoredbySDmodule canbeusedtofurtheranalysesthepatternusingdata analysisalgorithms likelinearregression,K-mean clusteringetc.Wecan alsoaddaminicameramodule availablewithesp32Wi-Fimoduletostoregrowth processintheSDcardwhichcan beconvertedtoa time-lapsetofurtheryourunderstandingofthegardening.

V.CONCLUSION

Designanddevelopa smartsystemthatcansensethe contentofwater inthesoil.Andbyanalyzingtheresults irrigationbecomeseasy,accurateand practical.The Volumes, volumetricwatercontentsplayanimportant role inproducingtheoutput.

Theprimaryapplicationofthisprojectis to provideplantswithadequatewaterwithoutwastefuluse ofwaterandmanuallabor.Thisprojectis makingthe useoffuzzy inferencesystem todecidetheplant

Wateringprocess.Thisprojectcanfurtherbeextendedto largerscalecombiningwiththeprinciplesof rainwater harvesting;itcouldbeinstrumentalinareaswithsevere shortageofrainfall.

Implementing System to Detect and Isolate BlackHole Attackin WirelessSensor Network

Mr. Manish Rana, Abhay Singh, PrathamYadav
Department of Computer Engineering
Thakur college of Engineering and technology
Mumbai, India
Manish.rana@thakureducation.org, abhayyogendrasingh@gmail.com, ypratham4@gmail.com

Abstract—***AmobileAdhoc network(MANET)isa collectionofautonomousnodestoformanetworkwithoutuse of any supportinginfrastructure. The networktopology isunstructuredandnodes may enter or leave attheirwill.A node can communicate toothernodeswhichare within itstransmission range.Soanynodecanactasahost ortherouterinthenetwork, whichresultsinsecurityissuesinMANETs.Aprominent attack in MANETs isaBlackhole attack. In theblackhole attack, theattackernode broadcastsgoodpathstothenode falsely duringthe route-establishmentprocess.IftheBlackHoleNodeispresentin thenetwork,itwillreducethe network performancealongwiththe depletion ofthe energy inthe network.***

Thetechnique presentedis for detectionandisolation of blackholenodesfromthesensornetwork.Inthistechnique,the blackhole nodeisidentified bymonitoringthefakereplypackets that aretransmitted bythenodesanditwillberemovedfrom the network.Wevalidateour approach usingnetworksimulator

Keywords—
1.AODV:*Adhoc On-DemandDistance Vector*

2. MANET:*MobileAdHoc Network*

3.WSN:*Wireless Sensor Network*

4.NS2:*Network Simulator*

I. INTRODUCTION

MobileAd-hocNetwork(MANET)isacollection of autonomousnodestoformanetwork withoutuseofany supportinginfrastructure.Ifthetwocommunicatingnode sare withinthesamesensingrangetheycancommunicate toeach otherindividually, otherwisetheycancommunicatethrough multihopswherenodesactasintermediaterouters.Inthis typeofnetwork, nodescanenterinthenetwork orleavethe networkatanytimewithoutinformingto others.InMANETs, thereisnoguaranteethatapathfromsourcetodestination is free from malicious nodes. Due to lack of central coordination, thereareseveralattacksinMANETs.Active attackmayharmoralterthedatabeingtransmitted acrossthe network. IntheSybilattack,awell-knownattackisaBlack holeattack, whichiscreatedbyamaliciousnodebysendinga veryquickreplywithhighestdestinationsequencenumbe r andshortest path.Blackholenodecaneasilycorruptthe information. Toavoidsuchtypeofattacks,research community paysmuchattentiontowardsthesecurityof MANETs.
TheBlackholeattackisaddressedintheliterature either byconsideringthe energies of thenodes. The firstapproachdoesnotprovideaneffectivesolutiontothe BlackWholeattackas the maliciousnodescan beavailablein thenetworkwithdifferent energies. Inthesecondapproach, providingcertificationstothenodesthataremobileisdiffi cult.

II. MOTIVATION

AmobileAdhocnetwork (MANET) isacollection of autonomous nodestoformanetworkwithoutuseofany supporting infrastructure.Thenetworktopologyisunstructured andnodes mayenterorleaveattheirwill.Anode can communicate toothernodeswhicharewithinitstransmission range .So any node can act as a host or the router in the network,whichresultsinsecurityissuesinMANETs. A prominentattackinMANETsisa Blackholeattack.

ObjectivesofProject

Withtheadvanceintechnologyandmethodology moreand morenetworksarebeingdevelopedduetowhichthesecuri tyof thesenetworks hasbecomeamajorconcernandmanyexperts andthinkersinthefieldoftechnology havecomeupwithnew techniquesin order todefendtheraisingsecurityissues.

Scopeof theproject

Asthetechnology evolvesdaybydayvarious breachesinthe existingtechnology cometolightandhencevariousattacks whichshouldbeprevented, thisprojectparticularly focuseson identification andprevention ofBlackHoleAttack.InBlack holeattack,anadversaryannounces avalidshortestpathtothe destinationbytransmittinganomalous routinginformation.Out of

repliesfromdifferentnodesduringroutediscovery, thesourcenodeconsiderspathfromthemaliciousnodeco nsidering itasagenuine node having fresherpathtothedestination.Asa result,a bogusroutewillbecreatedthroughthatnode.

ProjectsImpactAnalysis

MANETsaremorevulnerable toattacksbecausetheyhave somespecificcharacteristics ascomplexityofwireless communication andlackofinfrastructure. Hencesecurityisan important requirement inmobileadhocnetworks.Oneofthe attacksagainst networkintegrityinMANETsistheBlackHole Attack.Hencesecurityisan importantrequirementin mobilead hocnetworks. Oneoftheattacksagainstnetworkintegrityin MANETsisthe BlackHoleAttack.

ExpectedOutcome

Nodes withoutintroductionofanynewcontrolpacket; defaultroutingpackets propagateinformation of adversariestoothernodesinthenetwork.

Themechanismprovideshighpacketdeliveryrate withnoticeable normalized routingoverheadand acceptable average ToovercomeBlackHoleAttackinWirelessSensorNetwo rk sothatwecanprovideasafenetworktocommunicate with otherswithoutthefearofspoofing oranychancesof denialof serviceattack.

Applicationofproject

I. TodetectandIsolateblackholeattack Routingprotocol.
II. TheimprovementofroutingprotocolsinWSNin termsof security.
III. Analysisof RREQfloodingattackinMANET.

III. METHODOLOGY

TheProjectfollowsthesoftwaredevelopment lifecycleand usethespiralmodel.Thespiralmodelconsists ofthephases showninthefigure.

Abstract— **Public Intercom is an integral part of the railway system. At many public places like railway stations, when people walk-in they look for the basic information and this task is still being carried out by humans and is person-specific. The inquiry window becomes a bottleneck and leads to bad user experience. We have proposed a "Digital Public Intercom" system that can be used to manage public profiles in any physical space using Wi-Fi or data network connection. It consists of a chatbot that can answer frequently asked questions for location and also various questions related to the trains. The proposed system will surely help to improve the user experience. An individual would be able to schedule their train trips with the help of this system.**

Keywords— Chatbot, NLP, Train Suggestions, PNR

I. INTRODUCTION

Indian railways are backbone of transportation system. Around 30 million people travel daily in India. Public Intercom is an integral part of Railway System. It comes into the picture when user queries are infinite and enquiry window becomes a bottleneck due to chaos. Indian trains are always late which wastes passengers time. Almost all of the people who travel by train prefer to have their trip properly scheduled to reach the destination on time. Many people check the IRCTC website to check their (Passenger Name Record) PNR status and if it is confirmed, they look for basic information like live status of the train, "On which platform the train will arrive?" etc. Even to obtain the above-mentioned information from a mobile phone application, the user has to download an application which consumes internet bandwidth and wastes time as well. Thus, the passengers can save their time and internet data by using the Chatbot by just typing questions and getting their queries solved at faster rate.

II. LITERATURE SURVEY

A. Study on the Public Information Service Systems of Railway Industry

Railway transport has a special important status in the development of economy society. Transportation costs have a significant influence on people's choice of travel. The above paper focuses on railway information service for public and the main factor is how to achieve effectively sharing of information resources, how easily and efficiently it can be transmitted. An aim is to provide satisfactory customer Information service considering all the conditions of existing technologies.

B. Android Based Educational Chatbot for Visually Impaired People

The above android application provides an educational based chatbot for physically impaired people. The visually impaired people ask queries through chatbot which gives response to all the education related questions. The application can be easily launched using google voice search. The output will be received in terms of voice using text to speech method. An application gives voice instructions for its usage, once opened. Responses from the chatbot will be voice based as well as text based. So that everyone can use the application.

C. Home Automation using IoT and a Chatbot using Natural Language Processing

The purpose of the mentioned web application is to control the electrical home appliances over the internet. It allows user to text information through chatbot in order to control the appliances. The sent information will be processed using Natural Language Processing and any device connected to the local area network of the house controls the other devices. The NLP techniques like tokenization, removing stop words are performed. This system uses a Wi-Fi based Local Area Network Protocol. An interference problem can be solved by giving a specific Local Area Network to each application. Messages for controlling devices can be sent by a chatbot.

D. A Platform for Human-Chatbot Interaction Using Python

This paper describes a chatbot agent which is capable of communicating using natural languages. Also, it explains how human-chatbot interactions are analysed by providing web connectivity to evaluate chatbot on web-based platform. As users are having confidential problems in sharing their own data online, a web-based platform is provided to users in order to communicate with the world by their chatbot easily using python.

III. REQUIREMENT

The requirement for this project includes some software specifications which are: -

1. Heroku server- This is an open server which can be used to create the link between the chatbot and railway API.

2. Heroku CLI & Git – This is a command line interface for working and deploying the local repository to the Heroku server which take the help of Git or Github desktop.

3. Django- It is an open source high level python web application framework.

4. MYSQL- an oracle backed open source Relational Database System (RDBMS).

5. Railway API- Responsible for providing the information as JSON object like PNR status, Train between the stations, running status, etc. The module uses a unique API key provided by API providers such as erail.in and railwayapi.com.

6. NLP- Natural Language Processing is concerned with how technology can meaningfully interpret and act on human language inputs.

IV. SYSTEM ARCHITECTURE

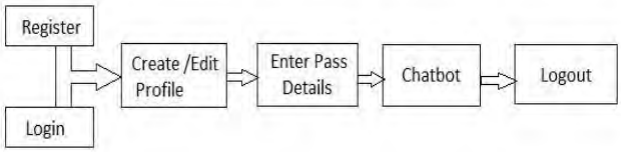

Figure.1. System Architecture

1. Input- To get PNR details user can give input as: "PNR 85451234".
2. Output- The output of above query will be "TRAIN NAME-Siddheshwar Express DOJ-1/2/2020, TRAIN NO. -13552, CUR STAT-RLWL/021‖".
3. Backend- a backend that is used to connect web application and railway API is MYSQL.

3.1 Heroku server- This is an open server which is used to create an application to store the backend database and creating the link between the chatbot and railway API.

3.2 Python- The backend is programmed using Python version 3.7 and pip. This is used to fetch the JSON object from the Railway API.

V. PROPOSED SYSTEM

Profile management helps user to store their data .User can enter source and destination to fetch list of trains to reach particular station by time. Alert notification regarding expiry of pass and PNR fetching facility are parts of public intercom platform. It also includes a chatbot that will answer any frequently asked queries by user. The queries could be of any type for example a query regarding particular location or a query like" On which platform a particular train will arrive?" and so on.

VI. IMPLEMENTATION

1. Profile Creation - Provide login panel for users to store their data.
2. Integration - Integrate Railway API to web application.
3. Storage - Create back end to store user profiles and pass data.
4. Alert Notification – Create a process to send push notification 2-3 days before the specified date.(pass expiry date)
5. Query Evaluation - Specify the intent name and describe the expressions that a user can ask. Specify the parameter and create a logic adapter.

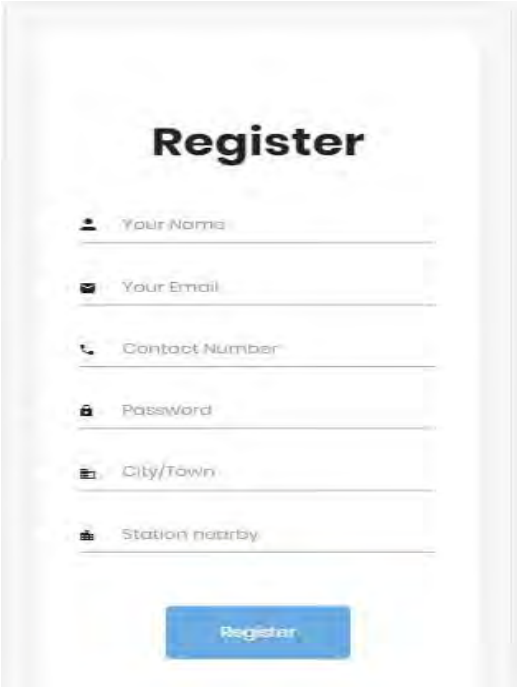

Figure.2. Registration Portal

Figure.3. Pass Input

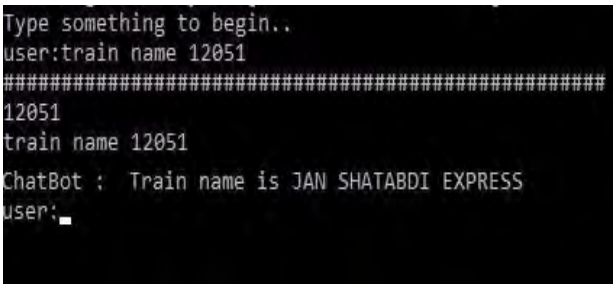

Figure.4. fetching train name from train number

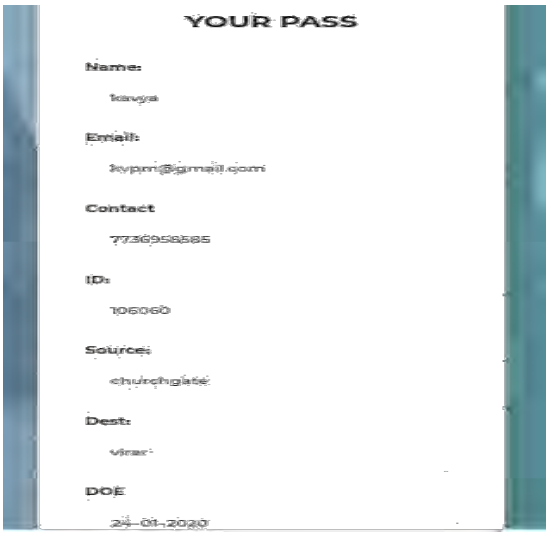

Figure.5. fetching train live status

The system will send notifications 2-3 days before user's pass expire.

VII. CONCLUSION

This paper successfully explains and implemented the public profile management and chatbot which can be used to get the required information from Indian Railway. In the future, we will include the voice automated chatbot for handling queries. The key feature of an effective chatbot is to make sure it enhances your customer's experience. This chatbot will benefit the passengers by saving time, memory space.

VIII. ACKNOWLEDGMENT

We want to thank our guide Mrs. Vidyadhari Singh., Assistant Professor, Thakur College of Engineering and Technology, Mumbai, India for his continuous support and his encouraging and fruitful advises in accomplishing this task.

I. INTRODUCTION

Fora longtime,people have beenlyingon theirresumestogetbetteropportunitiesand theyhavelargelybeenabletogetawaywith itbecausecurrently,there isnowayto verifytheclaimsmade ontheresume.This isabigproblemfor corporationsand educationalinstitutesfor hiring'sand admissions,andwe aimtosolvethis problem.Also,there presentlyexistsno resumescoringsystem,asitishardtoputa valueona largelysubjective approachto analyzingresumes.The systemof repsand nags[2] weaimtoimplementwillsolve thisproblem,andalso make thetaskof Hiring departmentsinmany organizations much easier.

A.Block chain

Blockchainisa databasethatisdistributed andmaintainsrecordsof acontinuously-growinglistsecured fromtampering and revision. Each blockisconnected tothe previousblock viaa linkwhichhasa timestampattachedonit.[5] The main technical innovation ofbitcoin-which was conceivedin2008 andfirstimplementedin 2009-Servesasthepublicledgerforbitcoin transactions.New blockscanbecreatedby every user, theyare alsoallowedtosend newtransactionsandattempttoverifythose transactions,andcreatenewblocks.TheInspirationfor other applicationshasbeen the bitcoinblockchain.

B.Ethereum

Ethereumisusedfor decentralized applicationsor dAppsandisbasically blockchain-based platform. An Ethereum Virtual Machine orEVM isa decentralized virtualmachineprovidedby Ethereum,which can execute scriptsusing aninternationalnetworkof public nodes. [6] In contrast to the Bitcoin Script, the virtualmachine's instructionset,isthought to beTuring-complete. An internal transaction pricingmechanism, known as "Gas", is usedto mitigatespam and allocate resources on thenetwork.

C.WordPress

WordPressbasedonPHPandMySQLis a contentmanagementsystemthatismostly usedwiththe SQLite databaseenginebut can also be used by MySQL orMariaDB database servers. It has a template systemanda pluginarchitecture, known asthemesinsideWordPress. Bloggingissomething whichismost associatedwithWordPressbutisnowoften usedtosupportother typesof webcontent aswellincludingmoretraditional mailing listsand forums&onlinestores.

D. MongoDB

MongoDBisadatabase programwhich provides cross-platformdocument-oriented database,itusesJSON-likedocumentswith schemaclassifiedasaNoSQL database program.

E.SmartContracts

A smartcontractissuchthatitisusedto digitallyverifyandprotectandenforce the termsunder which the contracthad been initiallywritten.These allow the performance ofcredibletransactions withoutthird partiesor anyexternal participation. [6]Thesetransactions are trackableandirreversible. Proponentsof smartcontractsmaybemade partiallyor fullyself-executing,self-enforcing,orboth,a claimthatmany kindsof contractual clausesmake.The mainpurpose of a smart contractsistoprovidea guaranteeand protection,thatissuperior totraditional contractlawandtoreduceother transaction costs associatedwithcontracting.Mostof these smartcontractsareusedin implementationof varioustypes of smart contracts.

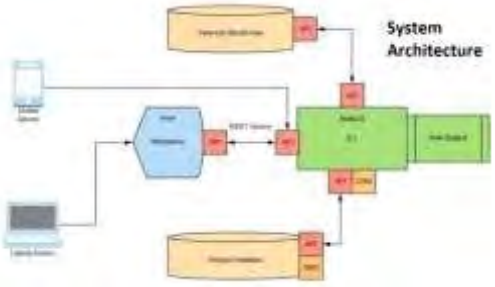
II. LITERATURE SURVEY

We have surveyedseveralresourcesand papers.Fromthese paperswe understood several principlesanddida gapanalysis. WefirstlookedatMethodsandsystemsfor employment and education verification usingblockchainweunderstoodhowtouse blockchaintodeployverification system butwe feltthatit hadalackofexplanation abouthow technologystackmay affectthe effectiveness.Further,we tookalookat multiple papers regardingComputerized methodandsystemforcreatinga digital resume,[4]A systemandmethodfor creatinga databaseof independently validated educationaland work experience profiles(curricula vitae)usingblockchain smart contracts,feedback based reputation ontopof thebitcoinblockchain,A Study on PrivilegeElevation Attack Management for SmartTransaction Securityon BlockchainEthereumBasedSystem.Agap analysiswasconductedonallof theseand taken into consideration for our paper. [5]

III. METHODOLOGY

A.ResumeCreation

Tocreatearesumeon ourwebsite,auserhas tofirstcreateanaccount on our websiteand select h i s a c c o u n t t y p e w h i c h w i l l b e a n ‘Employee’oran‘employer’.Thesewillbethe tworolesonourwebsite. Anyclaimsmadeby theemployee willbe verifiedby the organization orhispeers/supervisor. Upon loggingin,theuserhasto completearesume form,thedatafromwhich willbestoredinto themongoDBdatabase.



B. Database Storage

Themongo DBdatabasewillstorelogin credentials, resumedetails,userdetails,score and multipleotherdatafields. Thedatafrom themongoDBserverwill beinsertedtoand extracted fromusingREST APIservice.Weare intended on using RESTAPIaswearehopeful of further developingamobileapplicationand expandforward fromourwebsite.[3]

C.ServerScripting

WeareusingNodeJSand PHPforourserver-sidescripting.Themajor useofNodeJSisto fetchandpost to ourAPI’sfrommongo DB. NodeJSwillbe mainlyusedfordata transmission.[3] Also,PHPisbeingusedasit worksverywellwithWordPress,asWordPress itselfiscodedin PHP.Thus, PHPallowsusto implement avariety ofcustomfeatures on WordPress, as WordPress doesn’t match all ourneeds. WordPresshas avariety ofplugins wecanuse,buthoweveralot ofadditional programmingisneededthroughPHPto make them worktoour needs.

D.APICalls:

Everyinteraction withthedatabasewill happenthroughaREST APIcall.Thisis implemented keeping in mindfuture expansion ofthewebsitetootherplatforms andcreatea modularapproach.Currentlya fetchand astoragecallwillbemadetothe database.This mightincreaselateras development continues.

E.ScoreSystem

Everyprofilewill havea correspondingscore associatedwithit.[1] Thisscorecanbe changed via repsand negs. A rep isapositive increaseintheusersscore,whileanegisaDecreaseinthesc ore.Wehavereps andnegs [2]tied toeventsinourwebsitethatshall trigger them. These havebeendiscussed indepth furtherlater.

F. Verification using Block chain Every verifiedclaimon thewebsiteand the particularchangeinscore tiedtoitshallbe updatedontheblock chain.[7]Wewillbeusing Ethereumas ourblockchainandwillbeusing Ethereum smart contractsto reflect the changesmadetotherepscoreandverification statusof aclaimontothe Blockchain.[1]

IV. CONCLUSION

Thus,this projectwill beimplementedusing Block chaintechnologyand theusage of smart contracts.Asystemofrepsandnegs[2]willbe implementedasasystemofpointsin the website toincentivize website activityand enableaprofilescoring system. Every transactionwillcausetheexchangeofrepsand negs [2]tobeupdated inthepersonsresume. A verifiedresumewillbecreated and reputationwillbeused togradeeach resume.

shivaani.1512@gmail.com,harsheenkaur23@gmail.com,diadubey14@gmail.com,kalpana.iiitm@gmail.com

***Abstract*— Blockchain is a singly LinkedList of blocks, with each block containing a number of transactions. It provides a decentralized, immutable data store that can be used across a network of users, create assets and act as a shared black book that records all transactions. Each transaction can be easily queried, affording greater transparency and trust to all parties involved. Blockchain technology has gained a lot of attention due to it's attractive features such as security, transparency and immutability in the area of elections and voting. Many systems Have been created for small applications like a boardroom voting process. BitCongress is an example of such an online voting platform based on the blockchain technology. It gives a whole system for voting based on tokens.Using this technology of blockchain, voting application can be created for maximum privacy and authentication.The election system in India is not completely transparent and secure. The details of the citizen are not securely handled and also control of the whole process lies in the hand of a handful of people resulting in a centralised system. This project proposes a distributed system on blockchain technology for secure and immutable voting for each user having an AadharID , i.e., a verified citizen of the country. It introduces a voting system which does not rely on a third party for tallying the votes and has a self- tally function.**

Keywords—Blockchain, Solidity, Ethereum

I. INTRODUCTION

Blockchain technology is the new age technology that can be used as a distributed ledger for storing data and also for making transactions. Elections and voting is an essential part of any democracy. With the development of technology, online voting systems have appeared and being actively developed. Electronic voting systems can be very convenient and can be accessed by all the citizens living in remote areas. Voting ensures that all the citizens are a part of the legislation of a country indirectly. Citizens have a say in who they want as a representative for themselves. Blockchain is a growing list of records called blocks which are linked to each other as a continuous chain. Blockchain is a decentralised system where the users are connected to each other and can also view the whole process. There are a set of miners who mine on the blockchain. These miners get an incentive for mining on the blockchain. Oncea transaction is made on the blockchain, to include it on the chain, it must be first verified by all the nodes on the blockchain. If maximum of the nodes verify it as a valid transaction, then only it can be added to the chain or it is rejected. A group of transactions are included into a block to add to the blockchain. Each block contains a cryptographic hash of the previous block, a timestamp and transaction data. This kind of process to add transaction to the blockchain ensures that each transaction is connected to the previous transaction. Once a transaction is done on the blockchain, it cannot be reversed ordeleted.

II.EXISTING VOTING SYSTEMPROBLEMS

Existing system for elections in India has a few problems which are addressed below :

- Vote counting is done by a third party which makes it a centralised system. This kind of system may arise in tampering with the finalcount.
- Votes given are not anonymous, i.e., voters can be linked to a particular vote. In order to maintain voter privacy, vote anonymity must beprovided.
- Proper authentication of voters or candidates during the election process is of utmost importance. If authentication is not provided, anyone can pretend to vote on behalf of a validvoter.
- Tampering with the Electronic Voting Machine (EVM) provided at the polling booth can happen by a particular party member or anyoneelse.
- One person must vote only once in a particular election. Multiple votes from a single person results in double voting issue.

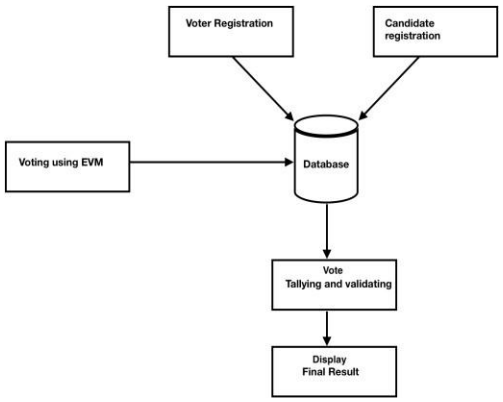

Fig: Existing system flow chart for voting

A) Objective:

The objective of this system is to create a secure and scalable environment for voting across the nation. It ensures that the election process of the country is as transparent as possible. The System must provide user authentication, it must provide verification and viewing of votes and it must prevent the double voting issues in current system. The major objectives of the proposed system are :

- Transparent and secure storage of details of all stakeholders of the system.
- Enable a secure anonymous voting and remove double voting.
- Transparent tallying of votes, which can be re - verified and talliedeasily.

III. PROPOSEDWORK

The proposed system introduces blockchain technology instead of using the regular database. Blockchain will ensure that once a transaction or a vote is cast, it cannot be tampered with and also the voters can be made anonymous. The voters and the candidates are all registered on the blockchain and the election officers verify the details of the users. Smart contracts written on the blockchain make sure that a voter can vote only once and also that the candidate has met all the conditions necessary to stand in the elections. The proposed system tries to overcome the shortcomings of the system followed right now in our country. It can be done by making use of the blockchain technology for complete transparency and anonymity and also makes sure that it is easy to use. There are four actors participating in this voting ecosystem. The following are the actors and their roles along with their functionalities in the system.

1. Voter Role: a voter will have the role of registering himself/herself on the blockchain. He/she has to provide necessary details for registering themselves on the blockchain. A voter also has the role of casting the vote on theblockchain.

2. Candidate Role: a candidate first has to register on the blockchain by providing the necessary details. Then to standintheelection,he/shemustapplyonthegiven election and provide his/her legitimate credentials. To apply for election, he/she must submit a security deposit. A candidate can also withdraw from the election. And also the candidate must register to a valid party.

3. Party Role: a party must first register itself on the blockchain. It must be a nationalised party and must have a party symbol. A party must also announce their representative candidate before the election process starts. A party can also dismiss any of its candidate if the candidate is notverified.

4. Officer Role: there will be two officers: election officer and presiding officer. Presiding officer will only create the election and watch over the election process. Election officer will be the one who verifies the voters, candidates and also the parties.

A) The proposed system can be divided into three kinds of modules :

1) User registration on the blockchain database:

There are three types of actors who will use the proposed voting system i.e., voters, candidates and parties. All the given three users must first register themselves on the blockchain database. All the relevant data regarding the users are to be submitted. Voters must submit their Voter Id for unique voting ID and also adhar card for verifying that the voter is a valid citizen of this country. Information like address, name, phone number, birth date, etc. must be asked by the system to store the relevant details of the voter. To ensure more security biometrics of the voter can also be taken so that the voter is fully authenticated. This information is stored on the blockchain and verified. There is also another actor called as the election officer who will verify the details of all the users of the system. The election officer will have access to the database. Candidates will have to register themselves as well. All the information that a voter has submitted must be given by the candidate as well as, a candidate must first be a valid voter. The candidate must also include the party he/she belongs to and also according to the Indian election system, a security deposit must be submitted before standing for any election. The deposit amount depends on the type of election he/she is standing in. This deposit fee must be taken at the time of registration of the candidate. Party is the third actor of this system. A party is a group to which a candidate belongs to. Each party must also register itself on the blockchain. Each party must have a symbol which a voter can recognise and vote for. Each party must mention the candidates belonging to theirparty.

2) The votingphase:

In this phase of the system, all the actors have registered themselves on the blockchain and the election can be started. There will be another officer called the presiding officer who will create the election and watch over the whole process. Once the election is created, the voters will be asked to vote for their choice of candidate. Before submitting the vote, the voter is first verified for authentication purpose. Once the verification is done, the vote is submitted for that candidate. A vote can only be submitted if that particular voter has not voted before andif the voted candidate is a valid candidate. If these conditions are not met, the vote is rejected by the blockchain. The whole election process can be seen by the candidates and parties for transparency.

3) The tally phase:

The last phase of this system will be the tally phase. This tally of votes has to be done along with the voting phase. If a third party is introduced for tallying, it can result in tampering of the final count if the third party is not honest. To avoid this kind of situation and to achieve full decentralisation, the tally is done along with the voting. When the vote is submitted, tally is also counted withthat.

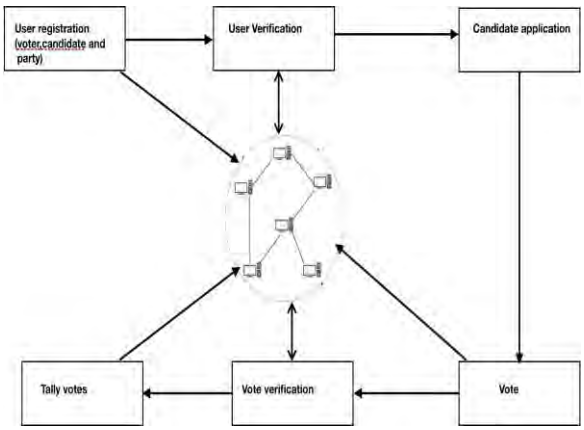

Fig: Overall workow diagram for proposed system.

IV. REQUIREMENTS

Software Requirements-

- Front End-HTML, CSS,JavaScript
- Back End-Solidity, SmartContract
- Operating System

Hardware Requirements-

- Min Memory:4GB
- Disk size: 1TB
- Processor: 64bit CPU with 8 cores and speedof 2.4 GHz

User requirements-
Officer-

- Creates and monitorselection
- Monitors voters andcandidates
- Depl oy result

Candidate-

- CreatesId
- Register himself/herself
- Gets vote count

Voter-

- CreatesId
- Castvote
- Observeresult

V. ARCHITECTURE

In the overall architecture of the online voting system, there will be four main entities. These four entities , i.e., Voter, Candidate, Party and Officer will be participating independently through the Blockchain. Each user will be linked to the Blockchain and all the transactions will be visible on the Blockchain.

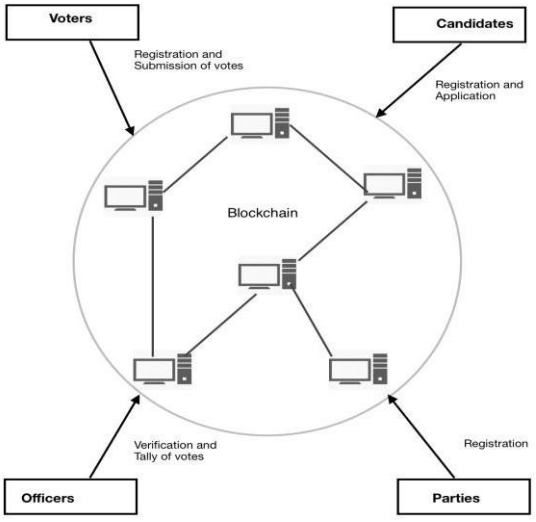

Fig: block diagram for proposedsystem.

VI. TECHNOLOGYUSED

1) Solidity:

Solidity is a contract-oriented programming language for writing smart contracts. It is used for implementing smart

contracts on various blockchain platforms. Solidity is a statically-typed programming language designed for developing smart contracts that run on the EVM. Solidity is compiled to bytecode that is executable on the EVM. With Solidity, developers are able to write applications that implement self-enforcing business logic embodied in smart contracts, leaving a non-repudiable and authoritative record oftransactions.

2) Truffle:

Using the Ethereum Virtual Machine (EVM) to create life simpler as a developer, a world-class development environment, testing framework and asset pipeline for blockchains. You get with Truffle: Built-in Smart Contract Compilation, Linking, Deployment and Binary Management, Automated Rapid Development Contract Testing, Scriptable, Extendable Deployment Migration Framework, Network Deployment Management for any amount of Public Private Networks, EthPM NPM Package Management, ERC190 Standard, Interactive Direct Contract Communication Console, Configurable build pipeline with tight integration assistance and external script runner runningscriptsinaTrufflesetting.Truffleisanenvironment developer, testing framework and blockchain asset pipeline. It enables developers to spin smart contract projectby clicking a button and offers you with a project framework, files and directories that make it much easier to deploy and test.

3) VSCode:

Visual code studio is a user friendly desktop application for compiling and running programs of various extensions. It has the solidity compiler as well.

3) MetaMask:

Metamask is a crypto-monetary wallet that can be used on browsers like Chrome, Firefox and Brave. It's also an extension to the browser. It operates like a bridge between ordinary browsers and the blockchain of Ethereum. The MetaMask wallet can be used on three distinct web browsers to store Ether and ERC20 tokens keys. It also enables users to browse a normal browser's Ethereumblockchain.

4) Ganache:

Ganache enables us to develop a personal Ethereumblockchain for testing, executing commands, and inspecting state while controlling how the chain works. It provides you the capacity to carry out without price all the activities you would have on the primary chain. Many developers use this to test their smart contracts during development. It offers easy instruments like sophisticated checks on mining and an integrated block explorer. Ganache offers 10 fake accounts and 100 ether for each account with a virtual network. Each account has an account address and also a private key associated with it.

VII. CONCLUSION

The current system used in India can be affected by double voting and intrusion of privacy of the voter. The proposed system provides privacy and transparency to the voters as the transactions can be viewed by all the users of the Blockchain. Data related to each and every election is safe and immutable as the data on Blockchain cannot be tampered by anyone and is irreversible. Blockchain provides advantages to all the stakeholders of the electoral system and also the citizens of the country. In a democracy like India, Blockchain technology can be effectively used. It can decrease the chances of double voting or false voting from the voter's side. Voters can validate their respective votes. Since Blockchain is transparent, it provides an unambiguous centralised system and also helps candidates to view the tally process themselves. It also helps reduce the time and energy spent by the officers for tallying as it is a self tally system and prevents the intrusion of duplicate voters. Blockchain helps create a transparent, secure and automated voting system for all the participants of the election process.

A Study of Live Streaming Practices in India

AdarshKumar Dubey, RahukKumar Jha, Salman Khan
Department of Computer Engineering
Thakur College of Engineering and Technology
University of Mumbai
Adarshdubey1998@gmail.com, Rj240499@gmail.com, iamjaankhan@gmail.com

Abstract - **Even though Live Streaming is on the rise in North America and Far East Asia, it's popularity in India is still negligible. Since 2016 there was an Internet Bloom in India because of the telecom revolution. As a result, there was a sudden upsurge in Live Streaming popularity. During the IPL Finals between Mumbai Indians and Chennai Super Kings in 2019, Hotstar a Live Streaming platform recorded 18.6 million concurrent viewers. To study this online gathering technological occurrence in India we conducted a survey of streamers and viewers. Based on their streaming, viewing and interacting practices we conducted an online survey of 500 people and even interviewed 10 streamers. The collected data revealed how different viewers react to different types of streaming content and streamers. We also observed the viewing perspective of viewers and the stimulus behind the streamers and even studied the interactions among the audience as well as between audience and streamers. Based on the collected data we are predicting the scope of live streaming in India.**

Keywords: live streaming, streamers, interactions, platform, reward-system.

I. INTRODUCTION

Live streaming refers to online streaming media simultaneously recorded and broadcast in real time. It is often referred to simply as streaming. Live stream services encompass a wide variety of topics, from social media to video games to professional sports. Platforms such as Facebook Live, Periscope, Kuaishou, and 17 include the streaming of scheduled promotions and celebrity events as well as streaming between users, as in videotelephony. User interaction via chat rooms forms a major component of live streaming. Platforms often include the ability to talk to the broadcaster or participate in conversations in chat.

Here we are creating a live streaming platform for gamers. We are using various tools and technologies like web technology, file transfer protocols like RTSP. This website will allow the streamer to stream their content and using this platform they can broadcast their content to users. It includes comment section used for comment, recommendation section, virtual money and many other features.

With live streaming becoming a financially viable market, particularly for esports, streamers and organizations representing them have looked for metrics to quantify the viewership of streams as to be able to determine pricing for advertisers. Metrics like maximum number of concurrent viewers, or number of subscribers do not readily account for how long a viewer may stay to watch a stream.

II. RELATED WORK

Twitch and Youtube gaming are two platforms where the gamers can broadcast their live matches with an audience which supports them through paid subscriptions and donations.

Twitch is available in US and requires subscription for $5 per month. Youtube gaming is a part of Youtube where normal users can watch their favorite gamers playing Esports. It has facility of Superchats and donations.

The highest ever live audience in Youtube Gaming was 400K when PewDiePie was playing Minecraft . Along with these 2, countries like China conduct Esports tournament which gather a large audience and generates revenue by sponsoring various companies.

III. TECHNOLOGY USED

HTML: HTML elements are the building blocks of HTML pages. With HTML constructs, images and other objects such as interactive forms may be embedded into the rendered page. HTML provides a means to create structured documents by denotingstructural semantics for text such as headings, paragraphs, lists, links, quotes and other items.

HTML can embed programs written in a scripting language such as JavaScript, which affects the behavior and content of web pages. Inclusion of CSS defines the look and layout of the content.

CSS: Cascading Style Sheets (CSS) is a style sheet language used for describing the presentation of a document written in a markup language like HTML. CSS is a cornerstone technology of the World Wide Web, alongside HTML and JavaScriptBootstrap:Bootstrap is a free and open-source CSS framework directed at responsive, mobile-first front- end web development. It contains CSS- and (optionally) JavaScript-based design templates for typography, forms, buttons, navigation and other interface components React JS: -Reactis a JavaScript library for building user interfaces. React can be used as a base in the development of single-page or mobile applications, as it is optimal for fetching rapidly changing data that needs to be recorded. However, fetching data is only the beginning of what happens on a web page, which is why complex React applications usually require the use of additional libraries for state management, routing, and interaction with an API: Redux, React Router and axiosare examples of such libraries.

Node.js: Node.js is an open-source, cross-platform, JavaScript runtime environment that executes JavaScript code outside of a browser. Node.js lets developers use JavaScript to write command line tools and for server-side scripting—running scripts server-side to produce dynamic web page content before the page is sent to the user's web browser.

PostgreSQL: PostgreSQL, also known as Postgres, is a free and open-source relational database management system (RDBMS) emphasizing extensibility and technical standards compliance. It is designed to handle a range of workloads, from single machines to data warehouses or Web services with many concurrent users. It is the default database for macOS Server, and is also available for Linux, FreeBSD, OpenBSD, and Windows

IV. IMPLEMENTATION DETAIL

The project implementation is divided into 5 steps.

1. **Web Server with Basic authentication:**

We will place our react components inside the client directory and backend code in the server directory. For this part, we will be working inside the server directory. We are using passport.js for authentication. We have already installed passport and passport-local modules. Before we define our local strategy for authenticating users, let's create an app.js file and add the necessary code to run a basic web server. Mongo DB needs to be installed before doing this. We also need to define the schema for our User model. Create a database directory with UserSchema.js file in it and add the following code. We have three methods on our User schema. generateHash method will convert plain text password to bcrypt hash. We are using it in our passport strategy for converting plain password strings to bcrypt hash before storing them in the database. validPassword method will take in a plain text password and validate it by comparing it to bcrypt hash stored in our database. generateStreamKey method will generate a unique string that we will issue to users as their streaming key for RTMP clients.

2. **Setting up an RTMP server in Nodejs:**

Real-Time Messaging Protocol (RTMP) was designed for high-performance transmission of video, audio, and data between broadcaster and server. Twitch, Facebook, Youtube, and many other sites who offer live streaming accepts RTMP streams and transcodes then into HTTP streams (HLS format) before distributing them to their CDNs for high availability.

We are using node-media-server, a Node.js implementation of RTMP media server. It accepts RTMP streams and remux them to HLS/DASH using ffmpeg.

3. **Displaying live streams:**

For this part, we will be working in the client directory. Since its a react app, we will be using webpack and necessary loaders to transpile JSX into browser ready JavaScript.

We are using react-router for routing and bootstrap on the frontend along with video.js for displaying live streams. Add components directory with Root.js file in it and add the following code.

4. **Issuing streaming keys to broadcasters:**

Create Settings.js component.

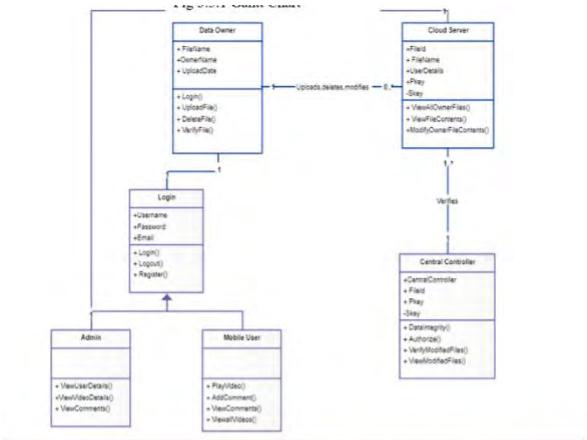
Inside our passport's local strategy, when a user successfully registers, we create a new user record with a unique streaming key. If a user visits /settings route, they will be able to view their existing key. When components mounts, we make an XHR call to the backend to retrieve user's existing streaming key and render it inside our <Settings/> component.

Users can generate a new key by clicking Generate a new key button which makes an XHR call to the backend to create a new key, save it to user collection and also return it so that it can be rendered inside the component. We need to define both GET and

POST /settings/stream_key routes. Create a server/routes/settings.js file and add the following code.

5. **Generating live stream thumbnails:**
In components, we are displaying thumbnail images for live streams. We will be generating these thumbnails whenever a new stream connects to our server. We will run a cron job to generate new thumbnails for live streams every 5 seconds. This cron job will execute every 5 seconds, retrieve active streams from NMS API and generate thumbnails for each stream using the streaming key. Import this job inside the app.js file and run it.

I. FLOWCHART AND RESULT



V. CONCLUSION

Live-Streaming platform will allow audience and gamers to connect in a very friendly and intriguing manner using the power of live broadcasting and live-chatting. It will revolutionize the gaming community like never before. It will help in smooth running of Esports tournament across the globe and will also allow advertisers to advertise in a very new way. It will also help to generate the revenue to the streamers by various means like ads, donations, live-streaming and sponsors.

Abstract—**Semantic Web Technologies enable machines to un- derstand and interpret data published in amachine-interpretable form on the web. In today's world where the smallest of the tasks require human-computer interaction, it is important that the data which is published on the internet along withbeing human understandable as well as machine understandable. This will improve the search results and will help the users in making informed decisions. Over 400 million searches are conducted every day on the Internet by people trying to find what theyneed. A majority of these searches include a web user looking forsomethingtobuy.Semanticsearchwillhaveadramaticimpact on the accuracy of these searches. It will possibly eliminate information asymmetry where a better informed buyer gets the best value. Currently, E-Commerce is critically vulnerable due to the scarcity of proper standards where HTML does not provide the syntax and semantics of information. Semantic web has the potential to influence the further development of the entire internet market, where e-commerce plays an important role. This paper discusses the semantic architecture for e-commerce using ontology language like RDF, in depth. It also discusses the shortcomings of the existing e-commerce websites and how semantic web will change the game for the internet market. This gives an overview of how the producer describes their resource online and how that data is made machine readable using the semantic web, which helps the consumer to retrieve efficientdata. There is a need for further developing these futuristic models based on our current understanding of e-commerce models and nascent semantic webtechnologies.**

Index Terms—semantics,ontology,RDF,e-commerce website

I. INTRODUCTION

A semantic web is a web that functions as an RDF knowl- edge graph. Google, Facebook etc. all have their versions of a knowledge graph. All databases contain entities and relationships. The entities are nouns (subjects and objects describing people and things) and the relationships are verbs, they describe how people, places and things are related toeach other. RDF graph databases address this shortfall by specializing in three things: 1) disambiguating the entities, 2) articulating the relationships between entities and 3) allowing large-scaleintegration.Thepointofthesemanticwebistomake the web more precise and more of a well-integrated whole that allows discovery at web scale. Ontologies, extensi- ble, flexible RDF graph data models are the main elements of semantic web that serve as rich description logic to live with the data and describe each individual context in a machine readable way. They make the data machine readable. Most companies use taxonomies, but some do use ontologies. Tax- onomies and ontologies both are hierarchical but ontologies goes further enabling any-to-any relationships, not just parents and children. Thus ontologies are more accurate and reflective of the natural world. Ontologies also allow inferencing, in which machines identify relationships between entities that are not spelled out in the initial data model, but which depend on relationships that were previously explicit. In this way, the whole graph can develop and grow at machine scale [1]. In today's world millions of people rely upon the information provided on the internet to make their purchasing decisions, but the ad hoc fashion in which the descriptions of products and services that are mentioned on the website are interpreted and offered up by mainstream search engines makes this process far less accurate than what the users might wish. As data moves out of the enterprise and onto the web the picture becomes quite less clear. Even on the product's own website the description and the information about the project is not conveyed properly. For the consumer wishing to compare and contrast video audio players from a number of competing providers, it is very difficult to ensure that they are comparing apples with apples. The web services aim to provide seamless interoperation among networked programs and devices. How- ever, the main obstacle of achieving interoperability among deployed Web services is that the computer is unable to interpret the data that is to be exchanged between the web services because the technical and functional description is based on semi formal free text language. The Semantic Web initiative's purpose is similar to that of the Web services :to make the Web machine processable rather than merely human processable. The main components of the Semantic Web are:a unified data model , • languages with well defined, formal semantics), and • ontologies of standardized terminology, used by semantically enriched service level descriptions The intent of this study is to enhance the usability and

usefulness of the Web and its interconnected resources by creating Semantic Web Services garden. The user needs to choose not only between brands but also between products and specifications and features. No person can have knowledge about all the different brands of products that are on the website. This may lead to the customer buying a product with unnecessary features. Knowledge graphs break down product features in a way that is easy for consumers to understand. The features and specifications of a product can be structured in such a way that is machine-readable. Users can then query this knowledge graph to find information and explanations tomake an informed purchasing decision. This simple example is one way in which we can implement the semantic web on an e-commerce site which will make it easier for customers to understandaproduct'sfeaturesandspecifications.Theinte rnet is made of millions and millions of web pages "stitched" together by links that humans (and also search engines) can follow. The search engines collect headings, meta tags and content, and create a way to help them gather and interpretthat data to say that your website is an e-commerce clothing store selling, specifically, clothes for men. This is where structured data comes into the picture and this is why it's important for everywebsitetohavestructureddataoneverypage.

II. LITERATUREREVIEW

E-Commerce framework is a strategic and excellent frame- work to bring your business online.E-commerce is a great and sustainable way to solve the problems as it contains the features which are not available in any canned solution available in market [5]. Semantics helps us to gather in- formation to solve this problem because with the help of semantics computer could understand the kinds of data it handles and how to interlink them in an intelligent way. This gathering of information will help us find better solution and structure to the problems faced. Network Security issue is a major part of information security framework which applied to components that affect to E-commerce security. The security threats or breaches or any kind of issue related to security is majorly due to guidelines for safe and secure online shopping through shopping web sites these are network related issues [5]. Using this data collected and processed through semantics we can learn how security issues can be solved in E-Commerce websites using different encryption techniques, public key, digital signature etc [5]. The semantic web vision, use different kinds of ontologies for different kinds of aims. The assessment of an E-commerce site for its semanticity requires a thorough analysis of its products or services. For example, to find a significant item over the net the customer can send few queries about the product and gather all the necessary information including its origin, make, description etc. The next step is to l analyze and look attheproductusingtheweb.However,inordertohaveamea ning, a product must have a relationship to other products, services etc. Therefore, there are many factors affiliated with the measurement of the semantic items. The main purpose of the semantics is to change the entire experience from general search to an intelligent search experience [6]. Hence toachieve this we can gather all the common information through the data collected. Each product will have a key attribute relatedto it.So with the help of similar key attributes and properanalysis of searches or any activities related to that data in the past we can give suggestions and make changes for the user experience respectively[4].

III. GAPIDEA

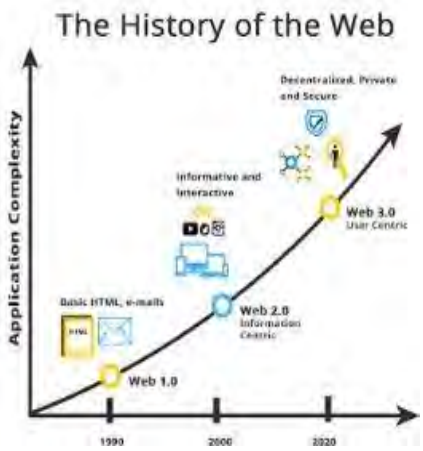

Fig. 1. **Timeline**

Semantic web is an attempt to intensify current web so that computers can process the information existing on WWW, understand and fix it, help humans to discover required knowl- edge. It is proposed to form a vast distributed knowledge based system to share data instead of documents.The aim of Semantic Web is to make Internet data machine-readable. To authorizetheencodingofsemanticswiththedata,technol ogies such as Resource Description Framework (RDF) and Web Ontology Language (OWL) are used.These standards promote regular data formats and exchange protocols on the Web, fundamentally the RDF.The Semantic Web is not a separate Web but it is an extension of the current one, in which information is given well-defined meaning, better enabling computers and people to work in cooperation Advances in information technologies have strongly and consistently boosted organizations to deliver the correct information to the right person

at the right time. E-commerce websites are among the applications that have high demand of information sharing and reusing. The domain itself is ambiguous and complicated to humans unless its meaning is processed and supported by machines. Searching for a particular product is a multi-dimensional activity which synchronizes machine to machine, human to machine and human to humaninteraction.

Searching for quality Ethiopian commodities on the web will result into a unsuccessful query result. This is mainly because many products and services are unstructured and published in local languages like Amharic. Amharic corpora's, words and theories on the web are not modeled on the semantic web platform ontologically. Nowadays a lot businesses and companies are getting semantic web service enabled. Marketers of the future will need to understand their audience so well that they are able to create valuable experiences and information before the question is asked or the need is conveyed. Creating machine readable information content and inserting it into the existing commercial websites of the country will enhance the information retrieval facility by consumers on one side and will generate the opportunity to join these businesses to the linked data platform. Many researchers researched text mining and information retrieval approaches on Ethiopic or Amharic corpus. But almost all of them suggested the further development of ontologies in the respected domains.The semantic web annotation is open to each and every language. Amharic is the official language of Ethiopia, in which major public tenders are expressed, processed and evaluated with it. More than one hundred tenders are released every day, in which the majority of them are in Amharic language. Although it is believed that ecommerce is a bridge and a new way to an efficient global market, its simplicity, accessibility and flexibility needs a high demand for research. To sum up the motivation of this thesis is to represent this rigorous knowledge formally in a systematic manner and adapting it to the semantic web or the future web by making use of ontology language as a tool of gumption.

Currently, while conventional search engines are able to hunt for keywords on Web sites,only human users are able to read and interpret product and service information on the Web.The innovative technology used by the Semantic Web enables intelligent applications and search engines to grasp the meaningofthedata,processthisdataanddisplayitsothatitis comprehensible and meaningful to human beings. A practical way in which we can make use of the semantic web is to help consumers understand products and purchasing patterns.The simple answer is that the semantic web behaves as a sales assistant. Imagine going to buy a night camera on Amazon or any e-commerce website to monitor your garden.You need to decide not only between brands but also between products and specificationsandfeatures.Unlessyouhaveusedthesecameras before, you may not have a clue of what features to go for. Worse still, you may go for a product with many unnecessary features which are of no use to you. [1].With knowledge graphs, it is possible to break down product features in a way that is easy for customers to understand.The product data that is its features and specifications can be structured in such a way that is machine-readable. Users can then query this knowledge graph to find information and explanations to make their purchasing decisions. Possibly even through an automated chatbot.This simple example is one of the ways we can implement the semantic web on an e-commerce website to make it easier for customers to understand a product's features andspecifications.

IV. PROPOSEDSYSTEM

To measure information quality on semantic web ,we iden- tified the enhancements that semantic web can bring to e- commerce websites by studying the field of research. The semantic web provides a common framework that allows data to be shared and reused across application and enterprise.

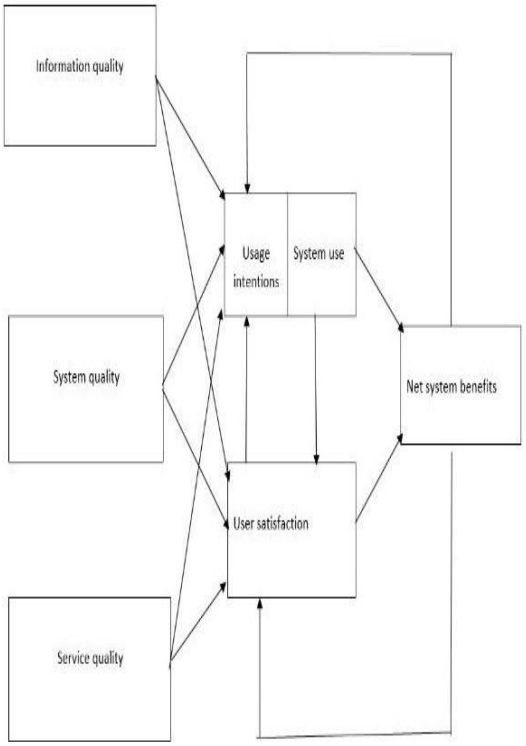

Fig. 2. **The representation of the model**

The machine-readable descriptions enable contentmanagers toaddmeaningtotheoriginalcontent,todescribethestruc

ture of the knowledge about that content. In this way, a machine can process knowledge itself, instead of text, using processes similar to human reasoning and inference, thereby obtaining results that are more meaningful and help the computers to perform automated information gathering and research .Good Relations improve search engine optimization for Google, Ya- hoo, Bing, and Yandex with schema.org, product information management, and e-commerce data quality management. The main question of our case study is whether the online con- sumers' satisfaction is associated with semantic enhancements oftheproducts'websitedescriptionintheonlineenviron ment.

V. METHODOLOGYANDTECHNOLOGY

The title Semantic Web is used to define a set of tech- nologies, tools and standards which form the basic construct a blocksofsystemthatcouldsupportthevisionofaWeb infused with meaning. The Semantic Web is a layered architecture, which is represented using a diagram which was proposed by Tim Berners-Lee, with many variations since. Figure gives a representation of thearchitecture.

Figure: Semantic Web layered architecture is a simplifica- tion which has to be used with some caution, it nevertheless gives a reasonable conceptualisation of the various parts of the

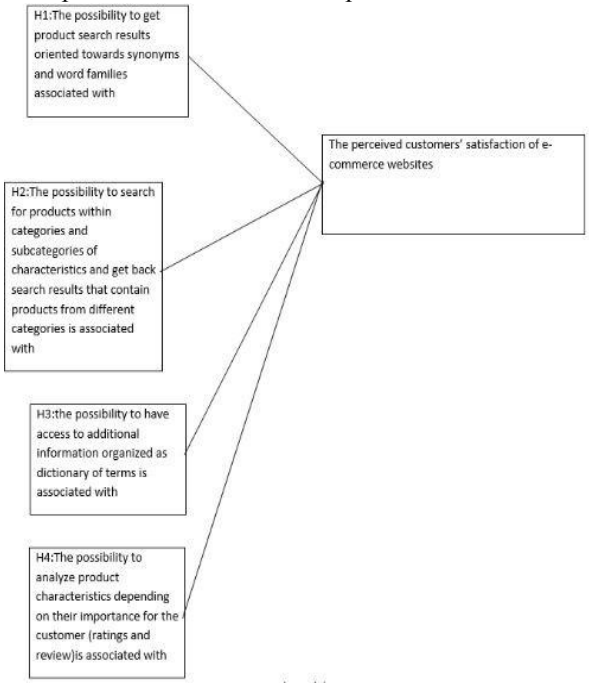

Fig. 3. **Research model**

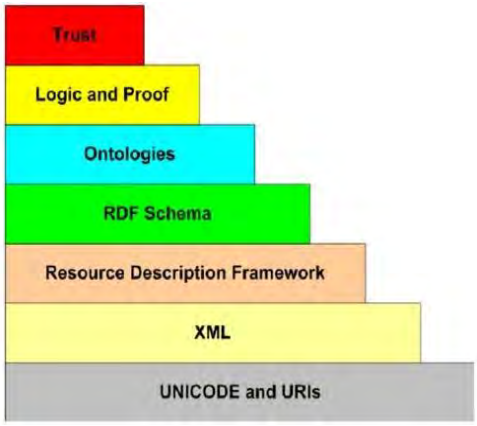
Fig. 4. **Semantic web layered architecture**

Semantic Web. We describe briefly these layers: Unicode and URI: Unicode, is a standard for computer character represen- tation, and URIs, is the standard which is used for identifying and locating resources (such as pages on the Web), provide a base for representing characters used in most of the languages in the world, and for identifying resources. XML: XML andits related standards, such as Namespaces, and Schemas are very well established within the Web already but they don't com- municate the meaning of the data but are used for structuring the data on the web. Resource Description Framework: RDF isthefirstlayerofSemanticWeb.RDFisasimplemetadata representation framework, using URIs to identify and find Web-based resources and a 4 JISC Technology and Standards WatchSemanticWebTechnologiesgraphmodelfordescrib ing connections between resources. Several representationsthat are according to the syntax are available, including standard XML format. RDF Schema: A Simple modelling language usedfordescribingclassesofresourcesandpropertiesbetwe en them in the basic RDF model. It provides a simple reason- ing framework for deducing types of resources. Ontologies: A richer language for providing more complex constraints relations and complex knowledge about things, groups of things, and relations between things. Logic and Proof: A reasoning system working on top of the ontology structure to introduce new inferences or conclusions. Thus, using such a system, a software analyst or an expert can make deductions as to whether a particular resource satisfies its requirements (and vice versa). Trust: The final layer of the architecture addresses issues of trust that the Semantic Web can support. This component has yet not progressed far beyond a purpose of allowing people to ask questions of the trustworthiness of theinformationontheWeb,inordertoprovideanassuranceo f its truthfulness. Resource Description Framework (RDF), Web Ontology Language (OWL), and Extensible MarkupLanguage (XML), Web Ontology Language (OWL). HTML describes documents and the links that occur between them. RDF, OWL, and XML, by contrast, can describe arbitrary things, such as people, meetings, or any event. Business applications include improving information retrieval, thereby reducing information overdose and increasing the refinement and precision of the information retrieved. The machine-readable descriptions en- able content managers to include meaning to the content, to describe the structure of the knowledge about the content. In this way, a machine can process data and knowledge itself, instead of text, using processes similar to human

deductive reasoning and inference, thereby obtaining results that are more meaningful and helping computers to performautomated informationgatheringandresearchonitsown.



VI. CONCLUSION

Implementing the semantic web will change the game for the existing ecommerce websites. It will make it easier for the customers to search and compare various products as the descriptions will be machine understandable as well. This will helpthecustomersinmakinginformedpurchasingdecisions.

Transformation Of Rural India Through Digitization

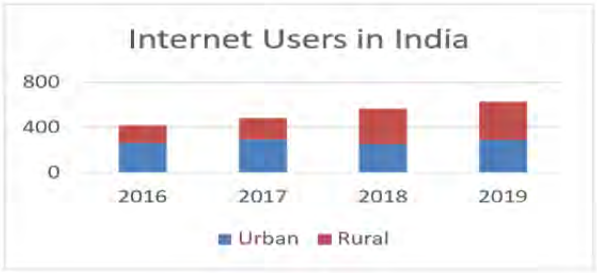
Sakshi Rai , Vij Patel , Prashant Upadhyay
B.E in Computer Engineering
Thakur college of Engineering and Technology
sakshirai0401@gmail.com , vijpatel22@gmail.com , prashant9upadhyay@gmail.com

Abstract:**The digital penetration within the Indian hinterland is growing silently but rapidly. The evolution and development in Information and Communication Technologies over the last decade has created a gap between urban areas and rural areas. Despite several initiatives being taken by the govt. NGO's, private social groups to use technology for efficient delivery of a spread of services, feasibility of such services is somewhere hindered by social or language barriers. So, in a developing economy like India, the success of any social development initiative relies on the government's involvement and active participation from both the private sector and people as well. India is continuing to create several success stories which will cause other initiatives by various interest groups.**

Keywords: Digital platform, Digitization, E-commerce, Rural markets, Digital literacy.

I. INTRODUCTION:

India's population now exceeds 1.3 billion with over two-thirds of its population and workforce residing in rural areas. Rural India contributes a considerable part of the total net value added in many sectors, with an overall 46% contribution to our national income. Studies conducted by IAMAI reflect some interesting patterns. 60% of those accessing the internet were using it for entertainment, 58% were using it for communications, 67% for online services, 65% for e-commerce and 49% for social networking. The number of internet users is estimated to cross 601 million internet users by June 2020 making India the world's second largest market for internet users. The purchasing aspirations of Rural Indians are often constrained by easy availability. Digitization and technology can facilitate access and availability of more and more services and products be made available to meet the rising aspirations of the underserved and unreached rural India. All these put together is now changing attitudes, awareness and lifestyles among rural Indians. A decade ago, the awareness, information and knowledge gap between the rural youth and his urban counterpart was significant which is now being narrowed significantly through the government's Digital India programme. One of the key factor supporting such development is the growing internet penetration, expected to grow from 25% in 2016 to 55% by 2025.



Internet Users in India

fig 1.1 Changing Face of the Indian Internet Users (2016-19)

II. BY IMPROVING DIGITAL LITERACY IN INDIA:

While, on one hand, the Govt is working towards creating the required infrastructure for e-enabling India, the other pre-requisite for realizing the vision of #Digital India is to make people digitally literate so that they can benefit from the action.

Illiteracy is a major obstacle to digital empowerment.
~ 'Offline and Falling Behind: Barriers to Internet Adoption' by McKinsey and Facebook
In villages, many children remain illiterate due to non-availability of schools in the vicinity, or due to

the lack of teachers in school.Illiterate people cannot derive any benefit from information or services available through text messages or other digital means, and so they depend on voice based programs for seeking and receiving advice.This holds true not only for people in the remote areas, but also for illiterate people in the urban areas too. My domestic help, for example, has little idea about the use of internet.

Conducting e-classes, and making
e- books or e-courses available in local languages can help in improving digital literacy, and gear up people for using internet to their advantage. Supporting the Digital India vision, companies like Intel and Microsoft will work the government to make 10 Lakh people digitally literate by the end of 2015.Intel India has launched the Digital Skills Training Application comprising of modules on Digital Literacy, Financial Inclusion, Healthcare and Cleanliness in five Indian languages. The company plans to impart digitalliteracy training to key resource persons in the first 1000 panchayats covered under NOFN rollout.

III. BY PROMOTING RURAL ENTREPRENEURSHIP THROUGH INTERNET KIOSKS:

Fig 2.Internet Kiosk in small towns | Image credit: dazeinfo.com

Providing training and capital to youths in rural/ semi urban areas to set up internet kiosksin the interiors will promote rural entrepreneurship.InternetKiosk with one or more computers, a tablet, Internet connection, with a web cam can be the set up in villages to be used as the hub of rural relatedness for providing education and training, information about agriculture and health care, employment news and market information. Gyandoot is an activity in Dhar district of Madhya Pradesh that connects villages throughout the district through numerous cyber-kiosks run by local entrepreneurs. More such activity in are needed in different districts throughout the country to promote the culture of rural entrepreneurship.

IV. BY IMPROVING TRANSPARENCY, EASE AND EFFICIENCY OF PROCESSES:

We know how tedious it used to be to apply for issuance or renewal of passport or any government related work we need an agent and it is time consuming and take lots of one's time and energy, before the process was e-enabled. Agents ruled the squat and there was no clarity on the process or the timeline. The online application and appointment for passport has streamlined the process to a great extent.E-enabling of processes such as filing tax, issue/renewal of driving licences, maintaining land records, results and shortlisting of candidates for employment schemes will improve the transparency, speed up these processes and save citizens from being bogged down by bureaucracy and corruption.

V BY ENABLING E-COMMERCE IN SMALL TOWNS AND RURAL AREAS

The small town people don't have more knowledge about limitation in the quality and variety of goods available in small towns or rural areas. Many products and brands are simply not available. The delivery of goods to consumer by bearer and postal services is also not very reliable in smaller cities, towns and rural areas. Setting up E-commerce hubs will enable people in small towns and farmers in rural areas to access markets, shop for better quality products, and get a better price for their produce without relying on middlemen. E-commerce can forward the selling of local goods such as herbal products, gardening supplies, traditional art etc while shopping for stuff such as electronics goods, solar energy panels etc.

VI. BY REDUCING RISK AND UNCERTAINTY:

Before setting out to sea, Madurai sits before a computer terminal collection information on the sea – like wave height, confusion and fish density. So do hundreds of other fishermen in Veerampattinam, a coastal village 15 km off Pondicherry city have the risk of collecting the fishes and also maintaining the cleaning process as well.

~ Wired to the future, India Today

The Information Village Research Project (IVRP) has redefined the lives of residents of villages in and around Pondicherry and also the surrounding coastal area of the sea.

Now, with the penetration of mobiles in rural areas, people can receive weather information or disasteralerts on their cells. This can especially be helpful in the coastal areas, where fishermen can be alarmed about weather warnings, or can be trained to check weather information on the net before dare to the sea.

VII. BY ENABLING DIRECT DISBURSAL OF MONEY TO BENEFICIARIES:

Financial involvement is another key area that can be impacted with the use of technology. Each year a vast number of people migrate from villages to cities to make a living. Any service that allows direct disbursal of money to beneficiaries will be immensely useful for people who want to remit money to their families living in thenative villages.A mobilewallet which allows consumers to send and transfer money, pay bills and do recharges, and take out cash, can greatly help in financial inclusion of people in the rural areas.

Vodafone's M-Pesa service for mobile money deportation, rolled out in April 2013, helps in disbursal of money of government schemes like the Mahatma Gandhi National Rural Employment Guarantee Act (MGNREGA) directly to the recipient in the circles of West Bengal, Kolkata, Bihar and Jharkhand.

Digitization can lead to a versatile development in India, by bringing the remote areas of the country within the fold of the mainstream economy. It is surely an ambitious plan, to realize the vision of IT +IT =IT; the benefits are aplenty, and so are the challenges. Nonetheless, with the hope that the challenges will be overcome, looking forward to the day when we have a virtually integrated #Digital India.

VIII. CONCLUSION:

The digital divide that exists between urban and rural India could become a thing of the past as we have experienced in the previous decades when it became feasible for every man to access television, cable and basic telephony through public booths. Thus the next decagon could catapult India to a new league of prosperity which will pave the way for elevating the living standards of sizeable number of rural poor and entitle them as never before if only we seize the convenience that digital mission provides.

***Abstract*-- Phishing is a cybercrime, an identity theft used to lure users by posing as legitimate websites.Theseattackscanbethroughmails,messages or pop-up ads. Phishers target vulnerable users, particularly organizations, to extract sensitive information. Spear phishing is another form of phishingwhichisevenmoredangerousasitistargeted and carefully designed for a single recipient within an organization using social media stalking. As phishing detection grows more and more accurate, Phishers continue to develop even more legitimate looking replicas of websites. Even though there are manyanti- phishing applications or websites, Phishers still succeedatluringvictims.Phishingcanbesolvedusing, eitherBlacklistingapproachorbyHeuristicapproach. Blacklisting approach is a common solution but it is inefficient as Phishers continue to develop new fraudulent websites. In Heuristic method we extract various features of a URL to predict whether a particularwebsiteislegitimate,suspiciousorphishing. In this paper, we elaborate on Phishing attack and the approach to overcome this problem through URL feature extraction using MachineLearning.**

***Keywords*— Phishing, Heuristic, URL feature extraction, Machine Learning.**

I. INTRODUCTION

Phishing is a homophone of the word fishing which means catching a fish. There are four things here,afisherman,afishingrod,abaitandafish.The fishermanpatientlywaitsforthefishtogetattracted tothebaitwhichisattachedtotheendofthefishing rod.SimilarlyinphishingaPhisher(fisherman)uses a transmission medium (a fishing rod) to send a phishing message (bait) to the intended recipient or the victim(fish).

Phishing is a broader term, used to refer to a malicious attack intended to extract sensitiveinformation from individuals. Phishing is classified into many types, each having a different mode of transmission. Although Phishing sounds a very recentissue,ithasbeenpracticedsincetheinvention of computers. What makes it even more difficult to solve is that it relies on human vulnerability rather than technologicalvulnerability.Phishing detection on the other hand is a very difficultprocedureasPhishingiseverevolving.The reason for this, is that it is easy to copy an HTML code of any website, make slight changes in it and present it as a flawless replica of the original website. Phishing Detection can be done in two possible ways, one being creating public awareness butthenagainnotveryeffectiveandtheotheroneis through software. Software approach requires Data Mining technique, but it still is a complex process due to lack of dataset. The rationale behind this is that there aren't a specific number of features that characterize a phishing website. Hence shaping a dataset that covers all the features is difficult. Identifying phishing by common people is not easy as not every user is technically sound. Hence, Intelligenceagenciesarehiredbycompaniestokeep a watch for possible data snooping or snarfing. The most popular phishing detection is by the use of Machine Learning along with NeuralNetworks.

II. TYPES OF PHISHINGATTACKS

A. Vishing

Vishing refers to voice-phishing. Here the phisher impersonates themselves as a part of a trusted organization and tries to collect data over calls. Here a fake caller-ID can be used to give a more real appearance to it. E.g. A person acting asa bank employee asks you for your credit carddetails.

B. Smashing

Smashing refers to SMS-phishing or text phishing. Here text messages are used to send links of phishing websites. E.g. receiving offermessages from e-shoppingwebsites.

C. Spearphishing

One of the most dangerous form of phishing is Spear phishing. Phishing and Spear phishing are different because phishing is generalized while Spear phishing is targeted. Here extensive research iscarriedoutonthevictimandtheorganizationthey are a part of. It involves stalking, both physical and online.Thevictimisthensentaphishingmailortext based on their activity such that it becomes almost undetectable and unavoidable. E.g. A person uploadstheirlocationas"atStarbucks"andinstantly receives a message or email with the name of the same.

A .Whaling

WhalingisanotherformofSpearphishingwhich is used to target high-profile individuals. It is done to acquire high-level access to an organization which is only available by a company's board of directors. E.g. Targeting a CEO of acompany.

B. EmailSpoofing

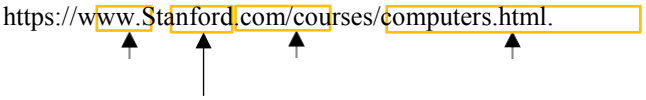
Email Spoofing occurs when an email header's from address is forged, so the recipient thinks that themailhasarrivedfromalegitimateemailaddress. Here the phisher can even impersonate a superior person or an organization. As a result, this is also called as Name Impersonation. E.g. receiving a mail from a superior.

C. MassTarget

Mass Target as the name suggests is intendedfor a large number of recipients who are sent an email or a message by the Phisher who impersonate themselves as a famous brand. The phisher collects information about a particular brand and then sends the customers their transaction invoices or giftcards etc. Due to this it is also called as Brand Impersonation. Here the URL usually contains spelling mistakes like amazon instead of amazon which isn't easily distinguishable.

D. URLManipulation

URL Manipulation refers to the manipulation of a certain part of the Uniform Resource Locator.The URL comprises of differentsections:



E.g. here https is the protocol, www is the subdomain, Stanford is the domain name and courses/computers.html is the path of the website. Since the domain name has to be registered, it can't be modified but the path and subdomain can be manipulated

With. Hence in URL phishing, the subdomainandpatharechangedtodirectthevictim to another website which looks almost the same as the originalwebsite.

III. PHISHING DETECTION

A. Blacklisting/Whitelisting

In this approach a predefined dataset is available which contains a list of phishing and legitimate websites. The drawback of this approach is that it cannot predict newly created phishing website. Asa result this method is highlyinefficient.

B. URL FeatureExtraction

This is a very efficient method of phishing prediction. This method extracts features which mainly characterize a phishing website and uses them to build a classification model. Data from known websites is collected and used to train this model. When any new website is accessed, it extracts its features and uses it to test the dataset to predict whether the given website is phishing or legitimate.

C. VisualSimilarity

1) Favicon: The phisher may copy the favicon (image associated with a particular website) anduse it in their phishingwebsite.

2) AddressBar:Thephishermayhidetheaddress bar with an image or script so that phishing URL is notvisible.

3) Appearance:ThephishermaycopytheHTML code of legitimate website to make a phishingone.

Visual Similarity based approach uses signatures to identify a phishing website. Signatures are basically features extracted from a whole legitimate website to compare it to a phishing one. A single signature may suffice to detect a phishing website.

D. ContentBased

Inthisapproachweexaminethewholecontentof a website to determine whether its phishing or not unlike the other approaches where we only looked superficially.Protocoldomainname pathsubdomain

TABLE 1

Comparison of Different Phishing Detection Approaches.

Approach	Advantages	Disadvantages
Blacklist/ Whitelist	Simple	Fails to detect newly created websites.
URL Feature Extraction	Highly efficient	Only takes into account the URL's and can be avoided. Frequently gives false positive results.

Visual Similarity	Effective image based anti-phishing	Only works if the websites are visually similar and doesn't take into account the code of the websites.
Content Based	Has the highest efficiency	Difficult to implement and time consuming.

IV. LITERARYREVIEW

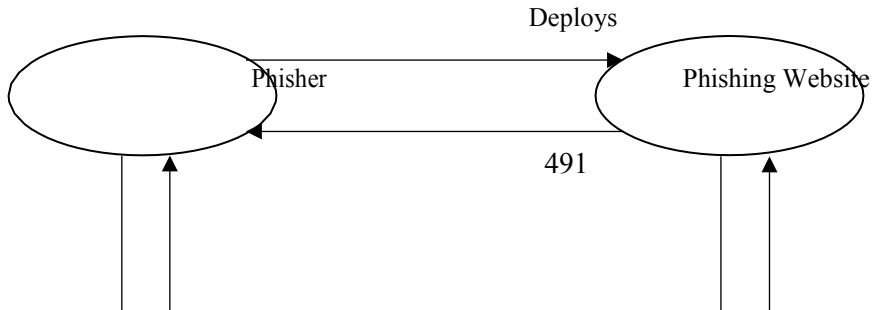
TABLE2

Listing and Gap Identification of Different Phishing Detection Methodologies and Approaches.

Reference Paper	Approach	Methodology	Conclusion
[1]	Content Based	Analysis of text-based content by itself.	TF-IDF approach: 97% of phishing sites and 6% false positives. Heuristics: 90% of phishing and 1% false positives.
[2]	Content Based	Novel heuristic based on URLs and website content.	Accuracy: 96.57% False Positive: 0.035%
[3]	Whitelist/ Blacklist	Creating a whitelist by registering the IP address of each site, which has Login user interface that the user has visited.	Classifies legitimate website as phishing when visited for the first time.
[4]	Whitelist/ Blacklist	Warns users on the web with a white-list of legitimate websites that is updated automatically	True Positive Rate: 86.02% False Negative Rate: 1.48%
[5]	URL Approach	Derivation of different components from the URL and computation of metric for each component.	Accuracy: 97%
[6]	URL Approach	Analysis of the lexical and host-based features of URLs	For Regression Trees: Success Rate: 91.08% (maximum) and Error Rate: 8.92% (minimum).
[7]	Machine Learning	Anti-phishing toolthat Can predict phishing attacks at a timescale using self-structuring neural networks(NN).	Accuracy: 92.48
[8]	Machine Learning	URL lexical Analysis and page content analysis.	Maximum Accuracy with ANN. Accuracy: 96.01% Approximate false positive rate: 0

PHISHING MECHANISM

In the fig. 1 given below, it is depicted how phishing mechanism takes place. The first step of phishing mechanism is the development of a phishing medium, in this case a website. In the case of spear phishing this comes after information gathering. This website is then deployed to the victim through any transmission medium available. The victim may or may not recognize that the website is malicious and may fall prey. The victim then enters their credentials into the portal. The data entered is then stored in the database available with the phisher. The phisher then uses this information to impersonate the victim and present themselves as the victim to the organization the victim is a part of. The phisher gathers information about the organization or uses this breach to implant any Trojan or virus in the company's entire workspace. Although this is the case only when the target is an organization rather than an individual. In the case of individual person, the information gathered is just used to perform unlawful transactions.



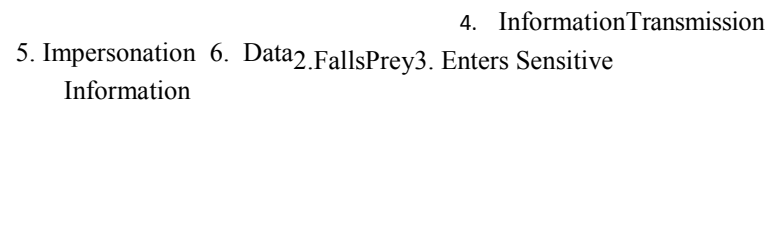


Fig. 1 Phishing Mechanism

V. URLFEATURES

TABLE 3

Major Features of a URL that can determine whether it is Phishing or not

Feature	Characteristic	Result
Length of URL	<54 characters	Legitimate
	>=54 characters <74 characters	Suspicious
	>=74 characters	Phishing
TinyURL	Present	Phishing
	Absent	Legitimate
HTTPS	Issuer Trusted	Legitimate
	Issuer not Trusted	Suspicious
	No Issuer	Phishing
IP Address in Domain Section	Present	Phishing
	Absent	Legitimate
@ Symbol	Present	Phishing
	Absent	Legitimate
Host name in URL	Present	Legitimate
	Absent	Phishing
DNS Record	Present	Legitimate
	Absent	Phishing
Domain Age	<6 months	Phishing
	>6 months	Legitimate
Domain Expiry	<1 year	Phishing
	>1 year	Legitimate

The above given table depicts the major features of a URL that can be used to depict whethera website is phishing or not. These features were identifiedbasedonthestudyofvariousphishingand legitimate websites. These features can be used to build a dataset to train and test a model. Although these features may not necessarily characterize all the phishing websites as there are many more features that can be manipulated with, these are the ones which can classify most of the phishing websites into the phishingcategory.

VI. PROPOSEDMETHODOLOGY

The following fig. 2 depicts a general methodology we propose to classify a website into phishingorlegitimate.Inthisprocesswefirstcollect a database of phishing and non-phishing website URLs to develop a whitelist and blacklist. We then extract the features of these websites. From these features we select the ones which are relevant to a phishingwebsite.Thenwepreprocessthesefeatures andconvertallthetextualdatatonumericform,tomake it easier to process them. This dataset is then split into train and test dataset and then given as an input to a classifier. This classifier then categorizes these URLs into phishing, suspicious and legitimate. This output is then evaluated using performance metrics. If the performance is low then hyper parameters are tuned and the process is repeated. Each of the following

processes is tried on various classifiers and the one with the optimum output is chosen. Then a new set of URLs are given to this final model to detect whether they are phishing or not.

A. Performance metrics

1) Jacquard Index (J): Calculates $(y,\hat{y})=\frac{|y\cap\hat{y}|}{|y\cup\hat{y}|}$

2) Precision: Calculates how many classes were correctly predicted.

similarity of actual values(y) and predicted values ($\hat{y}$).

$Precision=T.P.T.P+F.P.$

3) Recall: Calculates true positive rate. $Recall=T.P.T.P.+F.N.$

4) F-score: Weighted average of precision and recall.

$F_1= 2* \frac{Precision*recall}{Precision+recall}$

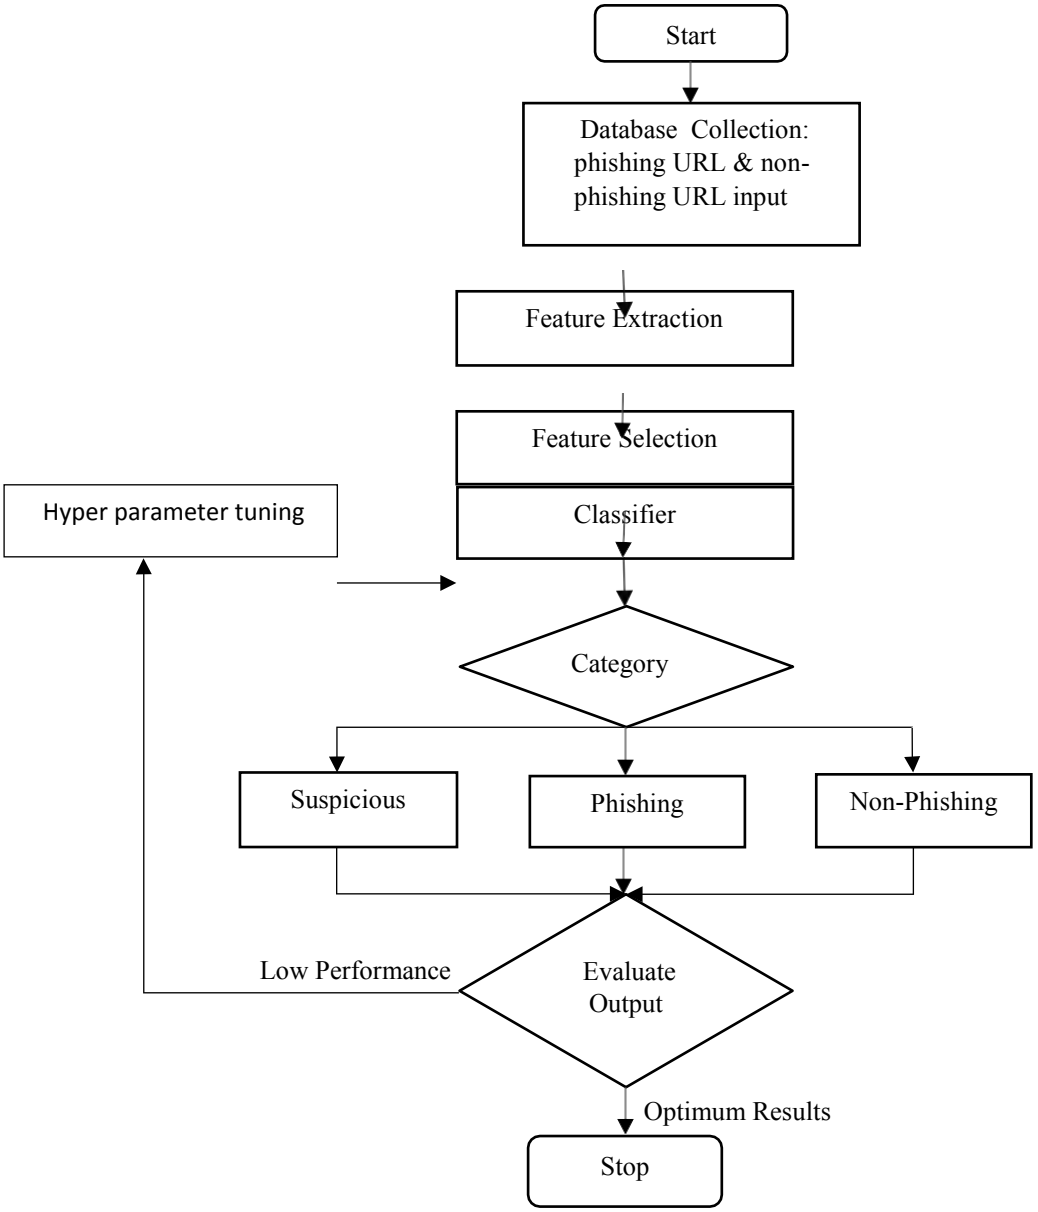

Fig. 2 Phishing Detection Mechanism

VII. Conclusion

In this paper, we first explained in detail about most of the possible types of phishing attacks that could

take place in today's world. We further gave details on how do they take place. We elaboratedon one of the most common method of phishing that is URL manipulation with an example. We also identified various types of phishing detection mechanism and their drawbacks. Then we focused on various URL features that are present in most phishing websites and can be used in phishing detection and their significance. We further proposed a general methodology that uses multiple classifiers and chooses the best one, to detect phishing. We listed various performance metrics to use to give better efficiency. This would result in higher phishing detection and lower security breach and data loss.

Abstract:
Web Security is also known as "Cyber Security" involves protecting information by preventing, detecting and responding to web attacks
Today, technology is evolving at an unprecedented rate. These rapid advancements in technology make it strenuous to protect information at all times in an effective and efficient manner. The lack or absence of proactive security measures puts several individuals and businesses alike at risk of being subjected to cyber-attacks. It has been observed that the number of cyber-attacks is at an alarming ratein thelastfewyears.Thereisanurgentneedtoemploy effective cyber security measures, to prevent illegal and unauthorized acres and usage of our information systems. This includes protecting databases, computers and networks withspecialized and technical measures ofsecurity.

Keywords- Web Security, Web Threats, Web Prevention, Web securityalgorithms, Virus, Worms.

I. INTRODUCTION

Web application security is a branch of Information Security that deals specifically with security of websites, web applications and web services. Web sites are unfortunately open to security risks. And so are the networks to which web servers are connected. Web servers open a window between yournetworkandtheworld.Thecaretakenwithserver maintenance, web application updates and your web site coding will determine the size of that window, limit the kind of information that can pass through it and thus helps in establishing the degree of web security we can have.

II. HISTORY

A. 1970sthe first modern day hackers appeared as they attempted to mislead the system and make free phone calls, a practice that became known as "phreaking."
PerhapsthemostwellknowphreakedwasJohnDraper, A.k.a. Captain Crunch, who helped lay the practice.

B. 1980s

The 1980s saw the birth of computer clubs. This decade lead in the era of malware, marking the first virus, named "Brain", in 1986 as well as the ill-famed MorrisWormin1988.TheComputerFraudandAbuse Act was instituted in 1986.

C. 1990s

The 1990's brought the modern information security industry. Observable threats witnessed during this decade included the Michelangelo virus, Melissa, and Concept. Distributed denial of service attacks and thebotsthatmadethempossiblewerealsoborn,suchas Trin00, Tribal Flood network andStacheldracht.

D. 2000s

The first decade of the 21st century saw malicious Internet activity turn into a major criminal enterprise aimed at monetary gain. Malware also started and phishing attacks also became mainstream, first heavily targeting online banking then moving onto social networking sites.

III. WEBTHREAT

A web threat is any threat that uses the World Wide Webtoeasecybercrime.Webthreatsusemultipletypes of malware and fraud, HTTP protocols and other components, such as links in email or on servers that accesstheWeb.Webthreatsposeabroadrangeofrisks, including financial damages, identity theft, loss of confidential information/data, theft of network resources, damaged brand/personal reputation, and erosion of consumer confidence in e-commerce and online banking. It is a type of threat related to information technology (IT). Phishing is another commonthreattotheWebapplicationandgloballosses .

IV. TYPES OFTHREAT

A. Denial-of-serviceattacks denial-of-service attack (Do's attack) ordistributed denial-of-serviceattack(Dodosattack)isatrytomake a computer resource unavailable to its intended users.It

Generally consists of the concerted efforts to prevent an Internetsiteorservicefromfunctioningefficientlyorat all, temporarily orindefinitely.

B. Phishing

Phishing occurs when the attacker acts to be a trustworthy entity, either through email or web page. Victims are directed to fake web pages, which are dressed to look legal, via spoof emails, instant messenger/socialmediaorotherapproach.Oftentactics such as email spoofing are used to make emails appear to be from appropriate senders, or long complex subdomains hide the real websitehost.

C. Maliciousssoftware

A computer user can be confused or forced into downloading software onto a computer that is of malicious intent. Malicious software, is any software used to disturb computer operation, gather sensitive information, or gain access to private computer systems. Such software comes in many forms, such as viruses, Trojan horses, spyware, and worms. Ransom ware and Shareware is a type of malware.
BelowisagraphthatshowsthegrowthrateofMalware infection

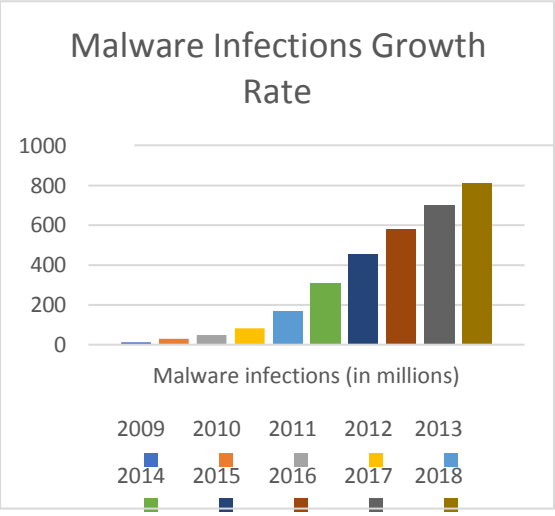

Fig. 1 Growth rate of Malware Infection

D. Application vulnerabilities

Applications used to access Internet resources may contain security vulnerabilities such as memory safety bugs or flawed authentication checks. The most severe of these bugs can provide network attackers full control over the computer. Most security applications and suites are incapable of adequate defense against these kinds of attacks.

V. PREVENTION

A. Network layersecurity

TCP/IP protocols may be secured with cryptographic methods and security protocols. These protocols include Secure Sockets Layer (SSL),Succeeded by Transport Layer Security (TLS) for web traffic, Pretty Good Privacy (PGP) for email, and IPsec for the network layer security.

B. Internet Protocol Security(IPsec)

IPsec is created to protect TCP/IP communication in a secure manner. It is a set of security extensions developedbytheInternetTaskForce(IETF).Itprovides security and authentication at the IP layer by transformingdatawiththehelpofencryption.Twomain types of transformation that form the basis of IPsec: the Authentication Header (AH) and ESP. These two protocols provide data integrity, data origin authentication, and anti-replay service. These protocols can be used alone or in combination to give the desired set of security services for the Internet Protocol (IP) layer.
The set of security services provided at the IPlayer includes access control, data origin integrity, protection againstreplays,andconfidentiality.Thealgorithmgives thesesetstoworkindependentlywithoutaffectingother parts of theimplementation.

B. Securitytoken

Someonlinesitesoffercustomerstheabilitytouse a six-digit code which randomly changes every 30–60 secondsonasecuritytoken.Thismeansthateverythirty secondsthereisonlyacertainarrayofnumberspossible which would be correct to validate access to the online account.

C. Electronic mailsecurity

Email messages are composed, delivered, and stored in a multiple step process, which starts with the message's composition. Then, the server opens up a connection(s) to the recipient mail server(s) and sends the message employing a process similar to that.

D. Message Authentication Code

A Message authentication code (MAC) is a cryptography method that make use of a secret key to encrypt a message. This method outputs a MAC value that can be decrypted by the receiver, using the same secret key used by the sender. The Message Authentication Code protects both a
Message's data integrity as well as its authenticity.

E. Firewalls

A computer firewall controls access between networks. It basically consists of gateways and filters which vary from one firewall to another. Firewalls also screen network traffic and are able to block traffic that is harmful. Firewalls puts restrictions on incoming and outgoingnetworkpacketstoandfromprivatenetworks. Incoming or outgoing traffic must pass through the firewall; only authorized traffic is allowed to pass through it. Types offirewall

- Packetfilter
- Stateful packetinspection
- Application-levelgateway

VI. WEB SECURITYALGORITHMS

A. AES (Advanced EncryptionSystem)

AESisasafeandreliablealgorithmwhichwhen employed, protects the confidentiality and integrity of data.AESisoneofthemostsecureencryptionstandards and thus, it is also one of the most widely used encryption algorithm. Breaking an AES algorithm necessitates computational powers that go far beyond the capabilities of the existing, moderncomputers.It is a symmetric cipher and thus uses the same secret code of 128 bits, 192 bits or 256 bits for the process of both encryption and decryption.AES is an iterative model and is based on substitution permutation.This algorithm utilizes a method for scrambling data. A key isusedtomixorscrambledatainacertainmannersuch that the new form of the data is unrecognizable. This form of the data can then be stored or transferred over a network securely. The jumbled data can only be unscrambled by individuals in possession of the key.AESemploysaseriesoflinkedoperations.Someof these operations replace their inputs by specific outputs.Each full chain or round, in the series of repeated ones, is made up of 4 primary sub-processes.
Process ofAES:

a. A fixed table is first referenced, to efficiently substitute the 16 input bytes. The thus obtained result comprises of a matrix of four rows and four columns.
b. A shift left operation is performed on each of the rows in the matrix. The first row is not shifted, the second row is shifted by one position, the thirdrow by two positions and finally, the fourth row is left shifted by threepositions.
c. Using a precise mathematical function, each column of four bytes is transformed. The four existing columns are take as input and four unrecognizable, new bytes are given out as the output. The resultant matrix consists of 16 new bytes
d. Thenew,calculated,16bytesofthematrixarenow considered to be of 128 bytes. This is then XORed to the 128 bits of the round key. If this is the final round, its output is considered to be the ciphertext. If not, the permutations are continued till the final round isreached.

B. RSA (Rivest, Shamir,Adleman)

RSA is an asymmetric cipher, thus it makes us of separate,distinctkeysforthepurposeforencryptionand decryption.Itisthemostwidelyrecruitedcryptosystem. Establishing a shared key is at times not possible or demands extra communications overhead. If oneperson hastocommunicatewithmultiplepeople,he/shewillbe forced to utilize multiple, distinct keys for each person. The sender would thus have to manage several keys and will have to send multiple messages to establishthem.

The use of an asymmetric cipher overcomes the above shortcomings and is a useful algorithm that makes use of cryptography at a large scale. It is based on simple yet clever concept.

RSA makes use of a public key as well as a privatekey, and the generation of these keys is the most complex part of its algorithm. Both public and private keys can beusedtoencryptamessage.Theprocessofdecryption of the message can be carried out by the opposite key, fromthekeyusedforitsencryption.Thereisanabsence of the need of historical use of the publickey.
Process of generating keys:

a. 2 large prime numbers p and q are selected. Using these, RSA modulus n is calculated using the following formula- n = p * q.
b. A derived number e is then selected. Here, e must be greater than 1 but less than(p-1)(q-1).
c. The pair (n, e) form the RSA public key. This key is then madepublic.
d. Then, the private key d is calculated using p, qand
e. For every n and q, there exists a unique d (private key). d is the inverse of e modulo (p-1)(q- 1).This security of this algorithm is acquired from the level od difficulty involved in factoring large integers, that are obtained from the multiplication of two large primenumbers.

C. Blowfish

Blowfish is a symmetric block cipher. Since its introduction, it has be conferred with inclusion in a huge number of encryption products and cipher suites.The encryption rate provide by blowfish cipheris impressive. It has also been observed that no other effective cryptoanalysis of it has been discovered to date. In terms of preference for usage, it rises above the other algorithms because of the fact that it has been placed in the public domain. It is non-proprietary and can be freely used by anyone.Blowfish has a 64 bit blocksize.Italsohasavariablesizedkeylength,which ranges from 32 bits upto 448 bits. This algorithm also makes use of 4 S-boxes or substitutionboxes.

D. Two Fish

The Two fish algorithm is derived from the Blowfish algorithm. This algorithm is considered to be a well-known algorithm employed for the encryption process. The scope of its usage lies within cryptrography and steganography. Twofish is used generally for the process of embedding. It can also be used for audio or images but has not yet claimed its efficiency in image steganography.This algorithm Has 128 bit blockcipher. A variable length key of upto 256 bits, is accepted by thiscipher.

VII. WEB SECURITYPRODUCTS

A. Antivirus

Antivirus software and Internet security programs can protect a programmable device from attack by

Detecting and removing viruses. Antivirus softwarewas mainly shareware in the early years of the Internet, but there are now several free security applications on the Internet to choose from for allplatforms.

B. Password managers

A password manager is a software application that helps a user store and organize passwords. Password managers usually store passwords encrypted, requiring the user to create a master password; a single, ideally very strong password which grants the user access to their entire password database.

C. Securitysuites

Socalledsecuritysuiteswerefirstofferedforsale in 2003 (McAfee) and contain a suite of firewalls, anti- virus, anti-spyware and more. They also offer theft protection, portable storage device safety check,private Internet browsing, cloud ant spam, a file shredder or make security-related decisions (answering popup windows) and several were free ofcharge.

VIII. CONCLUSION

History has taught us that we should never underestimate the amount of money, time, and effort someone will expend to hinder a security system.

The more secure we build the web today, the better and safer will be the future for all of us. Web services technology, is although very much in its developing stage, is all set to hit the mainstream enterprise computing. So, think before you click!

Abstract-:
Intelligenttransportationsystem (ITS)isanadvanced technology whichenablesuserstobebetterinformed andmakesafer,more coordinated, and smarteruseof transportnetworkstomitigatetraffic congestion. This paperpresentsatrafficpredictionmodelbasedon time series.Laterusingdecomposefunction, random and seasonal traffic trendswereobserved.For thegiven datasetAIC techniquewasusedtochoose thebest predictionmodel. Using the statistical technique: ARIMAmoreaccurate andefficientresultswere achieved.Thus,theexperimentalresultdemonstratestha t theproposedmodelcanattain efficienttraffic prediction.

Keywords:- IT'S(IntelligentTransportation System),ARIMA (Autoregressiveintegratedmoving average), logistic regression,

I. INTRODUCTION

A. PROBLEMDEFINATION

Trafficestimationandpredictionsystems (TrEPS)have thepotential to improvetraffic conditions and reduce traveldelays.Tomonitor,manage,andcontrol the transportationsystem,these systemsusecurrently available and evolving computer,communication,and controltechnologies.Theyalsoprovidevariouslevels of traffic information and tripadvisory tosystem users, including manyITSservice providers, so thattravelers canmaketimelyandinformedtraveldecisions.Atraffi c prediction model that incorporates relevant results on viewingannual,monthly, and weeklytraffic trends.

Timeseriesanalysiscomprisesmethodsforanalyzi ngtimeseriesdata in ordertoextractmeaningfulstatistics andothercharacteristicsofthe data. Timeseries forecastingis the use ofa modelto

Predictfuture values based on previouslyobserved values. [1]

ARIMA isan acronymthatstands forAutoregressive Integrated Moving Average. An ARIMA model is a class of statistical models for analyzing and forecasting time series data. It clearly serves to a suite ofstandard structures in time series data, and as such provides a simple yet powerfulmethod formakingskilfultime seriesforecasts.

II. LITERATURE SURVEY

Becauseroadtrafficisthe visibleresultofthecomplex interplay betweentraffic demand(theamountof travelersmaking atripataparticularplaceandtime) andtrafficsupply (network infrastructure),when modelingit is usual to findthat the input–outputdata relationship isnoisyand thatthe relationshipsbetween thesevariablesaremultivariateand (highly)nonlinear (vanLintand vanHansberger,2012), additionally the processisusually highdimensional,non-stationary and tackledinreal-time

In the literature,there aretwo main approachesadopted for road trafficprediction:model-drivenanddata- driven. [2]

Model-drivenapproaches try to reproducetheroad network behaviorthrough simulation,anddepending onthe levelofdetailand the underlying traffic flow theory. (Barceló,2010;TreiberandKeating, 2013)

Ontheotherhand, thedata-drivenapproach aimsto reproduce the input–outputmapping butusually neglecting the underlying datagenerationprocess. (Ermagun and Levinson, 2016)

Predicting Player's Value in Ipl UsingData Science

Mayank Roongta,Kartik Rawool,Nisha Varghese
Department of Computer Engineering. Thakur College of Engineering and Technology
Mumbai, India
mayankroongta101@gmail.com, kartikr2k133@gmail.com, nishawishing@gmail.com

Abstract---Selectingateamisoneofthemostimportanttasksof any sport and cricket is not an exception to it. The best playing XI is selected for the match from available pool of the players by the captain. The captain identifies the different characteristics and statistics of each player while selecting the playing XI. Sometimes they are right and sometimes they go horribly wrong. This paper predicts the value of each player based on various algorithms and what each player brings tothe table for the team. The collected past performances of each player are evaluated and the form of the player is also considered while calculating each player'svalue.

Keywords---Data Science, Cricket, IPL, Standard Normal Distribution

I. INTRODUCTION

Cricket has been the most popular sport of India since independence and the emergence of IPL has taken this craze to the next level. In the IPL the domestic as well as the international stars are bought by the different franchises to playforthem.Sometimestheplayersturnsouttobebargains for the franchises but few times the players they havebought byshellinghugeamountsofmoneyturnsouttobehugeflops. This happens as the players are bought just on the basis of player's past reputation and ignoring the data such therecent performancesandabilitytoperformincertainconditions.B ut with the advent of data science some franchises have started using it and have made some really smart deals in the recent auctions. Hence in this paper we will predict all the player's value based on their past IPL performances as well as their recent form with the help of datascience.

II. REVIEW OF LITERATURE

Variousresearchpapersareavailableforthedataanalyti cs in cricket but most of them are for the team result prediction andveryfewarethereforthevalueofaplayerincricketand none of them for the player value in the IPL. Parker, Burns andNatarajan[1]definedamodelforvaluationofplayersfor IPL auction. Their model considered factors like previous biddingpriceoftheplayer,experienceoftheplayer,strikerat e etc. But it was way back in 2008 when IPL was season in nascent stage but now it has grown into the most popular cricket league in the world. The most similar research paper to our work is of Prakash, Patvardhan and Lakshmi[2]. They defined batting index and bowling index to rank players' performance for their models to predict outcomes of IPL matches. Bhattacharjee and Pahinkar[3] used the combined bowling rate(bowling average, strike rate and economy) to analyze the performance of bowlers inIPL.

III. PROPOSEDMETHOLOGY

We obtained all our data from popular cricket website www.cricinfo.com.Wecollecteddataofplayersfromt helast 5 years IPL for batting as well as bowling. The different parameters we collected in batting are the runs scored, averages, strike rate, etc. The parameters for bowling are wickets taken, strike rate, economy, etc. We imported all the data in MySQL tables to study on thedata.

After collecting the data for extracting the value of the player and also to bring all the parameters on the same scale thedatawasnormalized.Foragivenparameterwecalcu lated themeanandalsothestandarddeviation,andthennorma lized the value using mean and standard deviation. We appliedthe conditions that if the parameter is greater than the mean then we added 0.5 to it and if the normalized parameter less then meanthenwesubtractedtheparameterby0.5.Thiswasd one so that all parameters can be scaled and also so that we get where a player ranks in a group ofplayers.

Fortestingourcalculations,weusedadatasetofbats men, bowlersandall-rounders,eachdatasetincludedtop50players based on their runs and wickets. The dataset also includes importantparameterssuchasaverageruns,strikerate,n umber of matches played, number of innings, number of centuries and fifties, number of wickets, economy, etc. These parametersarecrucialinjudgingtheperformanceofapl ayer.
Also,thedatacollectedwasonlyregardingtheIndianPr emier League and did not include international

matches played by theplayer.

IV. DATAANALYSIS

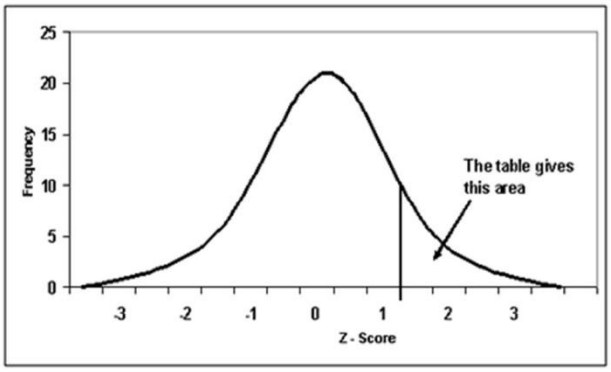
Brief introduction about the Analysis

Theanalysispartplayedthemostimportantinthispaper and hence it is better to get a brief introduction about it before startingtheanalysis.Sobasicallyforthispaper,wecollected the data and then started the analysis. The main parameters were average and strike rate for batsman and average, economyandstrikerateforbowlers.Soforunderstanding we haveshownacasestudywithdataofalltheplayersofoverall IPL seasons from 2008 to 2019. After importing the data, of top 50 players we calculated the mean and the standard deviation values of all the parameters. From mean and standarddeviationwecalculatedthestandardizednormalized value for each player with the help of standardized normal formula.

$Z = (x-m)/s$

x = the value that is being standardized
m = the mean of the distribution
s = standard deviation of the distribution

As the formula shows, a random variable is standardized by subtracting the mean of the distribution from the value being standardized, and then dividing this difference by the standard deviation of the distribution. Once standardized, a normally



distributed random variable has a mean of zero and a standard deviation of one. If we draw the graph with the standardized normal value it will look like this:

In this graph the z=0 at the peak or the mean value and z=1 at standard deviation value. This graph helps to find the probability of that normalized value. After calculating the z score of each player , a graph is hence drawn. A new value is calculated from the z score with the help of astandardized normal distribution table. Now here after calculating the value we consider 2cases:

Case 1: If z>0, we add 0.5 to the new value calculated from the table

Case 2: If z<0, we subtract the new value calculated from the table with 0.5

After getting the final values or probabilities, we convert it into percentile value by multiplying by 100. Suppose we get z = 0.4, we get 0.1554 from the table then we add 0.5 to it so it becomes 0.6554. On multiplying this probability by 100, we get 65.54 percentile value for z= 0.4. Hence we will give 6.554 to it in the range of 0 to 10.

A. Batsman

Whilecalculatingthevalueofthebatsmanweconsidered theformandexperienceofthebatsman.Themainparameters considered are average and strike rate. We devised an algorithm based on this and calculated Batting Power (BP1) of abatsman.

BP1=(0.4*((0.5*SR2019)+(0.5*Avg2019)))+
(0.25*((0.45*SR2018)+(0.55*Avg2018)))+
(0.15*((0.45*SR2017)+(0.55*Avg2017)))+
((0.1*((0.40*SR2016)+(0.60*Avg2016)))+
(0.1*((0.40*SR2015)+(0.60*Avg2015)))

In the above algorithm, the two main aspects of any player (form and consistency) are been taken care of by us. The performance of each player is calculated over 5 IPL seasons to consider each player's experience as well as consistency. Alsotheformistakenintoconsiderationbydecrementing the value of the performance over the 5 IPL seasons. The importanceofeachofthe5IPL(Total-1)isasfollows:

Performance in 2019 – 0.4

Performance in 2018 –0.25

Performance in 2017 –0.15

Performance in 2016 –0.1

Performance in 2015 –0.1

To calculate the performance of each batsman over the 5 IPL seasons, we have considered the 2 most important parameters in modern T20 cricket. They are:

1) Average

Average is considered to be one of the most important parametersinmoderncricket.Averageofabatsmanisdefined

asthenoofrunsbatsmanhasscoredineachinnings.Here for the above algorithm we have calculated the value of each batsmanusingNormalDistributionCurve.Wewillscaleeach Batsman value from 0 to 10. From the normal distribution curve,wegotthevalueofthepeak(meanvalue)inthecurve and set it as value5.

To help understand better, we have shown here the example of Average of top 50 batsmen in the entire IPL history.

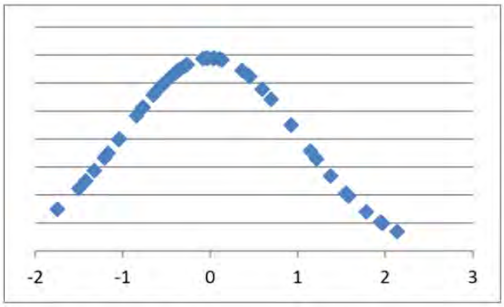


Figure 1 Normalized batting Average

As seen in the above example, the peak (mean value) is around30.Thataveragevaluewillbegivenvalue5basedonthepercentile.Thatmeaneachbatsmanhavingaverage30for that season will be rated 5 in thealgorithm.

2) Strike Rate(SR)

Along with average, strike rate is also considered an important factor. The strike rate is defined as the runs scored by a batsman per 100 balls. Similar to average, we have calculated the value of each batsman from 0 to 10.

The example graph for the strike rate:

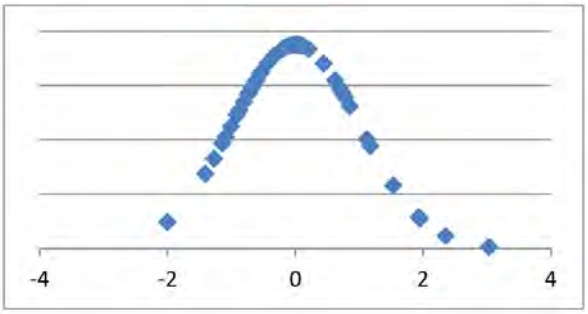

Figure 2 Normalized Strike Rate

Forthestrikerate,thepeakisatvaluearound130.Sothe batsman having strike rate 130 will be having value 5 in the above algorithm and accordingly the value for the remaining batsmen can be calculated with the help of standard normal distributioncurve.

3) Average VS Strike Rate

According to the various cricket analysts, over the years theimportanceofstrikeratew.r.taveragehasincreased.This hashappenedmajorlyduetomoreteamsoptingforexplosive players and giving less importance to the wicket of a player.
Soaccordinglythereisachangeinpercentagedistributionof average and strike rate over theyears.
Foryear2019–50%Averageand50%Strikerate
Foryear2019–55%Averageand45%Strikerate
Foryear2019–55%Averageand45%Strikerate
Foryear2019–60%Averageand40%Strikerate
Foryear2019–60%Averageand40%Strikeratepercentile we will subtract it by 10 to get the actual value of that bowler.

BP2=(0.4*((0.33*SR2019)+(0.33*Avg2019)+(0.33*Econo my2019)) +
(0.25*((0.33*SR2018)+(0.33*Avg2018)+(0.33*Economy20 18)) +
(0.15*((0.33*SR2017)+(0.33*Avg2017)+(0.33*Economy20 17)) +
(0.1*((0.33*SR2016)+(0.33*Avg2016)+(0.33*Economy201 6)) +
(0.1*((0.33*SR2015)+(0.33*Avg2015)+(0.33*Econo my201 5))

.

Intheabovealgorithm,thetwomainaspectsofanyplayer (form and consistency) are been taken care of by us. The performance of each player is calculated over 5 IPL seasons to consider each player's experience as well as consistency. Also,theformistakenintoconsiderationbydecrementingthe value of the performance over the 5 IPL seasons. The importanceofeachofthe5IPL(Total-1)isasfollows:

Performance in 2019 – 0.4

Performance in 2018 –0.25

Performance in 2017 –0.15

Performance in 2016 –0.1

Performance in 2015 –0.1

To calculate the performance of each bowler over the 5 IPLseasons,theparametersthatwehaveconsideredoverthe 5 IPL seasonsare:

1) Economy

Economy is defined in cricket as the no of runs conceded in 1 over (6 balls) by any bowler. Here

for the algorithm we will calculate the value for economy as per Normal Distribution Curve. From the normal distribution curve, we got the value of the peak (mean value) in the curve and set it as value 5.

B. Bowler

Whilecalculatingthevalueofthebatsmanweconsidered the form and experience of the bowler. The main parameters considered are economy and strike rate. We devised an algorithmbasedonthisandcalculatedBowlingPower(BP2) of a batsman. For bowlers while calculating value it will be oppositeofbatsmanastheminimumvaluesineachparameter meansbetterbowlersoaftercalculatingthevaluefromthe

The example Normal Distribution Curve for economy:curve, we got the value of the peak (mean value) in the curve

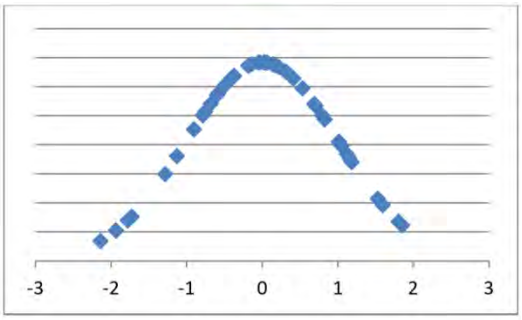

Figure 3 Normalized bowling Economy

Herethemeanvalueisaround7.8.Soitwillhavevalue5. But Economy of a bowler should be less for better value. Hence the calculating value of economy for each bowlerwill be(10-Value).Itmeansthatifabowlergetsvalue8fromthe curve,thefinalvalueforthebowlerwillbe(10-8)=2.

2) StrikeRate

Strike Rate of a bowler is the balls delivered per wicket takenbyabowler.Hereforthealgorithmwewillcalculatethe value for Strike rate as per Normal Distribution Curve.From the normal distribution curve, we got the value of the peak (mean value) in the curve and set it as value5.

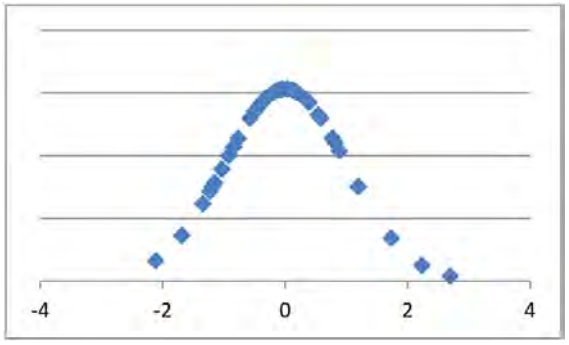

Figure 4 Normalized Bowling Strike Rate

The mean Strike Rate is around 21 and similarly standard deviationvalueisfound.Inthisaswellthevaluewillbe(10-valuecalculated).

3) Average

Average for a bowler in cricket is the number of runs conceded by a bowler per wicket taken. . Here for the algorithm we will calculate the value for Average as per Normal Distribution Curve. From the normal distributionThe example Normal Distribution Curve for Strike rate:

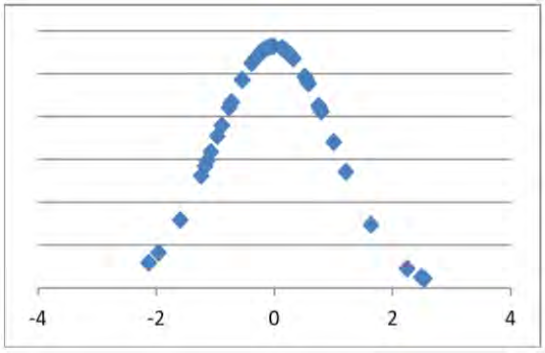

Figure 5 Normalized Bowling Average The mean value was found to be around 27.3.

4) Average VS Strike Rate VS Economy

According to the research paper of HemantaSaikia, DibyojyotiBhattajarchee, HoffieLemer [4] all the three parameters of each bowler should be given equalimportance hence0.33wasgiventoeachplayerinthecalculation.Butthe importance of each value has been fluctuating over time.But credible evidence has not been found to justify it. Hence the valueforeachparameterisconsideredtobethesameoverall the 5 IPLseasons.

C. ALLROUNDERS

InIPL,manyplayersdoeitherbattingorbowlingbut some of them perform both the skills on the cricket field. They are called as all rounders. There are

very few such players and hencetheyshouldhaveahighervaluethananysingleskilled player.Theallroundersarebasicallydividedinto3categories just for the convenience. Theyare:

1) *Batting All-Rounder*
These kind of all rounders have a batting value of more than 5 and bowling value of less than 5

2) *Bowling All-Rounder*
Thesekindofallroundershaveabattingvalueofless than 5 and bowling value of more than5

3) *ProperAll-Rounder*
ThesekindofplayersareveryrareinIPLbutthey are the most precious ones. They have a batting as well as bowling value of more than5

Algorithm to Calculate Value

Theyperformbothbattingaswellasbowling.Sobothe valueswillbeaddedheretoformAll-Roundervalue(AP).

AP = BP1+BP2

Calculation of Value (0-10)

So,understandingofvalueofeachplayerforthedifferent parameters (Average and Strike Rate for Batsman and Average, Strike rate and Economy for Bowler) is very essential to understand about the overall calculation. This value signifies about the percentile of players. For eg: If a batsmanhasavalue9.811calculatedaccordingtothegraphs, itmeansthatthebetteraveragethan98.11%playersthathave playedthatyear.Thevalueissimilartothebowlersaswell.

V. CONCLUSION AND FUTURE WORK

Selectingacorrectteamplaysaveryimportantroleinwinning acricketmatch.Hencethispaperplaysaveryhelpfulrole for that purpose as it provides each player's value irrespective of the player's past performances and reputation and helps to build a very strong team to win the IPL. In the above research paper, we have calculated each batsmen and bowler's value by a algorithm which consisted of different parts and the cumulative total of that algorithm gives the player's performance value. This is a unique kind of player thatcanhelpthefranchisestoselectsensiblyandsmartly.But therearevariousparametersthatarenotconsideredwhichcan enhance the algorithm. It includes Performance in winning matches, Performances in Knock-Out games and Fielding Performances. Also giving extra points to wicket-keepers, captains, all-rounders are the others aspects that can be discussed in the futurework.

Interaction of Farmers with the Buyers

ChaitanyaKale,PratikGehlot Nitesh Mishra ,Chandan Mishra
Thakur College of Engineering and Technology Mumbai, India

***Abstract*- Farmers are the pillar of any prosperous nation. They contribute towards the major part of the economy but still they are deprived of the profit they deserve. India is a land where farmers contribute to 50% of the work force and GDP contribution of agro products is 17 to 18 % countries overall growth. The world is driven by technologies like Artificial Intelligence, Block chain, Data science, Web development, etc. and this list is endless. With such a huge leaps and advancement in modern technologies still farmers suffer the most in boosting their productivity of their crops and maximizing their income. They are still in the clutches of middleman, Rich Farm land holders, vendors who are not allowing them to get the maximum profit of their food grains and exploiting them .This paper analysis the various technological aspects and focusses on overall growth of farmers in terms of providing them opportunities to interact directly with buyers, vendors, restaurants, local market retailers with use of website, mobile apps. Not only farmers are deprived of their original cost but the buyers also don't receive these products at fair price which sometimes leads to burden on them.**

Keywords: [Farmers, technology, Profit, Smart farming, websites, Android apps, Machine Learning, Natural language processing, API]

I. INTRODUCTION

The overall growth of any nation takes place when there is equal share and contribution from all sectors of society. In 21st century technology is booming and connecting millions of people across the world. A smartphone devices have become such powerful that it can let your business grow from small market to a huge prosperous market. In terms of agricultural production activity of $375.61 billion, India stands on the second position for the largest producer of agriculture product. The total agriculture product output stands around 7.39 percent from India around the world. On the other part our neighboring nation china has contribution of $991 billion GDP in agriculture sector which is much more from India. Recent studies have revealed that fusion of agriculture and technology matter, and China is doing the right way. The use of artificial intelligence is one way that farmers are streamlining operations, increasing efficiency and ensuring sustainability."China has introduced a cloud-basedagricultural intelligence which has aimed to help the farmers of china. This will lead to increase of their crop yield and help them to achieve income of (71,289.40 Indian rupee.)".The need of such sustainable development is also needed in India where farmers are the prime contributor for the development. They are the ones who are grow food grain and feed the society but still they don't get enough cost of their crops. Every day around 35 farmers give up their lives which is very embarrassing for our nation where slogans are given such as 'JAI JAWAN JAI KISHAN'. We just need to make use of knowledge like machine learning, NLP, Deep Learning to make an application which has all integrated environment with all around development make use of these to grow the farm productivity. With the use of 'APP' farmers can connect themselves to the buyers and sell directly their products, Similarly with the use of 'websites' it can be feasible for the governments to launch their schemes and make people aware about development things they are intending for . This initiative taken by government will help them to reduce huge production of excess food grains which results in wastage sometime and also ensure the food security for the country and give farmer a feeling of self pride and satisfaction. Lowering the ceiling increases profit,and with AI advancements and collaboration in other areas, this goal is becoming a reality. The basic idea of using these systems are connecting farmers directly to the buyers allowing them to sell the quality product at reasonable price to the buyer and also ensuring that the maker get the price they deserve. Majorities of farmers are smallholders living in rural areas and thus lack amenities which will give them direct access to markets for their products and also they are deprived of agriculture market information. Therefore farmers are exploited by these intermediaries who offer low prices for agriculture products. Over the next few years, the application of these technologies will greatly shape the way the country manufactures food and distributes it to the most valuable sector of the nation. The country is already well on its way.

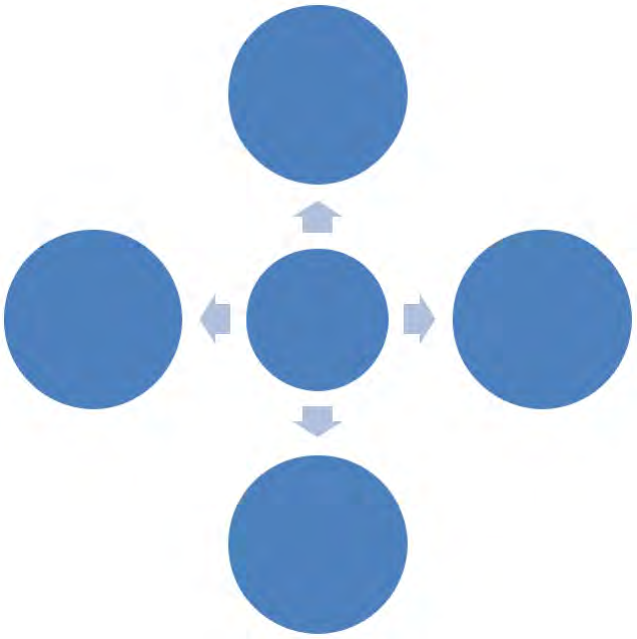
II. LITERATURE SURVEY

In India many attempts are made to improve the conditions of Indian farmers by the use of advance technologies. This would help the condition of farmers and farming. Studies are being carried to use implement E-farming with use of Artificial intelligence, cloud based technologies which will have a definite impact on the condition of farmers. It is proposed that there should be a web portal or android apps which would connect farmers to the buyer. These thingscannot be done individually by famers because farmers are not much educated so we also need special efforts from government and company professional in order to make famers aware of such existing platform.

III. IMPLEMENTATION

The system is formulated to improve farmers and buyer relation through an application based environment where famers can directly interact with buyers to sell their

products. In this farmers will grow their product and upload the details of their products so that buyer will come to know about the availability of the products. We make use of an integrated system where there will be facility of getting information about various schemes offered by the state and central government, improving the crop condition through the use of **Augmented Reality** by capturing the picture of **land** and make farmer aware what crops he should grow in repeated interval of time. In this application farmers will also get information whether he needs to grow crops in bulk amount or small quantity. This system also has an **AI** based **Chatbot** system which will interact with famer in his native language. Once the buyer will come to know about the product he can interact with famer through mobile Phones or **SMS** based **system** and make famer aware that he is interested in buying his product.



This system not only enables farmer to sell their products but also provides opportunities for vendors, restaurant owners, courier man, delivery agent to get employability through this. We also intend to have a SMS facility forthose farmers who cannot send their details through application.

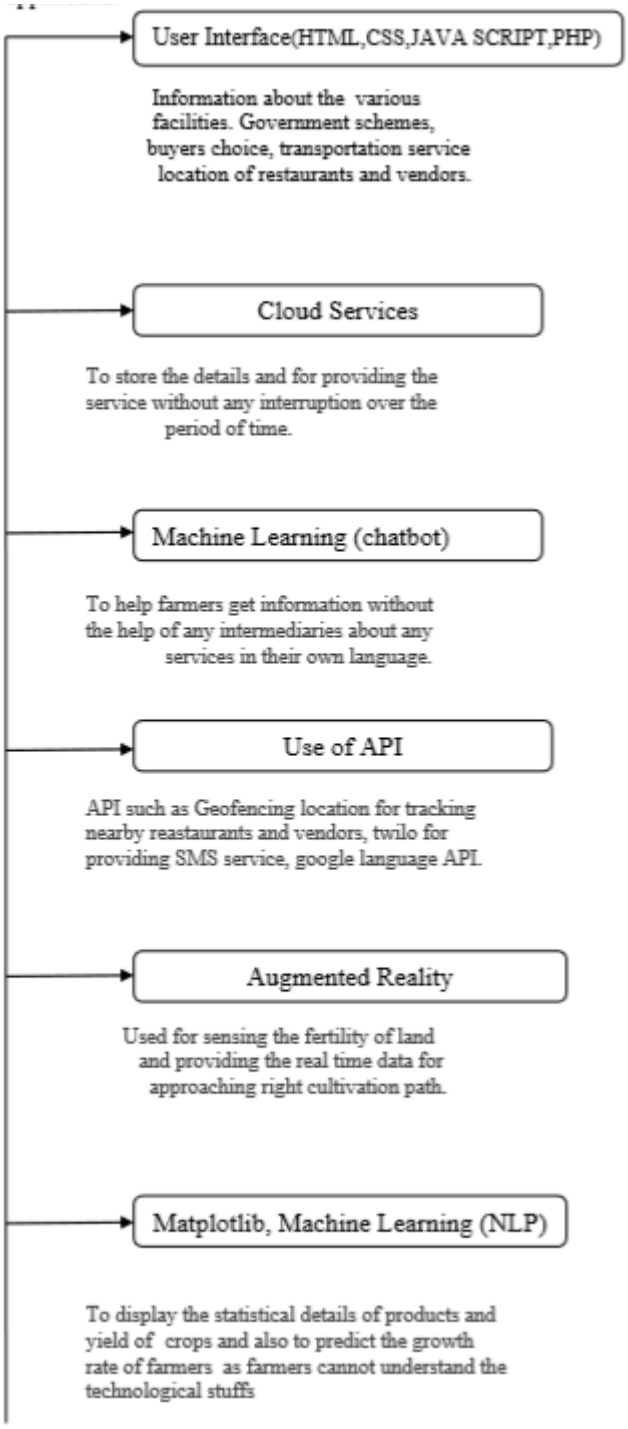


Fig A. Technology usage

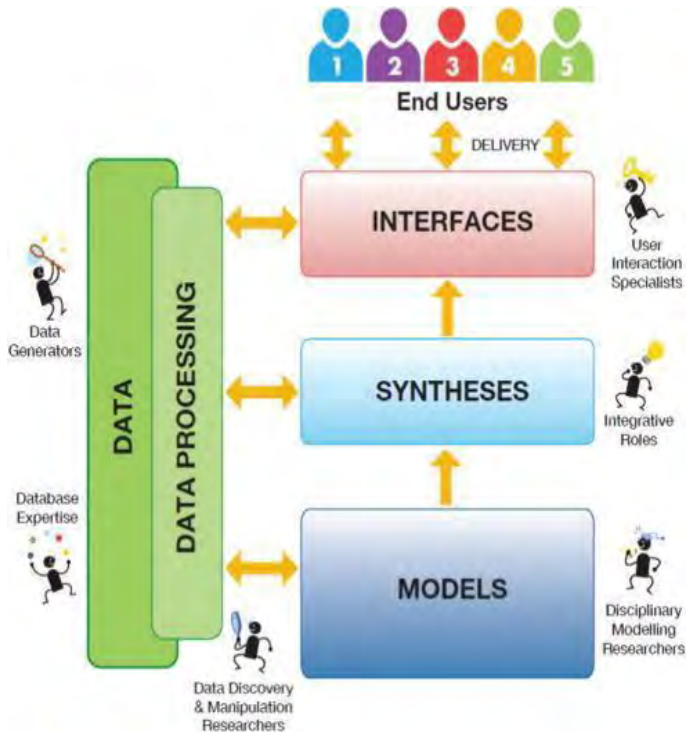
IV. WORKING MODEL



We consider to have a model where there will be preprocessing of data so that some useful insights can be carried out, These insights can be used to distinguish important features by government so that they can bring some major reform in their policy.

V. USE OF API

The working of API is such that it allows to monitor the services based on ones requirement. We would be able to fence the nearby region around farmers where he can go and sell his product. Also we have API called Twilo which is used for sending SMS to the farmers. GOOGLE language API is used to translate language of web application in their own language.

TWILO API

```
// Your Account SID and Auth Token from twilio.com/console
$account_sid = 'ACXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX';
$auth_token = 'your_auth_token';
// In production, these should be environment variables. E.g.:
//     $auth_token = $_ENV["TWILIO_AUTH_TOKEN"]

// A Twilio number you own with SMS capabilities
$twilio_number = "+15017122661";

$client = new Client($account_sid, $auth_token);
$client->messages->create(
  // Where to send a text message (your cell phone?)
  '+15558675310',
  array(
    'from' => $twilio_number,
    'body' => 'I sent this message in under 10 minutes!'
  )
```

USE OF AUGMENTED REALITY FOR CROP PREDICTION

Linear Regression (LR) is used to establish relationship between explanatory variables (AR, AUC, FPI) and the crop yield as response variable. R^2 value clearly shows that yield is mainly dependent on AR. AUC and FPI are the other two factors influencing the crop yield. This research can be extended by considering other factors like Minimum Support Price (MSP), Cost Price Index (CPI), Wholesale Price Index (WPI) etc. and their relationship with crop yield.

```
import pandas as pd
d={'ARHAR':1 ,'COTTON':2 , 'GRAM':3 , 'GROUNDNUT':4,'MAIZE':5,'MOONG':6,
df=pd.read_csv('datasetFINALdata.csv')
from sklearn.model_selection import train_test_split
X=df[['Climate' , 'Year']]
y=df['srno']
X_train , x_test , y_train , y_test=train_test_split(X,y,test_size=0.3)
from sklearn.linear_model import LinearRegression
lg=LinearRegression()
lg.fit(X_train , y_train)
lg.score(x_test , y_test)
x_test
y_test
c=lg.predict(x_test)
```

This is the basic functionality what is to be included for implementing this model considering all the technological variations.

VI. AI POWERED CHATBOTS

An AI powered chatbots that can recognize the users need, collect different data from it and will be able to frequently asked questions and reply to it. Autopilots uses a task-driven programming model where tasks correspond to outcomes what users want through interaction with your bot. Some of the examples may be like making a call with buyer who has asked for his product, giving information about the market driven requirement products to be needed,etc. It uses natural language understanding(NLU) to detect what users are saying and match it to the appropriate task.

VII. USE CASES

There are several existing model which is trying to solve the problems of the farmers but it is segregated into different parts, overall there exists no model which tries to cover entire problem in one application. Our studies revolves around scenario where we want a model which has all the features involving from security, connecting government agencies, involving the concept of crop prediction, real time monitoring of the services and most important a level of satisfaction from the farmers and buyers.

Various different types of existing solution available in the market such as E-Nam, Kisan Network, AgriApp, KisanYojana,etc.

These all application services are inclined in offering one of the services where the need of time is a web application which has all features incorporated in it.

VIII. DISCUSSION

Currently this system cannot be implemented directly by the farmers as they have lack of access to technologies. We need support from Non government agencies and professional who will help us to setup the centre in village areas and organize awareness program to make people aware. There is an need of such system in the market as the gap between urban and rural areas is widening up. The recent survey shows that people are less involving in agriculture works because they are not getting access to markets and most of the products cost are eaten up by intermediaries.

Agriculture is one of the activity which is done for feeding the large humanity but still if the makers are in trouble it is one of the saddest part of our society. Every year there are many farmers who give up their lives due to loss of crops, huge storage of produces also lead to wastages some time.

Farmers are not only the ones who suffer but the buyers too have to bear hefty cost of the vegetables, grains, etc. There is always a mismatch between the original price laid by the farmer and what a buyer pays. This system does not justifies to the equal share to be given to farmers and buyers.

IX. FUTURE SCOPE

This system can be used a model which can be used to form an organization which will maintain all the ecosystem and ensure that this application is maintained and updated with growing technologies. We also would like to include advance security system based on Blockchain which can be use to link payment option with the buyers. There are also multiple things which can be included along with this model.

X. CONCLUSION

The study evolves around how can we help farmers with modern technologies and making them independent in terms of growing and selling. We want to incorporate technologies such as Artificial Intelligence for chatbots, NLP for deducting references from regression model, having a web application with features such as providing interface for getting information on different things. We would like to have collective support from all the working bodies I bringing up this model. This is not an individual task but as a whole society we need to implement this.

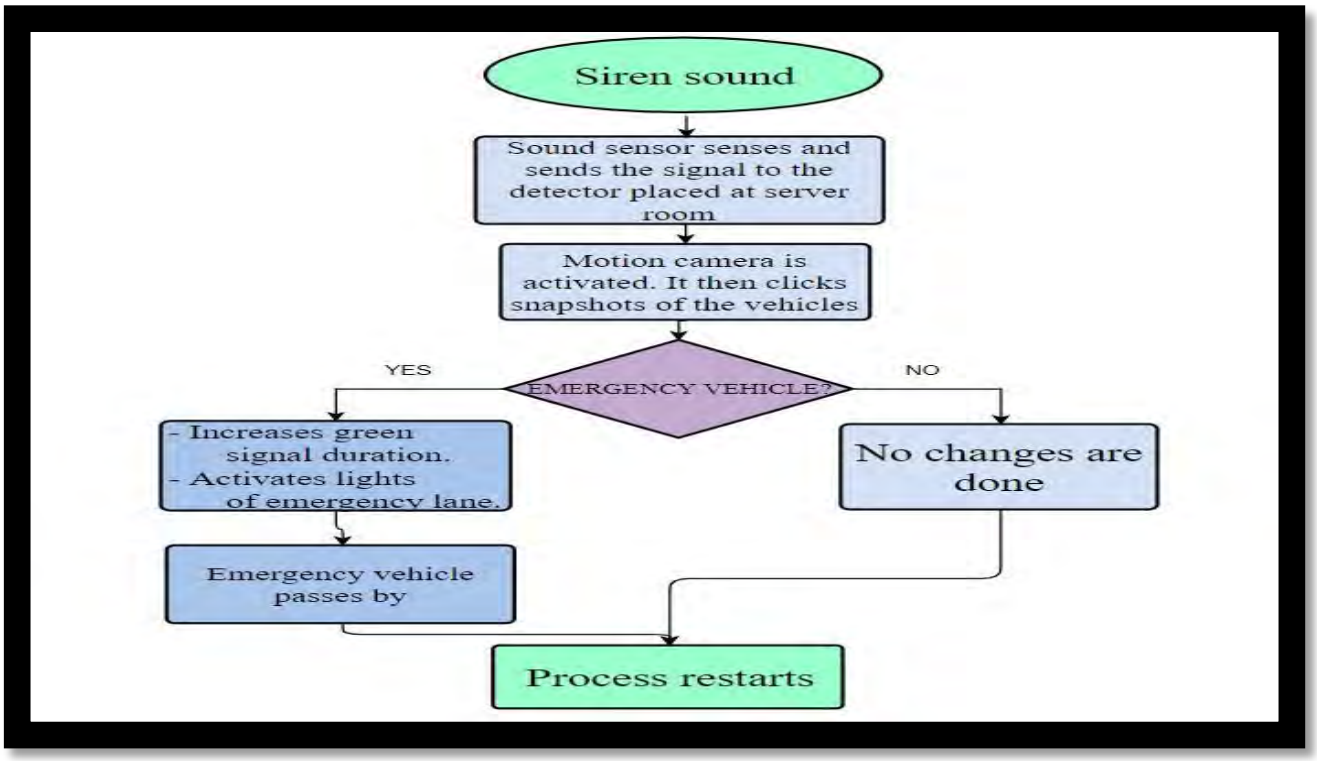
Traffic management for emergency vehicles

ABSTRACT: **- Technology can bring back anything but not life. Life is valuable. Everyday hundreds of people lose their lives due to delay in the reach of emergency services. The major contributor is traffic. Due to traffic the emergency vehicles like ambulance, fire engines, etc. are unable to reach in time at the destination, due to which the common people suffer. This project aims to solve the problem of traffic for the emergency services to some extent. The focus is to provide a way for the emergency vehicles on a busy road using artificial intelligence. A neural network is trained to identify emergency vehicles.**

KEYWORDS: -tesseract, neural network, artificial intelligence

WORKING: - All the emergency vehicles have a particular siren which is used when they have to reach a particular destination. The sound sensing sensors will be placed at about 2 km before the traffic signals and then at a distance of 1 km motion sensing cameras will be placed. When sound sensing sensor senses the sound of the siren it will be detected by the detector placed in the server room, and then the cameras will be activated. The camera will then start clicking pictures and send it to server room. Using these clicked pictures, neural network will identify whether the vehicle is an emergency vehicle or not. Once it is confirmed that the vehicle is an emergency vehicle, LED lights will start glowing in the emergency lane; a message will be displayed on the indicator as "Make way for the emergency vehicles" and the duration of green signal will increase. This will help the emergency vehicle to reach its destination in the shortest time it could.

FLOWCHART:-



Li-FI(DATA through ILLUMINATION)

Shashakt Jha , Shubham Joshi ,Utkarsh Kulkarni

Thakur College of Engineering and Technology

Mumbai INDIA

shashaktjha@gmail.com shubhamjoshi1303@gmail.com Kulutkarsh2000@gmail.com

*Abstract:-***This paper provides the basic idea, principle and applications of Li-Fi.**

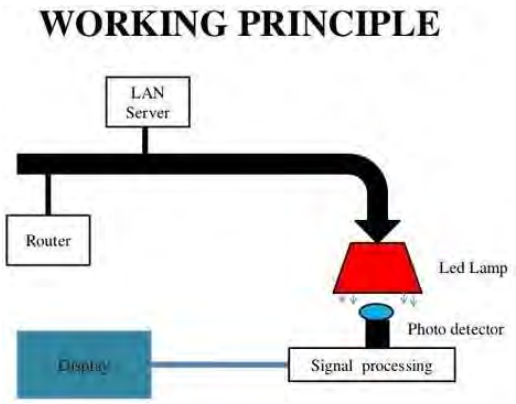
I. INTRODUCTION:-

From the beginning of mankind,
COMMUNICATION is one of the basic necessities for our survival as we share important data and Information with each other. But with ever increasing knowledge our current means (of data sharing) seems to be incompatible with the demand in terms of SPEED, RANGE and SECURITIES. In 2011, at TED Global Talk, Professor Harald Haas presented a new medium for sharing data via "VISIBLE LIGHT COMMUNICATION". This Technology is termed "LIGHT FIDELITY" or "Li-Fi". Li-Fi is a technology for wireless communicationBetween devices using light to transmit data andPosition. When an electrical current is applied to anLED light bulb, a constant stream of light is emitted from the bulb which we see as illumination. As LED bulbs are electronic devices the input current can be controlled and therefore the output light can be modulated at extremely high speed, this can be detected by a photo-detector and converted back to electrical current. Hence data can be transmitted at high speeds.Li-Fi is bi-directional full duplex and high speed i.e. data is transmitted and received at the same time resulting in a really fast and reliable network.

II. WORKING:-

Idea was very simple that if the LED is "on" then
The digital 1 can be transmitted and if the LED is "Off" then the digital 0 can be transmitted. Leds can be switched on and off very quick. For transmittingData this way all that we require is LED's andController that code data into LED's.

Parallel data transmission can be done by usingArray of LED's or by using red, green, blue LED'sTo alter light frequency with the frequency ofDifferent data channel. The data transmission is doneThrough binary codes which involve switching onLED can be done by logic 1 and switch off usingLogic 0. The encoding of information in light canTherefore be identified by varying the rate at whichThe LED's flicker on and off to give strings of 0'sAnd 1's. Visible light communication is this methodOf using rapid pulses of light to transmit information wirelessly



Visible Light Communication (VLC) is aData communication Medium, which uses visibleLight between 400 THz (780 nm) and 800 THz(375 Nm) as optical carrier for data transmission and Illumination. Fast pulses are used for wirelessTransmission. Communication system componentsAre:
1. A high brightness white LED which acts as aCommunication source
2. Silicon photo diode which shows good responseTo visible wavelength region.

LED illumination can be used as a communicationSource by modulating the LED light with the dataSignal. The LED light appears constant to the humanEye due to the fast flickering rate. The high data rateCan be achieved by using high speed LED's andAppropriate multiplexing techniques. Each LEDTransmits at a different data rate which can beIncreased by parallel data transmission using

LEDArrays. Many different reasons exist for the usage ofLED light in spite of fluorescent lamp, incandescentBulb etc. which are available.

Advantages over current systems:-

- Easy to install.
- Data Transfer rate for internet application is higher.
- Bandwidth of Li-Fi is 10000 times widerThan conventional radio waves system.
- It provides high amount of security as dataCommunication path is the Line of sightItself. Hence, this will avoid unwanted accessof Li-Fi signal by unauthorized users sittingIn the neighboring rooms.
- The Li-Fi devices consume low power forOperation and hence can be used in Iota(Internet of things) applications.
- Uses Optical spectrum and hence avoidsAlready crowded RF (Radio Frequency)Spectrum.
- There are no health concerns in Li-Fi basedSystems as it uses clean, pure visible band ofThe electromagnetic spectrum.
- There is a drastic energy reduction in Lighting industries that use Li-Fi based Devices.

III. DISADVANTAGES OR LIMITATIONS:-

- Internet can be used only where light sourceIs available.
- as light cannot penetrate optically opaqueBarriers, its range is limited.
- Though it draws low power, in order to availLi-Fi Internet services, light needs to be keptON throughout the day and also at night asInternet is the need of the hour.

IV. CONCLUSIONS:-

Li-Fi is a new emerging technology that mayReplace Wi-Fi in coming 10 years and opens newWays to explore an learn about data sharing with aVery high rate of transfer.

Abstract—**The TCP/IP model has been used forvarious data communication applications for several years based on a set of Protocols that govern the working of the Computer Networking System. This protocol suite is named TCP/IP due to the TCP (Transmission Control Protocol) and IP (Internet Protocol) protocols which are acknowledged as the most prominent protocols for digital communication. TCP/IP model is also referred to as the Internet Reference model or simply Internet model. TCP/IP Model is a four-layered data communication model that was developed by DARPA, an agency of the United States Department of Defence. The applications are based on the client-server model which contains a requesting node and a servicing node like sending an email, sharing files via the internet, visiting a website, etc. It consists of the Application layer at the top, followed by the Transport layer, Internet layer and Link layer at the bottom. The transmission of data is done by breaking the data into packets, frames, bits and then reassembled at the receiver's end where each layer has a particular task in the handling of data and to perform faithful communication between the nodes. In this article, an explanatory overview of the structure, working of the TCP/IP model, the importance of the essential protocols and its association of the model with the web world are explained.**

Keywords— Computer Networks, TCP/IP reference model, Web Based Applications.

I. INTRODUCTION

The TCP/IP model is a well-defined combination of protocols that define the process of data transmission from one node to another. This was developed earlier than the OSI model.[5] TCP/IP model provides complete assistance in assembling and presentation of data received by the receiver. This model is regarded as stateless because it considers every request as a new one and has got no relation with the previously made requests.[3] The model with the help of its 4 abstraction layers manages the assembling of data received, and provides the receiver with the desired message.

It is classified into four layers that help in the process of packetization, addressing, transmission, routing and receival at the other end. This has been the backbone of Computer Networking since its induction, it is found among applications that were produced a few years back such as Voice Over the Internet.[5] This feature is possible in this model with the help of Stream Control Transmission Protocol.

II. LITERATURE SURVEY

This was a result of the combined study of Defense Advanced Research Projects Agency in 1960's.The initial model of TCP consisted of datagram transmission as well as routing.. With the modifications being brought into this, it is considered as the most comprehensive suite for the general networking system. This technology was introduced to the market by IBM and AT&T during 1984.

A. Architectural structure

The working of this model is related to the end to end principle which states that the nodes in a network must be associated with Simplicity of communication. The modern day changes have caused this principle to be altered several times.

B. Comparison Between TCP/IP And OSI Model :

The difference between these two models begins with their classification of layers. The OSI model has a separate Application Layer that handles the interaction with user, the Presentation Layer that takes care about the encryption or Decryption of data and a Session Layer that manages the allocation of ports and sessions establishments. The TCP/IP model has classified all this under one head known as the Application Layer. The transport layer and Internet Layer remain the same for both the models. OSI models have a Data Link Layer and a Physical Layer towards the end which is converted to Link Layer for TCP model. Moreover, OSI model can be considered as a theoretical model whereas TCP/IP model is actually used for connecting to Computers (nodes) and Communication over a network. OSI model is utilised to Understand the working of the network. TCP provides with the feature of ease of connection whereas, OSI model helps the standardization of Routers or other Hardware Devices. TCP model actually helps to form a connection between two or more nodes.

III. FLOW OF DATA TRANSMISSION

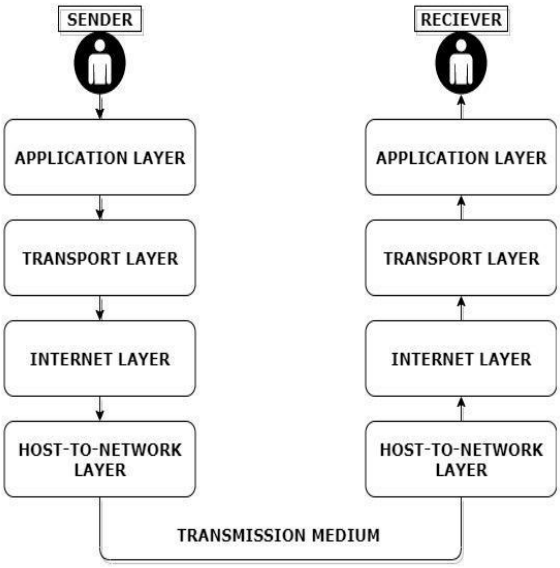

Fig 1.Flow of data Transmission

When a user sends a service request then it passes through four layers and finally through the transmission medium. Based on the Transmission medium the data can be passed in the form electrical signal (Analog or Digital) using cables, as a light signal by using fiber optic mode of transmission, etc. [5].The transmission of signals through cables is further divided into 2 types of viz. Baseband and Broadband. In the Baseband form of transmission, the data is directly transferred in the form of digital
pulses while the broadband uses the Modulator/Demodulator (Modem) circuit to convert the digital signal into analog and superimpose the data signal with a carrier wave and then transmit it through the channel [5].

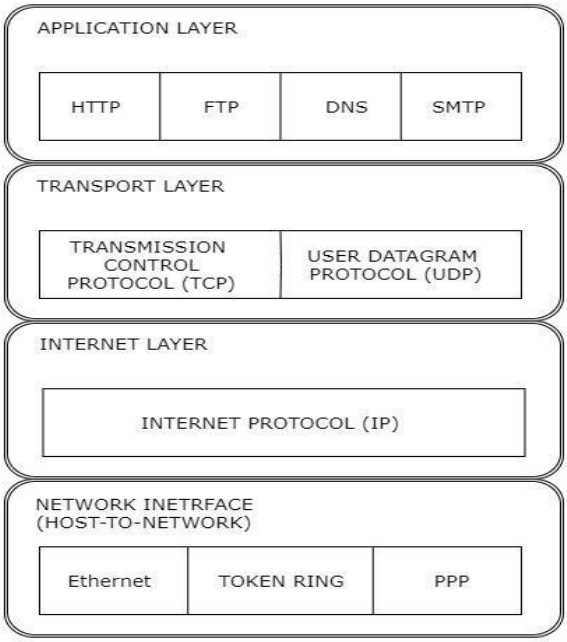

Fig 2. TCP/IP Protocol Suite

The brief Explanation of the 4 layers of the TCP/IP model :

A. Application Layer

The application layer is the interface between the user and the following layers. This layer enables the users to share data through the network and deals with the data generation, translations, formatting,
data compression and data encryption. This Application layer provides the following services:

Protocol	Used for
HTTP (Hyper Text Transfer Protocol)	Transmitting hypermedia documents e.g. HTML files, generally used between web browsers and web servers.
FTP (File Transfer Protocol)	Transmitting files over network amongst two or more hosts.
Telnet (Teletype Network)	For remote login and to execute functions remotely through the network which is bi-directional and provides a text based communication through terminal
DNS (Domain Naming System)	Naming the connected nodes in the network to make it easy to remember, also it translates the name to the IP address using a DNS server.
SMTP (Simple Mail Transfer Protocol)	Sending and receiving electronic mails (e-mails) on the network.

B. Transport Layer

The transport layer is considered to be one of the most important layers as this creates host-to-host communication. Even if the data reaches the receiver it is useless if it does not provide the detail of the process which requires that data. This issue is fixed by assigning port numbers to the processes running on the host machine. When the server responds to the request it encapsulates the port number at which the data needs to be delivered.

The most widely used protocols are shown in the below diagram:

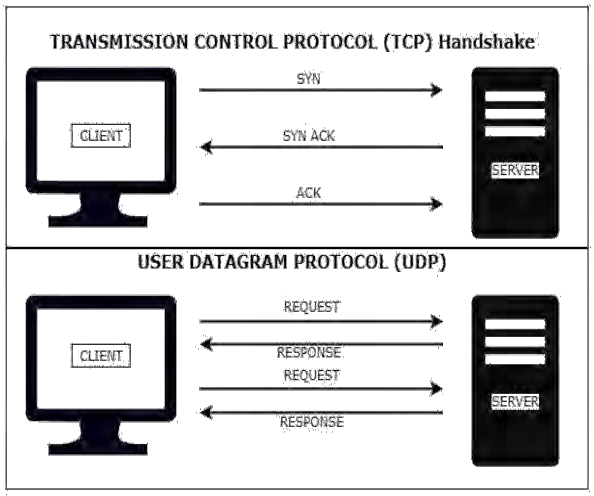

Fig 3. TCP and UDP protocols.

a) UDP (USER DATAGRAM PROTOCOL)

- It is a connectionless communication model.
- It doesn't keep track of the data transmitted
- Fails in identifying the retransmission condition.
- It is faster as compared to TCP protocol as it does not require a handshake before data transmission.
- It just verifies the checksum and accepts the data but no acknowledgement is sent back to the sender.
- The data block sent by the UDP protocol is called as Datagram.

b) TCP (TRANSMISSION CONTROL PROTOCOL)

- It provides a communication channel between the applications on client and server machines.
- TCP is a connection-oriented based protocol to enable host-to-host communication.
- In TCP a handshake is done between the two communicating nodes.
- TCP provides reliability, as it checks for errors in the received message and sends an acknowledgement if everything is alright within a specified time or else the sender resends the data.
- This enables retransmission of data as sender can make decisions based on the acknowledgement status [4].
- The transmitted block of data by TCP is called as Segment.

C. Internet Layer Or Network Layer

Network layer is completely responsible for inter-network communication. It doesn't rely on any physical topology of the network. The Datagrams/Segments are converted into Packet by adding sender and receiver's IP (Internet Protocol). This Packets are routed via different routers and reach the destination. The most commonly used hardware device working at this layer are routers.

D. Network Interface Layer

At this layer the Physical Address/MAC (Media Access Controller) Address of the source and destination are added to the packet. Also, the CRC (Cyclic Redundancy Check) bits are added as trailer also known as FCS (Frame Check Sequence) which help in error detection. The ready block to transfer is called Frame and now converted into bits of information and transferred through the medium. The devices working at this layer are Switches, Bridges , Hubs, Cables, Connectors, etc. These include the physical topology of the network and also these devices combine to form a single network.

IV. TYPES OF ADDRESSES

A. IP Address

IP Address is the unique id of a node in the network and beyond. Every device from the Internet layer has an unique IP address to give that device an identification. IP address is 32bit long i.e. 4 bytes. It has 4 8-bit numbers separated by '.' . These groups of binary numbers form decimal numbers in range 0-255. [1] For e.g. 192.168.10.5

B. Mac Address

MAC address is 6 bytes unique identification number assigned by the manufacturer to the NIC (Network Interface Card) .The 6 bytes are separated by-'. For eg. 00-1a-3f-f1-4c-c6

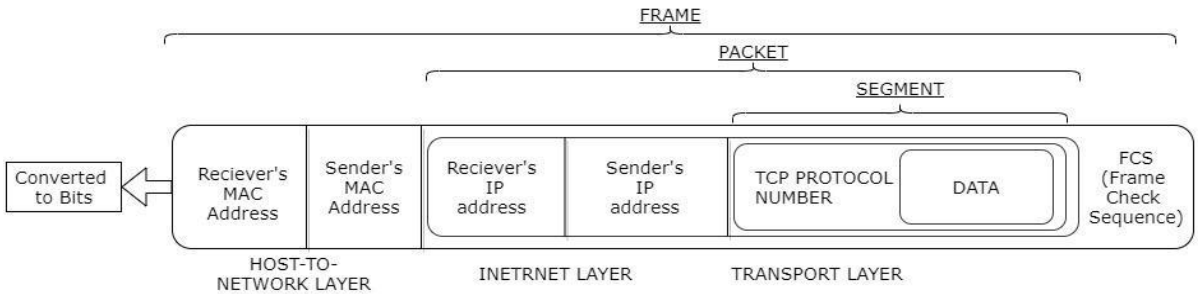

Fig. 4. Each layer Encapsulation

V. APPLICATION OF TCP/IP MODEL IN WEB

From loading a simple webpage onto the browser to uploading a picture on social media everything is dependent on the connection with the server and the network between you and server. Generally, the request sent by the browser is HTTP when requesting a web page. But before that, there's a middle-man called DNS server. We usually open a website by its URL (Uniform Resource Locator), this is a name given to a particular IP address that identifies the server. We cannot connect with the server without this.

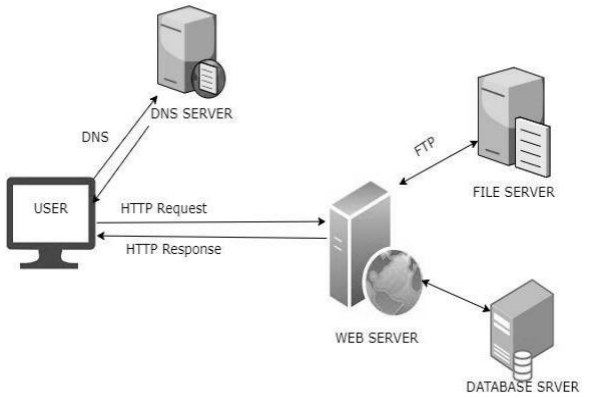

Fig. 5. WEB based Client- Server Communication model.

When a user sends a page request using URL, initially it acts as a DNS client and sends a DNS query to the DNS server requesting for the IP address allocated to the requested domain name. After receiving the IP address the connection is initiated. Then the host machine and Web server tries to do TLS (Transport Layer Security) handshake which basically runs on Transport Layer. This sets up the connection with the web server. Then all the data packets are sent to the server through routers using various routing algorithms and various other network devices. It is not necessary that all packets take the same route and reach the server at the same time. The reassembling of the segmented data is done at the receiver's end and then interpreted by the Web Server. If the user request is for data from a database or if the user is requesting images or some file so the web server connects to the database server using ssTCP/IP network or file server using FTP protocol respectively. The next step is to process the data received from database and file storage and send a HTTP response to the waiting user.

VI. CONCLUSION

The applications of TCP/IP protocols are vast, the model is used according to the convenience of the user group. The basic requirements of this modelscales down to a set of hardware devices and a particular software required for the sharing of data packets over a network[3]. Due to this factor TCP/IP model is implemented on all computer platforms. This model is responsible for data transmission, for all perspectives. The web browsers are being accessed every now and then, this shows that whenever we are trying to access some data from the internet or provide some data to the Internet, we are following the TCP/IP model.

While we request for some data from the internet, we have created a condition where two nodes exist, the requesting node and the server which responds and serves to our request becomes the servicing node. This technology model came into existence in 1960's

[3] but its applications are visible today as well. The model has gone through several changes according to the requirement of industry but the working still remains the well.

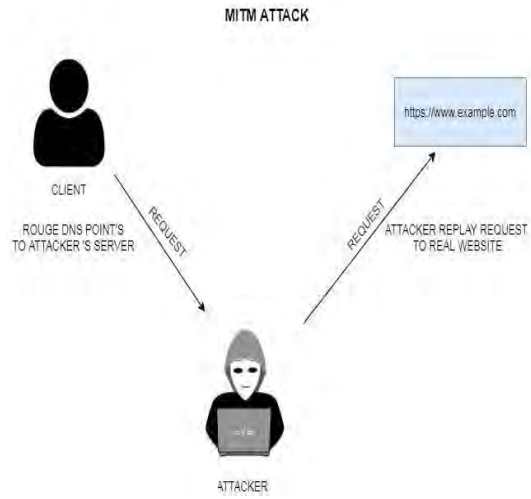
Abstract—**with the world becoming more connected than everwith the advent of internet, it has never become more important than ever to preserve the private and public data of fellow denizens.**
Many people are under the false influence that accessing a website which has HTTPS (Hypertext Transfer Protocol Secure) automatically makes them invulnerable from attacks and other third party data thieves, which isn't entirely true.
Most of the website uses SSL (Secure Sockets Layer) to ward off the Authorized detection and decoding of confidential data over the network. HTTPS protocol is used for communication between web browser and a websites server. While effective, HTTPS is not perfect and has its own flaws and loopholes, which a experienced hacker or any institute can manipulate the data, using SSL-MITM (Man in the middle) and other techniques. To be secure, while surfing the internet VPN(Virtual Private Network) ,SSL,HTTPS,ARP(Address Resolution Protocol) TABLE,ANTI-SNIFFING,ARP WATCH are advised to be used[1].

I .INTRODUCTION

The HTTPS is responsible for verifying/validating the communicating end points while providing confidentiality and integrity ensuing communication. However, as with most security solutions, it does not come with its own drawbacks. There are many research about protecting secure data, such as and focused on Wi-Fi Networks and human factors, secure the online retrieval of certificates by confirming certificate's fingerprint out-of-band. Identity-based cryptographic algorithms which do not require certificates i.e. a party's public key the party's identifier (e.g., fully qualified domain name or IP address).
This paper addresses the problem of the drawback of HTTPS and proposes 3
Different modus operandi to recover the loopholes of the protocol. [2]

II.SSL MITM Background

The following steps to decode the SSL using MITM.
1. Spoofing hacker-machine into victim-machine by Informing the gateway-router.
2. Spoofing hacker-machine into gateway-router by Informing the victim.
3. Enable packet routing feature on hacker-machine.
4. DNS Spoofing to enforce the victim to connects 443 portAt Attacker machine.
5. Forwarding fake certificate to victim.
6. Communication establishment with the victim using fakeCertificate.
7. Connecting with the HTTPS website by using genuine Certificate gathered from the HTTPS website. .
8. Capturing the packets transmission between devices.
9. Decrypt data. [3]

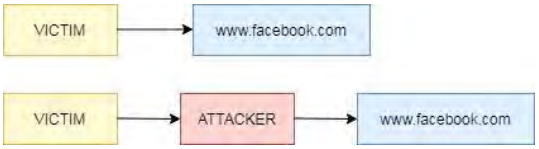


III. Offensive Way

Here we simulated a scenario in which we are trying to get Facebook password of a user. To do this, we need to understand 3 terminologies i.e. Victim IP Address(192.168.1.10), gateway-router IP address (192.168.1.1) and attacking machine IP address (192.168.1.20).Also, ensure that victim and attacker machines are in the same network. MAC Address of an attacker suppose is AA-BB-CC-00-11-22. The steps to perform the attack are:

1.Enable the packet routing in your Linux operating system. Command is echo 1 > /pros/sys/net/ipv4/ip_forward
2.Make sure that hacker spoof itself as a Gateway router. suds arpspoof –t 192.168.1.10 192.168.1.1
Thus, Victim believes that Gateway MAC Address is AA-BB-CC-00-11-22, which is originally attacker IP Address. As a result, all packets of data is been transmitted through attacker machine.
3.Attacker machine has to inform the Gateway router and spoof itself as a victim machine.

Suds arpspoof –t 192.168.1.1 192.168.1.10 Here hacker is performing Man in the middle attack.[4]



4. Whenever victim visits Facebook, the packets are been transmitted through attacker machine. Hacker can use any sniffing tools available such as Wire shark, Ethereal or website.
Thus, Attacker can capture username and password. And can store the credentials for later use.
5. Here we save a credentials in store data file and decode the data as follows:
Slump –r store data –kwebmitm.crt > out
Hacker can easily read data sent by victim in clear format. [6]

IV. DEFENSIVE WAY

1. Apply ARP WatchThis help to prevent attack as ARP Watch maintains the list of changes done in ARP value. This is applied at client side. This is useful as it can trigger and record the event. Disadvantages arise due to compatibility issue such as software cannot be installed on Router.
2. Apply Anti Sniff It can identify and indicates some IP Address that is, running a packet capture tool. The admin can block the IP Address.
3. Apply static ARP Advantage of using static ARP technique is admin is configuring switch rather than client. Since switches have "Port Secure" feature. Do note that some of the switches do not have "Port Secure". [5]

V.CONCLUSION

Scammers, phishers, hackers and other entities are always on the hunt to steal your public and private data .Our study proves that HTTPS, while a highly effective and secure way of protecting your data isn't entirely perfect. There a various ways which a user must follow to ensure his online privacy and safeguarding of personal data is being assured.

VI. FUTURE SCOPE

Confidentiality, Integrity and Authentication of the Website is ensured if the website is using HTTPS rather than HTTP. Most of the HTTPS servers are vulnerable to trivial MITM attack. Thus, to ensure the security which hasMonitoring AlertingAnti-SniffingTechnology must be integrated with HTTPS. Such as merging the technology contents of VPN, SSL, HTTPS, ARP TABLE, ANTI-SNIFFING, and ARP WATCH.

***Abstract*-The environment pays a heavy price for our fast fashion habits. Every year 300 million tons of plastic is produced out of which 8 million tons of plastic goes into the ocean. This is causing cross linked impact on the planet by not only affecting the sea life but also due to absorption PCBs and DDTs it poisons the food chain. Diverse solutions have been proposed ranging from source reduction to ocean based clean up. Our paper focuses on eliminating the plastic waste from the oceans by using the ocean currents. An installation of U-shaped screen channels moving with the help of waves similar to that of plastic which concentrates the floating plastic to a center point. This concentrated plastic can be extracted and recycled. Thus, making it profitable.**

Keywords—buoyancy, micro plastic, floater

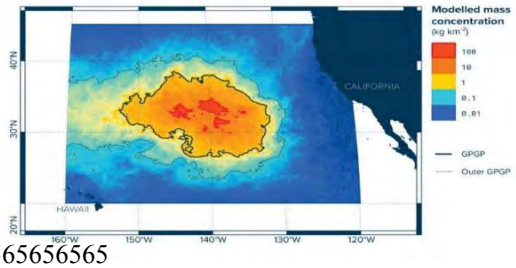
I. INTRODUCTION

Suppose a water pipe in your kitchen has broken up and the water is flowing continuously. What will you do? Close the main water supply while keeping the spilled water as it or cleaning the spilled water while the tap is still running? Sounds absurd to execute any one of the above ideas? It's the same with the oceans. We cannot focus only on the methods to reduce the plastic production while keeping our oceans unclean. Both the actions should go on simultaneously. Reduced plastic production and ocean cleaning should go hand in hand to improve the quality of sea water and enrich the marine biodiversity. There are various methods undertaken to reduce plastic usage. But the latter one is completely ignored. Our paper focuses on the need to clean the oceans while providing different, innovative ideas to do so.Plastic is cheap, durable and flexible. Hence, we use it in almost everything. But when the same plastic ends up in the ocean it has drastic impact on our life. Its imbalances the entire food chain by wiping out the marine species. The hazardous effects cannot be ignored. So, we thought of an idea to clean the oceans. The idea is to make the oceanic currents do the work. Because why move through the oceans when oceans can move through you? By installing our system in the ocean which consists of U-shaped channels with screens below. It is influenced by the wind, waves and the currents. It is a flexible, movable system which is self-supporting, receiving energy from sun, wind and waves. It can bring the plastic to the center of the system. This accumulated plastic can be collected by sending the ships to the area where the plastic is concentrated. The location of the concentrated plastic a be tracked down with the help of satellites by tracing the position of our system.

II.THE NEED FOR CLEANING

8 million tons of plastic founds its way to the oceans. Due to which 5 plastic gyres are found in the oceans. The great pacific garbage patch is one of the major plastic gyres situated in the north central Pacific Ocean. Its estimated area is 1.6 million square kilometers which is about thrice the area of France. 1.8 trillion tons of plastic is floating in this patch. The estimated weight of plastic is 80,000 tons in this gyre. The center of the patch has high density of plastic while the boundaries have low density of plastic. The density of plastic from center to the boundary ranges from 100skg/sq.km to 10skg/sq.km respectively. It would take thousands of years to clean such large amount of garbage using the conventional methods. But with our idea we can clean it by 50% in a span of five years [1].

Fig.1 (a): The great pacific garbage patch [2]



35656565656565

Fig.1 (b): mass concentration of plastic in the patch [1]

The high-grade density plastic used to make various materials is broken down by sun, waves and curious critters forming micro plastics. Micro plastics are plastics having size less than 5mm. they are categorized into two types a) primary micro plastics b) secondary micro plastics. The primary.

Micro plastics are intentionally produced like plastic pellets, industrial abrasive, exfoliates etc. The secondary micro plastic is formed by erosion of large sized plastic especially marine debris.

III. EFFECT ON MARINE LIFE

Every minute a truck full of plastic is unloaded in the oceans. The effects caused on our marine ecosystem cannot be ignored. The plastic started accumulating in the sea water from 1960s. Millions of marine animals are killed due to plastic debris every year. 700 species of marine life have gone extinct and the number will increase exponentially if we continue this trend [3].

Plastic is mistaken as food by the marine animals. This results into their death due to starvation because by eating plastic their stomach feels full and so they don't eat what they are supposed to. This leads to malnutrition. Sea turtles presumably are victims to this problem. Blockage in their digestive system is one of the major reasons for their percentage decrease in population. Marine mammals which swim closer to the surface of the water are found caught in marine litters like fishing gears, nets, plastic bags etc. In a study it was found that 388 sea lions entangled in plastic debris 3) Sea birds die each year due to consumption of micro plastics while catching fishes. 98% of albatross studied are found to have ingested some kind of plastics in different amounts [3]. The carcasses of whales and dolphins are frequently found on the shores with large amount of plastic ingested. These all incidents have led scientists and researchers to find ways to clean ocean.

Fig.2 (a): sea lion entangled in plastic. [3]

IV. PROPOSED SYSTEM

Instead of using conventional ideas to clean the oceans like vessels and nets we have proposed this system which deploys the ocean currents. It is heavily influenced by three factors-winds, waves and currents. The principle behind it is simple-to create coastline where there are none, concentrate the plastic and take it out.

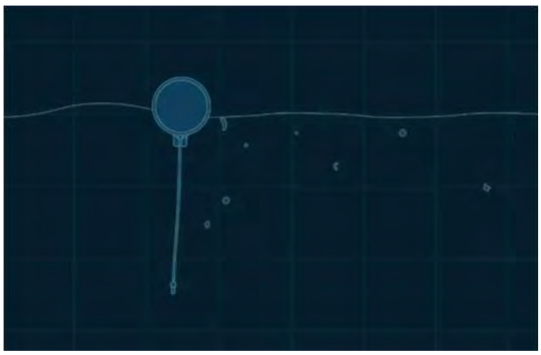


Fig.3 (a): floater above the surface with anchor and skirt below. [1]

The system consists of a 600m long floater and 3m deep skirt attached below. The floater provides buoyancy to plastic and prevents plastic from flowing over it. The skirt which is a screen prevents smaller particles from escaping underneath. The model has had undergone many modifications in the design. Instead of fixing the system to the sea bed which was proposed earlier, an anchor up to 600m deep is used. This provides stability whilst mobility. This allows to gather plastic in more efficient way. The system primarily depends on currents, winds and waves. The currents move the plastic and the system both. But the winds propel the floater only as it

lies above the surface of the water and as most of the plastic lies beneath the surface of the water. This pushes the system faster than the plastic thereby collecting garbage more efficiently. [1]

The skirt of the system is deeper in the central p art rather than the edges. As impenetrable skirt provides downward flow which helps the marine life to escape from below it. The current forces it to adopt U-shaped structure which concentrates the plastic like a funnel. The drag force generated by the skirt acts like a stabilizing force allowing the system to re-orient itself when wind changes direction. The system has solar power lights, anti-collision system, cameras, sensors and satellite antennas. The system communicates its position at all time and continuously gather performance data. Then a support vessel is sends to the live position where it extracts the plastic with the help of nets. [1]

The fleet of system consists of 60 such systems. If executed it will manage to clean the Great Pacific Garbage Patch by 50% in 5 years and by 90% until 2040. [1]

The biggest challenge is to survive storms. The key to the survival is flexibility. While designing the structure various cases were considered that can occur in many years. The model has undergone many tests to withstand the forces of the ocean. The system has been built in such a way that it follows waves because it's free floating.

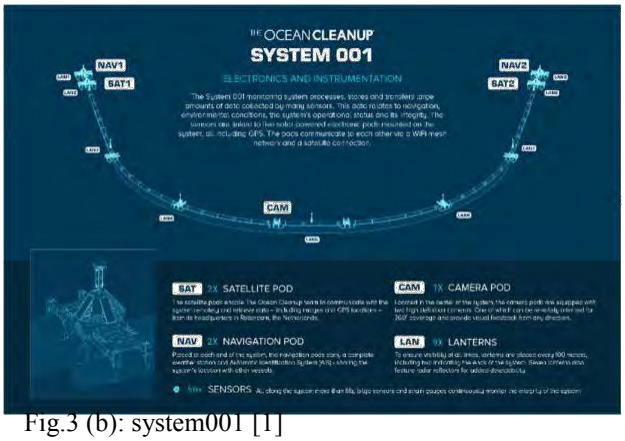

Fig.3 (b): system001 [1]

The plastic on the surface of the ocean or up to a depth of few meters deep can be cleaned using this system. But the plastic on the sea bed needs a different approach altogether for undertaking the cleaning process. Vast amounts of funds, manpower and emissions can be saved by executing thedf

V. FUTURE SCOPE

Waste production will not stop but will only minimize if we care enough to take preventive measures. Likewise dumping plastic in the oceans won't reduce to zero. We need to think many different and diverse solutions to clean the oceans. It is a really challenging task to clean the ocean. Conventional methods would take many years as well as large capital. By executing it and learning from mistakes various modification can be done. The system should be ocean friendly and feasible. The system is a pioneer in the advanced cleaning operation of the oceans. We need to invent and upgrade such models for dirt-free ocean.

VII. CONCLUSION

we, humans are solely responsible for creating this havoc which is causing serious threat to our marine life and ecosystem which indirectly affects us. To redeem the devastation caused by plastic to our oceans we proposed this
Idea. It will not eliminate plastic completely from the oceans as majority of plastic lies on the seabeds. But this measure will mitigate the amount of plastic present in our oceans. Thus,
Reducing the chances of damage to the marine life and ecosystem.
It is a breakthrough in the way of cleaning the oceans. The proposed approach is a basic effort to clean the plastic garbage that floats across our beautiful oceans thereby giving our

Advance Surveillance Security Using AI and Face Detection

Mr. P.U.Tembhare ,Dhanashri Adgurwar, Sharayu Bagmare, Anup Katre, Sanket Harinkhede ,Vaibhav Rahangdale

Department of Computer Technology, Priyadarshini College of Engineering

Nagpur, India

Abstract- **Face detection and recognition from an image or a video is one of the most interesting, and well known topic in biometric research as it deals with security and privacy purpose. The human face plays a very crucial role in the social association and offers each and every individual a unique identity face recognition technology has broadly attracted attention due to its massive application value, and market potential, such as real time video surveillance and fraud detection. It is widely recognized that the face recognition plays a prominent in surveillance system as it doesn't require the participation of an object. We used image set algorithm with the aid of OpenCV and Python programming development and having a pre-existing database of faces. The module distributed in three sub modules: Detection module, Training module and Recognition module.**

Keywords: Face detection, Face Recognition, OpenCV.

I. INTRODUCTION-

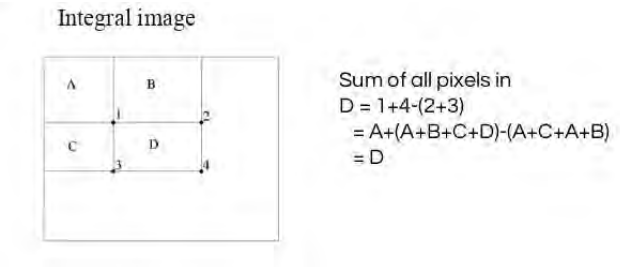
Face recognition technology was commonly observed as a something straight out of science fiction. But over the past decade, this groundbreaking technology has not just become viable, but also it has become widespread. Face detection and recognition is technology which is used to recognize an individual from a video or photo source. The pioneers of facial recognition were Woodrow Wilson Bledsoe, Helen Chan Wolf and Charls Bisson. In the 1960s the concept of face recognition was introduced by Woodrow Wilson Bledsoe. Bledsoe developed a system called as RAND tablet that could classify photos of faces by hand. RAND tablet is a device that people could use to input horizontal and vertical coordinates on a grid using a stylus that emitted electromagnetic pulses. The system could be used to record manually the coordinate locations of various facial features including the eyes, nose, hairline and mouth. These set of data could then be inserted in a database. Then, when the system was given a new image of an individual, it was able to retrieve the image from the database that most closely resembled to that individual. Ever since then recognition system is being improved and optimized constantly, the technology becomes gradually mature and is more and more widely used in human daily life. There are several industries benefiting from this technology. Law enforcement agencies are using face recognition technology to keep communities safer from impostors. Retailers are preventing crime and violence. Airports are improving traveler's convenience and security. Nowadays mobile phone companies are using face recognition technology to provide consumers with new layers of biometric security. In this paper, we propose a face detection and recognition system with the aid of python along with OpenCV. This system contains three modules which are detection module, training module and recognition module. The detection module recognizes the face which gets into the field of vision of the camera and saves the face in the form of an image in JPG format. Then the training modules trains the system with the aid of Haar cascade algorithm which was proposed by Paul Viola and Michael Jones. This method consists of four steps-

1. HAAR FEATURE SELECTION-

First step is to collect the Haar Features. [8]A Haar feature considers adjacent rectangular areas at a specific position in a detection window, which adds the pixel intensities in each area and calculates the difference between these additions.

II. CREATING INTEGRAL IMAGES-

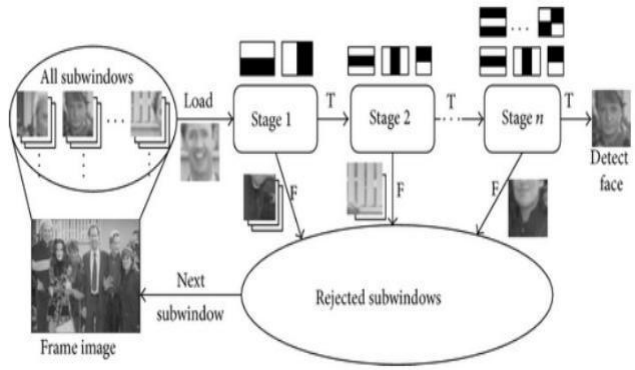
Integral Images are used to make this procedure swift. Most of the calculated features are irrelevant.



III. ADABOOST TRAINING-

A concept called Adaboost which selects the best features and then trains the classifiers which is used. This algorithm creates a sturdy classifier using a linear combination of weighted simple weak classifiers.

IV. CASCADING CLASSIFIERS-



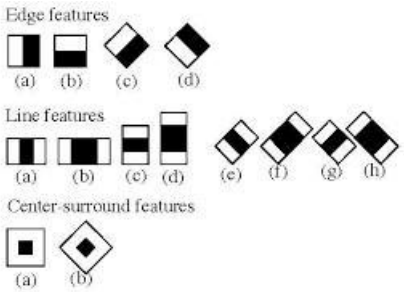
The cascade classifier comprise of a number of stages, where each stage is a group of weak learners. These weak learners are simple classifiers which are known as decision stumps. Each stage is trained by using a Technique called boosting. Boosting provides the potential to train a highly precise classifier by taking the weighted average of decisions which are made by the weak learners.

Finally, in the recognition module the fundamental components of the face from the new video are extracted. Then those features get compared with the list of elements stored during training and the ones with the best match is found and name of the person recognized is displayed. This monitoring system fulfills the basic needs of face detection and recognition system, also takes the cost into consideration to ensure the pervasive mode as economical as possible. Furthermore, it can also be combined with real-time analysis algorithms.

V. PROBLEM DEFINITION- FACE DETECTION

The main function of face detection is to determine [1] Whether human faces appear in a given image or not, and [2] where these faces are located at given image. The expected outputs of this step are patches containing each face in the input image. Hence to make face recognition more robust and efficient to design, face alignment are performed to justify the scales and orientations of these patches. [3]Once a face is detected, we have to extract a face signature. The finest facial recognition systems are aligning the faces before extracting the face signature as it makes the face signature improved. Aligning is the process of rotating and scaling the face in order to bring all of the key features into the same places (eyes, nose, mouth etc.).This is important because it allows the function generating the face signature to work on much cleaner input, and makes recognition perform much better.

VI. FEATURE EXTRACTION-



After the face detection step, human-face patches are removed from images via feature extraction phase. If we use these patches for face recognition directly, it may have some limitations; first, each patch usually holds over 1000 pixels, which are too enormous to build a robust recognition. Second, face patches may be taken under different illumination, with different face expressions, and with different camera alignment, and may suffer from occlusion and cluttering background. To overcome these drawbacks, we perform feature extractions to do dimensionality reduction, information packing, salience extraction, and noise cleaning. After this step, we transformed face patch into a vector with fixed dimension or a set of fiducially points and their corresponding locations. We can include feature extraction either in face detection or face recognition as per survey form some literatures.

VII. MODEL TRAINING

Simply put, model training is the process of taking several face representation belonging to the same person, and creating a classifier that can recognize more instances of face portrayal from the same person. The most favored approach is to use a linear SVM.

VIII. FACE RECOGNITION

After formulating each face patch in the above steps, the last step is to recognize the identities of these faces. For face recognition, a face database is required to build. [4]For each individual, some images are taken and their features are removed and stored in the database. Whenever an input image came, we perform face detection and face extraction and after this we compare features of each face with stored database.

We differentiate two applications of face recognition: identification and verification. Face identification means given a face image, we want the system to tell who he / she is and identify the individual ; while in face verification, given a face image and on the basis of a assumption from the identification, we want the system to tell true or false about the guess.

IX. DESCRIPTION OF TOOLS

In this section, the tools and approach to implement and calculate face detection and tracking using OpenCV are detailed.

X. OPENCV

[8]Open Source Computer Vision Library is widely known as OpenCV. It is a library of programming methods and mainly focused at the real time computer vision which is developed by Intel. The library is cross-platform and it mainly aims at real-time image processing. Originally the library is written in C and this C interface makes OpenCV portable to some distinct platforms such as digital signal processors. Wrappers for languages such as C#, Python, Ruby and Java (using JavaCV) have been developed to uplift adoption by a wider user. However, since version 2.0, OpenCV includes both its traditional C interface and a new advance C++ interface. This new interface seeks to eliminate the number of lines of code essential to code up vision functionality as well as eliminate common programming errors such as memory leaks (through automatic data allocation and deallocation) that can occurs when using OpenCV in C. The majority of developments and algorithms in OpenCV are now developed in the C++ interface. [9]It is much tougher to provide wrappers in other languages to C++ code as opposed to C code; since the other language wrappers are generally lacking some latest OpenCV 2.0 features.

VII. PROPOSED SOLUTION-

When image quality is taken into consideration, there is a plethora of aspects that influence the system's correctness. It is significantly important to apply distinct image pre-processing techniques to standardize the images that you supply to a face recognition system. [2]Most face recognition algorithms are very responsive to lighting conditions, so that if it was trained to detect an individual when they are in a dark room, it probably won't recognize them in a bright room, etc. This problem is mentioned to as "lamination dependent", and there are also many other issues, such as the face should be in a very steady position within the images (such as the pixel coordinates of eyes have to be same), compatible size, rotation angle, hair and makeup, emotion (smiling, angry, sad, etc.), position of lights (to the left or right, above, etc.). This is why it is foremost

to use a good image pre-processing filters before applying face recognition. You should also do things like removing the pixels around the face which are not in used, such as with an elliptical mask that shows the inner face region, not the image background and hairs, since they modify more than the face does. For clarity, the face recognition system presented in this paper is [1]Eigen faces with the aid of grayscale images. The paper assert how easily is to convert color images to grayscale, and then to apply Histogram Equalization as a very easy method of automatically standardizing the brightness and contrast of the facial images. For better output, you could utilize color face recognition, or employ more processing stages such as edge enhancement, contour detection, motion detection, etc. Also, this code rescales images to a standard size, but this may change the aspect ratio of the face. OpenCV utilize a type of face detector called a Haar Cascade classifier. An image, which can come from a real time video or from file, the face detector examines each image position and classifies it as "Face" or "Not Face." Classification assumes a stiff scale for the face, say 50x50 pixels. Since faces in an image might be larger or smaller than this, the classifier runs over the image multiple times, to search for faces across a range of particular scales.

VII. CONCLUSION-

In this paper we have developed a system whose main objective is to detect and recognize the faces for providing high security. The dataset is created for storing the images. The images of the person are then trained and defined before recognizing. The Haar cascade algorithm is used for identifying the faces. OpenCV offers pre-trained Haar cascade algorithms. By using tremendous amount of training data (in the form of images) the classifier begins by extracting Haar features from each image. Not all features are useful for identifying face. Adaboost a machine learning algorithm is used for selecting best features. In the coming future, as technology advances, more advance features will be added to the system.

Intelligent Chabot For E-Learning: A Study

Megharani Patil , Anand Khandare

Computer Engineering
Thakur College of Engineering and Technology
Mumbai, India
megharani.patil@thakureducation.org , anand.khandare@thakureducation.org

Abstract— **Nowadays India is moving towards digitalization in this context to provide any kind of help the use of Chatbots is very popular in many applications where systems provide an intelligence support to the user for solving their queries. To speed up the assistance many web based and mobile based systems are equipped with Chatbots that can interpret the user questions and provide the answers immediately. This work is all about prototype of a Chatbot in e-learning. This can provide support to college students to learn various courses. The design of the chatbot architecture should modelled in such a way that it can manage communication and provide the right answers to the student. Chatbot system should detect the questions and using the use of natural language processing techniques and available knowledge base provide the answers to student.**

***Keywords*—Chatbot, E-learning, NLP**

I. INTRODUCTION

Chatbot is a typical computer program designed to simulate an intelligent conversation with one or more users (human) through audio or text. Chatbots are set up as virtual assistants, represented visually in the form of a cartoon character, animation, or an avatar, and in some cases, a voice or text stream. Chatbots are designed to express human-like conversations through artificial intelligence. They can be programmed to operate as per a set of predefined instructions. The more a chatbot interacts and learns new things, the smarter it becomes. They can be accessed through various chat tools such as Facebook Messenger and other messaging applications[1]. They basically interact with the user just like a live person. Chatbots use the text-to-speech technology which helps them deliver responses in a simulated human voice, or even have text boxes that display the words being said. In eLearning, you can use chatbots as a means of communication. E.g you can enter text into a form field to which the chatbot will respond. If a system is set up with a speech recognition app, then you can vocally communicate with the chatbot. Chatbots are pre-programmed with a database containing a set of words, phrases, and questions. When a query is asked, it responds to the query by choosing a suitable word/phrase from the set of instructions in the database[2]. A Chatbot is a software that talks with an user. It is a virtual assistant able to answer a number of user questions, providing the required responses. Application areas of Chatbots are Health Care, Marketing, Educational, Supporting Systems, Cultural Heritage, Entertainment and many others. Chatbots can be developed both for industrial solutions and for research. Some example of chatbots are Apple Siri, Microsoft Cortana, Facebook M and IBM Watson. One of the most challenging tasks is the development of effective Chatbots: the emulation of human dialogues, which involves problems related to the NLP (Natural Language Processing) [3].

Chatbot has some problems. It is not possible to map all user requests, and the current Chatbots do not show remarkable performances because of the unpredictability of user thought during a conversation. The correct design of conversational flow plays an important role in the development of a Chatbot. For successful conversation, it is important to handle with all user requests and provide the required answers. This work is based on the knowledge base that can be used to interpret the intentions of the user and solve the problem of interpretation of sentences written by the user [4]. The Learning Connection at Chabot provides students and instructors with the support they need to achieve their learning and teaching goals as well as co-curricular activity. Chatbot technology can be considered an important innovation for e-learning. There are many innovative solution in filling the gap between technology and education. Chatbots creates an interactive learning experience for the students, like the one-to-one interaction with the teacher. Chatbot can also be used as a source of social learning, students from different backgrounds can share their views and perspectives on a specific matter while the bot can still adapt to each one of them individually. This technology can improve engagement among students and encourage interaction with the rest of the class by assigning group works and projects like teachers usually do. From testing the student's behavior and in order to keep track of their improvements, bots play an essential role in enhancing the skills of an individual student. They encourage a student to work by sending regular reminders and notifications. They provide a system for a personalized learning experience. Each student earns and absorbs things at a different pace. Using Chatbots is possible to adapt the speed at which a student can learn. They can also work as a support for teachers by identifying spelling and grammatical mistakes, checking homework, assigning projects and especially keeping track of progress and achievements of each student. . Chatbot

aims to be an e-Tutor for students. Some of the chatbot features in e-Learning are for

1. **Simulations:** Here you can use a robust version of a simulation bot where the bot plays a role of a character or guide. The bot can interact with the learner and guide him throughout the simulation.

2. **Chatbot as a source of reinforcement:** You can use chatbots for the reinforcement of learning. You can do this by pushing out information at certain intervals, in response to certain triggers.

3. **Social learning:** Social learning is another area where you can use chatbots. One of the benefits of social learning an environment is that the chatbot's interaction doesn't need to be limited to an individual. It can also communicate with a larger group.

Design considerations while designing chatbots for e-commerece.

1. If you are planning to use a chatbot as part of your eLearning, then you need to consider the nature and demographics of your intended audience. This will influence the syntax and tone of response of the chatbot.

2. You can use the existing course resourse books, handouts, and vidio clips of related media to boost the chatbot's database knowledge and vocabulary.

3. You can also use a list of Frequently Asked Questions to generate a chatbot's list of preprogrammed queries and responses. If you are planning to use an avatar or an animated character, ensure the chatbot's appearance is in sync with the audience it addresses. Pick a gender for your avatar and finally, don't forget to name your avatar.

II. RELATED WORK

Many Chatbot applications based on AIML are analyzed in particular an integrated platform which consists of a basic AIML knowledge is presented. In this project, Chatbot is called Tutorbot because it is functionality backing of didactics done in elearning environments. It contains some features as natural language management, presentation of contents, and interaction with search engine. Besides, e-learning platforms work is linked to indispensable services to web service. A continuous monitoring service has been created on e-learning platform servers which is another controlling machine[5]. Game based e-Learning tool used to teach digital forensic investigation. A Chatbot inside the learning platform helps students. A multiple-choice question based quiz is implemented for kinesthetic learners, and there is a pedagogical Chatbot agent that assists users. It provides easy navigation and interaction within the content. The Chatbot is implemented to be a pedagogical agent for the users, which is meant for discussions and help with the topics. It also acts as a navigation tool and can play video or use the advanced wiki if there are somethings to ask[6]. Investigated about the realization of intelligent agents on platform with IBM Watson technology. These agents in the form of Chatbots have to automate the interaction between the student and the teacher within the frames of Moodle learning management system. Watson is a cognitive system that combines capabilities in Natural Language Processing, analytics, and machine learning techniques. In this case, a Chatbot through the Facebook Messenger is realized to simplify communication between a teacher and a student: it could be arranged by acquiring Moodle test basis by Facebook Messenger Bot GUI Builder. A motivating example will be illustrated in the next session[7]. Using Bayesian theory to match the request of student and furnish the right response. In particular, Chatbot agent accepts to student's answers and extracts the keywords from the question using a lexical parser, then the keywords are compared with the category list database. The Bayesian probabilities are obtained for all categories in the list. Once the category is selected keywords are compared with the questions under the category using Bayesian probability theory. The answer to the question, which has the highest posterior probability, is then fed into the text to speech conversion module and thus the student receives the answer to his question as a voice response [8].

In literature, there are many approaches related to Chatbots, in particular on e-learning systems. From the beginning of the last decade the use of artificial intelligence as e-learning support has captured the interest of many researchers for its many applications. The web bot in an e-learning platform, to address the lack of real-time responses for the students. In fact, when a student asks a question on e-learning platform the teacher could answer at a later stage. If there are more students and more questions, this delay increases. Web bot is a web-based Chatbot that predicts future events based on keywords entered on the Internet. In this bot stores the questions and answers it on XML style language. This bot is trained with a series of questions and answers: when it cannot provide a response to a question, a human user is responsible for responding. In the last recent years some interesting research works can be found [9].

III. MOTIVATION

Teaching is a relational act based on communication and interaction, and chatbots have significant educational potential precisely due to their communicative ability through natural language. One of the reasons for the commitment to use chatbots in different economic activities such as customer care is increased process efficiency, for example, 24-hour care or specific information. This argument is also used in the case of education, as a chatbot can operate as a 24/7 support service, which can allow,

for example, teachers and service staff to avoid having to answer repetitive questions that can be easily resolved. The incorporation of chatbots in education has to be preceded by prior thought, whether its aim is educational or not. An institutional and organizational debate is needed to ensure functionality, feasibility and scalability within the institution. It is important to stress that the inclusion of chatbots will not replace teaching staff or administration and services staff but it can take over some of their tasks to complement and help them out. It appears to be feasible to think of a future where there is close collaboration between humans and machines, and, in the case of teaching, teacher roles may be distributed between both agents. The teacher of the future could become a sum of the human teacher and the AI teacher, with a complementary division of tasks. For example, the human teacher could take care of the creation of excerpts of learning materials, which could then be complemented or broadened by the AI teacher. The human teacher could take on personalized tutoring tasks, while the AI teacher provides uninterrupted support. The former could act in cases of dispute or in solving assessment appeals, while the AI teacher could answer FAQs, act as a virtual tutor to guide periodical tasks or redirect complaints and demands. This symbiosis would allow the human teacher to stop taking on more mechanical or repetitive tasks – which would be undertaken by the chatbot or AI teacher – and would consequently have greater availability to devote their time to more creative and high cognitive level tasks. We need to know, then, what the affordances of the different types of chatbot are to see how they operate as cognitive colleagues and not as potential threats. In the field of education, chatbots are used experimentally, making the most of the user interfaces and the boom in their popularity in different economic sectors for the promise of their benefits. However, it remains to be seen how they adapt to every context and how they are understood and rated by students, teachers, and administration and services staff. An example of an app that enables the creation of chatbots for education is SnatchBot. It is a free tool and has an interface that does not require programming knowledge. Its function will be determined by its creator's intention: either to answer informative queries (FAQ-type) or to act as a tutor to teach concepts and procedures. This presence of chatbots will also depend on the number and type of interactions that they can have with other chatbots or tools, either incorporating functions that are currently carried out by different apps or converging data so as to enable integrated actions. We are referring, for example, to the chatbot's ability to gather information from an individual's personal email, combine it with the calendar and the information available on a university's website, put the data together and be able to confirm a tutorial on the university's virtual campus. As has happened with other tools, chatbots may in the future undertake some assistant functions that have been done until now by specific apps. These affordances allow users to worry less about tasks closely related to memory (calendars, reminders, submission deadlines, instructions, etc). New advances in voice and emotional state recognition will end up smoothing these interactions.

IV. CLASSIFICATION OF CHATBOTS

Depending on the functions carried out by chatbots in education, we can classify them on the basis of the following tasks:

Administrative and management tasks to foster personal productivity: they provide personal assistance to students, aiding onboarding and personal productivity. Tasks include schedule or email management and task, submission deadline or assessment reminders. This uninterrupted personalization involves giving each student a rapid and personalized service, which takes pressure off academic services administration.

Taking care of FAQs: they provide a response to student FAQs regarding administration or learning concepts and contents. Unlike the first, they do not include personalization elements but student services in the form of FAQs. Tasks include information about admissions and enrolment, financial services, technical problems.

Student mentoring: they allow student mentoring during the learning process. They are able to respond emotionally, they monitor the student's understanding (cognitive control) and they can provide support and make suggestions to the student when needed. One of the main tasks is the provision and adaptation of contents. In this case, they are chatbots that enable educational programme contents to be generated and adapted, which are then sent straight to the user, taking their preferences into account.

Motivation: they contribute to exercising behavioural control by providing positive motivational reinforcement. This process means that students' retention is increased, which is especially relevant in online learning environments.

Practice of specific skills and abilities: they enable dialogues to be practiced in language learning, simulating conversations in contexts organized by level and with different roles and discourses.

Simulations: they simulate specific professional situations and can provide support for reflection or therapy. For example, in the field of healthcare, they can simulate patient treatment; in psychological care, they can simulate patient care; and in formal or social education, they can simulate the understanding of different school learning situations.

Reflection and metacognitive strategies: they help the students regulate their own metacognitive processes, they act as an expert classmate and they can provide support to aid learning. There are currently no examples of chatbots that offer this reflective function.

Student learning assessment: they can act as exercise assessors quickly and automatically. One example is automatic essay scoring, which gives feedback on mass courses based on automatic learning capable of analysing thousands of essays and giving an automated score. They also include tasks related to feedback to the student, who receives support thanks to learning feedback and the adaptation of the learning process at the student's pace and according to their needs.

V.ARCHITECTURE OF E-LEARNING CHATBOT

The architecture of composed of Front-End, Back-Office, Knowledge Base and E-learning BOT as shown in Figure 1. **Front-End**: it consists of different kinds of device like tablets, smartphones, PCs and so on.

Back-Office: It is used to manage operations that are not seen by end user. This module works in the background to better satisfy user demand. It handles business logic and data storage, working in collaboration with the knowledge base.

The Knowledge Base: It is a special type of database, where data is processed by a server, for the management of knowledge and information. Users representing all users of the application . Learning object is a collection of content items, practice items, and assessment items that are combined based on a single learning objective. **The E-learning BOT**: It is the main engine of the system. It is composed of Interaction Quality Tracker, Human- Computer Interaction Supervisor, Context-Aware Information Manager and Inference Engine.

- **Interaction Quality Tracker**: this module monitors interactions between users and Chatbot, evaluating conversation logs based on quality indicators and highlighting critical aspects of Human-machine interactions.

- **Human-Computer Interaction Supervisor**: it supervises dialogue, tracks interaction times, identifies ambiguous questions, recognizes nonconvergent interaction sessions, and indicates the need for community support if it is not possible to give a correct answer.

- **Context-Aware Information Manager**: this module allows to drive the dialogue based on contextual parameters. The goal is to provide a mechanism of dynamic and automatic invocation of information considering the context through the Context Dimension Tree [10].

- **Inference Engine:** It is designed to provide right answer to the user through Latent Dirichlet Allocation Algorithm and Workflow Manager. In first phase the definition of an ontology for the description of E-learning domain and the adoption of pre-existing ontologies is studied. The second phase is related to a workflow navigation module which can surf the ontology and select the more appropriate sentences. The description of the workflow can be achieved using Petri Net [11].

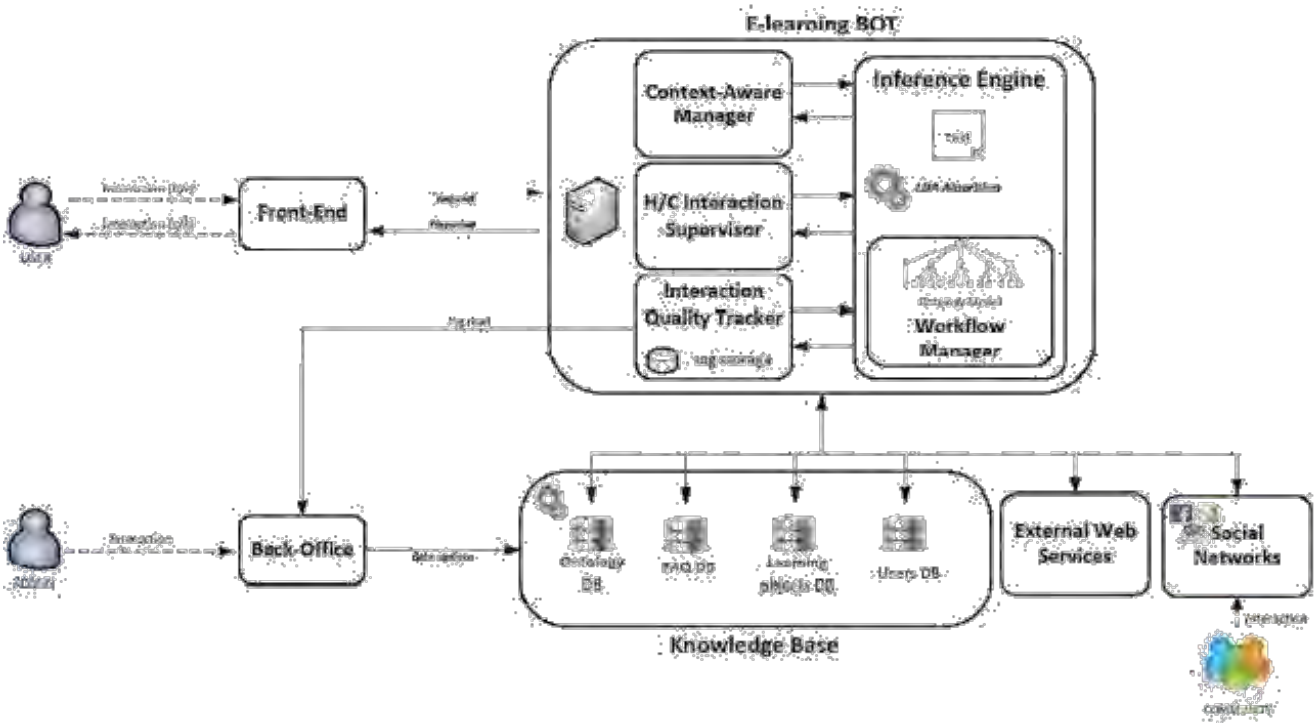

Fig 1: Architecture of E-learning chatbot

VI. CONCLUSION

This paper started with usefulness of chatbot in e-learning with features of chatbot and design consideration required to build a chatbot for e-commerce. There is summarization of related work and motivations towards the study of intelligent e-learning chatbots. It also included classification of chatbots followed by general architecture of intelligent e-learning chatbot.

VII. ACKNOWLEDGEMENT

My special thanks to our principal Dr. B.K. Mishra, Dean academic Dr.R. R. Sedamkar and HOD Dr. Sheetal Rathi for encouraging us to write this paper.

Abstract—**The healthcare industry collects a big amount of data which is not properly mined and not put to the optimum use. Discovery of these all hidden patterns and relationships often goes unexploited. Our research focuses on the all aspect of Medical diagnosis by learning pattern through the collected data of heart diseases and to develop intelligent medical decision support systems to assist the physicians. Cardiovascular disease remains the biggest cause of deaths worldwide and the Heart Disease Prediction at the early stage is important. Heart disease is one of the deadly diseases. A large population in the world is suffering from this disease problem. As we consider the death rate and a large number of people who are suffering from heart disease, it is disclosed how important is early diagnosis of heart disease problem. There are many traditional methods of prediction for such illness but they are not looking sufficient for every people. There is an urgent need of medical diagnosis system that can predict the heart diagnosis problem at an early stage and offers more accurate and correct diagnosis result than traditionalmethods.**

***Keywords*— heart disease, Convolution neural network, Decision tree, Random Forest, DeepLearning.**

I. INTRODUCTION

The healthcare industry collects a huge amount of data which is not properly mined and not put to the optimum use. Discovery of all hidden patterns and relationships often goes unexploited. This situation can be overcome by Advanced data mining modeling techniques .There is a huge amount of untapped data that can be turned into useful important information. The decision support systems that have been developed to assist physicians in the diagnostic process often are based on static data which may be out of date. A decision support system which can learn the relationships between history of patient, diseases in the population, symptoms, pathology of a disease, family history and test results, would be helpful to physicians and hospitals. The concept of Decision Support System (DSS) is very broad because of many different approaches and a wide range of domains in which decisions are made. DSS terminology refers to a class of computer-based information systems which will include knowledge-based systems thatsupportdecision making activities. In general, it can say that a DSS is a computerized system for assisting to make decisions. A DSS application can be composed of subsystems. However, the development of such type of system presents a daunting and yet to be explored task. Many factors have been attributed but insufficient information has been identified as a major challenge. To reduce the diagnosis time and improve the diagnosis accuracy, it has become more of a demanding issue to develop reliable and powerful medical decision support systems (MDSS) to provide support the yet and still increasingly complicated diagnosis decision process. The medical diagnosis by nature is a complex and fuzzy cognitive process, therefore soft computing methods, such as decision tree classifiers has shown great potential to be applied in the development of MDSS of heart diseases and other diseases. The main aim is to identify the most important risk factors based on the classification rules to be extracted.

II. REVIEW OF LITERATURE

Amin et al. Proposed a hybrid system in which genetic algorithm and ANN is used. This system predicts the heart disease problem based on the risk factor. They trained ANN in a similar way i.e. Using the back propagation as trained previously. They mainly highlight that two major disadvantages of the back propagation algorithm. First one is that to finding out the initial weights which are globally optimized is almost impossible. Second, in convergence back propagation is slow. To solve these type of issues, they applied the genetic algorithm to optimize the weights of ANN and got the better performance than simple ANN. They successfully achieved an accuracy of 96.2%

on the training set and the accuracy of 89% on the testingset.

Sarath Babu, Vivek EM et al. Proposed Heart Disease Diagnosis System Using Data mining technique. Data mining is an advanced technology, which is the process of discovering actionable main information from large set of data, which is used to analyze the large volumes of data and extracts patterns that can be converted to the useful knowledge. Medical data mining has a great potential for exploring all hidden patterns in the data sets of medical domain. These all the patterns can be utilized to do clinicaldiagnosis. All the data need to be collected in a standardized form. From the medical profiles fourteen attributes are extracted such as age, sex, blood pressure and blood sugar, obesity etc. Can predict the likelihood of the patient getting heart disease. These attributes are fed in to the K-means algorithms, MAFIA algorithm and Decision tree classification in heart disease prediction, applying the data mining technique to heart disease treatment; it can provide as reliable performance as that achieved in diagnosing heart disease problem.

Theresa Princy. R , J. Thomas proposed a system for Human Heart Disease Prediction using Data Mining Techniques. The main motivation of this paper is that to provide an insight about detecting heart disease risk rate using data mining techniques. Various Data mining techniques and classifiers are discussed in many studies which are used for the efficient and efficacious heart disease diagnosis. As per the analysis mode, it is seen that mostly many authors use various technologies and different number of attributes for their study. Hence, All different technologies give different precision depending on a number of attributes considered. Using KNN and ID3 algorithm the risk rate of heart disease problem was detected and accuracy level also provided for different number of theattributes.

Jayshril S. Sonawane , D. R. Patii proposed a system which Predict Heart Disease Using Learning Vector Quantization Algorithm. In this paper an efficient system for heart disease prediction is developed. This system accepts the 13 clinical features as input and the training of network is performed by using the Learning Vector Quantization algorithm. It gives the presence or the absence of heart disease. The system also computes various different parameters like accuracy, sensitivity, specificity, training time, testing time, error and ROC curve. To improve the performance of the heart disease prediction system, it is trained with different number of neurons and also the number of training epochs are varied. The results shows that our system when we compared with others it gives the highest accuracy of 85.55%.

III. RESEARCH ALGORITHM

A. Deep Learning

Deep learning is also known as deep structured learning or hierarchical learning. It is a part of a broader family of machine learning methods based on artificial neural networks. Learning can be in the form of supervised, semi-supervised or unsupervised. Deep learning architectures such as deep neural networks, deep beliefnetworks, the recurrent neural networks and convolutionalneural networks have been applied to various fields which include computer vision, speech recognition, naturallanguage processing, audio recognition, social network filtering, machine translation, bioinformatics, drug design, medical image analysis, material inspection and boardgame programs, where they have produced results comparable to and in some cases that are superior to human experts.*Convolution NeuralNetwork*CNN is the class of deep and feed-forward artificial neural networks where connections between nodes do not form a cycle. CNNs are mostly used in computer vision, however they've shown great results when applied to various NLP tasks as well. CNN's are performing good at extracting local and position-invariant features. CNN's work well for tasks where sequential modelling is more important. Choose a CNN for classification tasks such as sentiment classification since sentiment is generally determined by some key phrases .The structure of CNN includes two layers one is feature extraction layer and second is feature map layer. In feature extraction layer, the input of each neuron is connected to the local receptive fields of the previous layer, and extracts the local feature. Once the local features are extracted, the positional relationship between it and other features also will be determined. Every feature map is a plane where the weight of the neurons in the plane are identical. The neurons in the same feature map plane have the equal weight, so that the network can studyconcurrently.

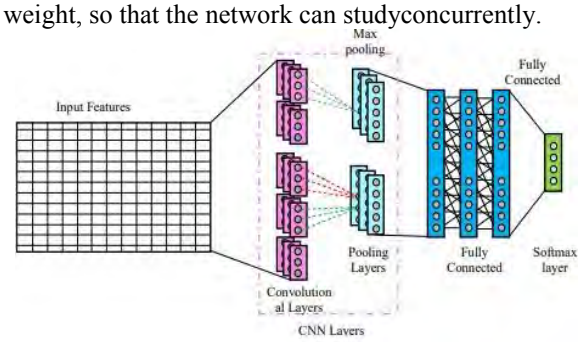

Figure 1: The architecture of CNN

B. Decision Tree

A decision tree is a flow-chart similar to tree structure, where each internal node represents a test on an attribute, each branch represents an outcome of the test, and leaf nodes represent classes or class distributions. The topmost node in the tree is called as root node. Internal nodes are represented by rectangles, and leaf nodes are represented by ovals. For the classification of an unknown sample, the sample attribute values are being tested across the decision tree. A path is drawn from the root to a leaf node which holds the class prediction for that

sample, so a decision trees can easily be converted to classificationrules.

C. RandomForest

Random forest is a decision tree which is a decision support tool. It uses a tree like model of decisions It is predominantly an band of unprimed classification trees. That provides remarkable performance on a number of practical problems Such as health care predictionproblems.it is not sensitive to noise ,in data set. It is not being subjected to over fitting. It is built by combining predictions of several trees. Each of them are trained separately. It works fast. Usually exhibits a great performance improvement over many other tree-based algorithms such as a decision tree. Three main choices to be made a random treeare

- Splitting theleaves.
- Predictor is to use in eachleaf.
- Inject randomness into the trees.KNN

IV. PROPOSED MODEL

Heart Disease prediction system is developed using the convolution neural networks. The main benefit of CNN is that CNN has high discriminative power. The flowchart of the proposed model is shown below in figure 2.

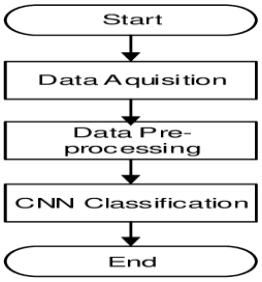

Figure 2: Flowchart of heart disease prediction based on CNN

A. Dataset

Data Set used for proposed system is obtained from UCI (University of California, Irvine C.A) Centre for machine learning and intelligent systems

Sr No	Risk Factors	Values
1	Age	Age of patient in year
2	Sex	Value=1: Male value=0:Female
3	Chest pain type	Value=1:typical type 1 angina Value=2: typical type angina Value=3: non-angina pain Value=4:asymptomatic
4	Resting blood pressure	In mm Hg on admission to the hospital
5	Serum Cholesterol	mg/dl
6	Fasting blood sugar	Value=1: > 120mg/dl Value=0:< 120mg/dl
7	Resting Electrocardiographic results	Values=0:normal Value=1: 1 having ST-T wave abnormality Value=2:showing probable or definite left ventricular hypertrophy
8	Maximum heart rate achieved	Heart rate
9	Exercise induced angina	Value=1:yes value=0:no
10	Old peak	ST depression induced by exercise relative to rest
11	The slope of the peak exercise ST segment	Value=1: unsloping value= 2: flat value=3:down sloping
12	Number of major vessels colored by fluoroscopy	Value in range of 0-3
13	Thal	value3 = normal value 6 = fixed defect value 7 = reversible defect

Table 1: Attributes of heart disease risk prediction.*Performance EvaluationCriteria*

Four different metrics i.e. accuracy, precision, recall, and F1-measures are used to evaluate performance of the proposed system. We denote TP, FP, TN, and FN as true positive means the number of instances correctly predicted as required, false positive means the number of instances incorrectly predicted as required, true negative means the number of instances correctly predicted as not required and, false negative means the number of instances incorrectly predicted as not required respectively. Then, we can calculate four metrics: accuracy, precision, recall, and F1- measure asfollows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\textbf{Precision} = \frac{TP}{TP + FP}$$

$$\textbf{Recall} = \frac{TP}{TP + FN}$$

$$\textbf{F - measure} = \frac{2*Recall*Precision}{Recall + Precision}$$

Accuracy, Pricision, Recall and F1-Measure are used to convey the success of pedicting Heart Disease. Using only Accuracy can be sometimes misleading. Sometimes selecting model which has lower accuracy is desirable, becouse it provide more robust predictor for the problem. All predictions can be predicted as the value of majority class by model when the problem domain has a huge class imbalance. Therefore, we are going to prefer the four different factor to get more accurateresults.

B. ExperimentalResults

Data Set used for proposed system is obtained from UCI Centre for machine learning and intelligent systems. Data Cleaning as well as filtering is done to remove duplicate records, normalize the values, accounting for missing data and removing irrelevant data items. So here we implement Decision Trees, Random Forest and Convolution Neural Network algorithm in our project. Our project will predict heart disease based on Convolution Neural Network but As well as these we also implement Decision Tree and Random Forest algorithm for comparing accuracy of the algorithm.

The Algorithm Use	Accuracy (Training Set)	Accuracy (Testing Set)
Random forest	98.58 %	80.2 1%
Decision Tree	100 %	72.5 2%

Figure 2: Accuracy of Random Forest & Decision Tree

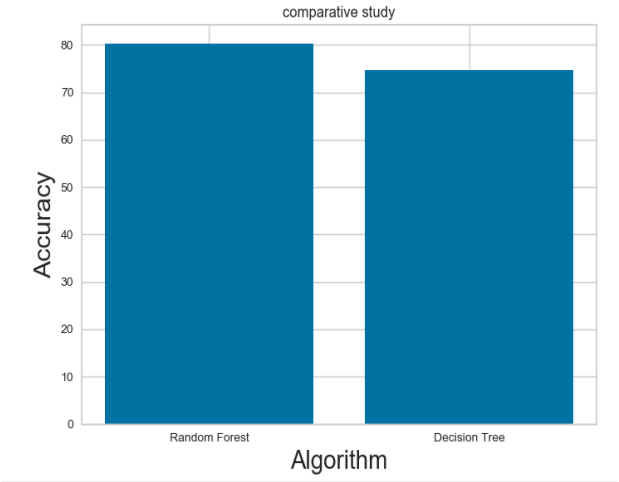

Figure 3: Comparative study of DT & RF

V. CONCLUSION

We have proposed Supervised Learning Algorithm for finding the risk of heart disease of a patient using the information collected from the patients. CNN has a different feature that it does not use a predefined set of hidden units, instead the hidden units gets added up one by one until the error is minimized. By exploiting this distinct feature of the CNN, a computerized prediction algorithm is developed that are not only accurate but also computationally effective for heart attack prediction with the proper adaptation of CNN classifies, the method can thus evolve number of hidden units within an architecture space. The neural network approach to generate accurate classification rules is proposed. To perform classification task of medical data, the neural network is trained using Convolutions Neural Network algorithm. The experiment is conducted with heart disease dataset of UCI by considering the single and multilayer neural network modes. Convolution neural network algorithm is the multilayer perceptron that is thespecial design for identification of two-dimensional image information. Always has more layers that ares input layer, convolution layer, sample layer and output layer. In addition, in a deep learning network architecture the convolution layer and sample layer can havemultiple.

Arduino Based Smart Blind Stick

Sandeep Pandey, Prem Patel, Riddhi Patel
Information Technology, Thakur College Of Engineering and Technology, Mumbai, India
Sp348220@gmail.com, patelprem616@gmail.com, patelriddhi1519@gmail.com

Abstract— **In the present scenario, a visually impaired individual is constrained to depend on someone else and can't make a trip autonomously to wherever without the assistance of others. So, here we propose ansmart blind stick that allows visually challenged people to navigate with ease using advanced technology. The blind stick is integrated with ultrasonic sensor, soil moisture sensor along with tilt sensor. On detecting obstacle, the sensor passes this information to the microcontroller. The microcontroller then processes this information and figures if it is sufficiently close If the obstacle is close the microcontroller sends a signal to sound a buzzer. If the obstacle isn't that nearby the circuit sits idle. It also detects water or mud and sounds a buzzer in different pattern and alerts the blind. By using tilt sensor blind man could remotely locate his stick. We have also used a motor vibrator which provides different vibration pattern for alerting the user.Thus, proposed system helps the people who are visually impaired in the aspect of mobility and making it safer by avoiding accidents.**

Keywords – Ultrasonic sensor, Soil Moisture Sensor, Tilt Sensor, Arduino UNO, Smart Blind Stick

I. INTRODUCTION

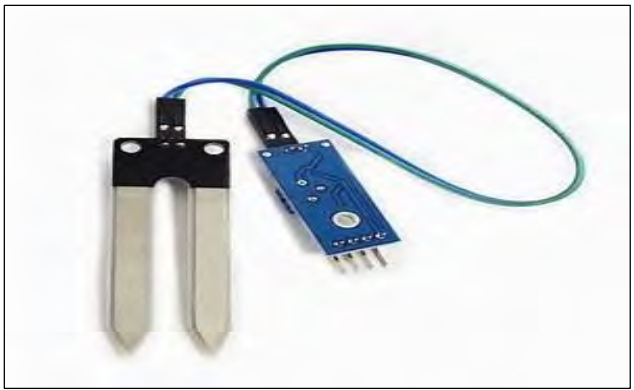
Visual deficiency is a common regular inability among the peoples throughout the world. As per the World HealthOrganization (WHO) 285 million individuals are outwardly impeded around the world, 39 million are visually impaired and 246 have low vision. About 90% of the world's outwardly impeded live in developing nations.Visually impaired persons have difficulty to interact with their environment. They have a very little contact with surroundings. Physical movement or mobility is a challenge for visually impaired persons, because it can become difficult to recognize obstacles appearing in front of them, and they are not able to move from one place to other. Smart Blind Stick is specially designed to detect obstacles which may help the blind to navigate care-free. The audio messages will keep the user alert and comparatively reduce accidents. The proposed system contains the ultrasonic sensor, Soil moisture sensor, Buzzerand Arduino UNO. The main objective of the paper is to discuss about development work of a stick that could communicate with the users through voice alert and vibration, which is named Smart Blind Stick which involves coding as software and physical installation as hardware part.

II. PROBLEM DEFINTION

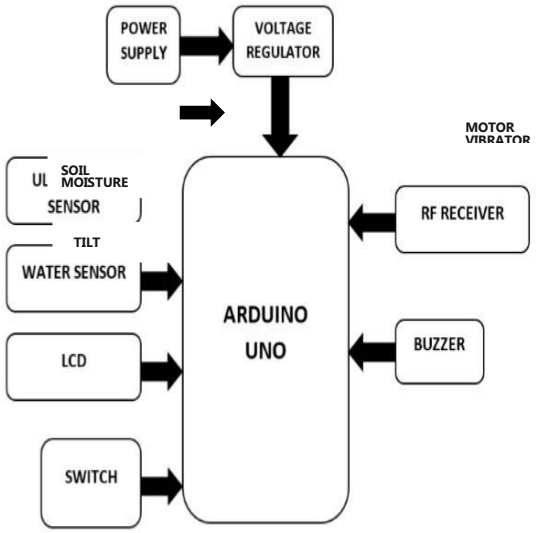
Physical movement is a challenge for visually impaired person. The conventional walking stick used by them is inefficient in detecting obstacle. The disadvantage of conventional cane,However,is its failure to detect obstacles outside of its reach. That is the user has to tap to the ground or obstacle to detect it. The visually challenged people can avoid the object better if the walking stick can produce sound and vibration warnings when there is a object in specified range.

III. BACKGROUND

More than 161 million people worldwide are visually impaired. Among them, 124 million have Low vision and 37 million are blind. Another 153 million people suffer from visual impairment Due to uncorrected refractive errors such as near-sightedness, far-sightedness or astigmatism. Virtually all these people could restore normal vision with eyeglasses or contact lenses. More than 90% of the world's visually impaired people live in low- and middle-income countries. Blindness is a condition of lacking visual perception and it is always described as severe visual impairment with residual vision. The blind people's life and activities are greatly restricted by loss of eyesight. They can only walk in fixed routes that are significant in their lives, with blind navigation equipment's and the accumulated memories in their long-term exploration. This situation has resulted in many difficulties to them in their normal work, lives, activities, and so on. Based on the investigation about daily activity characteristics and modes of the blind, the study found that the main difficulties encountered in a trip of the blind included walking on the road, finding way, taking a bus and looking for usual life-arena Several devices have been developed for mobility and navigation assistance of the blind and are typically known as travel aids or blind mobility aids.

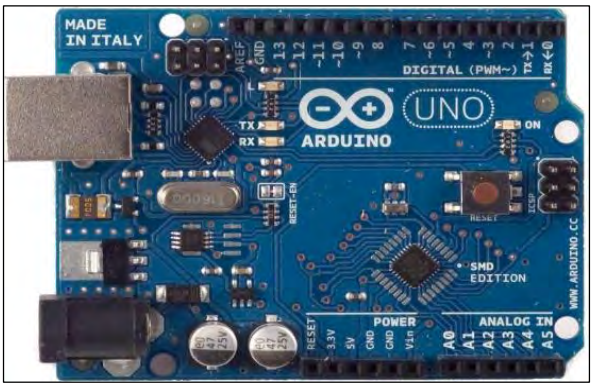


IV. BLOCK DIAGRAM

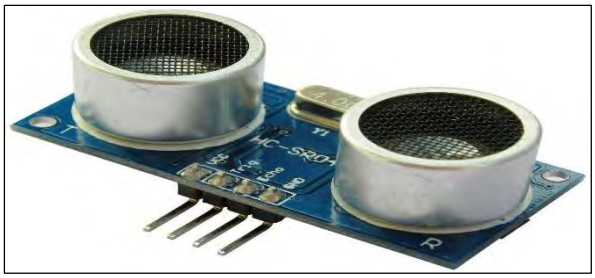


V. HARDWARE REQUIREMENTS

1. Arduino UNO:



Arduino UNO is a microcontroller board based on ATmega328p.It has 20 pins out of which 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. It contains everything needed to support the microcontroller. The Operation Voltage is 5V simply connect it to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. You can tinker with your UNO without worrying too much about doing something wrong.



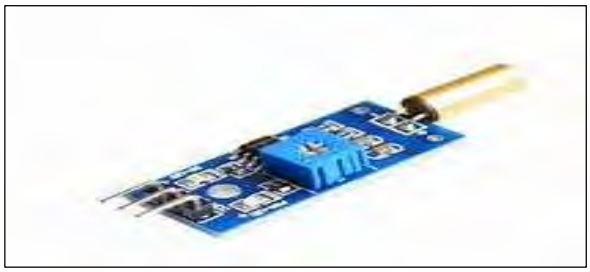
2. Ultrasonic Sensor:

As the name suggest, ultrasonic sensors measure distance by ultrasonic waves. The sensor head emits an ultrasonic wave and receives the wave reflected back from the targeted object. Ultrasonic Sensors measure the distance to the object by measuring the time between the emission and reception. An optical sensor has a transmitter and receiver, whereas an ultrasonic sensor uses a single ultrasonic element for both emission as well as reception. In a reflective model of ultrasonic sensor, a single oscillator emits as well as receives ultrasonic waves alternately.

3. Soil Moisture Sensor:

Soil moisture sensors measure the volumetric water content in soil. The direct measurement of free soil moisture process includes drying, removing, and weighing of a sample.Soil moisture sensors calculates the volumetric water content indirectly by using various property of the soil, such as dielectric constant ,electrical resistance or interaction with neutrons, as a proxy for the moisture content.Soil moisture sensors is used to estimate or calculates volumetric water content. There is a separate class of sensors that measure another property in soils called water potential; these are usually known as soil water potential sensors and which includes gypsum blocks and tensiometers.

4.Tilt Sensor:



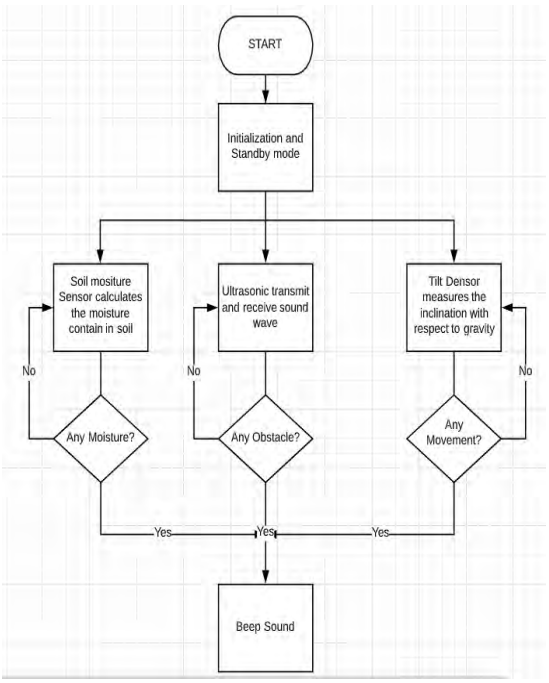
A tilt sensor is an instrument that is used for measuring the tilt in multiple axes with respect to particular plane. Tilt sensors measure the tilting position with respected to gravity and are used in number applications. They enable the easy detection of orientation or inclination of a object. Similar to mercury switches, they also be known as tilt switches or rolling ball sensors. The capability of tilt sensors is influenced by factors together with vibration, gravity, linearity, 0 offset, temperature, cross-axis sensitivity, acceleration/deceleration, shock, clean line of sight between the user and the measured point, and calibration of tilt sensors.

5.Buzzer:

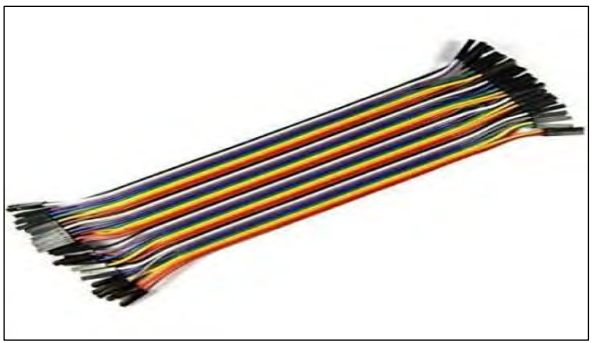
A buzzer is a small efficient component to add sound to our project/system. It iscompact and smallwith 2-pin structure hence can be easily mounted on breadboard, Perf Board and even on PCBs which makes this a widely used component in most electronic applications. There are commonly two types of buzzers available. First one is a simple buzzer which will make a Continuous Beeeeppp.... sound and other type of buzzer is called as readymade buzzer which looks bulkier than simple buzzer and produce a Beep. Beep. Beep. Beep Sound is produced because of the internal oscillating circuit present inside it.

6.Bread Board:

A breadboard is a solderless device for prototype model



with hardware and test circuit structures. Components in electronic circuits can be interconnected by inserting their terminals into the holes and then making required



connections through jumper wires. The breadboard has metal strips underneath the board and which connect the holes on the top of the board.

7. Jumper Wires:

A jumper wire is a conducting wire which is used to transfer electrical signals between two ends in a circuit. The wires can be used to modify circuits as well as to diagnose problems within a circuit. Jumper wires typically vary in size and color depending on what they are being used for. Jumper wires are used to establish connections between the central micro controller and other devices such as sensors and buttons..

VI. SOFTWARE REQUIRMENTS

The Arduino Integrated Development Environment (IDE)is a cross-platform application for Windows, Linux, macOS that is written in functions from C and C++. It is used to write and upload various programs to Arduino compatible boards, also, with the help of third party cores, other vendor developmental boards.

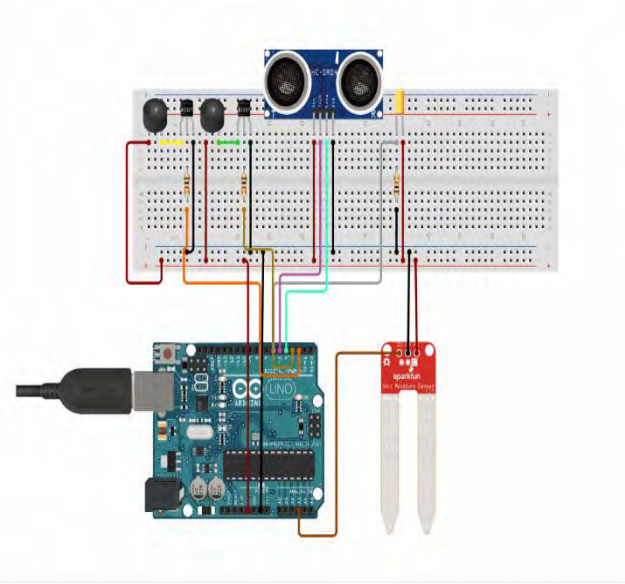
The source code for IDE is released under the GNU General Public License v2. The Arduino IDE supports the languages C++ and C with special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many input-output procedures. User defined code requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program into an executable cyclic executive program with the GNU tool-chain, also included with the distribution of IDE. The Arduino IDE provides the program avrdude to convert the executable code into text file in hexadecimal encoding format that is loaded into the Arduino board by a loader program in the firmware of board.

VII. DESIGN AND DEVELOPMENT:

1. Flowchart:

When circuit is switched ON the sensors placed on the stick goes intoactive state. There are three sensors mounted on the stick which are ultrasonic sensor to detect obstaclein front of the stick, soil moisture sensor to detect water on the ground and tilt sensor which enables the user to locate the stick from ground. Ultrasonic sensor transmit and receive sound wave which in turn helps to detect obstacle. If any obstacle is detected within a specified range then it will produce a beep sound or else do nothing. Soil moisture sensor calculates moisture contain in soil.is any moisture contain is detected in the soil then the stick will produce beep sound or else do nothing. Tilt sensor measures the inclination of the stick with respect to gravity. If the stick is inclined then it will produce a beep sound or else do nothing.

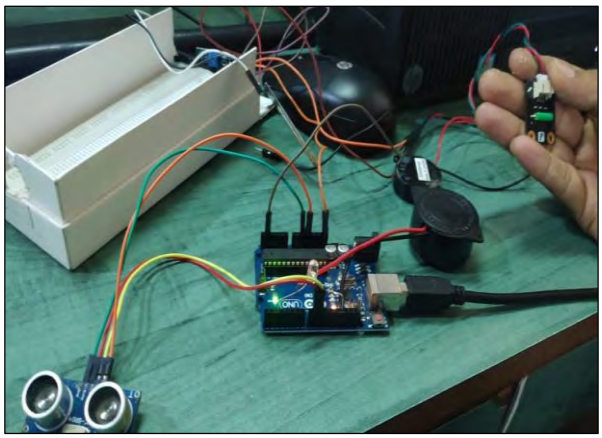
2.Circuit Diagram:



VIII. WORKING OF SYSTEM

Smart Blind Stick is basically designed to make sure that the people with visual disabilities can work on their

own without being dependent on others for their living. This innovative Stick allows visually challenged people to navigate on their own. This blind stick is integrated with Ultrasonic Sensor so that people with disabilities can walk with a sense of obstacle in between. This ultrasonic sensor makes sure that when there is any obstacle in front of the stick it indicates the user. Ultrasonic sensor sensesthe obstacle and passes this data to microcontroller. Then this microcontroller will process the data and calculate if the obstacle is close enough or not. If the obstacle is not close enough then it does nothing. If obstacle is close enough then it will produce a buzzing sound so that the user can understand that there is obstacle in front. Buzzer is used so that it can produce a sound when obstacle is ahead. This stick also contains soil moisture sensor. Soil moisture sensor is used so that the user can indicate the path where there is no detection of water and hence



selecting a simple path to walk. Soil moisture sensor is connected at the bottom of the stick and when the sensor detects water in the soil then it produces a buzzing sound to indicate the user that the path is not safe. We made use of vibrator motor for the people with hearing as well as visual disabilities. This motor vibrates while buzzing which in turn helps them to detect obstacle in between. This stick includes a tilt sensor which will help to locate the stick on the ground. Tiltsensor is of a great use to the people with visual disabilities. When this stick falls of the ground from the hand of the user then this stick produces a buzzing sound so that the user can easily locate the stick. This tilt Senor measures the angle of the stick with respect to gravity and then detect the inclination to decide whether to produce buzzing sound or not. This stick also contains a LDR which helps to produce light on the stick at times of dark which will allow the people surrounding the user to be aware and hence avoid collation.

This project is designed in such a way that the people with visual disabilities can easily use this stick and be independent. The look of this project is just like a normal stick with some sensors attached which does not give any problem to the user to use this stick.

IX. FUTURE SCOPE

By adding a GPS and GSM module to the stick we can track the actual location of the person as well as establish communication between mobile device or a computing machine. We can also add Vibrator motor which helps to make a vibration by recognizing it the person holding the stick and also feel the vibration and act accordingly, by this motor this stick can be used by people with hearing disabilities.

X. CONCLUSION

The project proposed alayout,design and architecture of a new concept of Smart Electronic Guiding Stick for blind people. It aims to solve the problems faced by the millions of visually impaired people worldwide in their daily life. The proposed system takes measures to ensure their safety and the main advantage of the system is that it can prove to be very low-cost solution to millions of visually impaired people worldwide with the proposed combination of various working units. It is a real-time system that monitors position of the user and provides dual feedback making navigation more safe and secure than the traditional cane. It can be further improved to have more decision taking capabilities by integrating various types of sensors such as GPS, GSM module and thus could be used for different applications.This our hope is to consider this stick as smart eye for the visual impairments. It is worth mentioning at this point that the aim of this study which is the design and implementation of a smart walking stick for the blind has been successfully achieved.

1. Abstract: OCR sands for Optical Character Recognition, it is the automated translation of images, printed or handwritten text into string, whether from a scanned document, a photo of a document or from subtitle text overlying on an image. In OCR first the text regions which are present in camera captured image or in the scanned copy are extracted and skew corrected. Then the regions with text are binaries and divided into parts, lines and characters. By using OCR system we can retrieve text from camera captured image or from handheld scanner andetc.

Natural language processing (NLP) is widely known for representing and analyzing human language by automatic manipulation of natural language, like speech and text, by software. It has a varied range of applications such as in fields like machine language translationwhichinvolvestranslatingdifferentforeign languagesintotheonerequiredbytheuserwhicheases communication, detecting spam emails, information (processed data) extraction and summarization, medical purposes etc.
The paper discusses about the different levels of NLP and components of Natural Language Generation (NLG) followed by discussing about how NLP can be used with OCR to enrich the process of intelligent document imaging by aiding in recognizing relevant conceptsintheinputtextwhichisbeneficialinsystems.

Using OCR and NLP text extraction can become very easy as OCR extracts the whole text and NLP is used to extract specific text from them.

Keywords: Optical character Recognition (OCR), Natural Language Processing (NLP), Natural Language Generation (NLG).

2. INTRODUCTION:

2.1 OCR:

A few decades ago, research in OCR was only limited to the document images acquired from Flat-bed scanners, but now we can use this system in every person's phone as every person's phones are acquainted with cameras and are portable. Due to the advancement of processing speed and internal memory of smartphones having digital camera give real time results.
But implementing OCR in hand held devices is not an easy task as images acquired from these digital cameras often suffer from skew and perspective distortion.
In addition to that, not everyone is professional in using this system, so while they perform capturing process, uneven and insufficient illumination and improper focusing yield poor quality images.

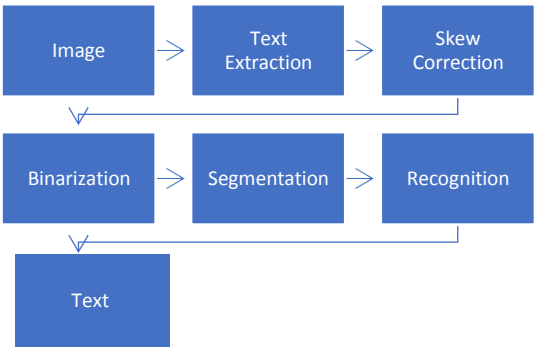

Fig 1. Process inside OCR

2.2 Natural Language Generation

Natural-language generation (NLG) is a softwareprocessthattransformsstructureddata or information into natural language which involvesconvertinginformationfromcomputer databases or semantic intents into language readable by humans. Its main use can be in producing long form content for organizations which helps in automating custom reports, as well as produce custom content for a web or mobile application. It can also be used to initiate short interactive conversations (a Chabot) with a human friendly machine which might even be read out by a text-to-speechsystem.

3 PRESENTWORK:

Presently the health reports are verified and data is entered into the database manually which consumes a lot of time and man power. Eachandeverykeyvaluepairisenteredstepby step by anemployee.

4 OURIDEA:

This process of manually entering of data into database can be done using by using two technologies simultaneously, that is OCR for recognition of characters from a set of images andNLPforextractingkeyvaluepairsformthe string provided by OCR. These key value pairs willbethenfeedintothedatabase.Throughthis method the whole process becomes faster affecting the waiting time of the clients of insurance companies and thus the overall thorough-put of thecompany.

4.1 Working ofOCR:

Image is nothing but a matrix of pixels, each pixel can have three different parameter on which they glow up, the parameters being the intensity of RGB (Red Green Yellow) colors with which they glow these values range from 0 to 255.

These values that range from 0 to 255 are first divided by 255 so that they come in a range of 0 to 1, this makes it easy to train the neural network. The NN is then trains over a set of dataset and makes predictions. The quality of NN thus trained is measured by it accuracy while predicting on a data that is similar to nut notexactlythetrainingdataset,thesedatasetare known as test dataset. The train dataset andtest dataset usually has a ratio of7:3.

Also while training a NN over a set of image the resolution of the image plays a very Importantrole.Thenoofcolumnsinthematrix mustbeequaltothenumberofnodesatthefirst layer of the NN. There are many hidden layers between the first and the last layer and at all layer a prediction takesplace.

OCR uses these previously trained NN tomake predictions and thus turn pictures intostring.

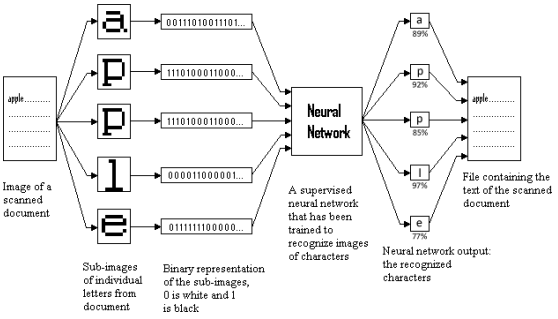

Fig 2. Training of Neural Network

Feature Extraction: In this stage, various features of characters are extracted. These features uniquely identify characters. The selection of the right features and the total number of features to be used is an important research question. Different types of features such as the image itself, geometrical features (loops, strokes) and statistical feature (moments) can be used. Finally, various techniques such as principal component analysis can be used to reduce the dimensionality of the image.

APPLICATIONS OF OCR:

OCR enables a large number of useful applications. Duringthe earlydays,OCRhasbeenusedformailsorting, bank cheese reading and signature verification Besides, OCR can be used by organizations for automated form processing in places where a huge number of data is available in printed form. Other uses of OCR include processing utility bills, passport validation, pen computing and automated number plate recognition. Another useful application of OCR is helping blind and visually impaired people to readtext.

4.2 NLP:

NLP in 4 Waves.

The history of natural language processing(NLP) can be timed back to 1950's where Alan Turing published an article titled "Computing Machinery and Intelligence" which proposed what is now called the Turing test as a criterion of intelligence. Mostnatural

Language processing systems were based on complex sets of hand-written rules in the past and the actual revolution in NLP was brought about in the late 1980's when machinelearning algorithms began to gain prominence for processing information. Scientists Richard Bundler and John Grinder started this as the basis of NLP around 1972 with modellingFritz Perl's (Gestalt Therapy), Virginia Stair (Systemic Family Therapy) and Milton Erickson(Hypnotherapy).

APPROACHES: The various approaches to natural language processing can be categorized into

1) Distributional 2) Frame-based 3) Model-

theoretical

4) Interactive learning

4.2.1 DISTRIBUTIONAL APPROACHES

Large-scale statistical tactics of machine learning and deep learning are included in distributional approaches. These methods basically converts content or input words into word vectors for mathematical analysis and performextremelywellattaskssuchaspart-of- speech tagging (identifying the word category inEnglishgrammar),dependencyparsing(does this part of a sentence modify another part?), and semantic relatedness (are these different words used in similar ways?). These NLPtasks don't depend on understanding the meaning of words, but relation betweenwords.

Such systems are broad, flexible, and scalable. They can be applied to most of the documents presentinthemarketwithoutexpertknowledge

In the domain.

4.2.1 FRAME-BASEDAPPROACH

Framesareacanonicalrepresentationforwhich specifics that can beinterchanged.

Sentences that are syntactically different but semanticallyidenticali.e.theyconveythesame meaning.

4.2.1 MODEL-THEORETICAL APPROACH

Model-theoretical approach is the third category of semantic analysis. "Model theory" and "compositionality" are the two important linguistic concepts to understand thisapproach. Model theory refers to the idea that sentences refer to the world, for example with grounded language (i.e. the block is blue). Meanings of the parts of a sentence can be combinedto deduce the whole meaning, this is knownasCompositionality.

4.2.1 INTERACTIVE LEARNING

British philosopher of language (Paul Grice), described language as a cooperative game between speaker and listener. It is believedthat a viable approach to tackling languagelearning istoemploydynamic,interactiveenvironments where humans teach computers gradually. In such approaches, the pragmatic (purpose and goals) needs of

Development.

- Rule-based.
- Traditional Machine Learning.
- Neural Networks.
- Text ClassificationTasks.
- Word SequenceTasks.
- Text MeaningTasks.
- Sequence to SequenceTasks.
- DialogSystems.

5. USES OF NATURAL LANGUAGE PROCESSING WITHOCR

In our project we aim to digitize different kind s of printed lab reports / health check reports to discrete values of each parameter captured. Conversion of data to a dataset of digitized value will help in automating lot of back-end approval process. Ability to read and classify comments/observations for common parameters will be implemented using natural language processing. OCR is used to translate printed, hand written, and scanned documents into a machine-readable format. The technology relieves employees of manual entry of data, cuts related errors, and enables automated data capture and we are going to use the same technology in digitization of lab reports by identifying key value pairs for the data entered. OCR is the core technology for automatic text

recognition. The technology relieves employees of manual entry of data, reduces errors, and provides automated data capture. Information in documents is usual y a combination of natural language and semi- structured data in forms of tables, diagrams, symbols etc. with NLP machines are able to inter act with the written form of human language. NLP along with the OCR technology, finds apeplacations for data retrieval, information extraction, and text summarization. For training a do cement classifying model, it is necessary to have thousands of samples that will make a training dataset. Then, machine learning engineers defines the parameters according to which it is possible to associate a document with one or another class and use these parameters later to create a classification model. Different training methods on deep neural nets can make a good fit. Everything depends on the type ofdata.

So in our case we will be using Tesseract OCR by Google demonstrates outstanding results enhancing and recognizing raw images, categorizing, and storing data in a single database for further uses. It supports more than 100 languages, and the accuracy of document recognition is good enough for somecases.

6. COMPARATIVE STUDY:-

This is a new technology. Here thephotoofthelab report will be uploaded and the text in the image will be extracted. The key values of the text will be extractedand Stored in the database of the company. All this work willbe done automatically and the time for doing this work willbe Reduced tremendously.	In the recent tech all the updates are to be done manually which is really very hectic and time Consuming.
The verification of the data is done twice. The data is Secured.	There is no verification for the data.

7 CONCLUSION:

In this paper, an overview OCR and NLP and howtheycanbeusedtogetherfordataentryhas been given. Different parts of OCR and NLP work together for this to happen. Also the accuracy of this project depends a lot on the ability of OCR to recognize text correctly and the power of NLP to extract the key valuepairs accurately.

Human Activity Recognition Smart watch

Prof. Prerna Deshmukh Riya Raipure Gayatri Wandhare,
Nirbhay Dawle Akshita Sagole Jay Darwankar
Priyadershani technology Collage of Engineering,
Nagpur

Abstract: **Sensor-based activity recognition seeks the profound high-level knowledge about human activities from multitudes of low-level sensor readings. Conventional pattern recognition approaches have made tremendous progress in the past years. Recently, the recent advancement in technology makes it possible to perform automatic high-level feature extraction thus achieves promising performance in many areas. Through a smart watch we tend to monitor human activities using different aspects. We also present detailed insights on existing work and propose grand challenges for future research. Automatic high-level feature extraction thus achieves promising performance in many areas. Through a smart watch we tend to monitor human activities using different aspects. We also present detailed insights on existing work and propose grand challenges for future research**

Keywords: Step tracker, Sensors, HAR, and Pulse.

I. INTRODUCTION:

Human Activity Recognition (HAR) is the event of a device where a particular device uses various types of sensors to detect human activity movements, collects the data, analysis it and then gives a brief result.

In today's time there are various devices that collects the data and predicts the Outcome with a ratio of probability and then displays result.

Its uses various aspects of deep learning and some parts of neural networks to connect the dataset which are used.

The data sets are the background activity where the actual work of recognition and results are given. We propose to build an application that will help to monitor different human activities to insure the health concerns.

The idea is to make an application for a low cost affordable smart watch which can count the number of steps on basis of your walk and then store the data and then monitor the pulse rate for the particular person and then monitors and verify the health of the person.

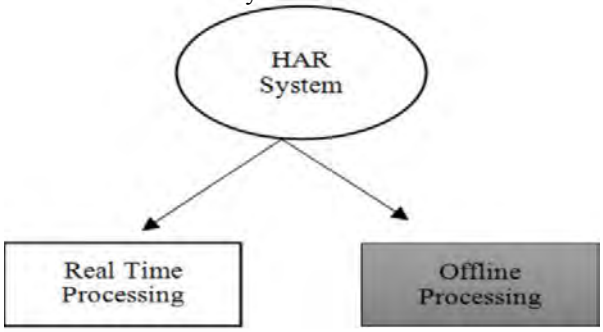
Considering the modern and hectic routine managing health without regular checkup from doctors and costly instruments seems hard but this device using HAR (Human Activity Recognition) which uses the sensor based modality to take readings for a particular amount of time and then check for alternate results for the given parameter makes it easy .

If any uncertainties are found in these readings the application will send a notification to inform the patient about their health on their watch and then it will also send a notification to the person monitoring.

This will help many people to keep a check on their family friends and provide with help as soon as possible.

II. LITERATURE SURVEY:

A Human Activity Recognition (HAR) system can automatically recognize physical activities, which is a key research issue in mobile and ubiquitous computing. An HAR system performs tasks of recognizing different human daily activities from simple to complex. The sensors involved in an HAR system can be video sensors, inertia sensors, and environment sensors. The GPS receiver can also be used for activity recognition but is limited to outdoor environments.
Bishoy Sefenet. al. [ICAART 2016] said that In order to achieve the best between the system's computational complexity and recognition accuracy, several evaluations were carried out to determine which classification algorithm and features to be used. The analysis results showed that naive Bayes performs best in our experiment in both the accuracy and efficiency of classification, while the overall classification accuracy is 87%.



Subhas Chandra Mukho padhyay [IEEE 2015] has reviewed the reported literature on wearable sensors and devices for monitoring human activities. The human activity monitoring is a vibrant area of research and a lot of commercial development are reported. It is expected that many more light-weight, high-performance wearable devices will be available for monitoring a wide range of activities. The challenges faced by the current design will also be addressed in future devices. The development of light-weight physiological sensors will lead to comfortable wearable devices to monitor different ranges of activities of inhabitants. Formal and Informal survey predicts an increase of interest and consequent usages of wearable devices in near future, the cost of the devices is also expected to fall resulting in of wide application in the society.

International Journal of Emerging Technologies in learning (iJET) 7(4):1-4 · January 2019 states Wearable sensor and internet of things technology for better medical science: A review E-health becomes one of the internet's products for healthcare. The problems of health service such as far hospital and expensive examination fees become the emergence of this technology. Consequently, people reluctant to check their health to hospital. E-health provides information on disease prevention, detecting early symptoms, and medical parameters from a far distance. Internet of things became the main concept in this system, which combines wearable sensors, communication systems, and mobile user interfaces. Reliable and valid system, easily carried, help the doctor to monitor patients from far distance expectantly to overcome the problems. The aims of this paper review are describing how an internet of things technology and wearable sensor help medical science and Find the best way to create a health monitoring system.

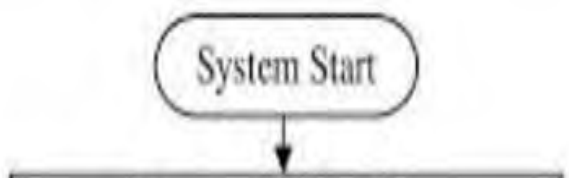
III. PROBLEM DEFINATION:

In the day to day life of a normal person it is hard to keep track of our and our loved once health. Many people need to move far away from family and in such situations taking care of someone is difficult and thus sometimes it leads to delay in providing with proper medical help. Our goal of the project is to decrease the delay and help monitor the loved once.

IV. APPROACH TO THE SOLUTION:

As many people of different age group were smart watch and like to keep a track of their day to day activities, we propose an application that count the number of steps the person is walking and also through the sensors already present in the smart watch it will also tell the pulse rate of the person this data will be available to another person who will be monitoring the person using smart watch. In case any readings are found to be fluctuated both the user and the person monitoring will be informed notified. This ensure that user is been provided with proper medical help when needed in time.

.



V. PROPOSED WORK:

In this project we try to reduce the time needed for the medical help to reach the patient. This can be achieved when someone monitors the patient or the user using the application and therefore keeps a proper watch over patient's record.
Two entities that is step tracking and pulse will be checked. The smart watch user will register upon the application and will receive a unique registration Id. Through this registration Id another person will keep a track of the user steps and pulse rate. So if the user is exhausted his pulse rate will fluctuate and hence a notification will be send on the smart watch to the user as well the person monitoring him/her. This will help the person to quickly connect with the user and check up on him, and if needed call the medical help to his /her location.

5.1 MODULE:

Module 1

Selection of the tool

We have selected a smart watch as our tool for inputs.

Module 2

Selection of simulation tool, learning the required language for the application.

Module 3

A quick notification to both user and the person monitoring.

Module 4

Designing Algorithms

Module 5

Final application

5.2 WORKING:

WORKING ON SMARTWATCH

Opening the application on smartwatch it will ask to register or monitor. On registering it will provide with a unique registration Id and will start calculating the entities. If found any fluctuation it will notify the user.

WORKING ON MOBILE PHONE

Opening the application it will ask for register or monitor. When selected monitor it will ask for the registration Id by providing the import of registration Id now the data of that registration Id can be Accessed to the person monitoring. If found any fluctuation it will notify the person monitoring.

Thus helps us keep proper check upon the user and if necessary provide proper medical help in time.

VI. SIMULATION TOOL

The core function of the project is to create an application to monitor the health of person for which the some following tools were used hardware and software.
As in hardware a low cost smart watch with basic functioning is used.

VII. HARDWARE REQUIREMENT

Model: W1, Chipset: MTK6261D,
Screen: 1.54" HD IPS Screen, Touch
Screen: Capacitive touch screen, RAM +
ROM: 64M + 32M, Resolution: 240*240

,Camera: Support, Bluetooth: Support Call: support, Size: 55.4*41*11.8mm.

VIII. SOFTWARE REQUIREMENT

The main aspect in the software part is android studio which can be used to make android application for implicit working with algorithms. Android studio work in two aspects as in two parts Front End and Back End

At Front end it contains various xml files which are the front representation of the application called as layouts. The working of those layout totally depends on the back end side work which either conation Java Files or Kotlin files. For this project we will be working with Java files.

IX. CONCLUSION

This paper introduced a low cost, low-power embedded system for HAR

Smartwatch with proper implementation made application including pedometer work and different parameters to keep a person's health in check.

This new innovative concept of the project will increase the rate of person health and keep it in check.

In this design we improved the way of tracking calories and steps in data section. This will make sure that whenever a person's health factors are differing in a unusual manner they can get help at ease through this project.

This will help in society for people who live away from their family and wants to monitor the health of their members.

X. FUTURE SCOPE:

We tend to develop this application supporting both ios and android platform.
As we tend to build this application to provide medical help in time to the people risk decreases and health issues can be handled.
This application is cheaper than to go and buy an expensive smartwatch.
In low cost we can provide proper help in time to the patient saving their lives.

Abstract:**As of late, the Android Technology with web administrations has acquired numerous exceptional changes the versatile applicationadvancementfield.Thisapplicationgivesasummed up answer for screen the different works that are done by a College for overseeing it. The framework gives a straightforward interface to support of understudy data. It tendstobeutilizedbyinstructivefoundationsorcollegestokeep up the records of students. The creation and the board of precise, state-of-the-art data with respect to a students' scholastic profession is fundamentally significant in the college just as colleges. Well-informed Connect manages all sort of understudy subtleties, scholarly related reports, college subtleties, course subtleties, educational program, batch subtleties, arrangement subtleties and other asset related subtleties as well. It will likewise have faculty subtleties, batch execution subtleties, students' subtleties in all viewpoints, the differentscholasticnoticestothestaffandstudentsrefreshedby thecollegeorganization.Itlikewiseencouragesusinvestigateall the exercises occurring in the college. Various reports and inquiries can be created dependent on tremendous choices identified with students, batch, course, faculty, exams, semesters, and certification and in any event, for the whole college.**

Keywords— Android Technology, Administration, Maintain Records, Student Information System

I. INTRODUCTION

The structure and execution of an extensive understudy data framework and UI are to supplant the present paper records. College Staff can straightforwardly get to all parts of an understudy's scholarly advancement through a protected, online interface inserted in the college's site. The framework uses client validation, showing just data important for a person's obligation. Moreover, each sub-framework has verification permitting approved clients to make or refresh data in that subsystem. All information is altogether assessed and approved on the server before genuine record change happens. Notwithstanding a staff UI, the framework plans for understudy UI, permitting clients to get to data and submit demands on the web, in this way lessening handling time. All informationisputawaysafelyonSQLserversoversawbythe college executive and guarantees the most noteworthy conceivable degree of security. The framework includes an unpredictable logging framework to follow all clients' entrance and guarantee adjustment to information get to rules and is relied upon to expand the productivity of the college's record the executives along these lines diminishing the work hours expected to get to and convey understudy records to clients.

Fig 1: Android Technology

Already, the college depended vigorously on paper records for this activity. While paper records are a conventional method for overseeing understudyinformationanddiversework,thereareafewdown sidestothis technique. Initially, to pass on data to the students, it ought to be shown on the notification board and the understudy needs to visit the notification board to watch that data. It requires some investment to pass on the data to the understudy. Paper records are hard to oversee and follow. The physical effort required to recover, adjust, and re- document the paper records are allnon- esteem included exercises. This framework gives a straightforward interface to the upkeep of understudy data. Instructive organizations or colleges to keep up the records of studentseffectivelyverywellmayutilizeit.Accomplishingthi s goalistroublesomeutilizingamanualframeworkasthedatais dissipated,canberepetitiveandgatheringimportantdatamight beverytedious.Everyoneoftheseissuesisunraveledutilizing Smart Connect. The paper centers around showing data in a simple and clear way that gives offices, for example,

profile production of understudy, teacher, head, and more significant position authority in this manner diminishing desk work and computerizing the record age process in an instructive organization.

II. EASE OFUSE

A) Purpose

Theobjectiveoftheprojectistomakeit easyforthestudentsto accesstheirdataviatheapp.Theappwillmanageallthestudent information in the institute. It will provide the centralized control over thesystem.

B) Scope

The app is based on students and teachers point of view. The goal is to make it easy for the students to access all the data remotely. Just some clicks and the data will be at fingertips.

Thebasicapproachistouseitonallthesmartphones.Allthe students will get access to student panel and similarly for teachers andadmin.

III. LITERATURESURVEY

All researchers have aimed to develop and provide a generalized solution to monitor the various works that are carried out by a College for automation of various tasks. They provided up to date information of the system, which improved efficiencyofcollegerecordmanagementanddecreasethespace between student and college. The major contributions to this topic are summarizedbelow:

S. Shivasubramanian, S. Sivasankaran ,and S. Thiru Nirai Senthi [1] proposed one of the first computational schemes An AndroidBasedMobileApplicationtoMonitorWorksatRemote Sites.Thisapplicationprovidedageneralizedsolutiontomonitor the various works that were carried out by a construction companyatdifferentgeologicalpoints.ByusingaWebService, the data was stored in the remote database. This mobile application requires General Packet Radio Service (GPRS) or Wi-Fi technology to reach the remote database. Using data in the remote database, various reports were generated and projected as a MIS [Management Information System] web application.

Sanjay T. Attendance [2] proposed attendance Management System to generate an android application to calculate the attendance of the students in colleges and updating the result directly into the college server. The data would be stored in the smart phone if the internet connection were unavailable at that time. When the internet connection was available, then the faculty could login into their college account and update the attendance result.

Shradha S. Chawhan, Mangesh P. Girhale, and Gunjan Mankar [3] worked on MPBAS that helped lecturers to take the attendance of students using Smart-phone. Lecturers would login to the phone application, are connected to the server and take attendance using Smart-phone. After taking theattendanceinthemobile,lecturerswouldsenditovertothe server using GPRS and attendance list would be updated automatically. Lecturers would be able to edit the attendance byloginontothewebsite.Studentswouldbeabletoviewtheir own attendance as well as curriculum details. To reduce the chances of fake attendance, the project would include Location detection using GPS. In addition, email would be send to the students by the lecturers, notifying them of their regularactivities.

S. R. Bharamagoudar, Geeta, S.G. Totad [4] worked on Web Based Student Information Management System that provided a simple interface for maintenance of student information. Educational institutes or colleges to maintain the records of students easily could use it. The creation and management of accurate, up-to-date information regarding a students' academic career is critically important in the university as well as colleges. Student information system deals withallkindofstudentdetails,academicrelatedreports, college details, course details, curriculum, batch details, placement details and other resource related detailstoo.

Eiichiro Tsutsui, Kazuharu Owade, Yusuke Kondo, Michiko Nakano [5] A Proposal For A New- Dimensional Online Feedback System: Focusing On Individual Learner

Differences purpose of this study was to create a new method of assessing individual learner differences in the contexts of language learning. Their questionnaire-type items used in that system was based on SILL (Strategy Inventory of Language Learning) questionnaire items.

Namrata Shahade, Priya Kawade and Satish Thombare [6], proposed Student Information Tracking System an Android application to manage student attendance on mobile. In many colleges teachers used to take attendance manually. Main objective of this project is to add mobility and automation in the existing attendance process. This system helps teachers to takeattendancethroughmobileandkeepintouchwithstudent insomeaspect.ThisSystemallowteacherstotakeattendance, edit attendance, view student's bunks, send important documents in pdf format such as exam time table, question bank etc. and also helps teachers to inform students about the events that college was going to organize. This system also helped students in specifying bunks, deleting bunks, viewing their bunks. This system gives a prior intimation to student as soon as his attendance goes below the specified attendance deadline in the form of an alert. This system helps students to keep in touch with the events that college wasorganizing.

Yohei Kawaguchi, Tetsuo Shoji, Weijane Lin, Koh Kakusho, Michihiko Minoh proposed a system that took the attendance of students for classroom lecture. Their system took the attendance automatically using face recognition. However, it is difficult to estimate the attendance precisely using each result of face recognition independently because

the face detection rate was not sufficiently high. Here they propose a method for estimating the attendance precisely using all the results of face recognition obtained by continuous observation. Continuous observation improves the performance for the estimation of the attendance. They constructed the lecture attendance system based on face recognition, and applied the system to classroom lecture.

IV. SYSTEMARCHITECTURE

The system design consist of following modules:

a) Adminlogin:
The central level authority will be able to login in this portal. The changes can be made in student database through this portal only.
This portal has the access to the following:

i) ViewAttendance:
The attendance of every student and teacher will be visible from this portal.

ii) Add/RemoveTeacher:
The newly appointed teachers can be added and the no longer employees can beremoved.

iii) Add/RemoveStudent:
Similarly for the students, the student can be added or removed based on their admission status.

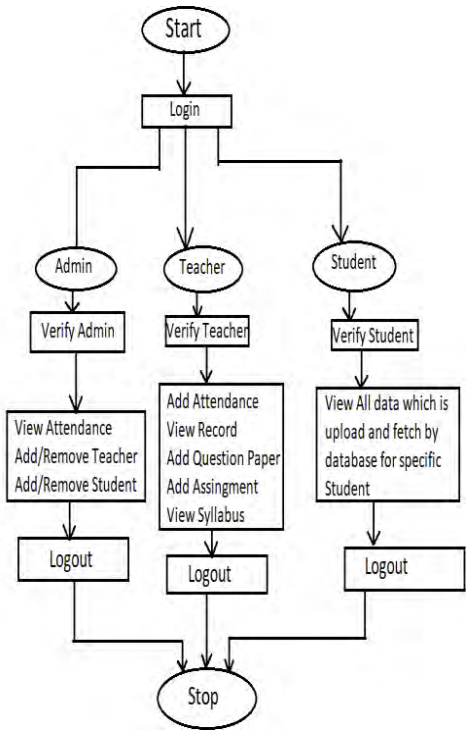

Fig: Data Flow Diagram

b)Teacherlogin:
The teachers will be able to login to this portal for taking attendance, uploading question banks, assignments, marks for the exams, and the basic student information.
i) AddAttendance:
The teacher can take attendance from the app and will be able to edit it. Total attendance will be counted.

ii) ViewRecord:
The record of the student will be visible to the teacher like student's marks and submissions.

iii) Add questionpaper:
The question paper can be uploaded through the app and will be visible to the students.

iv) AddAssignment:
The assignments can be uploaded through the app just like the question papers.

v) ViewSyllabus:
The syllabus for each and every branch will be displayed semester wise.

b) Studentlogin:
The students of the institute will be able to login to this portal and can view their personal information and attendance.Theywill beaccessibletothequestionbanks, assignments, notes uploaded by theteacher.

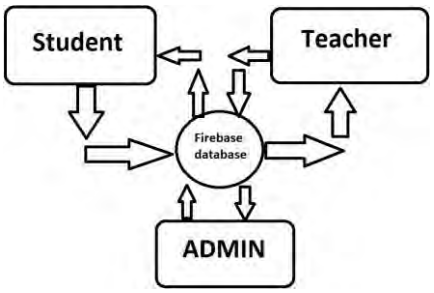

Fig: Model Flow Diagram

V. Evaluation

➢ Advantages:
- Mobility and automation will be added to the system.
- Application will be userfriendly.
- Access is granted to authorize personnonly.
- Best results are produced using multiple algorithmssimultaneously.

➢ Disadvantages:
- Designing the whole architecture can be a challengingpart.
- Tomakeitfullysecuresystemcertainencryption algorithms needs to beincluded.

VI. CONCLUSION

The framework offers unwavering quality, time investment funds and simple control. Students and their folks will likewise see results, participation and educational plan subtletiesutilizingthisapplication.Likewisestudentscansee subtleties, notices anyplace and whenever. The application will extraordinarily disentangle and accelerate the outcome arrangement and the executives procedure. It gives high security and a framework that diminishes the work and assetsrequired in customary procedure. The proposed framework gives the better approach for registering. Is playingatasks withresponsiveandappealingUI.Inthisway, based on writing study and by breaking down the current framework, we have arrived at a resolution that the propose framework will not just guide the robotization to the college, yet will likewise assist with digitizing the framework and thusly help to send assetsproductively.

M-Commerce Shopping Using Nfc Technology

Deepti S. Lawand, Prof. Prashant Nitnaware

Dept. of Computer Engineering

Pillai College of Engineering

Navi Mumbai, India

dlawand@mes.ac.in, pnitnaware@mes.ac.in

Abstract—**Mobile commerce (M-commerce) is the buying and selling of goods and services through wireless handheld devices such as smartphones, tablets. In traditional shopping, the customer needs to physically pick up the items to be purchased and carry cash or credit/debit cards with them to make payments M-commerce application become most popular amongst the mobile phone users who want to do their business, financial activities easily and securely anywhere, anytime. The use of physical cash is reduced tremendously after the e-cash comes in the picture. An emerging technology behind the mobile payments is Near Field Communication (NFC). Near Field Communication is a wireless technology which is a short-range, high frequency, low bandwidth radio technology that allows transferring data within a few centimeters.**

In this paper we propose an android based mobile commerce system using NFC. The system will read the NFC tag of the product and add it to the shopping cart. It would provide methods to change the quantity of products purchased and edit the cart. Invoice will be generated and NFC based payment will be done according to the generated invoice.

Keywords— M-commerce, NFC, wireless technology shopping cart

I. INTRODUCTION

In traditional shopping system the customers goes to the store and purchase the needed products and add it into the cart/trolley. The customer physically picks the product and keeps it in the trolley and carry the trolley all around till the shopping is done. Once they are done with the shopping, they need to stand in the queue for payment. Using M-commerce all this process can be done easily. M-commerce enables users to access online shopping without using a desktop computer. M-commerce include mobile banking, virtual marketplace apps like the Amazon mobile app or a digital wallet such as Apple Pay, Android Pay and Samsung Pay. In most M-commerce enabled platforms the mobile device is connected to a wireless network that can be used to conduct online product purchases [3]. In this paper, we propose an Android based mobile phone application which is integrated with NFC technology**.** The user will do the entire shopping process with the help of their Android mobile phones with a software application that would read and process NFC Tag of the products, which are to be purchased. To store products details in a shopping list/cart NFC tags of those products are are read. Users will be able to perform editing of existing products in the cart such as the process of addition, subtraction of quantity or deletion of the product all together from the cart. Users will be able to add new products, modify existing products, change the quantity or delete the product from the cart. The amount of money spent will always be known to the user and could verify the same.

II. LITERATURE SURVEY

A large population that neither had a landline nor a bank account in their names but now not only they own a mobile handset but are also well balanced to transact on their mobile. The mobile channel has provided a rare opportunity not only to leapfrog years of poor infrastructure development but also in bypassing geographical constraints to bring massive benefits and lifestyle changes to millions of under-served people across India. India is a land of many languages but only 2 percent of the Indian population prefers reading in English.[4] E-commerce stands for electronic commerce, on the internet. Customers can purchase anything right from an Insurance Policy to pen on sitting comfortably in their office or home and gift it to someone sitting miles apart just by click of a mouse Ease of internet access and navigation are the critical factors that will result in rapid adoption of E-commerce. Safe and secure payment modes are essential to popularize E-commerce in India. Though it offers many benefits to users, there are many reasons for not shopping online like are lack of trust, security concerns, uncertainty about product and service quality, delay or non-delivery of goods, and lack of touch-and-feel shopping experience [1][3][7][5][9].

Mobile Commerce (M-commerce) is the subset of electronic-commerce (e-commerce), which includes all e-commerce transactions, carried out using a mobile (hand held) device. M-commerce is the way of doing business in a state of motion [5][6][9]. M-commerce depends on the availability of mobile connectivity. We have become used to making mobile phone calls anywhere, at any time and m-commerce is built on that capability. According to IT experts, in the future, consumers will be able to shop using a handheld computing device, PDA, wearable computer, mobile phone or smart devices. In virtually any place – malls, restaurants, hotels, airports and other locations – this user will be able to receive coupons, download information, receive sales offers, and perform credit card transactions. In such future scenarios, M-commerce means that customers can shop anywhere, anytime.

III. PROBLEM STATEMENT

In traditional system the customer goes to the store and purchases the needed products and adds it into the cart/trolley. The customer physically picks the product and keeps it in the trolley and carry the trolley all around till the shopping is done. Once they are done with the shopping, they need to stand in the queue for payment. Using M-commerce all this process can be done easily and user friendly. Nowadays wireless communication technologies are in trend .One of the mostly used technology is RFID (Radio Frequency Identification), it uses the electromagnetic Field to track the information regarding the products. The products are classified by using RFID. There is an RFID tag attached to the products so by just scanning the tag in the products the details of the products is entered into the system. This system was helpful in the billing counter by making the billing service by just scanning the product to add them manually. The NFC technology comes in wireless world the NFC and RFID are related closely in the case of working but the NFC does not need any specialized device as it is inbuilt in most of the smartphones. The NFC tag is also called as smart tag or info tag as it contains the information about the particular product. They have a bit of memory storage and a radio chip.

IV. PROPOSED ALGORITHM

Step 1: Start
Step 2: Open the Application.
Step 3: Login into Application.
Step 4: If the login is successful, then scan the NFC tag of Product else go to step 3.
Step 5: After successful scan, retrieve information of product from database.
Step 6: Add the product to cart and send the list to the database.
Step 7: Place order and get the order details.
Step 8: Check if order accepted or not if accepted go to step 9.
Step 10: Receive OTP and verify it from the merchant.
Step 11: If OTP is valid, then pick up the Order else re-verify.
Step 12: End.

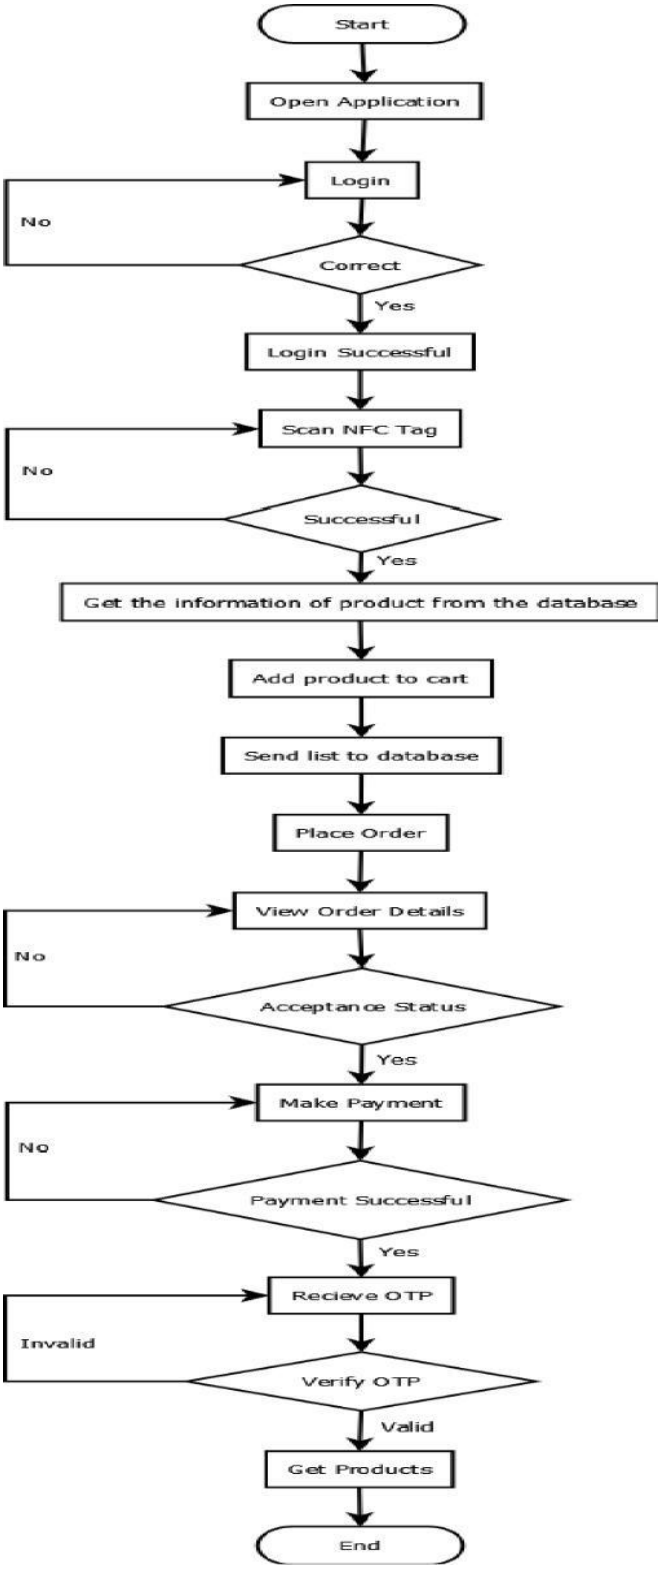

Figure 1 Flow Chart of shopping using NFC

V. RESULT AND ANALYSIS

The Proposed system provides online shopping with mobile phones with NFC technology. First it starts with sign in

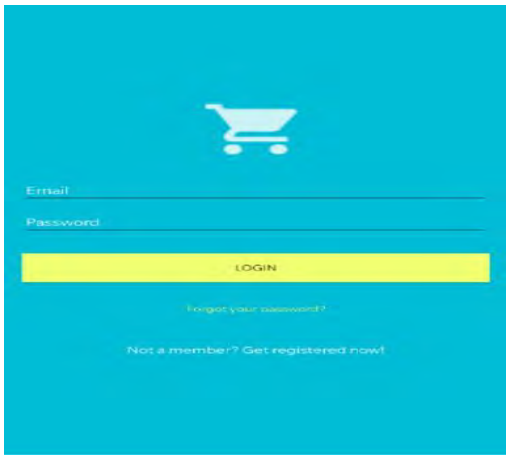

Figure 2 Login Screen

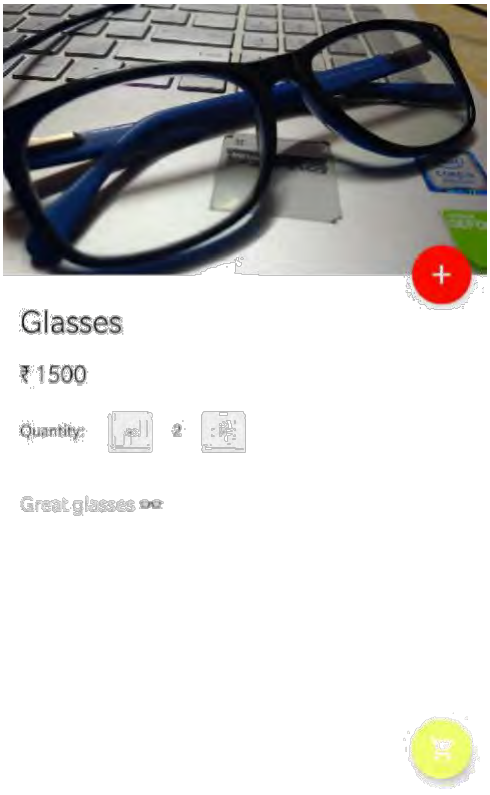

Figure 4 product Details after scanning tag

VI. CONCLUSION

The proposed system is a software prototype that provides a simplified method for shopping. It results in a fast and easy procedure saving customer time and allowing more access towards commodities. Our NFC based technique will prove to be highly efficient for shoppers to reduce the load of the goods carrying around as this application can scan NFC tags of products by NFC which is short-ranged wireless technology available in smart phones. The application could also be used for shopping by collecting users' personal information like address and let the mall or supermarket deliver the products to you home directly. In that way, the customer need not carry the goods with them, making it convenient for them. An Expert System can be integrated with application so the user's personal information regarding their health will be stored in database and then the system will suggest products related to his health.

Autonomous Agricultural Pesticides Spraying Hex Copter Drone.

P. U. TEMBHARE, A. KUMARI, N. A. SHAHU, R. R. MADHUMATKE, S. KUMBHALKAR, S. B. JAGTAP

Abstract- ***India is having approx. 159.65 million hectares of agricultural land and Agriculture plays an important role in the growth of any country. The production rate of crops is getting less because of climate issues, humidity, global warming, population pressure, etc. To cover the productivity of crops we need to prevent them from the diseases. Spraying the pesticides on crops may help the crops to be safe from insects, etc. but it also affects the human's health. Therefore, to solve the problem like this agricultural pesticide spraying by hex copter drone is one of the best solutions. This paper discusses special attention to this area of agricultural, and drones with their problems and solutions and their implementation for pesticide spraying.***

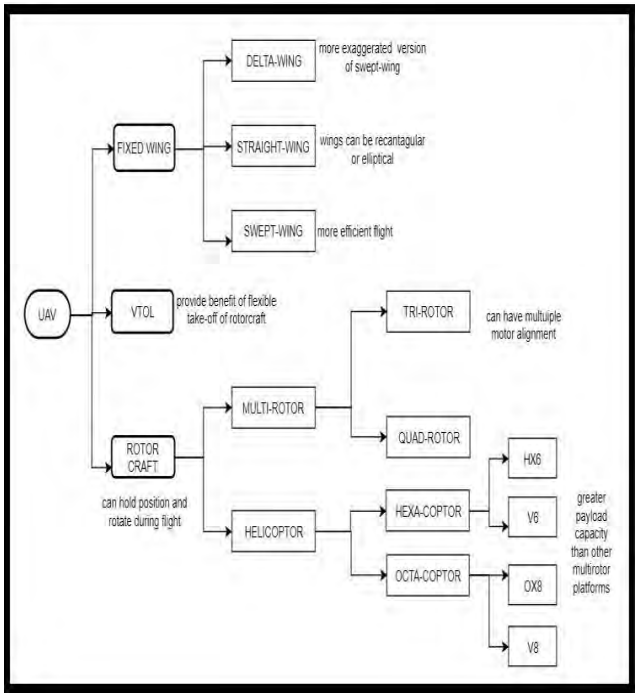
I. INTRODUCTION

In India, Agriculture is a major sector of our economy but still, it is far short of western countries when it comes to adapting the latest technologies for better farm output [1]. These technologies for spraying pesticides include Pulse width modulation improves accuracy, Spot spraying technology for herbicides, Drone spraying set to take off, Decision support tool to improve spray timing. Among these applications, the use of the drone for agriculture is called agricultural drones. Agricultural drones can be used for Soil and field analysis, Seed planting, Crop spraying and Spot spraying, Crop mapping and Surveying, Irrigation monitoring and Management.

To create better crop diversity more environment-friendly techniques are used. Due to changes in climate crops may suffer from different kinds of pests, and many farmers choose the use of the pesticide for their crops. This pesticide is used for plant protection. Farmers used to do pesticide spraying manually, resulting they harm more than just the "pests" at which they are targeted. They are poisonous, and contact with these pesticides can cause a number of health effects. They are linked to a variety of range of serious illnesses and diseases from respiratory problems to cancer. So, to avoid this a drone is used to spray the pesticide instead of human

In many developed or developing countries, they started to use these latest technologies in farming. These UAVs, if used for pesticide spraying, can reduce the workload of the farmer and also takes less time for spraying the fertilizers. It is also observed that the lower level of the plant also gets an efficient amount of pesticides because of spraying the pesticides by UAV drones. The use of agricultural drones for pesticide spraying will become easier for farmers if those drones are autonomous, i.e., once the fields length, breadth, area, or co-ordinates are set by the laptop or mobile then the drone will continue the work until any technical problem occurs like the battery is about to die, and an another solution to get back the drone if it has less battery by giving the in-build instructions suppose if it has left less battery then it will automatically calculate the distance (km) to cover and the distance(km) to get back to the place where it takes off and will come back automatically to that.

II. TAXONOMY



2.0 DRONE DESIGN OR CONFIGURATION SELECTION

After studying many designs of the drone, finally, the Hex copter configuration is selected. The Hex configuration consists of six motors and six propellers. The number of motor and propeller are the same. To reduce the manufacturing cost, a custom design is made with the hex copter frame as shown below. Hex copter configuration is selected because it has the characteristics of both, a Quad copter and an Octocopter. One of the advantages of the hex copter is the if in the mid-flight one of the components of the propulsion system fails i.e. if any one of the motor or propellers get damaged, it is capable of land safely with the 5 rotors. The Pixhawk flight controller is used for the programming of the drone because it is very much stable. The Pixhawk flight controller is also an open-source platform

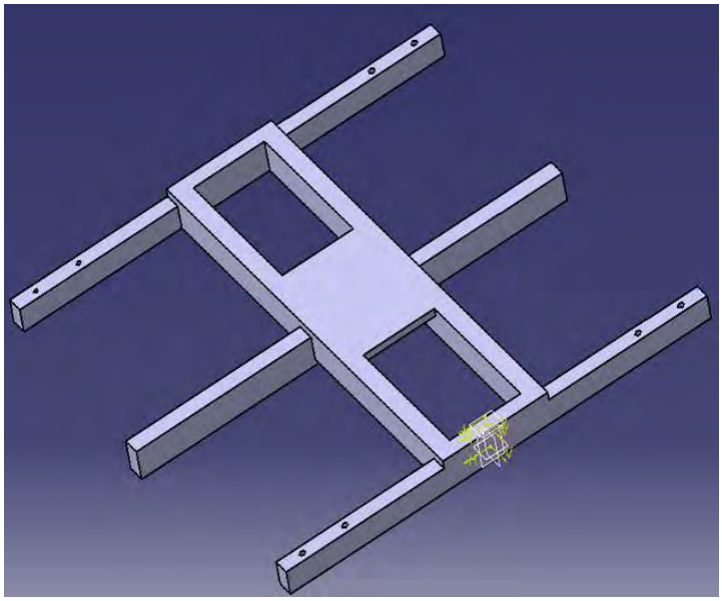


Figure 2.1.1 Hex copter frame with custom design.

2.1 OTHER DESIGN CONSIDERTIONS

Other designs we such as fixed-wing electric planes, liquid fuel UAVs, Quad copter, Octacopter were also taken into consideration for this project, but due to freeness and versatile quality of the hex copter, it is selected. Hex copter has a higher load-carrying capacity, like octocopter. Hex copter also has the accuracy of the quad copter. It can also fly in high wind also.

2.1.1 DESIGNING CONSTRAINTS

Designing constraints for the above model are specified below.

a) It should have a flight time of at least 10-15 minutes.
b) It should evenly spray the content in the field.
c) It should be working autonomously.
d) It should be carrying a sufficient amount of spraying material.

2.2 CALCULATIONS

2.2.1 BATTERY LIFE OR FLIGHT TIME

Flight time = (battery capacity in mAh) * 60

1000 * total current drawn

Ex. = 10000 * 60

1000 * 1202

= 5 min

For 1kg payload. This is theoretical calculation.
This is just a prototype for the proof of concept.

2.2.2 TOTAL FLYING WEIGHT CALCULATION

The total flying weight is also termed as the take-off weight. The total takeoff weight comprises of the weight of the all the components of the drone-like frame, battery, payload, etc. all the electronic components used example wires and connectors.

The total flying weight calculations are as follows:

Motor = 66gm * 6 = 396gm
ESC = 4gm * 6 =24gm
Propellers = 12gm * 6 = 72gm
Power distribution board = 20 gm
Flight controller kit = 150gm
Raspberry pi and camera = 160gm
Spraying mechanism = 200gm
Battery = 650gm
Airframe = 500gm

Total weight without payload = 2172gm approximately.

III. FLYING SYSTEM OR PROPULSION SYSTEM SELECTION

3.2 CUSTOMISED MOTOR MOUNTS

In this project custom made motor mounts are being used. The Motor Mounts are manufactured by the 3D printing process. The material used for the manufacturing of the motor mount is Acrylonitrile Butadiene Styrene (ABS). It is strong and light in weight as compared to others.

3.3 PROPELLERS

The Propellers we are using here is the DJI Propeller. We are required to use 6 propellers. This propeller along with the motor generates a sufficient amount of thrust required for the hex copter configuration.

3.4 ELECTRONIC SPEED CONTROLLERS OF ESC

The maximum current drawn by a motor is 24.2amp, thus we are using 35amp ESC.

3.4 POWER MODULE

A power module is used to supply the required amount of power to each component of the drone. It is also used as a stabilizer. It avoids the unnecessary shortening of the electronic component due to excess of power supply. The power module is connected with the power distribution board.

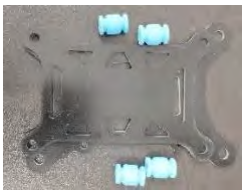
IV. CONTROLLING AND NAVIGATION MODULES

4.0.1 FLIGHT CONTROLLER (PIXHAWK)

A flight controller is basically the brain of the drone. For the proposed model we are using the Pixhawk flight controller, due to its stability and endurance. It is also an open-source and independent platform. It is also user-friendly.

4.0.2 ANTI VIBRATION KIT FOR FLIGHT CONTROLLER

It is used to secure the flight controller. It increases the stability as well. It reduces the unwanted jerks form the drones.



4.0.3 GPS MODULE

A GPS module is used to locate our drone properly. It is the main component responsible for the autonomous factor of the drone. Using GPS drones can take off and land on their own.

4.0.4 TELEMETRY

Telemetry is the connecting link between the ground station and the drone. It consists of the two components one is attached with the drone and other is attached with the ground station. A ground station can be a mobile phone or a computer. Telemetry is used to give the desired command to the drone, to set new way points, to monitor where our drone is flying.

4.0.5 LiDAR MODULE

LiDAR stands for light detection and ranging. It is basically a remote sensing technology. It is used to create a high-resolution image of the area. It is very much useful in the night for mapping and surveillance.

V. DESIGNING MATERIAL

5.0.1 ALUMINIUM SQUARE BAR

Aluminum is used for the above suggest prototype of a drone. Aluminum is selected because of its high tensile strength and ductile quality, means it bends or transform easily. It also light in weight as compared to other materials.

5.0.2 Acrylonitrile Butadiene Styrene (ABS)

Acrylonitrile Butadiene Styrene (ABS) is a thermoplastic material. It has good tensile strength and rigidity. It has excellent resistance power against stress. In this project, the motor mount is manufactured by this material.

VI. CONCLUSION

This project designed to serve a user-friendly of the technology with the farmers. This reduces the manpower required for the pesticide spraying purpose by the farmers all around. All the information and data specified above proves our concept of Autonomous spraying of pesticide through hex copter drone. This project will also have an auto take-off and auto land mode. For the take-off and landing purpose, a QR Code scanning will be done. The project is still under development phase. All the calculation specified here is theoretical. Also, we are working on to make this project to give the initial command through the Android mobile phone.

Smart Guide Stick for Blind People Using Artificial Intelligence

Divya Rathore,Damini HardePratiksha Nagrare
Department Of Computer Technology,
Priyadarshini College of Engineering
Nagpur, India

Mona, KomalMadarkar, Prof. Dr. (Mrs.) A. V. Dehankar
Department Of Computer Technology,
Priyadarshini College of Engineering
Nagpur,

Abstract:**Visual defect is a condition in which a person unable to see that causes problem, which cannot solve by medical means. The difficult situations coming in front of blind person is to distinguish obstacles appearing in front of them. Due to this, they are not able to move from one place to another. Thus, the smart blind stick helps the blind people to perform navigation and to do their work easily and comfortably.Innormalstick,thedetectionoftheobstacle is not done and normal stick is not efficient for visually impaired person. The typical blind stick is not able to identify what type of things or what type of objects come in front of him/her. The rapid advancement in technology has seen the innovation of better system for assisting the disabled, including the blind, such as AI image processing, which can provide intelligent navigation capabilities to the blind. This paper reviews the design of the smart guide stick having A.I. technologies such as object detection which helps the blind person to navigate easily.**

***Keyword: Image processing, filtering, feature extraction*.**

I. INTRODUCTION

Thevision,constructamentalrepresentationoftheworld around us. This contribute to our ability to successfully navigate through physical space and interact with important individuals and objects in ourenvironments.

Eye is the most crucial part of human body, considering that 83% of the information that a person obtain from the environment is through the sight. However, there are many people with serious visual impairment that prevent them from travelling individually.

According to a 2018 report by the World Health Organization(WHO)thereareroughly1.3billionpeopl e in the world who are visually impaired, 39 million of whom are blind, and 246 million are low vision. Accordingly, these individuals must use a range of technique and tools to help them in movement.

Some of the oldest equipment for the visually impaired havebeenthewalkingcanealsoknownasthewidestick, and the guide dog though useful these aids have significant setbacks. The rapid advancement of modern technology has, however seen the advent of better system such as the assisted vision smart glasses and smart stick that can provide intelligent navigation capability to the blind. This paper reviews the design of a smart guide stick, i.e. an Artificial Intelligence based smart guide stick, equipped with image recognition technologiesthatcapturefront,side,andbackendimage s and use AI and machine learning to process them.

Smart guide stick is mainly design to detect obstacles whichmayhelptheblindpersontotraversecarefree.The audio messages will keep the user attentive and thus reduce the chances of accidents. A voice enable automatic switching is also incorporated to help them in private space as well. The propose system detect the obstacle images which are present in outdoor and indoor with the help ofcamera.

ThesmartGuideStickisasimpleandpurelymechanical device to detect the obstacles on the ground. Thisdevice is light in weight and portable. But its range is limited due to its own size. It provides the best travel aid for the person. The blind person can move from one place to another independently without others help. The main goal of the system is to provide an efficient navigation means for the blind persons which gives an eyesight by providing the information about objects present in their surroundings.

AI based smart guide stick is an innovative stick which will help in making smart decisions about the selection

Of path that has no obstacles till a certain distance. Our blind stick involve predefined commands for a blind person by using image processing technique from camera and sensors front, left and right that will

provide theblindpersonthepredefinedmessageinordertomove over their path. The camera sense the obstacles and process the image and direct the blind person with a specified message to move in a particular direction. The message will be given in the form of voice via headphones. This helps blind person inwalking.

II. SystemDesign:

System design is the process of defining theelements of a system such as the architecture, module and components, the different interfaces of those component andthedatathatgoesthroughthatsystem.Thesystemcan be broadly classified into the input unit, the control unit and the output unit. This units are aligned on the blind stick for the perfect object and the edge detection. The stick is embedded with Sensors, Adriano Nano,Batteries, Buzzer, Bluetooth, andCamera.

If the visually impaired person is walking with his/her stick into his/her hand they will be knowing the obstacles cominginfrontofthemthroughthecamerawhichwilldo the image processing of the obstacles coming before its path.

The sensors like Ultrasonic sensor HC-SR04 are placed over the blind stick which makes it robust.

If the stick of the visually impaired person has been dropped then the buzzer will is going to buzz.

If the blind person is moving in a particular direction and in a certain path, the obstacles coming in the path of the blind person are being recognised by the camera and the audio message will be given to the blind person via Bluetooth. The stick is made artificially intelligent by image processing technique and feature extracting method.

2.1 Block Diagram:

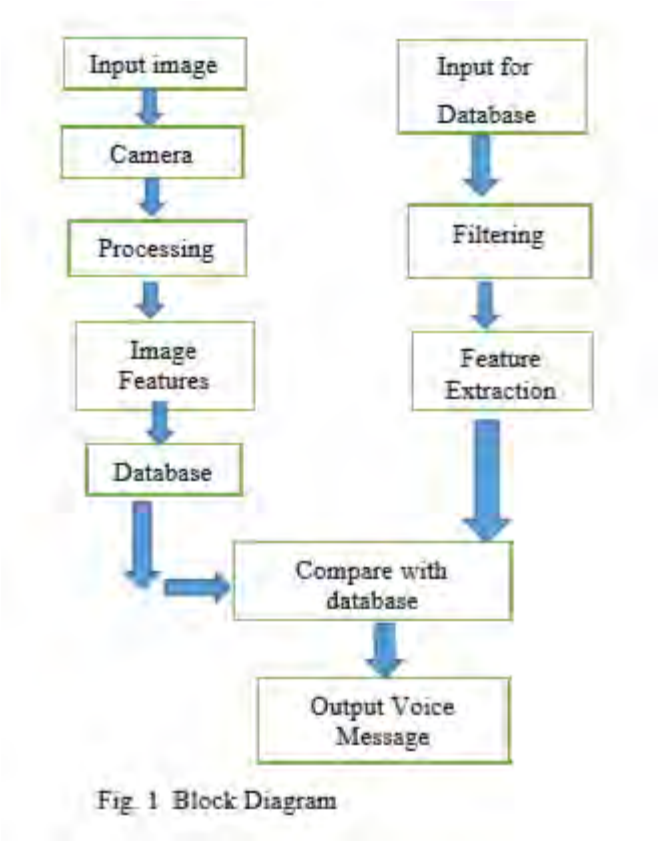

Fig. 1 Block Diagram

2.2 Camera:

A web cam is a small digital video camera directly or indirectlyconnectedtoacomputeroracomputernetwor k. Webcams are having the software that will be installed in the computer to help the blind person to record image of theobstaclescominginthepathofhim/her.Theclusterin g algorithm is used for image detection which will take the image of the obstacles as input. These input arecompared with images stored in database in order to identify them. The MATLAB is coded in C language to get the number ofimagesrecognizedbythecamerainthetextformat.Th e output is given after converting the text i.e. code in the form of voicemessage.

2.3 Ultrasonic SensorHC-SR04

The HC-SR04 ultrasonic distance sensor is a sensor used for detecting the distance to an object using sonar. The transmitters emit a high frequency ultrasonic sound, whichbounceoffanysolidobjects,andthereceiverlisten foranyreturnecho.TheHC-SR04ultrasonicsensorinthe smartguidestickwilljudgethedistanceoftheobstacleby the time taken by the ultrasonic signal to strike the obstacle and return. The ultrasonic sensor is connected with arduino. The output of these sensor is

connected by a buzzer. Arduino can be coded according to the requirements.

Fig. 2 Ultrasonic Sensor

2.4 Battery

A Battery is used for providing the electrical power to the smart guide stick. 9volt battery is used in the smart guide sticktoprovideprocessingoftheequipmentattachedover the smart guide stick.

Fig.3 : Battery.

2.5 Buzzer

Buzzer is an audio signalling device, which may be mechanical or electromechanical. The buzzer on the smart guide stick is used to indicate the blind person about the position of the bling stick when it is dropped. This will help the blind person to find his/her blind stick without any problems

2.6 Arduino Nano

The Arduino Nano is a small , complete, and breadboard- friendly board based on the AT Mega 328P i.e. Arduino Nano 3.8. The Ultrasonic Sensors are connected with the Arduino and the output is given further.

Fig. 4 : Adriano Nano

2.7 Bluetooth

Bluetooth is a wireless technology standard used for exchanging data between fixed and moving device over short distances. The Bluetooth is connected to the smart guide stick to provide information in the form of audio message of the obstacles coming in the path of blind person.

III. 3A. Image Processing

Imageprocessingtoremovenoisefromtheimageorothe r object removal, different processing unit. Here, we are using K-clustering algorithm which will help in image processing and manipulate the image to transform according to the shape andsize.

3B. Feature Extraction:

Feature Extraction is an important part in the identification of the obstacles coming in the path of theblind person. Feature extraction is used in many applications in image processing. Colour, texture, edges are the features which are used in image detection.In feature extraction here we are using K-clustering algorithm, which first extract the feature of image and after the whole implementation of process it transforms the image.

K- Means Clustering Algorithm

K-Means Clustering is a type of unsupervised learning, which is used when you have data without defined categories or groups. The goal of this algorithm is to find groups and the data, with the number of groups represented by the variable k. The algorithm works iteratively to provide each data point to one of k groups based on the features that are provided. Data points are cluster based on feature similarity. The k clustering algorithms are:

1. The centroid of the k cluster, which can be used to label newdata.
2. Each data point is labels for the each data point is assigned to a singlecluster.

Advantages:

- Obstacles detection with indicationsupport.
- Speech matching which helps blind and physical disable to recognize thedestination.
- Alert blind people about dig coming in front of them.
- Simple to use and lowcost,

IV. Conclusion:

The assistive device for blind people has been

designed focusing upon the ease of travelling for the blind people. Theprojectproposedthedesignandarchitectureofanew concept of smart A.I. based guide stick for blind people. The advantage of the smart blind stick lies in the fact that it can prove to be very low cost solution to millions of blind persons worldwide. The proposed combination of various working units makes a real-time system that makes navigation more safe and secure. The smartguidestick helps the blind people when the obstacle occurs in frontoftheperson.Thestickgivessignaltothepersonby buzzersoundwhenitdetectstheobstacle.Itcanbefurther improved to have more decision taking capabilities by employing varied types of sensors and thus could be used for different applications. It aims to solve the problem faced by the blind people in their dailylife.

Abstract
Given the hasty technological encroachment, social media and communication devices prolong to grow exponentially. Hence, social network has become a chief communication method in modern-day society. As a mobile application, college diary has been extensively used for personal reason as well as business dealings. Due to the lack of prose in understanding why people use college diary in emergingmarkets.Thetheoryofreasonedaction(TRA) was tailored so as to provide conjectural base to explain specific viewpoint about college diary. This provides better indulgent of mind-set and convention behavior towards college diary. Qualitative method wasadoptbymeansofpersonalinterviewinorderto bring forth belief factors about college diary.Atranscriptions were subsequently analyze using content analysis. Results indicate that behavioral beliefsaboutcollegediaryaretranquiloffivefactors, andtheyarelabeledaspersonalindulgence,features usefulness, socializing role, artifact information and entertainment.Normativeidea,inturn,ismadeupby sixfactors,andtheyarelabeledassiblings,relatives, close peers, friends in common, friends, and applicationreviewers.Thistentativestudycontributes a fundamental knowledge about college diary and social networking communication with a conjectural posture. From managerial standpoint, it also elucidatestheupshotofcommunicationcomportment andpeoplefromthesameage-grouponadoptingthe artifact.

II. SOCIAL NETWORKING

Social network is normally distinct as a web-based communication platform that aims to connect individuals and develops social relationships. It has become a pervasive interacting mechanism and the most popular onlineactivityinrecentyears.Itisyetregardasaformof tradition because users tend to use it regularly or repeatedly.Facebook,LinkedIn,MySpaceandTwitterare someofthepopularsocialnetworkingsitesthatexemplify wide-ranging,attractiveandinnovativeweb-basedservices. One of the most appealing functions about social networking is that it allows users to create public, semi-publicorprivateprofileswithinaboundedsystem,viewor share information and develop virtual connection and interactionwithothersinapragmaticmanner.Inaddition,it can help compile and organize information that is of substance

to the users, and provide links to expand contacts and connections. Over the years, it has also become an efficient channel to send or receive emails, photos, and videos, in relevant social circles, like what Yahoo and Hotmail mainly do. Given its usefulness and convenience in performing multiple tasks, it is of no surprisethatFacebookhasemergedasthemostpopular socialnetworkingsitewithoveronebillionusers.Twitteris a new admired real-time information network due to its minimalismconnectingpeoplethroughoutheworld.

College diary is a mobile-based application that enables users to take photos or pictures, apply the different manipulationtoolstotransformtheappearanceofimages, and share them instantly with friends on different social networkingsitethisapplicationtheyounger generation,and appeals to diverse societies more prevailingly than other social networking services youngsters today spend more time on Instagram than Face book and is likely because youngmobileusersareextremelydriventotakephotosor pictures using their mobile phones, and share them with others instantly. As such, the giving out of images rather than words alone has made statement with friends and broadergroupsofuserswhosharesimilarinterestsmore ideal, expedient and fascinating. On another note, by connecting physical and digital realms, college diary application enhances online presence and identity, and allows more effective interaction not only for personal reasons,butalsoforbusinesspurposes.Sinceitperforms likeasocialmediachannelwhereindividuals,companies, vendors and interest groups can easily join in, photos or pictures which are uploaded from any of them can be posted again, thus speeding up dissemination of information. As a result, a lot of established offline organizationhaveslowlybuilt-insocialnetworkingservicesinto their business in order to reach and be in touch with their actual and budding clients more efficiently.

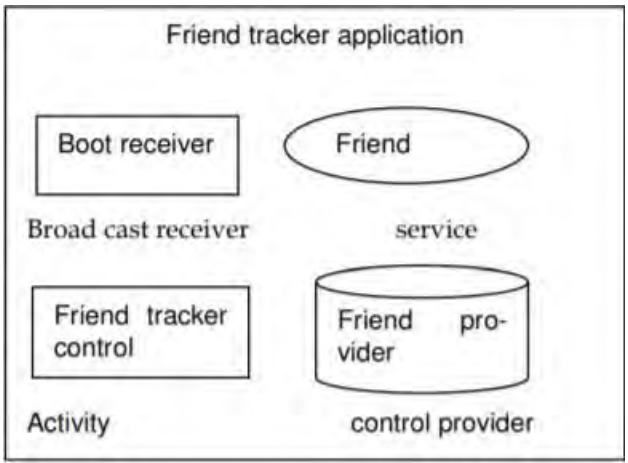
III. ANDROID APPLICATION DEVELOPMENT:

AndroidisaLinuxdisplayplaceprogrammedwithJavaand improved with its own security mechanism tuned for a mobile environment. Android join OS features like able sharedmemory,blockingmulti-tasking,Unixuseridentifiers (UIDs)andfilepermissionswiththetypesecureJavawords and its familiar class library. The ensuing security mold is muchmorelikeamulti-userserverthanthesandboxstart offontheJ2MEorBlackberryplatforms.Nothinglikeina desktopcomputeratmospherewhereauser'sapplication all run as the same UID, Android applications are individuallysoiledfromeachother.Androidapplicationsrun in split processes under diverse UIDs each with diverse permissions.Programscannaturallyneitherreadnor-write each other's data or code, and sharing data between applications must be done clearly. The Android GUI situation has some novel defense features that help support this separation. Mobile platform are mounting in magnitude, and have complex requirements as well as regulatory observance. Android supports building applicationsthatusephonefeatureswhileprotectingusers by and malevolent software. Android's process seclusion obviates the need for complex policy design files for sandboxes. This gives applications the litheness to use local code without compromise Android's security or conceding the intention additional rights. Android permissionsarerightsgiventoapplicationtoallowthemto dostuffliketakepictures,usetheGPSormakephonecall.

Wheninstall,applicationisgivenaexclusiv

eUID,andthe purposewillalwaysrunasthatUIDonthatparticulardevice. The UID of an function is used to care for its data and developersneedtobeexplicitaboutsharing datawithother applications. Applications can think about users with graphics,playmusic,andstartonotherprogramswithout special permissions. Malevolent software is an untoward realityonacknowledgedplatforms,andthroughitsfeatures Android tries to minimize the impact of malware. nevertheless,evenpoormalwarethatgetsinstalledonan Android device perhaps by pretending to be a useful application) can still temporarily wreck the user's experience).Userinthisuntowardstatewill havetoidentify and remove the hostile application. Android help user do this, and minimize the degree of cruelty possible, by requiringuserpermissionforprogramsthat dodangerous things like: – Directly dialing the calls (which may incur tolls), – Disclosing the user's private/public data, or – Destroyingaddressbooks,email,ID,etc.normallyauser's response to annoying, buggy or malicious software is simply to uninstall it. If the software is troublemaking the phone adequate that the user can't uninstall it, they can rebootthetouchtonephoneoptionallyinsafemode,which stopsnon-systemcodefromrunningandthengetridofthe software before it has a chance to run again. minimizing theconsequencesofbugs

The Android function framework services a formation on developers.Itdoesn'thaveamain()purposeor singleentrypoint for carrying out instead, developers must propose applications in terms of components. The user then uses thepalobserverapplicationtoregainthestoredgeographic coordinate and view friends on a plot. Both applications contain multiple components for the theater their respective tasks; the components themselves are classified by their module types. An Android developer chooses from predefined component types depending on the component'spurpose.



IV. SOCIAL NETWORK MARKETING

A social network site is a place for one to connect with people from their offline network and as well public they know through an online society. Look at the opportunity gained through social media to interact with latent customers, social networking sites have become a searing issue for marketers. Social network encouragement has built-in both the fixed and the non-traditional sense of marketing approach Cowden also stated that social media has not only allow the companies to interact with their patrons, but also allowing the customer to interact with other customers. It is also used to convince purchaser that the company's product or services are good .To conduct successful social network marketing, it is important to first determine who the target customers for that business are. After influential the goal customers, one can look into the most suitable platform to be in touch with the targeted customers. It is important to pay attention on what the customers want and not lay to rest them with excessive information and resources. Also mentioned that many businesses make a mistake on demanding on the quantity of their followers instead of accepting who the people that are interested in their business are. Social network marketing is a marketing involving online communities.The communities in the social networking sites are large and the gathered users often share parallel awareness. Unlike thetraditionalmarketingstrategy,socialnetw

orkmarketing requiremarketertobemoreattentivetocustomerstobuild a better image and relationship with customers Many international companies acknowledge that societal network marketing is a prospective marketing stage. According to the study, Smith school of Business, 75% of the small business has a company page on a social networking site. This has showed a momentous amount of the recognition ofsocialnetworkmarketingamongthebusinesspeople.

According to study as cited in customers these days are busierandmorepowerful,sosocialnetwork marketingcan helpthegrouptobefriendliertotheregularsatany time.In the social network promotion, the large number of social mediausershasgiventheadvantagetothecompanytoget recovered well-known in the market even though social network promotion is a potential selling strategy, there is still disadvantage for it. As the social networking siteswill allowconsumerstocommentaboutyourkindwhetheritis goodorbad;oftenthecommentofthecustomersaremore leadingandcompelling.Ontheotherhand,socialnetwork marketingdoeshaveadvantagessuchaspromotioncanbe done at almost zero cost, create huge exposure to businesses,increasingsalesandrisingthepopularityofthe brand An application developer defines one activity per "screen." actions start each other, possibly transient and recurringvalues.

V. SECURITY RESPONSIBILITIES FOR DEVELOPERS

DeveloperswritingforAndroidneedtoconsiderhowtheir code will keep users safe as well as how to deal with constrained memory, dealing out a battery power. Developersmustguardanydatausersinputintothetool withtheirapplication,andnotallowmalwaretocontactthe applicationuses,aswellasanyextensiontotheplatform anAndroiddistributionhasmade.Oneofforty **J**ournalof telecommunication,theticketsbigpicturethingto

understand about android is that every to part runs with a different UID .Typically on desktop every user has single UID and running application launch runs that program as the users UID .On Android the system gives every application fairly that every person , ties own UID For example when launching a new program the new process isn't going to run as the launcher but with its own identity its they don't know in particular if it requires a batch of permissions from a developers perception permission are just series associated with a program and its UID you can user the context class check permission method to programmatically check if a process had a particular permission like PEAD_CONTACTS this is just one of many ways permission are exposed by the runtime to developer the user view of permission is simple and consistent the idiomforenforcementmechanismManifestpermissionlike the above have a few key properties two text descriptions are required a shot t text label and longer description used on installation and icon for the permission can also be provided all permission must Also have a name which is globally unique the name is identifier used byprogrammers fo the permission and is the first parameter to context check permission permission also have a protection level thereareonlyfouprotectionlevelforpermission

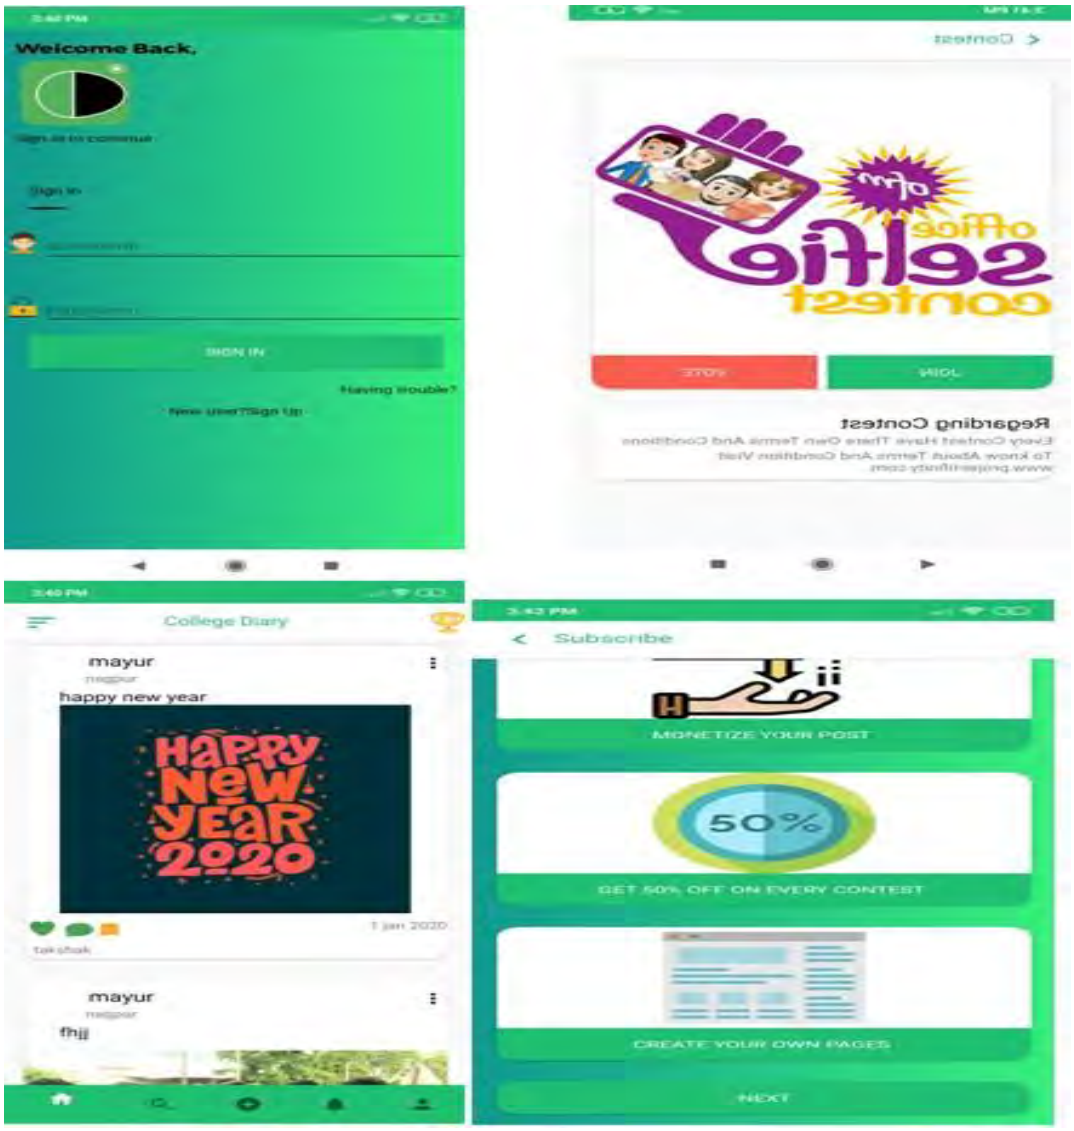
VI. ANDROID PERMISSIONS REVIEW:

Application need authorization to do thing their vendor might object to like transfer sms messages using the camera or access the owner contact database androiduser

manifest permission to follow the user agree applicationtodoanapplicationauthorizatio nneedsareexpressedinits android Manifes.xml and the user agrees to them upon install.Wheninstallnewsoftwareusershav eachanceto thinkaboutwhattheyaregoinganddecideto rustsoftware base on evaluate the developers reputation and the authorizationrequireddecidingtheupfront allowthemto focus on their goal rather than secretly while using applications permissions are sometimes called maize permissionorandroidpermissiontodisting uishthemfrom file permission to be useful permission must be associate with some goal that user understand for example an applicationneedsthereadcontentpermissio ntoreadthe users tackle book a contact administrator app needs the shouldn'tkeepingthemodelsimpleit'sposs ibletosecure the use of all the special android inter process communication mechanism with just a single kind of permission staring actives starting and receiving relay intents and invoking binder interfaces can all require the same permission therefore users don't need to recognize morethanmynewcontactmanagerneedstor eadcontact onceinstalledanapplicationspermissionca n'tbechanged by minimize the permission and application uses it minimizes the consequences of potential security flawsin theapplicationandmakesusersfeelbetterab outinstalling it when installing an function users see requested permissions in a dialog similar to the one show in install softwareisalwaysariskanduserswillinhibit edawayfrom software.

VII. RESULT:

The screenshots below show the output of the android application



Normal	Permissions for application features whose consequences are minor like VIBRATE which lets applications vibrate the device. Suitable for granting rights not generally of keen interest to users, users can review but may not be explicitly warned.
Dangerous	Permissions like WRITE_SETTINGS or SEND_SMS are dangerous as they could

	be used to reconfigure the device or incur tolls. Use this level to mark permissions users will be interested in or potentially surprised by. Android will warn users about the need for these permissions on install.
Signature	These permissions can only be granted to other applications signed with the same key as this program. This allows secure coordination without publishing a public interface.
Signature Or System	Similar to Signature except that programs on the system image also qualify for access. This allows programs on custom Android systems to also get the permission. This protection is to help integrate system builds and won't typically be needed by developers.

CONCLUSION:

Social media is a really convenient and important communicatenetworkforallthepeoplenowadays.Wecan use it to know friends and keep contact with friends that camefromdifferentcountries.

Wecanalsoshareourideassoquicklysothat allthethings could develop so fast because people could tell us their ideasandwecouldimproveitimmediately. Wecouldalso learnnewthingsonsocialmediabywatching orreadingthe thingsthatpeoplesharedontothesocialmedia.

Therearemoreadvantagesforusingsocialmedia;however, thereisalwaysadvantagesanddisadvantagesforathing. Associalmediaistooconvenientforpeople, almostmost ofthemdon'tevenhaveto'speakout'tocommunicatewith people.

***Abstract*— Data analysis necessarily require data compression forreductioninsizeofthedatasoastoincreasetheefficiencyof data transmission and memory management. The process of representing the information in a compressed manner so as to reduceitsmemoryrequirementiscalledDatacompression.Iti s the process of Encoding and Decoding the bits structure ofdata in such a way that it occupies less memory. Compressing data can conserve storage capacity, accelerate file transfer, and minimizecostsforhardwarestorageandnetworkcapacity.Th is paper reports the theoretical and practical nature of all the salient data compressionalgorithms..**

Keywords*— *Data Compression , Lossless Compression , Lossy Compression , Compression , Decompression

I. INTRODUCTION

Withthetremendoususageofcomputersinvariousfieldsa large number of data processing applications that require large storage memory and high speed for data transmission are increasing at a huge rate. For instance , a scheme for compressing a video may require an expensive hardware for decompressing the contents of a video[1].Thusdevelopers felt a need for various compression algorithms that will help in minimizingthesizeofdatainordertousememoryefficiently and to ease the process of data transmission. Reducing the size of a file to its half may double the amount of data to be transmitted in that space. This lead to introduction ofvarious schemes that will help in data compression.

II. BODY

Data compression is an operation of taking raw information as input , processing it through various componentsthat involve compression and decompression algorithms and producing a compressed output of the entered data. The entered data can be of the form : text, audio, picture, video, etc. Storage and transmission of a bulk of redundant data increases the space and time complexity of the system. Itcan be interpreted as a process that reduces the complexity ofthe data and thereby produces a non redundant output. In Computer Networks , Data Compression is performed in the 6th layer i.e. the Presentation layer of the 7 layer OSI Model. Along with the input and output blocks , The process of data compression depends on the following twocomponents:

Encoder:

Encoder block consists of an algorithm that is used for accepting the raw data as input and converting it into a compressedonebyreducingthesizeofthedata.Basedonits functions , it is also knoxwn as aCompressor.

Decoder:

Decoder block consists of an algorithm that is used for reconstructing the original message and providing the output without any noticeable loss of the data. Due to its functions , it is known as a Decompressor.

MEASUREMENT PARAMETERS:

Performance of a compression algorithm majorly dependson the measurementparameters.Various measurement parameters are asfollows:

Compression Ratio:

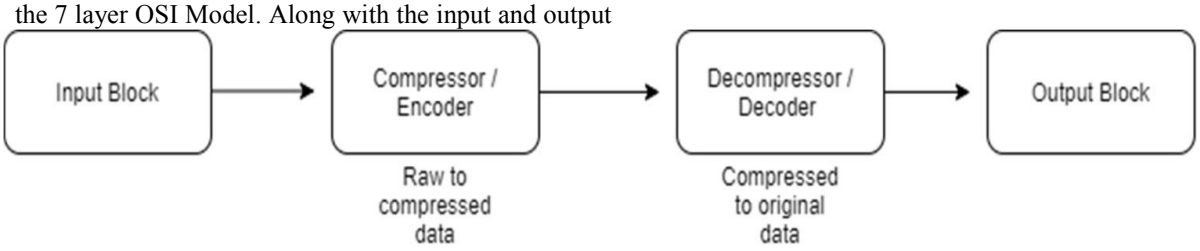
Compression ratio is basically the quantity of compression done byanalgorithm. Compressed ratio = Size of compressed file / Size of originalfile
Compression Factor : Compression factor is the inverse of compression ratio[4]

Compressed factor = 1 / Compression ratio
Compressedfactor=Sizeoforiginalfile/Sizeofcompresse d file
Compression time:

The amount of time taken by an algorithm to compress the given data is called as compression time. Unit of compression time is milliseconds (ms).

Decompression time:

The amount of time taken by an algorithm to decompress or retrieve the compressed data completely is called as decompression time[4]. decompression time is milliseconds (ms).
Saving Percentage:



The amount by which the size of a file is reduced after compression is called Saving percentage [4] Compression algorithms are used to eliminate the redundant data. Over a period of time , various data compression algorithms have been developed. There are basically two types of algorithms

:

Lossy algorithm:

Lossless

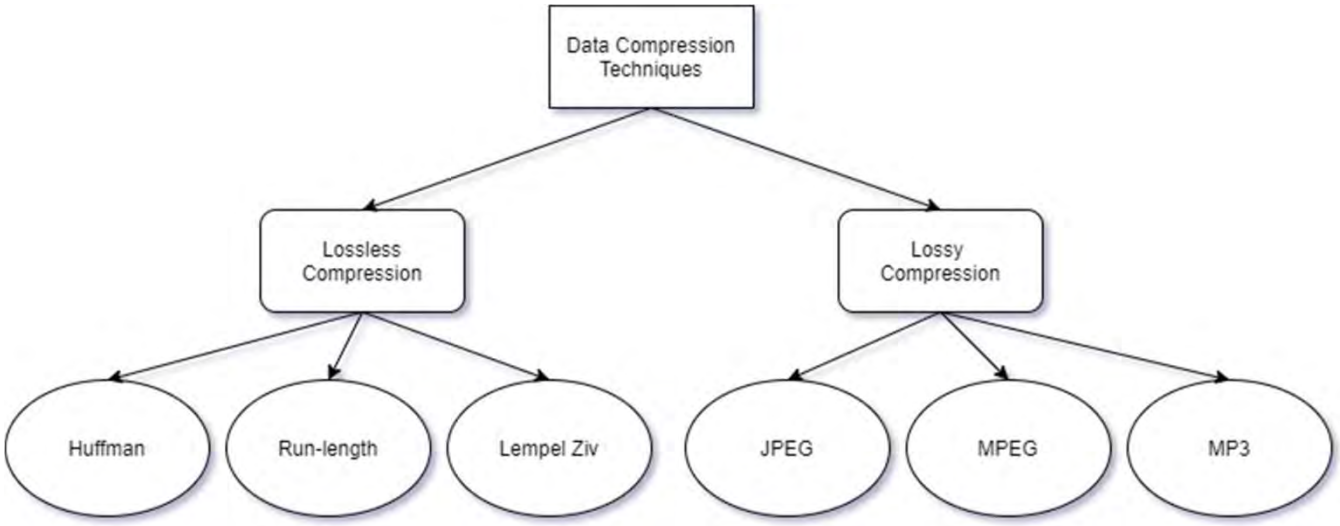
algorithm doesn't directly eliminates the redundant data, rather it temporary terminates the unuseful data.[3] The original data can be recovered or reconstructed exactly. Quality of data is maintained throughout the compression. This algorithm is mainly

Lossy algorithm directly eliminates the redundant data.

The original data can not be recovered or reconstructed exactly.[2]Quality of data degrades but it is undetectable by the user.This algorithm is mainly used for compression of images , audio or video i.e. jpeg, mp3, mpeg.

Losslessalgorithm:

used for compression of text files , programs or softwares. Data compression in lossless algorithm is comparatively less as compared to Lossy algorithm. These two algorithms can be further classified as follows:



Huffman Coding Technique:

Huffman coding technique is a type of lossless data compression algorithm where the exact data can be retrieved after decompression. It is based on binary tree frequency sorting method. In this technique, we first arrange the input data in a descending order of their frequency count. Then, according to algorithm, the least two frequency counts are added and a new node with the new frequency is generated. Wecontinuethisprocessuntilonlylastnodeispresentinthe list. The characters with comparatively higher occurance (frequency) are assigned with lower number of bits and the ones with lower frequency are assigned higher number of bits[5].

Algorithm:

S1: Create sorted nodes in descending order of their frequency count.

S2: Loop - Find two nodes (as node 1 and node 2) with the smallest frequency count.

S3: Create new node , weight of new node = weight (node 1)

+ weight (node 2)

S4: Insert new node back to the sorted list

S5: Repeat the loop until only one node is present in the list.

Advantages of Huffman Coding Algorithm:

The Compression ratio of Huffman Coding algorithm is less as compared to other algorithms[6] Saving percentage is less in Huffmanalgorithm

Disadvantages of Huffman Coding Algorithm:

In case of a fixed length code, the algorithm is inefficient as it uses more number of bits. In case of a variable length codeit becomes harder to encode and

decode as number to bits assigned to each bit may vary.

Run - Length Coding technique:

Run - length coding technique is the simplest data compression technique. This technique is basically used
when a repeated data set is entered by an user. It combines the repeated data as data value along with a counter. The counteristhenumberoftimesthatdatavalueisrepeated.Due to this , the number of bits of a large repeated data set is reduced and data compression is doneefficiently.

Algorithm:

S1: Check the current data value with the next value.
S2: If the value is same , return data value along with a counter that indicates the number of repetition.[7]
S3: If the neighbouring value is not identical , proceed to the further data value of the data set.
S4: Repeat the above processes until all the data elements of the set are being traversed.

Advantages of Run- Length CodingAlgorithm:

Itisthesimplestalgorithmandthusimplementationiseasier . For repeated data items in a data set, Run - length algorithm is quiteefficient.

Disadvantages of Run- LengthAlgorithm:

The efficiency of this algorithm depends on the number of repeateddataentriesintheinputdataset.Incaseofadataset in which the data values aren't repeated, this algorithm fails. Instead the number of bits after compression increaseswhich leads to a complete failure of the algorithm.

Lempel - Ziv Coding Algorithm:

In Lempel - Ziv Coding algorithm , a dictionary is assigned to a single character string that corresponds to all possible input character[8]. This algorithm works on continuous scanning of sub-strings that are not in the dictionary. The entered input is divided into unique sub-strings that haven't occurred before and corresponding location is assigned to each string. Then sub-strings containing previoussub-strings as their subsets are written as their location along with the remaining part of the string. In the end everything is expressedinbinaryanddatacompressionisdoneeffectivel y. Algorithm:
S1:Theenteredstringisseparatedintonumberofunitstring s which haven't occurred before.
S2: After each separation , consider input string and find the shortest string which isn't marked before.
S3: Each separation is given a location
S4: This encoding is done by assigning the location of data item and value of last bit
S5: Further , encoding is done by representing the numerical locationinbinaryandthedataitembyitspreviouslyassigne d location

- Advantages of Lempel - ZivAlgorithm:

This algorithm can complete the compression in one pass. A dynamic codeword table is built for each file.

- Disadvantages of Lempel - ZivAlgorithm:

Creates entries in dictionary that may never be used. Useful for a large amount of text where data redundancy is quite high.

III. DRAWBACKS

Every system always has somedrawbacks

- The vascular structure can be influenced by physical activities , temperature , ageing as well as by diseases buttill now there is no empirical evidence for thesame[11].
- The free flow access is denied because it can either be touch based or can be accessed from a distance and not both at the same time in current available commercialsensor.[12]

IV. RESULTS

In this paper we came across various data compression parameters. These parameters are used to define the efficiency of various algorithms. We studied about the two majordatacompressiontechniquesthatisLossyandLossl ess algorithms. These algorithms were compared with respect to eachother.Theyservevariouscompressionpurposesanda re usedeffectively.Further,Varioustypesoflosslessalgorith ms were overlooked and a comparative result was generated as the advantages and disadvantages of the algorithms with respect to each other.

V. CONLCUSION

Data compression technique is topic of prime importance in today's generation due to an increasing advancements in technology. data compression is studied from past 4 decades[4] . this paper gives an overview of various data compressiontechniques. these algorithms are then being compared with each other and results are generated.

VI. FUTURESCOPE

Veinscannersystemcanhavemoreresearchinordertohav e contact and contactless security access simultaneously . Algorithmscanbedevelopedtodetectthecauseofchangei n the veins pattern based on the change as it would help the system to know whether the change is natural or the input is manipulated.

riddhidoshi1996@gmail.com,vivekkute@rediffmail.com

Abstract—**Database is a diversified field which has increased extensively. This extensive increase has elevated the complexity of queries. The processing time of query increases with the complexity of the query. This processing time is minimized by optimizing query. Cloud computing possesses facilities like repository, database, networking and significantly more. With focus on enhancing the execution in cloud demands the optimization of data transit time and optimization of resource rent time in cloud environment. In traditional database, query optimization is intended with one - dimensional objective whereas in distributed database query optimization is intended with multi – dimensional objectives. There are numerous optimization strategies such as randomized, static and dynamic; however these strategies require a prior knowledge of entire system. In this paper we have briefly described various methods for query optimization and proposed query optimization models for traditional and distributed databases.**

Keywords—Query Optimization, Relational Database, Distributed Database, Cloud Database, Cloud Computing, Re-Optimization, Neural Network, Query Processing, Materialization, Sub query Elimination

I. INTRODUCTION

Query optimization is the method of producing an optimal execution plan for a specific query where optimality is contingents confunction to be diminished. The fundamental aim of query optimization is to determine an execution approach that is practically optimal [1].Query is optimized in two stages:

STAGE 1: First stage is to produce the search space.

STAGE 2: In second stage an ideal plan from the Search space is identified [2].

There are three fundamental components of query optimization: access method, join criteria and transmission cost. The query optimization process is performed in three parts. First part is formation of search space; this is the accumulation of alternate execution to represent the input query. Second part is picking up the search strategy, search space is explored and the ideal execution plan is determined. Search strategies are comprehended as exhaustive strategies and heuristic strategies. Exhaustive strategies develop all feasible plans by the creation routine. BFS and DFS are frequently applied as search strategy. Heuristic strategies are noted as domain independent that confines the creation of query evaluation plan in every single point to a selection. Third part is creation of cost model, this predefines the cost of given plan which incorporates the elements such as transmission cost, memory storage cost, computation cost and so on [1]. There are two fundamental approaches for query optimization:

1. First approach is to make use a rule based or heuristic based approach for sequencing the actions in query execution strategy.
2. Second approach methodically considers the metric of various execution strategies and selects the least cost solution [1].

Different techniques used for generating adequate query execution plans are:

- Heuristic optimization
- Syntactical optimization
- Cost based optimization
- Semantic optimization.

Heuristic optimization is a rule based approach for generating better execution plans for query. Syntactical optimization is based on user intelligence of both the primary database schema and the division of data stored among the tables. The optimizer aims to enhance the capability of these joins by recognizing indexes that are effective for data retrieval. Cost based optimization requires particular information regarding stored data. The main purpose is not to generate the ideal execution plan for fetching the specified data, but –is to create a logical execution plan. In semantic optimization, optimizer utilizes the understanding of system controls to clarify or to overlook particular query if it is assured to yield an empty set. Query execution operator in particular selection operator, join operator, set operator, aggregate operator and many more assist to optimize specified query. This paper reviews different methods for query optimization and proposed models. Finally we summarize the paper along with future work.

II. QUERY OPTIMIZATION METHODS IN TRADITIONAL DATABASE

A. Generalized method for Query Optimization

Author in paper [3] briefs about generalized method for query optimization. In generalized method,

optimizer identifies the most ideal approach to execute a SQL statement after examining many elements associated to the object mentioned and situation prescribed in query. This generalized illustration comprised of query transformer, estimators, plan generator and dictionary. In this method parsed query is provided as input to the query transformer. Parsed query is described as a set of query blocks which can be embedded or connected. The function of query transformer is to identify whether it is beneficial to modify the form of query so that it allows creation of best query plan. The function of estimator is to evaluate the overall cost of given plan. Optimizer produces three types of metric named selectivity, cardinality and cost. Selectivity portrays a fragment of rows from row set. Cardinality portrays the number of rows from row set. Cost represents the work or resource used. The function plan generator is to examine different feasible plans for a particular query and selects one with lowest cost. [1]

B. Traditional Methods / Query Optimization in Relational Database

Traditional methods for query optimization are broadly used in relational databases. There are five fundamental methods as follows:

- Elimination of redundant evaluation
- Continuous or Iterative queries or results
- Caching intermediate queries or result
- Materialization
- Pipelining

Some of these methods work on reducing communication cost, some focus on reducing execution time for a given query and some focus on utilization of system resources in cloud [2].

I) Elimination of Redundant Evaluation:

Composite queries are made up of common sub – queries or common sub – expressions. Assessing these types of frequent queries only once will reduce evaluation time. Systems named IGNITE was developed, it removes redundant evaluation. This system operates on start – fetch wrapper with request window scheme. System transmits the common sub-queries to the identical data source so unnecessary answers within the queries are abolished. Source wrappers in which multiple queries comprising of common sub-queries are wrapped as a whole are decoupled by IGNITE system and execution engine provides the sub-queries to the identical source which improves data sharing within sub-queries. Authors worked on similar system to reduce the communication traffic by rebuilding the initial sub-queries to alternative sub-queries. A model was drafted where parallel query processing system accomplishes multiple queries scheduling to minimize the response time. The queries are fragmented into analogues subtasks and execution plan is reorganized maximizing reutilization of cache data [2] [3].

II) Continuous or Iterative Processing:

This method is completely distinct from other optimization methods. Principle purpose of this method is on the accumulation and propagation of data statistics prior to query execution. An approach was proposed that constantly check query execution, gather the run-time score and modulates execution plans as the query executes. Whenever novel run-time statistics are obtained, query optimizer is activated. It is complex to determine better quality statistics on intermediate computation results. Another method was proposed, which overcomes the above issue. This method produces several plans at compile time. One plan from these is adopted to execute when unfamiliar quantities are detected at the run-time with the help decision tree mechanism. It is complex to determine how many plans should be produced and retained at compile time. Progressing query optimization (POP) is another method that identifies the cardinality evaluation defects in mid execution. It contrasts the evaluated cardinality values with the actual run-time score. If inconsistency occurs, the current plan is re-optimized [2] [3].

III) Caching Intermediate Queries or Results:

Query can be optimized by caching intermediate results in single sliding window. Author proposed a model that optimizes overlapping queries with common sub-queries with the help multiple sliding windows. Implementing and temporarily storing that is caching the common sub-queries at the site with minimum communication and transmission cost and transporting the result to the site that require them as input are considerably crucial element that enhances overall execution time. Some of the proposed systems based on caching intermediate queries are EARL, Blink DB, Chive, NOVA, CBP and REX [2] [3].

IV) Materialization:

Query optimization can be obtained by considering materialized view for aggregated or clustered queries across the vast relation. Positive outcome or success of this approach relies on powerful view matching algorithm. A system was proposed based on materialization where physical functions are requited with entities present in cache during the course of run – time which removes the necessity for changes to the query optimizer. ReStore is another proposed system that makes the use of result of Map Reduce jobs which are mentioned in analytical query languages such as pig.

The output effects of Map Reduce jobs are retained to acknowledge future reutilization probability by following future jobs. An algorithm was suggested to identify either a component or all of a query can be estimated from materialized views. [2]

V) Pipelining:

By using Map Reduce the entire data processing expense for joins elevates the intensive level of work. In pipelining approach, task consisting functions is distributed into several tasks. One task reads the results of pervious task for continue processing. Nested Triple Group Data (NTGD) is a proposed model that reduces overall execution cost by minimizing the numbers of map reduce cycle. Another proposed model named AQUA (Automatic Query Analyzer) was developed with an aim

to minimize the generation of excessive intermediate results so as to diminish network and storage costs. This model makes use of two phase optimizer:

- PHASE 1: This phase creates groups of join operators for minimizing total number of jobs in map reduce so that query can be evaluated.
- PHASE 2: This phase binds intermediate results of group to produce final query results. [2]

III. QUERY OPTIMIZATION METHODS IN CLOUD DATABASE

A. Query Optimization Methods for Cloud

Cloud computing provides paid utilities for customers like repository, servers, networking, databases and software on demand. Cloud computing allows customers to hire a large number of resources for a short period of time so that complicated queries can be executed efficiently on huge amount of data. [3].In distributed environment such as cloud, data is distributed to several number of site. This data is stored in its integrality on every site or distributed on various sites. In cloud query is handled and optimized in distinct manner [4]. In distributed database, effectiveness of query is obtained by incorporating a pure key value data model [4].

In distributed database query processing involves data transmission from one site to another site across a network. The distributed database enables the association of data from various distributed sites with the help of queries [3]. These optimization methods in traditional databases are not applicable for cloud distributed database systems because they provide users on-demand services as and when needed by the users. Cloud database systems are reliable for ensuring the users with a viable query optimization solution to give the query outputs that fulfill the user constraints as well as reduce the various costs included in query execution. During query optimization, time and monetary costs are determined depending on data statistics that is readily available at that instance with query optimizer. These statistical data may be indefinite and unreliable. Therefore the query execution plan produced before the query is processed may not be the optimum one. So, adequately optimizing the query execution plan (QEP) while executing query to utilize more precise statistics will generate optimum QEP selection. Prevailing techniques either concentrate on optimizing queries depending solely on time, which is inadequate for cloud database, or do not include query re-optimization for more optimum statistics. [5]

Different approaches are described below.

I) APPROACH – 1:

This is an adaptive approach for optimizing queries based on query execution time and monetary costs. The approach is explained as follows:

1. Develop several query execution plans with distinct time and monetary costs.
2. Now based on time and monetary cost estimation each query execution plan is allotted a score with the help of Normalized Weighted Sum Algorithm (NWSA).
3. Select the query execution plan that satisfies both user limitations of time and monetary cost by applying NWSA model.
4. The evaluated execution time and monetary cost of every execution plan are systematized with the help of user-specified maximum value for every target.
5. The score is the aggregation of this systematized value
6. The query execution plan with the least score is identified and executed in phases.
7. After a phase is executed, the data statistics are updates and utilized to re – optimize the other phases until all phases are executed and the query is executed completely [5].

II) APPROACH – 2:

1. Here the execution of query is terminated for numerous times at instance defined by re-optimization strategy.
2. At each instance, a new evaluation of the cost to execute the rest of query is done with the data statistics taken from the finished query parts of the query.
3. The parts of the query which are not executed are amended with the new estimation.
4. The amended query employs more optimum estimations [5].

III) APPROACH – 3:

1. This approach proposed an adaptive optimization algorithm which actively adjusts the number of nodes.
2. In this approach initially, optimizer estimates the terminating time for recent query frequently.
3. Whenever the optimizer identifies that terminating time violated the service level agreement (SLA) between user and cloud service provider.
4. When the violation have been identified the query will be re – optimized and a new computational node will be included to contribute in query execution.
5. If there is no violation, query goes on to be executed [5].

IV) APPROACH – 4:

In this approach the re-optimization of queries is done during run-time. The approach is as follows:

1. The part of query which is executed will be diminished from the search space and a new query execution plan will be developed depending on unfinished part of the previous query.
